CONTRIBUTORS

abdomen
The region of the body between the chest and the pelvis. The abdominal cavity is bounded by the ribs and diaphragm above, and by the pelvis below, with the spine and abdominal muscles forming the back, side, and front walls. The abdominal cavity contains the liver, stomach, intestines, spleen, pancreas, and kidneys. In the lower abdomen, enclosed by the pelvis, are the bladder, rectum, and, in women, the uterus and ovaries.

STRUCTURE
The spine, pelvis, and ribs provide attachments for the layers of muscle that make up the abdominal walls. There is a layer of fat between these muscles and the skin. The inner surface of the abdominal muscles is covered by a thin membrane, the peritoneum, which also covers the organs, such as the pancreas and kidneys, that are fixed to the back wall. Folds of peritoneum also cover the mobile organs, such as the stomach and intestines.

abdomen, acute
The medical term for persistent, severe abdominal pain, of sudden onset, that is usually associated with spasm of the abdominal muscles, vomiting, and fever.

CAUSES
The most common cause of an acute abdomen is peritonitis (inflammation of the membrane that lines the abdomen); underlying causes include appendicitis, abdominal injury, or perforation of an internal organ as a result of disorders such as diverticular disease (the presence of small, protruding pouches in the intestinal wall) or peptic ulcer.

SYMPTOMS
Acute abdomen commonly begins as a vague pain in the centre of the abdomen that gradually localizes to a particular region of the body, depending on the condition. For example, pain is felt on the right side of the body in appendicitis.

DIAGNOSIS AND TREATMENT
An acute abdomen requires urgent medical investigation usually comprising detailed questioning about the condition, a physical examination, laboratory tests, and imaging procedures such as ultrasound scanning. The investigation may also involve a laparoscopy (internal examination using a rigid or flexible viewing tube) or a laparotomy (surgical exploration of the abdomen). Treatment depends on the underlying cause.

abdominal
Relating to the abdomen.

abdominal hysterectomy
The surgical removal of the uterus (womb) through an incision in the abdomen (see hysterectomy).

abdominal pain
Discomfort in the abdominal cavity. Symptoms accompanying abdominal pain may include belching, nausea, vomiting, rumbling and gurgling noises, and flatulence (wind).

CAUSES
Mild abdominal pain is common and is often due to excessive alcohol intake, eating unwisely, or an attack of diarrhoea. Pain in the lower abdomen is common during menstruation but may occasionally be due to a gynaecological disorder such as endometriosis (in which fragments of uterine lining are present in abnormal sites within the abdomen). Cystitis (inflammation of the bladder) is another common cause of pain or discomfort in the lower abdomen. Bladder distension due to urinary obstruction may also cause abdominal pain.

Abdominal colic is the term used for pain that occurs every few minutes as one of the internal organs goes into muscular spasm. Colic is an attempt by the body to overcome an obstruction such as a stone or an area of inflammation. The attacks of colic may become more severe and may be associated with vomiting (see abdomen, acute).

A peptic ulcer, which is associated with an increase in the amount of acid formed in the stomach, often produces recurrent gnawing pain. Other possible causes of abdominal pain are infection, such as pyelonephritis (infection of the kidneys) and pelvic inflammatory disease (infection of the internal female reproductive organs), and ischaemia (a lack of blood supply), as occurs when a volvulus (twisting of the intestine) obstructs blood vessels. Tumours affecting an abdominal organ can cause pain. Abdominal pain may also have a psychological cause, such as anxiety.
TREATMENT
For mild abdominal pain, self-treatment measures, such as a wrapped hot-water bottle or a milky drink, are often effective. Pain due to peptic ulcer can be temporarily relieved by consuming food or by taking antacid drugs.

Abdominal pain that is not relieved by vomiting, persists for more than six hours, or is associated with sweating or fainting requires urgent medical attention. Urgent attention is also necessary if pain is accompanied by persistent vomiting, vomiting of blood, or passing of bloodstained or black faeces. Abdominal pain that is accompanied by unexplained weight loss or changes in bowel habits should always be investigated by a doctor.

INVESTIGATION AND DIAGNOSIS
The doctor makes a diagnosis of abdominal pain based on a physical examination and a detailed description of the patient’s symptoms. Investigation of severe abdominal pain may also include blood tests, imaging tests such as ultrasound scanning, and endoscopy (examination of a body cavity using a flexible viewing tube) in the form of laparoscopy (viewing the abdominal cavity), gastroscopy (viewing the stomach and duodenum), or colonoscopy (viewing the large intestine). Abdominal swelling

Enlargement of the abdomen, which may be due to a variety of causes. Abdominal swelling is a natural result of obesity and enlargement of the uterus during pregnancy.

Some causes of abdominal swelling are harmless. Wind in the stomach or intestine may cause uncomfortable, bloating distension. Distension as a result of temporary water retention may occur in some women just before menstruation. Other causes may be more serious. For instance, ascites (fluid accumulation in the abdominal cavity) may be a symptom of cancer or disease of the heart, kidneys, or liver; swelling may also be due to intestinal obstruction (see intestine, obstruction of) or an ovarian cyst.

DIAGNOSING ABDOMINAL PAIN

The doctor conducts a physical examination and listens to the patient’s description of the pain. More investigations, such as blood tests, X-rays, or imaging tests (including ultrasound scanning), may be carried out. If the diagnosis is still in doubt, endoscopic inspection of the stomach and duodenum (gastroscopy), large intestine (colonoscopy), or abdominal cavity (laparoscopy) may be performed.

Oesophageal reflux
A burning pain in the chest that is accompanied by regurgitation of stomach acid and is often worse after meals or when lying down at night.

Duodenal ulcer pain
This pain often occurs in the same small area and may be temporarily relieved by eating or taking antacids.

Wind
Excess wind in the digestive system affects a large area of the abdomen and can cause an uncomfortable, distended feeling.

Pelvic organ inflammation
A constant diffuse pain, usually accompanied by vaginal discharge or fever, that extends over the lower abdomen.

Gallbladder pain
A cramplike or steady pain under the right ribs that is often accompanied by vomiting and fever.

Appendicitis pain
This pain starts around the navel before finally settling in the lower right side of the abdomen.

inflammation
A constant diffuse pain, usually accompanied by vaginal discharge or fever, that extends over the lower abdomen.

abdominal X-ray
An X-ray examination of the abdominal contents. An abdominal X-ray is often one of the first steps in the investigation of acute abdominal disease.

X-rays do not reveal the internal structure of organs, but they do show their outlines. X-rays can therefore show whether any organ is enlarged and can detect swallowed foreign bodies in the digestive tract. X-rays also show accumulations of fluid and gas: distended loops of bowel containing collections of fluid often indicate the presence of an obstruction (see intestine, obstruction of); gas outside the intestine indicates intestinal perforation.

Calcium, which is opaque to X-rays, is present in most kidney stones (see calculus, urinary tract) and in some gallstones and aortic aneurysms; these can sometimes be detected on an abdominal X-ray.

Abdominal X-rays may need to be followed by procedures that provide more information, such as ultrasound scanning, barium X-ray examinations (use of a contrast medium to detect disorders of the gastrointestinal tract), laparoscopy (internal examination of the abdomen using a viewing instrument), CT scanning or MRI (techniques that produce cross-sectional or three-dimensional images of body structures).

abducent nerve
The sixth cranial nerve. The abducent nerve supplies the lateral rectus muscle of each eye, which is responsible for moving the eyeball outwards. The abducent nerve originates in the pons (part of the brainstem) and passes along the

ABDUCENT NERVE
A

**ABDUCTION**

base of the skull, entering the back of the eye socket through a gap between the skull bones.

The abducent nerve may be damaged in fractures of the base of the skull, or by disorders, such as tumours, that distort the brain. Such damage may give rise to double vision or a squint.

**abduction**

Movement of a limb away from the central line of the body, or of a digit away from the axis of a limb. Muscles that carry out this movement are called abductors. (See also adduction.)

**abductor**

Any one of the muscles that carry out the movement of abduction.

**aberrant**

A term meaning abnormal; in medical usage the word is often applied to a blood vessel or nerve that deviates from its normal route.

**abetalipoproteinaemia**

A rare, inherited genetic disorder of lipoprotein (a protein that combines with fats or other lipids) metabolism. It is inherited in an autosomal recessive manner and is characterized by malabsorption of fats, acanthocytosis (distorted red blood cells), retinopathy (disease of the retina), ataxia (incoordination and clumsiness), slurred speech, muscle weakness, curvature of the spine, neuropathy (peripheral nerve disease), fatty stools, diarrhoea, and failure to thrive in infancy.

Treatment with high doses of fat soluble vitamins (vitamin A, vitamin D, vitamin E, and vitamin K) may slow the progression of certain abetalipoproteinaemia-related problems such as retinal degeneration.

**ablation**

The removal or destruction of diseased tissue by excision (cutting away), cryosurgery (freezing), radiotherapy, diathermy (burning), or laser treatment.

**ablepharia**

A birth defect in which the eyelids fail to develop normally, leaving the eyeball completely covered over.

**abnormality**

A physical deformity or malformation, behavioural or mental problem, or variation from normal in the structure or function of a body cell, tissue, or organ.

**ABO blood groups**

See blood groups.

**abort**

A term meaning to terminate a pregnancy, either spontaneously (see miscarriage) or through medical intervention (see abortion, induced).

**abortifacient**

An agent that causes abortion. In medical practice, abortion is induced using prostaglandin drugs, often given in the form of vaginal pessaries. These cause the softening and widening of the cervix (neck of the uterus) and muscular contractions of the uterus.

**abortion**

In medical usage, a term denoting either spontaneous abortion (see miscarriage) or medically induced termination (see abortion, induced) of pregnancy. (See also complete abortion; habitual abortion; incomplete abortion; septic abortion.)

**abortion, induced**

Medically induced termination of pregnancy. In the UK abortion can legally be performed up to the 24th week of pregnancy. Legally, abortion may be performed if continuation of the pregnancy would constitute a greater risk to the woman’s life than the termination, if the mental or physical health of the woman or her existing children is at risk, or if there is a substantial risk of serious handicap to the baby.

**MEDICAL REASONS FOR ABORTION**

A doctor may recommend an abortion if the woman suffers from a life-threatening condition, such as severe heart disease, chronic kidney disease, or cancer, especially of the breast or cervix.

If a serious fetal abnormality is discovered, for example severe developmental defects (such as anencephaly) or chromosomal abnormalities (such as Down’s syndrome), the parents may be offered the option of a termination. Abortion may also be recommended if the mother contracts rubella (German measles) during early pregnancy.

**HOW IT IS DONE**

**Early abortion** Up to the ninth week of pregnancy termination may be induced by treatment with a combination of two drugs, mifepristone and a prostaglandin drug. These end the pregnancy by inducing the uterus to contract and expel the embryo and the placenta; the process usually takes at least 48 hours.

If this drug treatment is unsuccessful, a surgical termination will be required. Until the 12th week, pregnancy may be terminated by vacuum suction curettage performed under either a general or a local anaesthetic (see anaesthesia, general; anaesthesia, local). The cervix is dilated with curved metal rods and a thin plastic tube is inserted into the uterus. The tube is connected to an apparatus that sucks out the fetal and placental tissues.

Recovery is generally fast, although strenuous activity should be avoided for several days. There is usually some bleeding, and occasionally mild cramps, for up to a week. Menstrual periods typically return four to six weeks after the termination. Sexual intercourse can be resumed after two to three weeks.

**Late abortion** Between the 12th and 15th weeks of pregnancy, either the suction procedure used in early abortion or the evacuation procedure may be recommended. In the evacuation procedure, which is routinely performed after the 15th week, the uterus is forced to contract so that the fetus is expelled, as in natural labour. Contractions are induced by oral administration of a dose of mifepristone, followed 36 to 48 hours later by the introduction, high into the vagina, of a prostaglandin hormone pessary. The prostaglandin medication may need to be repeated for the contractions to be maintained.

It usually takes from 12 to 24 hours for the fetus to be expelled using the evacuation procedure, during which time the woman is given analgesic drugs (painkillers). She usually remains in hospital for up to 48 hours after completion of the termination in order to be monitored for complications.

**COMPLICATIONS**

If termination is performed by a qualified gynaecologist in a well-equipped clinic or hospital, complications are rare. Infection, resulting in a condition called septic abortion, or serious bleeding occasionally occur. Repeated terminations may increase the risk of miscarriage occurring in subsequent pregnancies; but a single termination is unlikely to affect future fertility. (See also complete abortion; habitual abortion; incomplete abortion.)

**abrasion**

Also called a graze, a wound on the surface of the skin that is caused by scraping or rubbing.
**abrasion, dental**  
The wearing away of tooth enamel, which is often accompanied by the erosion of dentine (the layer beneath the enamel) and cementum (the bonelike tissue that covers the tooth root). Dental abrasion is usually a result of brushing the teeth too vigorously.

Abraded areas are often sensitive to hot, cold, or sweet food and drink; a desensitizing toothpaste and/or protection with a bonding agent (see bonding, dental) or filling (see filling, dental) may be necessary.

**abrasive**  
A substance that is used in dentistry for polishing and cleaning the teeth. (See also dentifrice.)

**abreaction**  
In psychoanalysis, the process of becoming consciously aware of painful feelings and memories that have previously been repressed (buried). The emotional discharge of such experiences is believed to have therapeutic benefits. The concept of abreaction originates in Freudian theory, in which the process ideally occurs as a result of catharsis (the open expression of emotions that are associated with forgotten memories).

**abruption**  
The medical term for the separation of one structure from another. (See also placental abruption.)

**abruptio placentae**  
The medical term for the premature separation of the placenta from the wall of the uterus (see placental abruption) during pregnancy.

**abscess**  
A collection of pus caused by infection by microorganisms, usually bacteria. Pus is formed from destroyed tissue cells, from leukocytes (a type of white blood cell) that have been carried to the area to fight infection, and from dead and live microorganisms. A lining, known as a pyogenic membrane, often forms around the abscess.

**TYPES**  
An abscess may develop in any organ, and in the soft tissues beneath the skin, sometimes as a collar-stud abscess, a small cavity that connects to a larger cavity in deeper tissues. Common sites of abscesses include the armpit, breast (see breast abscess), groin, and gums (see abscess, dental). Rarer sites include the liver (see liver abscess) and brain (see brain abscess).

**CAUSES AND INCIDENCE**  
Common bacteria, such as staphylococci, are the usual cause of abscesses, although fungal infections are another cause. Amoebae (single-celled microorganisms) are an important cause of liver abscesses (see amoebiasis). Infectious organisms reach internal organs via the bloodstream or penetrate to tissues under the skin through an infected wound or bite.

People with impaired immunity, such as those who are taking immuno-suppressant drugs and those with HIV infection or AIDS, are especially susceptible to abscesses.

**SYMPTOMS**  
An abscess may cause pain, depending on where it occurs. Most larger abscesses cause fever (sometimes with chills), sweating, and malaise. Abscesses may produce a sensation of intense pressure and those close to the skin may cause redness and swelling.

**TREATMENT**  
Antibiotic drugs are usually prescribed to treat bacterial infections, antifungal drugs are used to treat fungal infections, and amoebicides are used for amoebiasis. Most abscesses need to be drained by making a cut in the lining of the abscess cavity to allow the pus to escape; a tube may be left in place to allow continuous drainage (see drain, surgical). Some abscesses burst and drain spontaneously.

**OUTLOOK**  
Many abscesses subside following drainage alone; others subside after a combination of drainage and drug treatment. Occasionally the presence of an abscess within a vital organ damages enough surrounding tissue to cause permanent loss of normal function, or even death. (See also appendix abscess; Bartholin’s abscess; bone abscess; caseous abscess; cold abscess; hot abscess; metastatic abscess; pelvic abscess; periodontal abscess; peritonsillar abscess; sterile abscess; subphrenic abscess; tubercular abscess.)

**abscess, dental**  
Also called a periapical abscess, a pus-filled sac in the tissue around the end of the root of a tooth, usually caused by bacterial infection.

**CAUSE**  
A periapical abscess may occur when bacteria invade the pulp (the tissues in the central cavity of a tooth), causing the pulp to die. This commonly happens as a result of dental caries (see caries, dental), as the tooth’s enamel and dentine are destroyed allowing bacteria to reach the pulp. Bacteria can also gain access to the pulp when a tooth is injured. The infection in the pulp then spreads into the surrounding tissue to form an abscess.

An abscess that occurs when bacteria accumulate in pockets that form between the teeth and gums is called a periodontal abscess. This type of abscess indicates chronic periodontal disease, in which the periodontal membrane (attachment of tooth to bone) is damaged and, in severe cases, the supporting bone eroded.

**SYMPTOMS**  
The affected tooth aches or throbs, and biting or chewing is often painful. The gum around the tooth is tender and may be red and swollen. An untreated abscess may eventually erode a tooth (a channel) through the jawbone to the gum surface, where it forms a gumboil (a swelling). If the gumboil bursts, pus is discharged into the mouth, and the pain usually lessens. As the abscess spreads through the surrounding tissues and bones, glands in the neck and face may become swollen and symptoms of infection, such as headache and fever, may develop.
TREATMENT
A periapical abscess may be drained by drilling through the crown of the tooth into the pulp cavity in order to allow the pus to escape, followed by root-canal treatment (filling of the pulp cavity with dental cement). In some cases, extraction of the tooth (see extraction, dental) is necessary. Antibiotic drugs are prescribed if the infection has spread. A periodontal abscess can usually be treated by careful scraping away of the infected material by the dentist.

absence
In medical usage, a temporary loss or impairment of consciousness that occurs in some forms of epilepsy, typically generalized absence (petit mal) seizures in childhood.

absorption
The process by which fluids or other substances are taken up by body tissues. The term absorption is commonly applied to the uptake of nutrients (from digested food) into the blood and lymph from the digestive tract.

The major site of absorption is the small intestine, which is lined with millions of microscopic fingerlike projections known as villi (see villus). The villi greatly increase the surface area of the intestine, thereby increasing the rate of absorption.

abuse
Malpractice of a person or misuse of a substance. (See also child abuse; drug abuse; heroin abuse; sexual abuse; solvent abuse; substance abuse.)

acamprosate
A drug used in the treatment of alcohol dependence.

acanthoma
A noncancerous tumour composed of cells of the outer layer of skin. There are various types of acanthoma. They are most likely to occur on the face, where they develop in hair follicles, or on the legs. (See also keratoacanthoma.)

acanthosis nigricans
A rare, untreatable condition in which thickened dark patches of skin appear in the groin, armpits, neck, and other skin folds. Acanthosis nigricans may occur in young people as a genetic disorder or as the result of an endocrine disorder such as Cushing’s syndrome. The condition also occurs in people with carcinomas (cancerous tumours) of the lung and other organs.

Pseudoacanthosis nigricans is a much more common condition that is usually seen in dark-complexioned people who are overweight. In this form, the skin in fold areas is both thicker and darker than the surrounding skin, and excessive sweating usually occurs in affected areas. Pseudoacanthosis nigricans may improve with weight loss.

acarbose
A drug that is used in the treatment of type 2 diabetes mellitus. Acarbose acts on enzymes in the intestines, inhibiting the digestion of starch and therefore slowing the rise in blood glucose levels after a carbohydrate meal.

accessory nerve
The 11th cranial nerve. Unlike the other cranial nerves, most of the accessory nerve originates from the spinal cord.

The small part of the nerve that originates from the brain supplies many muscles of the palate, pharynx (throat), and larynx (voice-box). Damage to this part of the nerve may lead to dysphonia (difficulty in speaking) and dysphagia (difficulty in swallowing).

The spinal part of the accessory nerve supplies large muscles in the neck and back, most notably the sternomastoid (which runs from the breastbone to the side of the skull) and trapezius (the large, triangular muscle of the upper back, shoulder, and neck). Damage to the spinal fibres of the nerve paralyses these muscles.

accidental death
Death that occurs as a direct result of an accident. A high proportion of deaths in young adults, particularly among males, are accidental. Many of these deaths are as a result of road traffic accidents, drowning, or drug overdose; and alcohol is a significant contributory factor.

Falls in the home, and burning or asphyxiation as a result of fires, are common causes of accidental death in elderly people. Important causes of accidental death in infants are choking on food or smothering by bedclothes or other materials such as plastic bags. Fatal accidents at work have become less common with the introduction of effective safety measures.

acclimatization
Physical or psychological adjustment to a different climate, environment, or situation. (See also heat disorders; mountain sickness.)

accommodation
Adjustment, especially the process by which the eye adjusts itself to focus on near objects. At rest, the eye is focused
for distant vision, when its lens is thin and flat. To focus on a nearer object, the ciliary muscle of the eye contracts, which reduces the pull on the outer rim of the lens, allowing it to become thicker and more convex.

With age, the lens loses its elasticity. This makes accommodation increasingly difficult and results in a form of longsightedness called presbyopia.

accouchement

The French word for the delivery of an infant from the uterus (womb). (See also childbirth.)

accretion

A manner of growth involving the accumulation of additional material of the same type as that already present. The term accretion is used in dentistry to refer to the collection of foreign material, such as plaque (see plaque, dental), on the surface of a tooth or in a dental cavity.

acebutolol

A beta-blocker drug used to treat hypertension (high blood pressure), angina pectoris (chest pain caused by impaired blood supply to the heart muscle), and certain types of arrhythmia (abnormal heart rhythm) in which the heart beats too rapidly.

ACE inhibitor drugs

COMMON DRUGS

- Captopril
- Lisinopril
- Perindopril
- Ramipril
- Trandolapril

A group of drugs that are used to treat heart failure (reduced pumping efficiency of the heart), hypertension (high blood pressure), and kidney problems associated with diabetes mellitus. ACE (angiotensin-converting enzyme) inhibitors are often prescribed with other drugs such as diuretic drugs or beta-blocker drugs.

HOW THEY WORK

ACE inhibitors block the action of an enzyme that is responsible for converting angiotensin (a protein present in the blood) from inactive angiotensin I to angiotensin II. Angiotensin II encourages blood vessels to constrict; its absence permits them to dilate, thus reducing blood pressure. In diabetic nephropathy, ACE inhibitors slow the progress of the disorder and reduce the loss of albumin in the urine.

SIDE EFFECTS

Possible side effects include nausea, loss of taste, headache, dizziness, and a dry cough. The first dose may dramatically reduce blood pressure.

acellular

A term meaning “without cells” that is generally used to describe pertussis (whooping cough) vaccines that contain only certain parts, rather than the whole, of the pertussis bacteria cell.

acetabulum

A cuplike hollow in the pelvis into which the head of the femur (thigh bone) fits to form the hip joint.

acetaminophen

An analgesic drug that is more commonly known as paracetamol.

acetazolamide

A drug that is used in the treatment of glaucoma (raised pressure in the eyeball) and, occasionally, to prevent or treat symptoms of mountain sickness (headache, weakness, and other symptoms occurring at high altitudes).

Possible side effects of acetazolamide include lethargy, nausea, diarrhoea, and reduced libido.

acetic acid

The colourless, pungent, organic acid that gives vinegar its sour taste. In medicine, acetic acid is an ingredient of antiseptic gels that are used to treat certain vaginal infections.

acetone

A chemical produced naturally when the body enters a state known as ketosis, in which fats are broken down to produce energy. This can occur as the result of metabolic changes caused by diabetes mellitus or, sometimes, as the result of extreme dieting.

Pharmaceutical preparations containing acetone are used as antiseptics and solvents. Acetone is also used in cosmetics such as nail varnish remover. (See also solvent abuse.)

acetylcholine

A type of neurotransmitter (a chemical that transmits messages between nerve cells or between nerve and muscle cells). Acetylcholine is the neurotransmitter found at all nerve-muscle junctions and at many other sites in the nervous system. The actions of acetylcholine are called cholinergic actions, and these can be blocked by anticholinergic drugs.

acetylcholinesterase inhibitors

COMMON DRUGS

- Donepezil
- Rivastigmine

A group of drugs that are used in the treatment of mild to moderate dementia caused by Alzheimer's disease, in which there is a deficiency of the neurotransmitter acetylcholine in the brain.

HOW THEY WORK

Acetylcholinesterase inhibitors work by blocking the action of acetylcholinesterase, the enzyme in the brain responsible for the breakdown of acetylcholine. This raises acetylcholine levels, and, in up to half of all patients, the drugs slow the rate of progression of dementia. However, they have no effect on dementia due to other causes, such as stroke or head injury.

SIDE EFFECTS

Common side effects include nausea, dizziness, and headache. Rarely, difficulty in passing urine may occur.

acetylcysteine

A drug that is used in the treatment of paracetamol overdose and also as a mucolytic drug to loosen sputum in chronic bronchitis.

To be effective as an antidote to paracetamol poisoning, acetylcysteine must be given by injection within a few hours of the overdose having been taken. The drug works by reducing the amount of toxic substances produced during the breakdown of paracetamol, thereby reducing the risk of liver damage. When taken orally, acetylcysteine makes the mucus in sputum less sticky and therefore easier to cough up.

When acetylcysteine is taken in large doses, vomiting, rash, or breathing difficulties may occur as rare side effects.

achalasia

A rare condition, of unknown cause, in which the muscles at the lower end of the oesophagus and the sphincter (valve) between the oesophagus and the stomach fail to relax to allow food into the stomach after swallowing. As a result, the lowest part of the oesophagus is narrowed and becomes blocked with food, while the part above widens.

SYMPTOMS AND SIGNS

Symptoms include difficulty and pain in swallowing, and pain in the lower chest
and upper abdomen. A foul taste in the mouth and bad breath may arise due to the regurgitation of food. The ability to swallow gradually deteriorates until the swallowing of liquids is also impeded.

**DIAGNOSIS AND TREATMENT**

A barium swallow (a type of barium X-ray examination) and gastroscopy (in which a narrow viewing tube is passed down the oesophagus) may be performed in order to investigate achalasia.

Drug treatment for achalasia is rarely successful. It is possible to widen the oesophagus for prolonged periods by oesophageal dilatation (passing a cylindrical rod or a balloon catheter down the oesophagus). Surgery to cut some of the muscles at the stomach entrance may be necessary to widen the passage for food.

**ache**

A continuous, fixed, and often dull pain that is distinct from twinges. (See also bone pain; earache; headache; stomach-ache; toothache.)

**Achilles tendon**

The tendon that raises the heel. The Achilles tendon is formed from the calf muscles (the gastrocnemius, soleus, and plantaris muscles) and is attached to the calcaneus (the heel-bone). The Achilles tendon is named after Achilles, the legendary Greek hero who was vulnerable only in his heel.

Minor injuries to the Achilles tendon are common. They are usually provoked by too much exercise, faulty running technique, or the wearing of unsuitable footwear. All of these injuries can result in inflammation of the tendon (tendinitis) and tearing of the tendon fibres. In most cases, these conditions clear up with rest and physiotherapy.

Violent stretching of the Achilles tendon can cause it to rupture, creating a snapping sensation in the injured area, and pain, swelling, and impaired movement of the affected part. In such cases, surgical repair may be needed, but immobilization of the ankle in a plaster cast may be sufficient.

**achlorhydria**

Absence of stomach acid secretions. This may be due to chronic atrophic gastritis or to an absence or malfunction of acid-producing parietal cells in the stomach lining.

Achlorhydria may not produce symptoms and is not in itself a cause for concern. However, it is sometimes associated with stomach cancer and is also a feature of pernicious anaemia, a blood disorder caused by defective absorption of vitamin B₁₂ from the stomach (see anaemia, megaloblastic).

**achondroplasia**

A rare genetic disorder of bone growth that leads to short stature. Individuals affected with achondroplasia have short limbs, a well-developed trunk, and a head of normal size, except for a protruding forehead.

The condition is caused by a defect of a dominant gene (see genetic disorders) but often arises as a new mutation, rather than being inherited from a parent. The long bones of the arms and legs are affected mainly. The cartilage that links each bone to its epiphysis (the growing area at its tip) is converted to bone too early, preventing further limb growth.

Achondroplasia is usually obvious at birth or during the first year of life and no treatment is available to alter the outlook. Intelligence and sexual development are not affected, and lifespan is close to normal.

**aciclovir**

An antiviral drug that can be taken orally in tablet or liquid form, applied to the skin as a cream, taken as eye-drops, or given intravenously for viral infections including herpes simplex (cold sores), herpes zoster (shingles), and varicella zoster (chickenpox) in adults.

Aciclovir can be used as a life-saving treatment for encephalitis (inflammation of the brain). When it is used to treat cold sores or recurrent genital herpes, for which an ointment is available over the counter, aciclovir does not provide a cure but does, however, reduce the severity of the attacks.

Side effects of aciclovir are uncommon, but they can include nausea, vomiting, and fatigue. Local reactions commonly occur after topical use.

**acid**

A substance that is defined as a donor of hydrogen ions (hydrogen atoms with positive electrical charges). Acid molecules, when mixed with or dissolved in water, split up to release their constituent ions; all acids release hydrogen as the positive ion (positive ions are known as cations; and negative ions are called anions).

Examples of acids within the body include hydrochloric acid (a corrosive mineral acid that is produced by the stomach lining), and many organic acids, such as lactic acid, carbonic acid, ascorbic acid (vitamin C), and pyruvic acid. (See also acid–base balance; alkali.)

**acid–base balance**

A combination of mechanisms that ensures that the body’s fluids are neither too acid nor too alkaline (alkalis are also called bases). The body functions normally only when its fluids are close to chemical neutrality.

Metabolic processes cause fluctuations in the acidity and alkalinity of the blood and other body fluids. The body has three mechanisms for maintaining normal acid–base balance: buffers, breathing, and the activities of the kidneys. Buffers are substances in the blood that neutralize acid or alkaline wastes. Rapid breathing increases the rate at which carbon dioxide is eliminated from the blood, resulting in the blood becoming less acidic; slow breathing has the opposite effect; the kidneys help to maintain a constant acidity level in the blood by regulating the amounts of acid or alkaline wastes in the urine.

Disturbances of the body’s acid-base balance result in either acidosis (excessive blood acidity) or alkalosis (excessive blood alkalinity).
Acid-fast
A characteristic of particular bacteria (especially those responsible for tuberculosis) that are resistant to the acids used to dye specimens for microscopic examination (see staining).

Acidosis
A disturbance of the body’s acid–base balance in which there is an accumulation of acid or loss of alkali (base). There are two types of acidosis: metabolic and respiratory.

Causes
In metabolic acidosis, an increased amount of acid is produced by metabolic processes. One form of metabolic acidosis is ketoacidosis, which occurs in uncontrolled diabetes mellitus and starvation. Metabolic acidosis may also be caused by loss of bicarbonate (an alkali) as a result of severe diarrhoea. In kidney failure, there is insufficient excretion of acid in the urine.

Respiratory acidosis occurs when breathing fails to remove enough carbon dioxide from the lungs. This causes increased acidity of the blood because the excess carbon dioxide remains in the bloodstream, where it dissolves to form carbonic acid. Impaired breathing leading to respiratory acidosis may be caused by chronic obstructive pulmonary disease (see pulmonary disease, chronic obstructive), bronchial asthma, or airway obstruction.

Acid reflux
The regurgitation of acidic fluid from the stomach into the oesophagus (the tube that connects the throat to the stomach). Acid reflux is the result of inefficiency of the muscular valve at the lower end of the oesophagus.

Also known as gastro-oesophageal reflux disease (GORD), acid reflux may inflame the oesophagus, resulting in heartburn (a burning pain in the chest) due to oesophagitis (inflammation of the oesophagus).

Mild acid reflux is common but is not serious. It may occur during pregnancy and often affects overweight people. Repeated episodes of discomfort may indicate a hiatus hernia (in which part of the stomach protrudes into the chest).

Acne
A chronic skin disorder in which there is inflammation of the sebaceous glands at the base of hair follicles in the skin.

Types
The most common type of acne is sometimes known as acne vulgaris, which almost always develops during puberty. Chemical acne is caused by exposure of the skin to certain chemicals and oils. This results in the development of acne in areas where the chemical has come into contact with the skin, such as on the thighs. Certain prescribed drugs, such as corticosteroid drugs, can also cause acne.

Acne
The spots on this boy’s face are typical of acne; the darker marks are healed spots, which fade gradually. Severe acne may leave pits in the skin.

Cause
Acne spots are caused by the obstruction of hair follicles by excess sebum (the oily substance secreted by the sebaceous glands). Bacteria multiply in the follicle, causing inflammation. Hormonal changes at puberty, including increased levels of androgen hormones (male sex hormones) in both males and females, stimulate the production of sebum. There may also be a genetic predisposition to acne.

Symptoms
Acne develops in areas in which there is a high concentration of sebaceous glands, mainly the face, centre of the chest, upper back, shoulders, and around the neck. Milia (whiteheads), comedones (blackheads), nodules (firm swellings under the skin), and cysts (larger, fluid-filled swellings) are the most common types of spot. Some, particularly cystic spots, leave scars.

Treatment and outlook
There is no instant cure for acne, although washing the affected areas at least twice a day with a mild soap may help to keep it under control. Over-the-counter topical drug treatments such as benzoyl peroxide or azelaic acid are often effective. Prescribed topical antibacterial drugs or retinoic acid (a derivative of vitamin A) are used to treat moderate acne. Alternative treatment is with oral antibiotics, often tetracycline drugs. In very severe cases, isotretinoin may be given under hospital supervision. In all cases, exposure to ultraviolet light (either natural or artificial) may also be beneficial. However, it is important not to burn the skin.

Acne improves slowly over time, and it often clears up by the end of the teenage years.

Acoustic nerve
The part of the vestibulocochlear nerve (the eighth cranial nerve) concerned with hearing. The acoustic nerve is also called the auditory or cochlear nerve.

Acoustic neuroma
A rare, noncancerous tumour arising from supporting cells that surround the vestibulocochlear nerve, usually within the internal auditory meatus (the canal in the skull through which the nerve passes from the inner ear to the brain).

Cause and incidence
Acoustic neuromas most commonly occur in people between the ages of 40 and 60 and are slightly more common in women than in men.

Usually, the cause of an acoustic neuroma is unknown. However, tumours that affect the nerves on both sides of the head simultaneously may be part of a widespread neurofibromatosis (a disease characterized by changes in the nervous system, skin, and bones).

Symptoms
An acoustic neuroma can cause deafness, tinnitus (noises in the ear), loss of balance, and pain in the face and the affected ear. As the tumour enlarges, it may lead to additional complications, such as ataxia (loss of coordination) due to the compression of the brainstem and cerebellum.

Diagnosis and treatment
Diagnosis is made by hearing tests followed by X-rays or by CT scanning or MRI (techniques that produce cross-sectional or three-dimensional images of body structures).

Surgery may be necessary to remove an acoustic neuroma, but treatment with radiotherapy to shrink it may also be effective.
acquired
A term relating to a condition that occurs after birth rather than being attributable to heredity. Acquired contrasts with congenital, which means present from birth.

acquired immunity
A form of immunity that develops after birth through exposure to microorganisms or through immunization.

acrocyanosis
A circulatory disorder in which the hands and feet turn blue, may become cold, and sweat excessively. Acrocyanosis is caused by spasm of the small blood vessels and is often aggravated by cold weather.

Acrocyanosis is related to Raynaud’s disease, in which the skin of the fingers and toes may be damaged by reduced blood flow.

acrodematitis
Inflammation of the skin, principally on the hands or feet. Acrodematitis enteropathica is a chronic (long-term), inherited variety of the condition.

acrodematitis enteropathica
A rare, inherited disorder in which areas of the skin (most commonly of the fingers, toes, scalp, and the areas around the anus and mouth) are reddened, ulcerated, and covered with pustules (pus-filled spots).

Acrodematitis enteropathica is inherited in an autosomal recessive manner (see genetic disorders) and is due to the inability to absorb sufficient zinc from food. Zinc supplements usually bring about a rapid improvement.

acromegaly
A rare disease that is characterized by abnormal enlargement of the skull, the jaw, the hands and feet, and also of the internal organs.

CAUSE
Acromegaly is caused by excessive secretion of growth hormone from the anterior pituitary gland at the base of the brain and is the result of a noncancerous pituitary tumour.

If such a tumour develops before puberty, the result is gigantism (in which growth is accelerated) instead of acromegaly. More commonly, however, the tumour develops after growth in the long bones of the limbs has stopped. This leads to acromegaly, although it may take several years for the symptoms and signs of the condition to appear.

SYMPTOMS AND SIGNS
Symptoms and signs of acromegaly include enlargement of the hands, feet, ears, and nose; a jutting lower jaw; and a long face. There may also be deepening or huskiness of the voice. Symptoms common to any brain tumour, such as headache and visual disturbances, are also possible.

DIAGNOSIS AND TREATMENT
Acromegaly is diagnosed by the measurement of blood levels of growth hormone before and after a quantity of glucose has been administered. Glucose usually suppresses the secretion of growth hormone; if the glucose has no effect on the blood level of the hormone, uncontrolled secretion of growth hormone by the pituitary gland can be confirmed. CT scanning or MRI (techniques that produce cross-sectional or three-dimensional images of body structures) may be carried out to reveal a tumour or overgrowth of the pituitary gland.

A tumour of the pituitary gland may be removed surgically or treated by radiotherapy. The drug octreotide prevents growth hormone production and may be used to control symptoms by a person awaiting surgery or until the effects of radiotherapy are felt. Bromocriptine sometimes causes the tumour to become smaller.

Appearance of acromegaly
Enlargement of the hands is a typical feature of acromegaly. The condition is apparent when the acromegalic hand, on the left, is compared to a normal hand.

acromioclavicular joint
The joint that lies between the outer end of the clavicle (collarbone) and the acromion (the bony prominence at the top of the shoulderblade).

INJURIES TO THE JOINT
Injuries to the acromioclavicular joint are rare. They are usually caused by a fall on to the shoulder and may result in subluxation (incomplete dislocation with the bones still in contact) or, rarely, to dislocation (complete displacement of the bones so that they are no longer in contact).

In subluxation, the synovium (joint lining) and the ligaments around it are stretched and bruised, the joint is swollen, and the bones feel slightly out of alignment. In dislocation, the ligaments are torn, the swelling is greater, and the bone deformity is more pronounced. In both cases, the joint is painful and tender, and movement of the shoulder is restricted.

TREATMENT
Treatment for subluxation is by resting the arm and shoulder in a sling. If the pain and tenderness persist, injection of a corticosteroid drug and a local anaesthetic (see anaesthesia, local) into the joint may help.

Dislocation of the acromioclavicular joint requires strapping around the clavicle and elbow, for about three weeks, to pull the outer end of the clavicle back into position. Surgical correction may occasionally be required.

acromion
The bony prominence at the top of the scapula (shoulderblade) that articulates with the end of the clavicle (collarbone) to form the acromioclavicular joint.

acroparaesthesia
A medical term for tingling sensations that occur in the fingers or toes (see pins-and-needles).
**ACTH**

The common abbreviation for adrenocorticotrophic hormone (also called corticotrophin). ACTH is produced by the anterior part of the pituitary gland (at the base of the brain) and stimulates the adrenal cortex (the outer layer of the adrenal glands, situated on the top of the kidneys) to release various corticosteroid hormones. ACTH is also necessary for the growth and maintenance of the cells of the adrenal cortex.

**ACTIONS**

The most important function of ACTH is to stimulate the adrenal cortex to increase its production of hydrocortisone (cortisol). ACTH also causes the adrenal cortex to release aldosterone and androgen hormones.

The production of ACTH is controlled by a feedback mechanism that involves both the hypothalamus (an area in the centre of the brain) and the level of hydrocortisone in the blood. When ACTH levels are high, the production of hydrocortisone increases, which in turn suppresses the release of ACTH from the pituitary gland. If ACTH levels are low, hydrocortisone production falls and the hypothalamus releases factors that stimulate the pituitary gland to increase production of ACTH.

ACTH levels increase in response to stress, emotion, injury, burns, infection, surgery, and decreased blood pressure. Cancerous tumours, particularly those of the lung, can sometimes produce a chemical that is similar to ACTH and which causes symptoms.

**DISORDERS OF ACTH PRODUCTION**

A tumour of the pituitary gland can cause excessive production of ACTH, which, in turn, leads to overproduction of hydrocortisone by the adrenal cortex, resulting in Cushing’s syndrome (a hormonal disorder). Insufficient ACTH production results in decreased production of hydrocortisone, causing hypotension (low blood pressure).

**MEDICAL USES**

Synthetic ACTH was once given in the treatment of arthritis or to treat allergy, but it is now rarely used.

**Actin**

A protein component of muscle fibres that, together with myosin (another protein), provides the mechanism for muscles to contract. The microscopic filaments of actin and myosin slide in between each other to make the muscle fibres shorter.

**Actinomycosis**

An infection caused by Actinomyces israelii or related actinomycete bacteria. These bacteria resemble fungi and cause diseases of the mouth, jaw, chest, and pelvis.

**ACTINOMYCES ISRAELII**

Another form of actinomycosis affects the pelvis in women, causing lower abdominal pain and bleeding between menstrual periods. This form was associated mainly with a type of IUD, no longer in use, that did not contain copper. Rarely, forms of the disorder affect the appendix or lung.

Actinomycosis is usually treated successfully with antibiotic drugs.

**Acute**

A term often used to describe a disorder or symptom that develops suddenly. Acute conditions may or may not be self-limited, and they are usually of short duration. (See also chronic.)

**Acute heart failure**

See heart failure, acute.

**Acyanotic**

A diagnostic term meaning without cyanosis, a bluish coloration of the skin that is seen when blood oxygen levels are abnormally low. The term is commonly used in relation to the classification of congenital (present from birth) heart disease (see heart disease, congenital).

**Adam’s apple**

The projection at the front of the neck, just beneath the skin, that is formed by a prominence on the thyroid
LOCATION OF THE ADAM’S APPLE

This projection at the front of the neck, beneath the skin, is formed by a prominence on the thyroid cartilage.

ADD

The abbreviation for attention deficit disorder, more commonly known as attention deficit hyperactivity disorder.

addiction

Dependence on, and craving for, a particular drug, such as alcohol, diazepam (a tranquillizer), or heroin. Reducing or stopping intake of the drug may lead to characteristic physiological and/or psychological symptoms (see withdrawal syndrome), such as tremor or anxiety. The term addiction may also be used in relation to compulsive behaviour, such as gambling. (See also alcohol dependence; drug dependence.)

Addison’s disease

A rare chronic disorder in which there is deficiency of the corticosteroid hormones hydrocortisone and aldosterone, which are normally produced by the adrenal cortex (the outer parts of the adrenal glands, which are situated on the top of the kidneys). In addition, excessive amounts of the hormone ACTH are secreted by the pituitary gland (at the base of the brain) in an attempt to increase output of the corticosteroid hormones. The secretion and activity of another hormone, melanocyte stimulating hormone (MSH), also increase, which leads to increased synthesis of melanin pigment in the skin.

CAUSES

Addison’s disease can be caused by any disease that destroys the adrenal cortices. The most common cause is an autoimmune disorder in which the immune system produces antibodies that attack the adrenal glands.

SYMPTOMS

Symptoms of the disease generally develop gradually over months or years and include tiredness, weakness, abdominal pain, and weight loss. Excess MSH may cause darkening of the skin in the creases of the palms, pressure areas of the body, and the mouth.

Acute episodes, called Addisonian crises, brought on by infection, injury, or other stresses, can also occur. The symptoms of these are mainly due to aldosterone deficiency and include extreme muscle weakness, dehydration, hypotension (low blood pressure), confusion, and coma. Hypoglycaemia (low blood glucose) also occurs due to a deficiency of hydrocortisone.

DIAGNOSIS AND TREATMENT

Diagnosis of Addison’s disease is generally made if the patient fails to respond to an injection of ACTH, which normally stimulates hydrocortisone secretion.

Lifelong corticosteroid drug treatment is needed to replace the deficient hormones. Treatment of Addisonian crises involves rapid infusion of saline and glucose and supplementary doses of corticosteroid hormones.

additives

See food additives.

adduction

Movement of a limb towards the central line of the body, or of a digit towards the axis of a limb. Muscles that carry out this movement are often called adductors. (See also abduction.)

adductor

Any one of the muscles that carry out the movement of adduction.

adenitis

Inflammation of lymph nodes. Cervical adenitis (swelling and tenderness of the lymph nodes in the neck) occurs in certain bacterial infections, especially tonsillitis, and the viral infection glandular fever (see mononucleosis, infectious).

Mesenteric lymphadenitis is inflammation of the lymph nodes inside the abdomen and is usually caused by a viral infection.

In many cases of adenitis, treatment is not necessary. When it occurs as the result of a bacterial infection, treatment of the infection with antibiotic drugs will generally also result in an improvement in the condition of the lymph nodes.

adenocarcinoma

The technical name for a cancer of a gland or glandular tissue, or for a cancer in which the cells form glandlike structures. An adenocarcinoma arises from epithelium (the layer of cells that lines organs).

Cancers of the colon (the main part of the large intestine), breast, pancreas, and kidney are usually adenocarcinomas, as are some cancers of the cervix, oesophagus, salivary glands, and various other organs. (See also intestine, cancer of; kidney cancer; pancreas, cancer of.)

adenoidectomy

Surgical removal of the adenoids. An adenoidectomy is usually performed on a child with abnormally large adenoids that are causing recurrent infections of the middle ear or air sinuses. The operation may be performed together with tonsillectomy.

There are few after-effects, and the patient can generally begin to eat normally the following day.

LOCATION OF THE ADENOIDs

These swellings of glandular tissue are found at the back of the nasal passage above the tonsils. Enlarged adenoids are sometimes implicated in sleep apnoea.
adenoids
A mass of glandular tissue at the back of the nasal passage above the tonsils. The adenoids are made up of lymph nodes, which form part of the body’s defences against upper respiratory tract infections. They tend to enlarge during early childhood, a time when such infections are common.

DISORDERS
In most children, the adenoids shrink after the age of about five years, and disappear altogether by puberty. In some children, however, they enlarge, obstructing the passage from the nose to the throat and causing snoring, breathing through the mouth, and a characteristically nasal voice. The eustachian tubes, which connect the middle ear to the throat, may also become blocked, resulting in recurrent middle ear infections and deafness.

Obstruction to the flow of secretions behind the nose can result in rhinitis (inflammation of the nose), which may spread to the middle ear (see otitis media) and to the air sinuses behind the nose (see sinusitis).

TREATMENT
Infections usually become less frequent as the child grows. If they do not, adenoidectomy (surgical removal of the adenoids) may be recommended.

adenoma
A noncancerous tumour or cyst that resembles glandular tissue and arises from the epithelium (the layer of cells that lines organs).

Adenomas of endocrine glands (such as the pituitary gland, thyroid gland adrenal glands, and pancreas) can result in excessive hormone production, leading to disease. For example, an adenoma of the pituitary gland can result in acromegaly or Cushing’s syndrome.

adenomatosis
An abnormal condition of glands in which they are affected either by hyperplasia (overgrowth) or by numerous adenomas (noncancerous tumours).

Adenomatosis may simultaneously affect two or more different endocrine glands, such as the adrenal glands, pituitary gland, and pancreas.

adenosine diphosphate
See ADP.

adenosine triphosphate
See ATP.

ADH
The abbreviation for antidiuretic hormone (also called vasopressin), which is released from the posterior part of the pituitary gland and acts on the kidneys to increase their reabsorption of water into the blood.

ACTIONS
Water is continually being taken into the body in food and drink and is also produced by the chemical reactions in cells. Conversely, water is also continually being lost in urine, sweat, faeces, and in the breath as water vapour. ADH reduces the amount of water lost in the urine and helps to maintain the body’s overall water balance.

ADH production is controlled by the hypothalamus (an area in the centre of the brain), which detects changes in blood concentration and volume. If the blood concentration increases (in other words, the blood contains less water), the hypothalamus stimulates the pituitary gland to release more ADH. If the blood is too dilute, less ADH is produced; as a result, more water is lost from the body in the urine.

DISORDERS OF ADH PRODUCTION
Various factors can affect ADH production and thus disturb the body’s water balance. For example, alcohol reduces ADH production by direct action on the brain, resulting in a temporary increase in the production of urine. Urine production is also increased in the disorder diabetes insipidus, in which there is either insufficient production of ADH by the pituitary gland or, more rarely, failure of the kidneys to respond to the ADH produced.

The reverse effect, water retention, may result from temporarily increased ADH production after a major operation. Water retention may also be caused by the secretion of ADH by some tumours, especially of the lung.

MEDICAL USES
Synthetic ADH is used in the treatment of a variety of conditions, such as diabetes insipidus. Side effects of the drug may include abdominal cramps, nausea, headache, drowsiness, and confusion.

ADHD
The abbreviation for attention deficit hyperactivity disorder.

adhesion
The joining of normally unconnected parts of the body by bands of fibrous tissue. Adhesions are sometimes con-
therapy is to destroy any microscopic deposits of malignant cells that may exist, which reduces the risk of recurrence of the cancer and increases survival times.

Adlerian theory
The psychoanalytical ideas set forth by the Austrian psychiatrist Alfred Adler (1870–1937). Also known as individual psychology, Adler’s theories were based on the idea that everyone is born with natural feelings of inferiority. Life is seen as a constant struggle to overcome these feelings; and failure to do so leads to neurosis. (See also psychoanalytic theory.)

adnexa
An anatomical term meaning the structures that are adjacent to an organ. Most commonly, the word adnexa is used to refer to the various appendages of the uterus: the ovaries, fallopian tubes, and ligaments.

adolescence
The period between childhood and adulthood, which broadly corresponds to the teenage years. Adolescence is a complex stage of psychological development. It commences at and overlaps with, but is not the same as, puberty.

Common patterns of adolescent behaviour include moodiness, a general lack of interest, and fluctuating academic performance. Adolescents often worry about their changing body shape and physical appearance. They may lack self-confidence, feel nervous and shy and be unsure of their personal identity.

Adolescents experiment with their appearance, with views and opinions, with allegiances to peer groups, and with political movements or other role models. Gender identity and sexuality may be questioned. Adolescents may also experiment with drugs and alcohol; those who do so to relieve anxiety or depression are more likely to become dependent than those who experiment due to peer-group pressure. Sexual activity is common during adolescence and may result in unwanted pregnancies and sexually transmitted infections.

Some adolescents are assertive and strive for independence. Rebellion against parents is common but conflicts with the emotional and financial support that adolescents still require. Aggression and delinquency usually constitute a transient phase. However, a teenager who remains too dependent may not develop sufficiently to make his or her own decisions or to form new relationships outside the family.

Most behavioural problems resolve themselves over time. Maintaining open lines of communication between parents and children is important in easing this process. The most valuable support parents can offer is to encourage self-confidence and responsibility and thus prepare their children for adult life. Parents should also ensure that their children are informed about issues such as contraception and safer sex.

ADP
The abbreviation for adenosine diphosphate, the chemical that takes up energy released during biochemical reactions to form ATP (adenosine triphosphate), the body’s main energy-carrying chemical. When ATP releases its energy ADP is reformed. (See also metabolism.)

adrenal failure
Insufficient production of hormones by the adrenal cortex (the outer part of the adrenal glands, situated on the top of the kidneys). Adrenal failure can be acute (of sudden onset) or chronic (of gradual onset). The condition may be caused by a disorder of the adrenal glands, in which case it is called Addison’s disease, or by reduced stimulation of the adrenal cortex by ACTH, a hormone produced by the pituitary gland. (See also adrenal glands disorders box, overleaf.)

Adrenal gland
A pair of small, triangular endocrine glands (glands that secrete hormones directly into the bloodstream) that are located on the top of the kidneys. Each adrenal gland has two distinct parts: the outer adrenal cortex and the smaller, inner adrenal medulla.

ADRENAL CORTEX
The adrenal cortex secretes aldosterone, which, by inhibiting the amount of sodium excreted in the urine, helps to maintain blood volume and blood pressure. The cortex also secretes hydrocortisone and corticosterone, as well as small amounts of androgen hormones. Hydrocortisone controls the body’s use of fats, proteins, and carbohydrates and is also important in helping the body to cope with stress. Hydrocortisone and corticosterone also suppress inflammatory reactions and some activities of the immune system.

Hormone production by the adrenal cortex is governed by other hormones, such as ACTH, that are produced in the hypothalamus, in the centre of the brain, and the pituitary gland beneath it (see feedback mechanism box).

ADRENAL MEDULLA
The adrenal medulla is part of the sympathetic division of the autonomic nervous system, which is the body’s first line of defence against physical and emotional stress. The medulla secretes the hormones adrenaline (epinephrine) and noradrenaline (norepinephrine) in

ANATOMY OF THE ADRENAL GLANDS
Also sometimes called the suparenal glands, the adrenal glands are situated on top of the kidneys. Each gland is divided into two regions: the adrenal cortex (which secretes hormones that affect the metabolism) and the adrenal medulla (which is part of the sympathetic nervous system).
response to stimulation by sympathetic nerves. These nerves are most active during times of stress.

The release of these hormones into the circulation produces effects similar to sympathetic nerve stimulation. The heart rate and force of contraction of the heart muscle increase so that more blood is pumped around the body and the airways are widened to ease breathing. The hormones constrict blood vessels in the intestines, kidneys, and liver, and widen blood vessels supplying the skeletal muscles. Consequently, more blood is supplied to the active muscles and less to the internal organs.

**adrenal hyperplasia, congenital**

A rare genetic disorder, present from birth, in which an enzyme (a protein that acts as a catalyst) defect blocks the production of corticosteroid hormones (hydrocortisone and aldosterone) from the adrenal glands.

**SYMPTOMS**

The enzyme block results in production of excessive amounts of androgens (male sex hormones), which can cause abnormal genital development in an affected fetus. In females, these androgens cause enlargement of the clitoris and some fusion of the outer lips of the vulva, resulting in genital ambiguity (see sex determination). Some affected males have an enlarged penis, which may either be evident at birth or may develop later.

Other effects of the enzyme defect include hypotension (low blood pressure), hypoglycaemia (low blood sugar levels), weight loss, and dehydration. Hyperplasia (enlargement) of the adrenal gland occurs due to excessive secretion of the hormone ACTH, which is a result of insufficient production of hydrocortisone. Excessive skin pigmentation may occur in skin creases and around the nipples.

In severe cases, congenital adrenal hyperplasia is apparent soon after birth. In milder cases, symptoms appear later, sometimes producing premature puberty in boys and delayed menstruation, hirsutism (excessive hairiness), and potential infertility in girls.

**DIAGNOSIS AND TREATMENT**

A diagnosis is confirmed by measuring corticosteroid hormones in the blood and urine. Ultrasound scanning may be carried out to verify that there is no tumour of the adrenal glands.

Treatment of congenital adrenal hyperplasia is with hormone replacement. If the treatment is started early, normal sexual development and fertility generally follow.

**adrenaline**

Also called epinephrine, a hormone released by the adrenal glands in response to signals from the sympathetic nervous system, part of the autonomic nervous system. These signals are triggered by stress, exercise, or emotions such as fear.

Adrenaline increases the speed and force of the heartbeat. It widens the airways to improve breathing and narrows blood vessels in the skin and intestine so that an increased flow of blood reaches the muscles.

Synthetic adrenaline is sometimes given by injection as emergency treatment of anaphylactic shock (a severe allergic reaction) and cardiac arrest (a halt in the heart’s pumping action). Eye-drops containing dipivefrine (a drug that passes quickly into the tissues and converts to adrenaline), may be used to treat acute (closed-angle) glaucoma. Regular use can cause a burning pain and, occasionally, blurred vision or pigment deposits on the eye surface. (See also noradrenaline.)

**adrenal tumours**

Rare cancerous or noncancerous tumours in the adrenal glands, usually causing excess secretion of hormones.

Tumours of the adrenal cortex may secrete aldosterone, causing primary aldosteronism (also called Conn’s syndrome), or hydrocortisone, causing Cushing’s syndrome.

Tumours of the adrenal medulla may cause excessive secretion of adrenaline (epinephrine) and noradrenaline (norepinephrine). Two types of tumour affect the medulla: phaeochromocytoma and neuroblastoma, which affects children. These tumours may cause intermittent hypertension (high blood pressure) and sweating attacks.

Surgical removal of a tumour or an adrenal gland usually cures noncancerous tumours. Cancerous tumours may require additional treatment with radiotherapy and/or chemotherapy. (See also adrenal glands disorders box.)

**adrenocorticotrophic hormone**

See ACTH.
ADRENAL GLANDS

Adrenal gland disorders are a range of uncommon but sometimes serious conditions that result from deficient or excessive production of hormones by one or both of the adrenal glands.

**Congenital defects**
A genetic defect causes congenital adrenal hyperplasia, in which the adrenal cortex is unable to make sufficient hydrocortisone and aldosterone. As a side effect of the reduced hydrocortisone production, the glands are stimulated into producing excess androgens (male sex hormones); this can cause masculinization of female babies.

**Autoimmune disorders**
Deficient production of hormones by the adrenal cortex is called adrenal failure; if the deficiency is due to disease of the adrenal glands themselves, it is called Addison's disease. The most common cause of Addison's disease is an autoimmune process (in which the body's immune system attacks its own tissues). Addison's disease can take a chronic course characterized by weakness, weight loss, and skin darkening, or an acute form (Addisonian crisis or acute adrenal failure), in which the patient may become confused and comatose.

**Infection**
Destruction of the adrenal glands by tuberculosis was once a major cause of Addison's disease but is now uncommon. The onset of an infection or another acute illness in someone with Addison's disease can precipitate acute adrenal failure.

**Impaired blood supply**
Loss or obstruction of the blood supply to the adrenal glands, sometimes as a result of arterial disease, is another possible cause of Addison's disease or acute adrenal failure.

**Tumours**
Cancerous or noncancerous growths in the adrenal glands are rare but generally lead to excess secretion of hormones. A tumour of the adrenal cortex can secrete aldosterone, causing primary aldosteronism (also called Conn’s syndrome), a condition that is characterized by thirst and high blood pressure. A tumour can also secrete hydrocortisone, causing Cushing's syndrome, which has various features including muscle-wasting and obesity of the trunk. Androgens may also be produced in excess, causing masculinization in females.

**Other disorders**
In many cases, disturbed activity of the adrenals is caused, not by disease of the glands themselves, but by an increase or decrease in the blood level of hormones that influence the activity of the glands.

Hydrocortisone production by the adrenal cortex is controlled by the secretion of ACTH (adrenocorticotropic hormone) by the pituitary gland.

A tumour or other pituitary gland disorder, or tumours in the lung, breast, and elsewhere, can cause excess ACTH secretion, leading to excess production of hydrocortisone by the adrenals and, hence, to Cushing’s syndrome. Pituitary disease is a cause of Cushing’s syndrome.

**Investigation**
Blood and/or urine tests can detect the high levels of adrenal hormones that occur with adrenal tumours. They can also detect the high levels of natural corticosteroids that occur in Cushing’s syndrome, and the low levels that occur in congenital adrenal hyperplasia. Blood tests are used to measure salt and potassium levels if Addison’s disease is suspected; further blood tests may be carried out to measure corticosteroid hormone levels. Diagnosis of Addison’s disease can be confirmed by the response to an injection of ACTH, which, under normal circumstances, will stimulate the adrenal glands. MRI or CT scanning can detect abnormalities of the adrenal glands and can confirm the presence of an adrenal tumour. They can also distinguish between raised hormone levels due to an adrenal tumour, or those due to a pituitary tumour. Ultrasound scanning can rule out an adrenal tumour as the cause of congenital adrenal hyperplasia.

**adrenogenital syndrome**
See adrenal hyperplasia, congenital.

**advanced life support**
Treatment of cardiac arrest (a halt in the heart's pumping action) by medical or paramedical professionals when basic life support, (which may be performed by a first- aider) has failed to restore a normal heartbeat and spontaneous breathing. Advanced life support involves the use of drugs and medical equipment.

An ECG monitor is used to record the electrical activity of the heart muscle. Ventilation delivers oxygen by way of an endotracheal tube inserted, via the mouth, into the trachea (windpipe). A cannula (a thin plastic tube inserted into a vein) allows administration of drugs such as adrenaline (epinephrine). In the event of ventricular fibrillation (rapid uncoordinated contractions of the heart), defibrillation (a brief electric shock to the heart using two paddles placed on the chest) may be used.

**adverse reaction**
See side effect.

**Aedes**
A genus of disease-transmitting mosquitoes. Many species of Aedes are responsible for spreading important viral infections; Aedes aegypti is the main vector of dengue and yellow fever. (See also mosquito bites.)

**aerobic**
A term that refers to anything that requires oxygen to live, function, and grow. Humans and many other forms of life are dependent on oxygen for “burning” foods in order to produce energy (see metabolism). Because of this dependence, they are described as obligate aerobes.

In contrast, many bacteria have fundamentally different metabolisms and thrive without oxygen (some are even killed by exposure to oxygen); such microorganisms are described as anaerobic. There are also certain bacteria and yeasts, known as facultative aerobes, that flourish in oxygen but can also live without it. (See also aerobics.)
aerobics  
Exercises, such as swimming, jogging, and cycling, that allow muscles to work at a steady rate with a constant, adequate supply of oxygen-carrying blood that allows them to be sustained for long periods. Oxygen is needed to release energy from the body’s stores. To fuel aerobic exercise, the muscles use fatty acid, burning it completely to produce energy, carbon dioxide, and water.  
Anaerobic exercise relies on a different series of biochemical reactions to obtain energy from the muscles’ stores of fat and sugar. The waste products of anaerobic exercise are acidic and, as they accumulate in muscles, cause muscle fatigue; high-intensity exercises, which are anaerobic, can be performed only for relatively short periods.  

**BENEFITS OF AEROBIC EXERCISE**

When performed regularly, aerobic exercise improves stamina and endurance. It encourages the growth of capillaries (small blood vessels), thereby improving blood supply to the cells. It improves the body cells’ capacity to use oxygen and increases the amount of oxygen that the body can use in a given time.  
As the body becomes fitter, the condition of the heart also improves: the heart rate becomes slower, both at rest and during exercise; the heart muscle becomes thicker and stronger; and the amount of blood pumped with each beat (the stroke volume) increases. The overall result is that the heart needs to do less work to achieve the same level of efficiency in pumping blood around the body. (See also exercise; fitness.)

aerodontalgia  
Sudden pain in a tooth brought on by a change in surrounding air pressure. Flying at high altitudes or in a changed atmosphere can cause a pocket of air in the dental pulp to expand and irritate the nerve in the root. Aerodontalgia is more likely with improperly fitted fillings or poorly filled root canals.

aerophagy  
Excessive swallowing of air, which may occur during rapid eating or drinking or may be caused by anxiety. After laryngectomy (surgical removal of the larynx), voluntary aerophagy is used to produce oesophageal speech.

aerosol  
A suspension of minute liquid or solid particles in the air, producing a fine mist. Some drugs are prescribed in this form for use in an inhaler or in a vaporizer. (See also solvent abuse.)

aetiology  
The cause of, or the study of the various factors involved in causing, a disease.  
For some cases of a particular disorder, a specific aetiology can be identified. For example, laboratory studies may show that an attack of diarrhoea is the result of a particular type of virus or bacterium. Other disorders have a multifactorial aetiology: the causative factors of degenerative arthritis, for example, include genetic susceptibility, repeated joint injuries, and excess weight. On the other hand, many disorders, such as schizophrenia, are of unknown aetiology.

afebrile  
A medical term meaning without fever. (See also febrile.)

affect  
A term used to describe a person’s mood. The two extremes of affect are elation and depression. A person who experiences extreme moods or changes in moods may have an affective disorder. Shallow or reduced affect (in which responses to events seem flat) may be a sign of schizophrenia or of an organic brain syndrome.

affective disorders  
Mental illnesses that are characterized predominantly by marked changes in affect (mood). Mood may vary over a period of time between mania (extreme elation) and severe depression. (See also manic-depressive illness.)

afferent  
A term meaning carrying towards. Afferent is used mainly to describe blood vessels that supply organs, or nerves that carry impulses from peripheral sense receptors to the brain and spinal cord.

affinity  
A term used to describe the attraction between chemicals that causes them to bind together, as, for example, between an antigen and an antibody (see immune response). In microbiology, affinity describes the physical similarity between organisms (viruses, for example). In psychology, the term refers to attraction between two people.

aflatoxin  
A poisonous substance produced by *Aspergillus flavus* moulds, which contaminate stored foods, especially peanuts, grains, and cassava. Aflatoxin is believed to be one of the factors responsible for the high incidence of liver cancer in tropical Africa.

afterbirth  
The common name for the tissues that are expelled from the uterus following the delivery of a baby (see childbirth). The afterbirth consists of the placenta and the membranes that surrounded the fetus.

aftercare  
The medical care of a patient following treatment, particularly after surgery.

afterpains  
Contractions of the uterus that continue after childbirth. Afterpains are normal, indicating that the uterus is shrinking as it should, and are experienced by many women, especially during breast-feeding. Afterpains usually disappear a few days after the birth, but analgesic drugs (painkillers) may be needed.

agammaglobulinaemia  
A type of immunodeficiency disorder in which there is an almost complete absence of B-lymphocytes and immunoglobulins in the blood.

agar  
An extract of certain seaweeds that has similar properties to gelatine. Agar can be taken for constipation to soften and give bulk to faeces, and to relieve indigestion and heartburn. It is also used as a gelling agent in media for growing bacterial cultures.

age  
A person’s age is usually measured chronologically but can also be measured in terms of physical, mental, or developmental maturity. Age may be of medical significance in diagnosis and in determining treatment.

**PHYSICAL AGE**  
The age of a fetus is known as gestational age, which can be calculated from the date of the mother’s last menstrual period. Alternatively, it can be assessed by ultrasound scanning, which is more accurate. The estimation of gestational age is important in neonatal paediatrics for identification of babies...
who are too small and who may subsequently have problems as a result of their low birthweight.

In children, bone age (the degree of bone maturity as seen on an X-ray) can be a useful measure of physical development because all healthy individuals reach the same adult level of skeletal maturity and each bone passes through the same sequence of growth. Assessment of bone age is useful in the investigation of delayed puberty or short stature in children. A prediction of the final adult height can be made if the chronological age, bone age, and current height are known.

Dental age, which is another measure of physical maturity, can be assessed by the number of teeth that have erupted (see eruption of teeth) or by the amount of dental calcification (see calcification, dental), as seen on an X-ray, compared with standard values.

In adults, physical age is difficult to assess other than by physical appearance. It can be estimated after death by the state of certain organs, particularly by the amount of atheroma (fatty deposits) lining the arteries.

MENTAL AND DEVELOPMENTAL AGE

Mental age can be assessed by the comparison of scores achieved in intelligence tests with standard scores for different chronological ages. A young child’s age can be expressed in terms of his or her level of developmental skills, manual dexterity, social skills, and language when compared to those of other children. Patterns of development in these fields have been described for children up to the age of five. (See also child development.)

agenesis

The complete absence, at birth, of an organ or a component of the body. Agenesis is caused by developmental failure in the embryo.

agent

Any substance or force capable of bringing about a biological, chemical, or physical change. (See also reagent.)

Agent Orange

A herbicide and defoliant of which the major constituent (50 per cent by volume) is the phenoxy acid herbicide 2,4,5 T. The highly toxic contaminant TCDD, commonly known as dioxin, may be added to this substance during manufacture (see defoliant poisoning).

age spots

Blemishes that appear on the skin with increasing age. The most common type are brown or yellow slightly raised spots called seborrhoeic keratoses, which can occur at any site. Also common in elderly people are freckles, solar keratoses (small scaly patches, often appearing on the backs of the hands, that are a result of overexposure to the sun), and De Morgan’s spots, which are red, pinpoint blemishes on the trunk.

THE PRACTICAL EFFECTS OF AGING

In the body, aging is associated with loss of elasticity in the skin, blood vessels, and tendons. There is also progressive decline in the functioning of organs such as the lungs, kidneys, and liver. Mechanical wear and tear causes cumulative damage to certain organ systems. Brain cells, specialized kidney units, and many other body structures are never replaced after they have reached maturity.

EFFECTS OF AGING

<table>
<thead>
<tr>
<th>Organ or tissue</th>
<th>Natural effects</th>
<th>Accelerated by</th>
</tr>
</thead>
<tbody>
<tr>
<td>Skin</td>
<td>Loss of elastic tissue causes skin to sag and wrinkle. Weakened blood capillaries cause skin to bruise more easily.</td>
<td>Exposure to sun; smoking.</td>
</tr>
<tr>
<td>Brain and nervous system</td>
<td>Loss of nerve cells leads to reduction in ability to memorize or to learn new skills. Reaction time of nerves increases, making responses slower.</td>
<td>Excessive consumption of alcohol and other drugs; repeated head trauma (for example from boxing).</td>
</tr>
<tr>
<td>Senses</td>
<td>Some loss of acuity in all senses, mainly due to loss of nerve cells.</td>
<td>Loud noise (hearing); smoking (smell/taste).</td>
</tr>
<tr>
<td>Lungs</td>
<td>Loss of elasticity with age, so that breathing is less efficient.</td>
<td>Air pollution; smoking; lack of exercise.</td>
</tr>
<tr>
<td>Heart</td>
<td>Becomes less efficient at pumping, causing reduced tolerance to exercise.</td>
<td>Excessive use of alcohol and cigarettes; a fatty diet.</td>
</tr>
<tr>
<td>Circulation</td>
<td>Arteries harden, causing poor blood circulation and higher blood pressure.</td>
<td>Lack of exercise; smoking; poor diet.</td>
</tr>
<tr>
<td>Joints</td>
<td>Pressure on intervertebral discs causes height loss; wear on hip and knee joints reduces mobility.</td>
<td>Athletic injuries; being overweight.</td>
</tr>
<tr>
<td>Muscles</td>
<td>Loss of muscle bulk and strength</td>
<td>Lack of exercise; starvation.</td>
</tr>
<tr>
<td>Liver</td>
<td>Becomes less efficient in processing toxic substances in the blood</td>
<td>Damage from alcohol consumption and virus infections</td>
</tr>
</tbody>
</table>
Treatment is usually unnecessary for any of these age spots, apart from solar keratoses, which may eventually progress to skin cancer. Freezing the keratoses with liquid nitrogen or applying a cream containing a cytotoxic drug is the usual treatment. They may also be removed surgically under a local anaesthetic (see anaesthesia, local).

**ageusia**
The lack of, or an impairment of, the sense of taste (see taste, loss of).

**agglutination**
See clumping.

**aggregation, platelet**
The clumping together of platelets (small, sticky blood particles). Aggregation takes place when a blood vessel is damaged. It is the first stage of blood clotting, helping to plug injured vessels.

Inappropriate aggregation can have adverse effects; if it occurs in an artery, for example, thrombosis (a blood clot forming in an undamaged blood vessel) may result. Many drugs, including aspirin and clopidogrel, help to reduce platelet aggregation.

**aggression**
A general term for a wide variety of acts of hostility. A number of factors, including human evolutionary survival strategies, are thought to be involved.

**CAUSES**
Androgen hormones (male sex hormones) seem to promote aggression, whereas oestrogen hormones (the female sex hormones) may suppress it. Age is another factor; aggression is more common in teenagers and young adults, and some people believe that it can result from frustration or lack of affection as a child. Sometimes a brain tumour or head injury may lead to aggression.

Psychiatric conditions associated with aggressive outbursts are schizophrenia, antisocial personality disorder, mania, and abuse of alcohol or amphetamine drugs. Temporal lobe epilepsy, hypoglycaemia, and confusion due to physical illnesses are other, less common, medical causes.

**aging**
Aging is the physical and mental changes that occur with the passing of time and is associated with degenerative changes in various organs and tissues, such as loss of elasticity in the skin and a progressive decline in organ function.

Wear and tear causes cumulative damage to the joints, and the muscles lose bulk and strength. Wound healing and resistance to infection also decline. Gradual loss of nerve cells can lead to reduced sensory acuity and difficulties with learning and memory. However, dementia occurs in only a minority of elderly people.

Heredity is an important determinant of life expectancy, but physical degeneration may be accelerated by factors such as smoking, excessive alcohol intake, poor diet, and insufficient exercise. With advances in medical science, life expectancy in the developed world has risen dramatically over the last century.

**agitation**
Restlessness and the inability to keep still, usually as a result of anxiety or tension. People who are agitated engage in aimless, repetitive behaviour, such as pacing up and down or wringing their hands, and they often start tasks and fail to complete them.

Persistent agitation is seen in anxiety disorders, especially if there is an underlying physical cause such as alcohol withdrawal. Depression may also be accompanied by agitation.

**agnathia**
A developmental defect in the fetus in which the lower jaw is only partially formed or may be entirely absent. (See also birth defects.)

**agnosia**
The inability to recognize objects, despite adequate sensory information about them reaching the brain via the eyes or ears or through touch. In order for an object to be recognized, the sensory information it provides must be interpreted, which involves the recall of memorized information about similar objects. Agnosia is caused by damage to areas of the brain involved in interpretative and recall functions. The most common causes of this kind of damage are stroke or head injury.

**TYPES**
Agnosia is usually associated with just one of the senses of vision, hearing, or touch and is described as visual, auditory, or tactile respectively. For example, an object may be completely recognizable by hearing and touch, but it cannot be recognized by sight, despite the sense of vision being perfectly normal (an example of visual agnosia).

Some people, after suffering a stroke that damages the right cerebral hemisphere, seem unaware of any disability in the affected left limbs. This is called anosognosia or sensory inattention.

**outlook**
There is no specific treatment for agnosia, but some of the lost interpretative ability may eventually return.

**agonist**
A term that means to have a stimulating effect. In pharmacology, an agonist drug, which is sometimes known as an activator, is a drug that binds to a specific area on the surface of a cell (a receptor) and triggers or increases a particular activity in that cell.

**agoraphobia**
Fear of going into open spaces or public places. Agoraphobia may sometimes overlap with claustrophobia (a fear of enclosed spaces). Agoraphobic individuals who do venture out may have a panic attack, further restricting their activities, and may eventually be housebound. Treatment with behaviour therapy is often successful; antidepressant drugs may also help.

**agranulocytosis**
A potentially life-threatening disorder, in which there is a severe acute lack of neutrophils (white blood cells that seek and destroy infective microorganisms). This deficiency seriously weakens the body’s defences against infection.

In agranulocytosis, the bone marrow fails to produce adequate neutrophils. This may be an adverse effect of a drug such as carbimazole (used to treat thyroid diseases) or an effect of some drug treatments for cancer (see chemotherapy). Fever and mouth ulcers commonly occur.

Treatment is with antibiotic drugs, which should be started immediately to prevent the development of severe, and potentially fatal, infections.

**agraphia**
Loss of or impaired ability to write, despite normal functioning of the hand and arm muscles. Agraphia can result from damage to the parts of the cerebrum (the main mass of the brain) concerned with writing.

**CAUSES**
The ability to write depends on a complex sequence of mental processes, including the selection of words and
recall from memory of these words are spelled, formulation and execution of the required hand movements, and visual checking that written words match their representation in the brain. These processes may take place in a number of connected regions of the brain. Agraphia may be caused by damage to any of these regions (most commonly as a result of a head injury, a stroke, or a brain tumour) and can therefore be of different types and degrees of severity.

Agraphia is often accompanied by alexia (loss of reading ability) or may be part of an expressive aphasia (a general disturbance in expression of language).

OUTLOOK
There is no specific treatment for agraphia, but some of the lost writing skills may return in time.

ague
An outdated term for the fever in malaria and similar diseases, in which the sufferer alternately feels excessively hot and shiveringly cold.

AIDS
The abbreviation for acquired immune deficiency syndrome, a deficiency of the immune system due to infection with the human immunodeficiency virus (see HIV). The interval between infection and the development of AIDS is highly variable. Without treatment, around half of those individuals infected will develop AIDS within eight to nine years. In about one in ten cases, however, progression to AIDS is very slow, taking up to 20 years or longer. Illness and death from AIDS is a growing health problem worldwide, and there is, as yet, no cure or vaccine.

METHODS OF TRANSMISSION
HIV is transmitted in body fluids such as semen, blood, vaginal secretions, and breast milk. Major methods of transmission are sexual contact (vaginal, anal, or oral), blood to blood (via transfusions, or needle-sharing in drug users), and mother-to-fetus. HIV has also been transmitted through blood products donated semen; but improved screening has greatly reduced these risks. HIV is not spread by everyday contact, such as hugging or sharing crockery.

EFFECTS OF THE VIRUS
The virus enters the bloodstream and infects cells with a particular receptor, called the CD4 receptor, on their surface. These cells include a type of white blood cell called a CD4 lymphocyte (a T lymphocyte with a CD4 receptor), that is responsible for fighting infection, and cells in other tissues such as the brain. The virus reproduces within the infected cells, which then die, releasing more virus particles into the blood. If the infection is left untreated, the number of CD4 lymphocytes falls, resulting in greater susceptibility to certain infections and some types of cancer.

SYMPTOMS AND SIGNS
Some people experience a short-lived illness similar to infectious mononucleosis when they are first infected with HIV. Many individuals have no obvious symptoms. After the initial illness, many people remain well. Some may suffer from enlarged lymph nodes, muscle pain, and excessive sweating. Severe bacterial infections, such as pneumonia, are common. Later, vague complaints, such as weight loss, fevers, sweats, or unexplained diarrhoea (described as AIDS-related complex) may herald the development of AIDS.

Other features of infection with HIV include skin disorders and a variety of viral, fungal and bacterial infections. HIV may also affect the brain, causing neurological disorders such as dementia. Certain conditions, known as AIDS-defining illnesses, mark the development of full-blown AIDS. These include cancers (lymphoma of the brain, Kaposis sarcoma, and cancer of the cervix) and various infections (pneumocystis pneumonia, cytomegalovirus infection, toxoplasmosis, diarrhoea as a result of Cryptosporidium or Isospora, candidiasis, disseminated strongyloidiasis, and cryptococcosis), many of which are described as opportunistic infections.

DIAGNOSIS
Confirmation of HIV infection involves testing a blood sample for the presence of antibodies to HIV (see HIV test), which may not develop for three months after initial infection. The condition is monitored using blood tests that measure the number of CD4 lymphocytes in the blood or by measuring viral load (the amount of virus detectable in the blood). Diagnosis of full-blown AIDS is based on a positive HIV test along with the presence of an AIDS-defining illness.

TREATMENT AND OUTLOOK
Treatment of HIV infection with a combination of antiviral drugs can slow the progress of the disease, and may prevent the development of full-blown AIDS. The main types of antiviral drug used are protease inhibitors, such as indinavir, and reverse transcriptase inhibitors such as zidovudine. Several drugs are usually used together to prevent resistance from developing. AIDS-defining illnesses are treated as they develop.

Since the introduction of antiviral drug combination therapies, deaths from AIDS in the developed world have been reduced dramatically. HIV infection remains life-threatening, however, and the most effective strategy for defeating it is prevention of infection.

PREVENTION OF INFECTION
The risk of infection can be reduced by practising safer sex. and by intravenous drug users not sharing needles. There is a small risk to health workers handling infected needles or blood products, but this can be minimized by the adoption of safe practices in the workplace.

AIDS-related complex
A combination of symptoms including weight loss, fever, neurological problems, and recurrent infections in an individual who has been infected with HIV (the virus that causes AIDS) but has not yet developed AIDS. Many people with AIDS-related complex will eventually develop the features of AIDS.

air
The colourless, odourless mixture of gases that forms the Earth’s atmosphere. Air consists of 78 per cent nitrogen, 21 per cent oxygen, small quantities of carbon dioxide and other gases, and some water vapour.

The balance of atmospheric gases is maintained largely by the mutual needs of plants and animals. Plants use carbon dioxide and release oxygen in a process called photosynthesis; animals use oxygen during respiration, and produce carbon dioxide as a waste product; However, the level of carbon dioxide in the atmosphere is gradually increasing as a result of large-scale deforestation and the burning of fossil fuels, which may lead to significant global warming, also known as the greenhouse effect. (See also pollution.)

air conditioning
A system that controls the temperature, humidity, and purity, of the air in a building. Contaminated air-conditioning systems may cause legionnaires’ disease (a type of pneumonia) and
AIDS is caused by the human immunodeficiency virus (HIV) (right), which consists of some nucleic acid (genetic material) inside two protective shells and an outer envelope. Full-blown AIDS develops in only some people infected with HIV.

HIV (the AIDS virus)
The electron micrograph at left shows a human immunodeficiency virus (HIV) particle erupting from an infected human lymphocyte (cell of the immune system).

**CAUSES AND PREVENTION OF AIDS**

**HOW HIV AFFECTS THE IMMUNE SYSTEM**

1. HIV enters the bloodstream and infects cells that have CD4 receptors on their surface, particularly CD4-lymphocytes, which are responsible for fighting infection.

2. The virus attaches to and enters the CD4-lymphocytes. It then loses its protective shell, releasing its RNA and reverse transcriptase (an enzyme).

3. Reverse transcriptase enables the viral RNA to use the host CD4-lymphocyte's genetic material to reproduce itself. The new virus particles are released into the blood, killing the infected CD4-lymphocyte.

4. When disease organisms invade, immune responses may fail, due to a shortage of CD4-lymphocytes. The disease organism may then overwhelm the immune system and lead to the features of AIDS.

**RECOMMENDATIONS FOR PREVENTING THE SPREAD OF AIDS**

- Do not have sexual intercourse with many partners, and especially not with people known to have HIV, without using a condom.

- Do not use intravenous (IV) drugs. If you use IV drugs, do not share needles or syringes.

- Do not have sex with people who use IV drugs.

- People with AIDS or who have had positive HIV antibody test results may pass the disease on to others and should not donate blood, plasma, body organs, other tissues, or sperm. They should not exchange body fluids during sexual activity.

- There is a risk of infecting (or being infected by) others through sexual intercourse, sharing needles, and, possibly, exposure of others to saliva through oral-genital contact or "wet" kissing. Condoms substantially reduce the risk of infection.

- Toothbrushes, razors, or other implements that could become contaminated with blood should not be shared.
humidifier fever (a lung disease causing coughing and breathing difficulties). Air conditioning is also thought to be a factor in some cases of sick building syndrome, which produces headache, irritability, and loss of energy.

**air embolism**
The blockage of a small artery by an air bubble carried in the blood. Air embolism is rare. In most cases, it is caused by air entering the circulation through a vein, either as a result of injury or following surgery. Air embolism can also occur during scuba-diving or air-travel accidents, in which lung tissue ruptures, releasing air into the bloodstream.

**air pollution**
See pollution.

**air swallowing**
See aerophagy.

**air travel**
See aviation medicine; barotrauma.

**airway**
A collective term for the passages through which air enters and leaves the lungs (see respiratory system). The airway is made up of the nasal passages, the oral cavity, the upper part of the pharynx (throat), the larynx (voicebox), the trachea (windpipe), the bronchi (the main air passages to the lungs), and the bronchioles (the smaller air passages in the lungs that branch off from the bronchi).

The term airway is also applied to a tube that is inserted into the mouth of an unconscious person to prevent the tongue from obstructing breathing. Preservation of the airway can also be achieved by inserting an endotracheal tube into the trachea, either through the mouth or nose or via an incision in the neck, as in a tracheostomy operation. (See also respiratory system.)

**airway obstruction**
Narrowing or blockage of the respiratory passages. The obstruction may be due to a foreign body, such as a piece of food, that becomes lodged in part of the upper airway and may result in choking. Certain diseases and disorders, such as diphtheria and lung cancer, can cause obstruction. Additionally, spasm of the muscular walls of the airway, as occurs in bronchospasm (a feature of asthma and bronchitis), results in breathing difficulty. (See also rescue breathing; lung disorders box.)

**akathisia**
The inability to sit still, which occasionally occurs as a side effect of an antipsychotic drug or, less commonly, as a complication of Parkinson’s disease.

**akinesia**
Complete or almost complete loss of movement. Akinesia may result from damage to part of the brain due, for example, to a stroke or Parkinson’s disease.

**albinism**
A rare, inherited disorder that is characterized by a lack of the pigment melanin, which gives colour to the skin, hair, and eyes.

Oculocutaneous albinism (the most common type of albinism) is transmitted as an autosomal recessive trait (see genetic disorders). The genetic defect results in deficiency of a specific enzyme (a protein that acts as a catalyst); this deficiency interferes with the production of melanin in the affected tissues.

In oculocutaneous albinism, the hair, skin, and eyes are all affected. The skin cannot tan and ages prematurely. In addition, skin cancers may develop on areas of skin exposed to the sun. Less often, only the eyes are affected. Visual problems affecting people with albinism include photophobia (an intolerance to bright light), nystagmus (abnormal flickering movements), myopia (short-sightedness), and squint.

Glasses are usually needed from an early age, and tinted glasses help to reduce photophobia. If the skin is affected, it should be carefully protected from the sun.

**albumin**
The most abundant protein in the blood plasma. Albumin is made in the liver from amino acids that have been absorbed from digested protein.

Albumin helps to retain substances (such as calcium, some hormones, and certain drugs) in the circulation by binding to them to prevent them from being filtered out by the kidneys and excreted in the urine. Albumin also regulates the movement of water between tissues and the bloodstream by osmosis (the movement of water to an area with a higher concentration of salts or proteins). (See also albuminuria.)

**albuminuria**
The presence of the protein albumin in the urine; a type of proteinuria. Normally, the glomeruli (the filtering units of the kidneys) do not allow albumin to pass into the urine. Albuminuria therefore usually indicates that there is damage to the kidneys’ filtering mechanisms. Such damage may be due to a kidney disorder, such as glomerulonephritis or nephrotic syndrome, or it may be a sign that the kidneys have been affected by hypertension. In diabetes mellitus, the presence of even small amounts of albumin in the urine (a condition known as microalbuminuria) is an early indicator of kidney damage. Albuminuria can be detected by a simple urine test.

**alcohol**
A colourless liquid produced from the fermentation of carbohydrates by yeast. Also known as ethanol or ethyl alcohol, alcohol is the active constituent of alcoholic drinks such as beer, wine, and spirits. In medicine, alcohol is used as
an antiseptic and a solvent. *Methanol*, also known as methyl alcohol, is a related, highly toxic, substance.

**MENTAL EFFECTS**

Alcohol is a drug and produces a wide range of mental and physical effects. The effect of alcohol on the *central nervous system* (the brain and spinal cord) is as a depressant, decreasing its activity and thereby reducing anxiety, tension, and inhibitions. In moderate amounts, alcohol produces a feeling of relaxation, confidence, and sociability. However, alcohol slows reactions, and the more that is drunk, the greater the impairment of concentration and judgment. Excessive consumption of alcohol results in poisoning or acute *alcohol intoxication*, with effects ranging from euphoria to unconsciousness.

**PHYSICAL EFFECTS**

Short-term physical effects include peripheral vasodilation (widening of small blood vessels), causing flushing and increased flow of gastric juices, which stimulates the appetite. Alcohol increases sexual confidence, but high levels can cause impotence. Alcohol also acts as a diuretic, increasing urine output.

In the long term, regular excessive consumption of alcohol can cause gastritis (inflammation and ulceration of the stomach lining) and can lead to *alcohol-related disorders*. Heavy drinking in the long term may also lead to *alcohol dependence*. However, individuals who drink regular, small amounts of alcohol, (1–2 units (see alcohol, unit of) per day) seem to have lower rates of *coronary artery disease* and stroke than those who abstain totally.

The consumption of alcohol during pregnancy may result in *fetal alcohol syndrome*, miscarriage, or a disruption in normal fetal development.

**alcohol dependence**

An illness characterized by habitual, compulsive, long-term, heavy alcohol consumption and the development of withdrawal symptoms when drinking is stopped suddenly.

**CAUSES**

Causative factors that interact in the development of alcohol dependence include: personality, environment, and the addictive nature of alcohol. People of an inadequate, insecure, or immature personality are at greater risk. Environmental factors are important, especially the ready availability, affordability, and widespread social acceptance of alcohol. Genetic factors may play a part in causing alcohol dependence in some cases, but it is now widely believed that anyone, irrespective of personality, environment, or genetic background, is capable of becoming dependent. Stress is often a major factor in precipitating heavy drinking.

**DEVELOPMENT OF DEPENDENCE**

Alcohol dependence usually develops in four main stages that occur over a number of years and merge imperceptibly. In the first phase, tolerance (being able to drink more alcohol before experiencing its effects) develops in the heavy social drinker. In the second phase, the drinker experiences memory lapses relating to events during the drinking episodes. In the third phase, there is loss of control over alcohol consumption. The final phase is characterized by prolonged binges of intoxication, and mental or physical complications.

**SYMPTOMS AND EFFECTS**

Behavioural symptoms of alcohol dependence are varied, and they can include grandiose, aggressive, or furtive behaviour; personality changes (such as irritability, jealousy, or uncontrolled anger); neglect of food intake and personal appearance; and lengthy periods of intoxication.

Physical symptoms of the condition may include nausea, vomiting, or shaking in the morning; abdominal pain; cramps; numbness or tingling; weakness in the legs and hands; enlarged blood vessels in the face; irregular pulse; unsteadiness; confusion; memory lapses; and incontinence. Sudden withdrawal from alcohol may lead to delirium tremens (severe shakes, hallucinations, and convulsions).

**TREATMENT**

Many problem drinkers require medical help in overcoming their physical withdrawal symptoms (detoxification) when they stop drinking alcohol, followed by long-term treatment. There are different methods of treatment, which may be combined.

Psychological treatments for alcohol dependence involve *psychotherapy* and are commonly carried out as *group therapy*. Social treatments may offer practical help, such as with problems at work, and tend to involve family members in the process. Physical treatment includes the use of *disulfiram*, a drug that sensitizes the drinker to alcohol so that he or she experiences unpleasant side effects when drinking, or acamprosate, which helps to reduce craving.

*Alcoholics Anonymous* and other self-help organizations can provide support and advice.

**Alcoholics Anonymous**

A worldwide, independent, self-help organization that is operated locally by people working on a voluntary basis to overcome *alcohol dependence*. Regular group meetings are held in which members are encouraged to help one another to stay sober by sharing their experiences openly and by offering support and advice.

**alcohol intoxication**

The condition that results from consuming an excessive amount of *alcohol*, often over a relatively short period.

**ALCOHOL AND PREGNANCY**

The damage to a fetus by alcohol intake during pregnancy has been recognized only recently. Intake of more than two units (see alcohol, unit of) per day increases the risk of *fetal alcohol syndrome* (consisting of facial abnormalities such as cleft lip and palate, heart defects, abnormal limb development, and lower-than-average intelligence). The risk of miscarriage is also increased. Binge drinking can have the same effect, even if the mother drinks little otherwise. Because a proportion of the alcohol reaches the baby, there is a risk that even small amounts can disrupt normal development (causing, for example, low birth weight).

**Fetal alcohol syndrome**

An affected baby is abnormally small, with small eyes and a small jaw. He or she may also suffer from heart defects or a cleft lip and palate, may suckle poorly, sleep badly, and be irritable.
Alcohol intoxication

Alcohol is a drug and, even in small amounts, its effects on the body are noticeable. Problems arise when people fail to take into account the effects of alcohol on tasks requiring coordination (such as driving) when they become intoxicated or when they become dependent on the drug. Alcohol dependence can cause early death and is a major factor in crime, marital breakdown, child abuse, accidents, and absenteeism.

Prolonged heavy drinking that stops just short of dependence still may cause a wide variety of diseases, such as cardiomyopathy and cirrhosis of the liver.

The table below highlights the effects of alcohol on the occasional social drinker. These effects occur with higher concentrations as alcohol tolerance increases.

### EFFECTS OF INCREASING BLOOD ALCOHOL LEVELS

<table>
<thead>
<tr>
<th>Concentration (milligrams per 100 millilitres)</th>
<th>Observable effects</th>
</tr>
</thead>
<tbody>
<tr>
<td>30-50</td>
<td>Flushed face, euphoria, talkativeness, increased social confidence</td>
</tr>
<tr>
<td>50-150</td>
<td>Disturbed thinking and coordination, irritability, reduced self-control, irresponsible talk and behaviour</td>
</tr>
<tr>
<td>150-250</td>
<td>Marked confusion, unsteady gait, slurred speech, unpredictable shows of emotion and aggression</td>
</tr>
<tr>
<td>250-400</td>
<td>Extreme confusion and disorientation, difficulty remaining upright, drowsiness, delayed or incoherent reaction to questions progressing to coma (a state of deep unconsciousness from which the person cannot be aroused)</td>
</tr>
<tr>
<td>400-500</td>
<td>Risk of death due to arrest of breathing (although habitual drinkers may survive even such high levels) and choking on vomit</td>
</tr>
</tbody>
</table>

### LONG TERM EFFECTS ON THE BODY

Persistent heavy drinking eventually damages body tissues; the main effects are shown below.

**Liver**
- The liver is the main organ responsible for metabolizing alcohol from the blood; it manifests many of the long-term effects of heavy drinking. These effects include fatty liver, hepatitis, cirrhosis, and liver cancer.

**Brain and nervous system**
- Alcohol depresses the central nervous system. Prolonged alcohol abuse permanently impairs brain function and damages peripheral nerves.

**Skin**
- Alcohol causes facial flushing, which becomes constant in heavy drinkers.

**Heart and circulation**
- Prolonged heavy drinking can cause heart failure, hypertension, and stroke.

**Digestive system**
- Irritation from large amounts of alcohol can cause gastritis and pancreatitis.

**Reproductive system**
- Alcohol increases sexual confidence, but in the long term can cause shrinkage of testes and breast development in men.

**Urinary system**
- Alcohol acts as a diuretic, increasing urine output.

**Cirrhosis of the liver**
- This condition is commonly caused by heavy drinking. When compared to a normal liver (far left), the cirrhotic liver clearly shows the formation of bands of scar tissue, which impair its function.
EFFECTS
The effects of high intake alcohol depend on many factors, including mental and physical state, body size, social situation, and acquired tolerance; but the important factor is the blood alcohol level. Mild intoxication promotes relaxation and increases social confidence.

However, alcohol causes acute poisoning if it is consumed in sufficiently large amounts. It depresses the activity of the central nervous system, (the brain and spinal cord), leading to loss of normal mental and physical control. In extreme cases, consumption of a large amount of alcohol over a short period of time may lead to loss of consciousness and even death.

TREATMENT
In most cases, recovery from alcohol intoxication occurs naturally as the alcohol is gradually broken down in the liver. Medical attention is required if the intoxication has resulted in coma.

For a description of the effects of long-term heavy drinking, see alcohol dependence and alcohol-related disorders.

alcoholism
See alcohol dependence.

alcohol-related disorders
A wide variety of physical and mental disorders associated with heavy, prolonged consumption of alcohol.

High alcohol consumption increases the risk of cancer of the mouth, tongue, pharynx (throat), larynx (voice-box), and oesophagus (gullet), especially if combined with smoking. Incidence of liver diseases, such as liver cancer, alcoholic hepatitis and cirrhosis, is higher in alcohol-dependent persons. High consumption of alcohol increases the risk of cardiomyopathy (disease of heart muscle), hypertension (high blood pressure), and stroke. Alcohol irritates the digestive tract and may cause gastritis. Heavy drinking during pregnancy increases the risk of miscarriage and fetal alcohol syndrome. Problem drinkers are more likely to suffer from anxiety and depression and to develop dementia.

Many problem drinkers have a poor diet and are prone to diseases caused by nutritional deficiency, particularly of thiamine (see vitamin B complex). Severe thiamine deficiency (see beriberi) disturbs nerve function, causing cramps, numbness, and weakness in the legs and hands. Its effects on the brain can cause confusion, disturbances of speech and gait, and eventual coma (see Wernicke-Korsakoff syndrome). Severe deficiency can also cause heart failure (reduced pumping efficiency of the heart).

A prolonged high level of alcohol in the blood and tissues can disturb the body chemistry, resulting in hypoglycaemia (low blood glucose levels) and hyperlipidaemia (high blood fat levels). These may damage the heart, liver, blood vessels, and brain; irreversible damage may cause premature death.

aldosterone
A hormone secreted by the adrenal cortex (the outer part of the adrenal glands). Aldosterone plays an important role in the control of blood pressure and regulation of sodium and potassium concentrations in the blood and tissues.

Aldosterone acts on the kidneys to decrease the amount of sodium lost in the urine; the sodium is reabsorbed into the blood from urine before it leaves the kidneys and is replaced in the urine by potassium. The sodium draws water back into the blood with it, thereby increasing the blood volume and raising the blood pressure.

Aldosterone production is stimulated mainly by the action of angiotensin II, a chemical produced by a series of reactions involving the enzymes renin and angiotensin-converting enzyme. Production of aldosterone is also stimulated by the action of ACTH, which is produced by the pituitary gland.

alcohol, unit of
A measure that is commonly used to define the amount of alcohol that is present in a single alcoholic drink. A unit is defined as 10 millilitres of pure alcohol. The number of units in one drink is calculated by multiplying the alcohol content of that drink with its volume, then dividing by 1000. As a rough guide, half a pint (or a bottle) of beer, lager, or cider has one unit; a single measure (25 ml) of spirits has one unit; and a small glass of wine has one unit.

Various countries have official guidelines on the maximum number of units that can be consumed per day without endangering health. In the UK, the Department of Health has defined safe limits for men as three to four units per day (or less) and for women as two to three units per day (or less). In addition, one or two alcohol-free days per week are usually recommended.

aldosteronism
A disorder that results from excessive production of the hormone aldosterone from one or both of the adrenal glands. Aldosteronism caused by an adrenal tumour is known as Conn’s syndrome. Aldosteronism may also be due to disorders, such as heart failure (reduced pumping efficiency of the heart) or liver damage, that reduce blood flow through the kidneys. This reduction in the flow of blood flow leads to overproduction of renin and angiotensin, which, in turn, leads to excessive aldosterone production.

SYMPTOMS AND SIGNS
Symptoms of the condition are directly related to the actions of aldosterone. Excess sodium is retained in the body, leading to a rise in blood pressure, and excess potassium is lost in the urine. Low levels of potassium cause tiredness and muscle weakness and impair kidney function, leading to thirst and overproduction of urine.

TREATMENT
Treatment in all cases of aldosteronism includes restriction of salt in the diet and use of the diuretic drug spironolactone. This drug blocks the action of aldosterone on the kidneys, leading to increased loss of sodium from the body, lowered blood pressure, and reduced potassium loss. If the cause of aldosteronism is an adrenal tumour, this may be surgically removed.

alendronate sodium
See alendronic acid.

alendronic acid
A bisphosphonate drug that is used in the treatment of osteoporosis and Paget’s disease of bone. The most common side effect of alendronic acid is inflammation of the oesophagus, which causes heartburn or difficulty in swallowing. Other side effects can include headache, abdominal pain and distension, and diarrhoea or constipation.

Alexander technique
A therapy that aims to improve health by teaching people to stand and move more efficiently.

Developed in the 1920s by F. Mathias Alexander, the technique is based on the belief that bad patterns of body movement interfere with the proper functioning of the body and therefore contribute to the development of disease. By releasing unnecessary muscle
tensions, the Alexander technique aims to eliminate or reduce the severity of many disorders, including back pain, asthma, and stammering.

Alexia

Word blindness; the inability to recognize and name written words. Alexia results from damage to the part of the cerebrum (the main mass of the brain) by, for example, a stroke. The condition severely disrupts the reading ability of an individual who was previously literate. (See also dyslexia.)

Alcohol-related Disorders

<table>
<thead>
<tr>
<th>Cancer</th>
</tr>
</thead>
<tbody>
<tr>
<td>High alcohol consumption increases the risk of breast cancer in women and cancers of the mouth, tongue, pharynx (back of the throat), larynx (voicebox), and oesophagus, probably due to irritant action. In each of these cancers, alcohol intake, along with smoking, produces a much higher total risk of cancer than the sum of their separate risks. The risk of liver cancer, along with most types of liver disease, is also higher among problem drinkers.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Liver damage and disease</th>
</tr>
</thead>
<tbody>
<tr>
<td>Liver diseases caused by a high alcohol consumption include fatty liver, alcoholic hepatitis, cirrhosis, and liver cancer. They develop in sequence over a period of years. It is thought that a breakdown product of alcohol (acetaldehyde) has a toxic effect on liver cells and is the main cause of these diseases, although nutritional deficiency may also play some part. The risk of alcoholic hepatitis and cirrhosis developing increases in proportion to the amount of alcohol consumed and the number of years of high consumption; liver cancer develops in about one in five sufferers of cirrhosis.</td>

Alkali

Also called a base, an alkali is chemically defined as a donor of hydroxyl ions (each of which comprises one atom of oxygen and a hydrogen linked to an atom of oxygen) and has an overall negative electrical charge. Antacid drugs, such as sodium bicarbonate (bicarbonate of soda), are examples of alkalis. Some alkalis, such as sodium hydroxide, can be corrosive and cause burns. (See also acid; acid–base balance.)

Alkaloid

A group of nitrogen-containing substances that are obtained from plants. Morphine, codeine, nicotine, and strychnine (see strychnine poisoning) are examples of alkaloids.

Alkalosis

A disturbance of the body’s acid–base balance in which there is an accumulation of alkali (base) or a loss of acid. There are two types of alkalosis: metabolic and respiratory. In metabolic alkalosis, the increase in alkalinity may be caused by taking too much of an antacid drug or by losing a large amount of stomach acid as a result of severe vomiting. In respiratory alkalosis, there is a reduction in the blood level of carbonic acid (derived from carbon dioxide). This reduction is a consequence of hyperventilation (overbreathing), which

And protects codeine (which disturbs nerve functioning), nicotine (an incorrect bite), beriberi acid–base balance (thinning of the bones), and, such as sodium or by losing a

Alexia

Word blindness; the inability to recognize and name written words. Alexia results from damage to the part of the cerebrum (the main mass of the brain) by, for example, a stroke. The condition severely disrupts the reading ability of an individual who was previously literate. (See also dyslexia.)

Alphacalcidol

A synthetic form of vitamin D.

Alginates

Substances used in certain types of antacid drugs. Alginates float on top of the stomach contents, forming a raft, which reduces acid reflux and protects the oesophagus.

Alienation

Feeling like a stranger, even when among familiar people or places, and being unable to identify with family, a culture, or a peer group. Alienation is common in adolescents, and it also occurs in individuals who are isolated by cultural or language differences. In some people, alienation may be an early symptom of schizophrenia or a personality disorder.

Alignment, dental

The movement of teeth by the use of either fixed or removable orthodontic appliances (braces) to correct malocclusion (an incorrect bite).

Alimemazine

An antihistamine drug that is used mainly to relieve the itching that occurs in allergic conditions such as urticaria and atopic eczema. Alimemazine frequently causes drowsiness.

Alimentary tract

Also known as the alimentary canal, the tubelike structure that extends from the mouth to the anus (see digestive system).
may occur during a panic attack or at high altitudes due to lack of oxygen. (See also acidosis.)

Alka-Seltzer
A brand-named analgesic and antacid containing aspirin, sodium bicarbonate, and citric acid. Alka-Seltzer is used to treat headaches and stomach upset.

alkylating agents
A class of anticancer drugs.

allele
One of two or more different forms of a gene that occupies a specific position on a chromosome. (See also inheritance.)

allergen
A normally harmless substance that causes an allergic reaction (see allergy) in people who have become sensitized to it. Allergens can include foods (for example, nuts, eggs, and shellfish); inhaled substances (such as pollen, house dust, and fur); and some drugs.

Electron micrograph of various pollen grains
Pollen is a common example of an allergen. The airborne pollen grains from plants (such as grasses and trees) can trigger an allergic reaction, the most common of which is allergic rhinitis (hay fever).

allergic alveolitis, extrinsic
See extrinsic allergic alveolitis.

allergic rhinitis
See rhinitis, allergic.

allergy
Various conditions caused by inappropriate or exaggerated reactions of the immune system to a wide variety of substances known as allergens. Many common illnesses, such as asthma and hay fever (see rhinitis, allergic), are caused by allergic reactions to substances that, in the majority of people, cause no symptoms.

Allergic reactions occur only on second or subsequent exposure to the allergen, after first contact has sensitized the body. It is unclear why only certain drugs, and some foods, most commonly dairy products, seafood, strawberries, and cereals, can also cause allergies. In diagnosing an allergy, the individual's medical history is important. The doctor needs to know if the symptoms vary according to time of day or season, and if there are pets or other likely sources of allergens in the home.

The immune system is sensitized once it has been exposed to an allergen (steps 1 to 3). Symptoms occur when the allergen is met again (step 4).

1. An allergen enters the body and is recognized by lymphocytes (blood cells that form part of the body's immune system).
2. A few days to weeks later, the lymphocytes produce antibodies that are specific to the allergens.
3. The antibodies attach to cells in the tissues called mast cells, which contain granules of histamine.
4. Binding of allergens to antibodies on the surface of mast cells leads to the release of histamine and to the symptoms of allergy.

Allergic reactions occur only on second or subsequent exposure to the allergen, after first contact has sensitized the body. It is unclear why only certain
people develop allergies, but about one person in eight seems to have an inherited predisposition to them (see atopy).

**TYPES AND CAUSES**
The function of the immune system is to recognize antigens (foreign proteins) on the surfaces of microorganisms and to form antibodies (also called immunoglobulins) and sensitized lymphocytes (white blood cells). When the immune system next encounters these antigens, the antibodies and sensitized lymphocytes interact with them, leading to the destruction of the microorganisms.

A similar immune response occurs in allergies, except that the immune system forms antibodies or sensitized lymphocytes against harmless substances because these allergens are misidentified as potentially harmful antigens.

The inappropriate or exaggerated reactions that are seen in allergies are known as hypersensitivity reactions and can have any of four different mechanisms (which are termed Types I to IV hypersensitivity reactions).

**TYPE I HYPERSENSITIVITY REACTIONS**
Most well-known allergies are caused by Type I (also known as anaphylactic or immediate) hypersensitivity, in which allergens cause immediate symptoms by provoking the immune system into producing specific antibodies, belonging to a type called immunoglobulin E (IgE), which coat cells (known as mast cells or basophils) that are present in the skin and the lining of the stomach, lungs, and upper respiratory airways. When the allergen is encountered for the second time, it binds to the IgE antibodies and causes the granules in mast cells to release various chemicals, which are responsible for the symptoms of the allergy.

Among the chemicals released is histamine, which causes widening of blood vessels, leakage of fluid into tissues, and contraction of muscles, especially in the airways of the lung. Symptoms can include itching, swelling, sneezing, and wheezing. Particular conditions associated with Type I reactions include asthma, hay fever, urticaria (nettle rash), angioedema, anaphylactic shock (a severe, generalized allergic reaction), possibly atopic eczema, and some food allergies.

**TYPES II TO IV HYPERSENSITIVITY REACTIONS**
Because Types II to IV hypersensitivity reactions have different mechanisms to Type I reactions, they are less often implicated in allergies. However, contact allergic dermatitis, in which the skin reacts to prolonged contact with substances such as nickel, is the result of a Type IV hypersensitivity reaction.

**TREATMENT**
Whenever possible, the most effective treatment for allergy of any kind is avoidance of the relevant allergen.

Drug treatment for allergic reactions includes the use of antihistamine drugs, which relieve the symptoms. Some antihistamines have a sedative effect, which is useful, for example, in treating itching at night due to eczema; many do not cause drowsiness, making them more suitable for daytime use.

Drugs such as sodium cromoglicate and corticosteroids can be used regularly to prevent symptoms from developing. Hyposensitization can be valuable for a minority of people who suffer allergic reactions to specific allergens such as bee stings. Treatment involves gradually increasing doses of the allergen to promote formation of antibodies that will block future reactions. Hyposensitization must be carried out under close supervision because a severe allergic reaction can result. (See also delayed allergy.)

**Stages in male pattern baldness**

In this common form of alopecia, the man first loses hair from the temples and the crown, then the bald area gradually widens.

In generalized alopecia, the hair falls out in large amounts. Such hair loss occurs when all the hairs simultaneously enter the resting phase; they then fall out about three months later. Causes include surgery, prolonged illness, or childbirth. In such cases, the hair will regrow without treatment. Many anticancer drugs cause temporary alopecia. The hair usually regrows when the treatment is completed.

Localized alopecia may be the result of permanent skin damage (for example, following burns or radiotherapy) or of trauma to the hair roots by styling or, rarely, trichotillomania (a disorder in which sufferers pull out their hair). The most common type of localized hair loss is alopecia areata, an autoimmune disorder (in which the immune system attacks the body’s own tissues). There is no specific treatment for alopecia areata, but the hair usually regrows within a few months. Alopecia universalis is a rare, permanent form of alopecia areata that causes loss of all hair on the scalp and body, including the eyelashes and eyebrows.

**Allograft**

The practice of conventional medicine.

**allopathy**

The practice of conventional medicine. (See also homeopathy.)

**allopurinol**

A drug used in the long-term prevention of gout attacks. Allopurinol works by decreasing production of uric acid in the body, thereby preventing the formation of uric acid crystals in the joints.

Possible adverse effects of allopurinol include itching, rashes, and nausea. The drug cannot relieve the pain of an acute gout attack and may even precipitate one at the start of treatment. Such attacks can be prevented by taking a combination of allopurinol and a nonsteroidal anti-inflammatory drug (NSAID) or colchicine.

**almond oil**

An oil prepared from the seeds of the bitter almond tree (Prunus Amygdalus). Almond oil is a common ingredient of emollient skin preparations.

**almotriptan**

A serotonin agonist drug that is used in the treatment of acute migraine attacks.

**aloe**

The juice of leaves from various plants of the Aloe genus. Aloe may be added to compound benzoin tincture, an aromatic inhalation for relieving sinusitis and nasal congestion.
eyebrows. Skin diseases such as scalp ringworm (see tinea), lichen planus, lupus erythematosus, and skin tumours may also cause localized hair loss.

**TREATMENT**

Treatments for male-pattern baldness include hair transplants or drug treatments with minoxidil or finasteride. Generalized alopecia often resolves without treatment. Treatment of localized alopecia depends on the cause.

**alpha-antitrypsin deficiency**

A rare genetic disorder in which a person is missing the enzyme alpha-antitrypsin, which protects the body from damage by other enzymes. The disease mainly affects tissues in the lungs, resulting in emphysema, and the liver, causing cirrhosis. The effects of alpha-antitrypsin deficiency may not become apparent until after the age of 30. There is no cure, but symptoms can be relieved by drug treatment. In severe cases, a liver transplant may be a possibility.

**alpha-blocker drugs**

**COMMON DRUGS**

- Alfuzosin
- Doxazosin
- Indoramin
- Prazosin
- Tamsulosin
- Terazosin

A group of drugs used to treat hypertension (high blood pressure) and urinary symptoms resulting from an enlarged prostate gland (see prostate, enlarged).

Alpha-blocker drugs interfere with the nerve signals that govern the contraction of blood vessels. This causes the vessels to widen (vasodilation), thereby reducing the blood pressure. In the treatment of an enlarged prostate gland, alpha-blockers relax the ring of muscles at the bladder outlet, which improves the outflow of urine.

Side effects may include dizziness and fatigue (caused by a drop in blood pressure on standing up), drowsiness, headache, nausea, and a dry mouth.

**alpha-fetoprotein**

A protein that is produced in the liver and gastrointestinal tract of the fetus and by some abnormal tissues in adults.

**ALPHA-FETOPROTEIN IN PREGNANCY**

Alpha-fetoprotein (AFP) is excreted in the fetal urine into the amniotic fluid; the fluid is swallowed by the fetus, which introduces AFP into the fetal digestive system. Most of the AFP is broken down in the fetal intestine, but some of it passes into the mother’s circulation. AFP can be measured in the maternal blood from the latter part of the first trimester of pregnancy, and its concentration rises between the 15th and 20th weeks.

Raised levels of AFP are associated with fetal neural tube defects, such as spina bifida or anencephaly, and certain kidney abnormalities. High levels of AFP also occur in multiple pregnancies (see pregnancy, multiple) and threatened or actual miscarriage.

AFP levels may be unusually low if the fetus has Down’s syndrome. For this reason, measurement of blood AFP is included in blood tests that are used to screen pregnant women for increased risk of Down’s syndrome.

**ALPHA-FETOPROTEIN IN ADULTS**

AFP levels are commonly raised in adults with hepatoma (see liver cancer), cancerous teratoma of the testes or ovaries, or cancer of the pancreas, stomach, or lung. For this reason, AFP is known as a ‘tumour marker’.

AFP levels can be used to monitor results of treatment of such cancers; increasing levels after chemotherapy or surgery may indicate recurrence. However, AFP levels are also raised in some noncancerous conditions such as viral and alcoholic hepatitis and cirrhosis.

**alprazolam**

A benzodiazepine drug that is used in the treatment of anxiety, panic attacks, and phobias.

**alprostadil**

A prostaglandin drug used to minimize the effects of congenital (present from birth) heart defects in newborn babies prior to corrective surgery; it is usually administered in hospital. Alprostadil is also used as treatment for impotence. To produce an erection, it is self-administered, either by injection into the penis or as a gel introduced into the urethra.

**alternative medicine**

Also called complementary medicine, any medical system based on a theory of disease or method of treatment other than orthodox Western medicine.

**altitude sickness**

See mountain sickness.

**aluminium**

A light, metallic element that is found in bauxite and various other minerals. Aluminium compounds are used in antacid drugs and in antiperspirants.

Most of the aluminium taken into the body is excreted. Excessive amounts are toxic and are stored in the lungs, brain, liver, and thyroid gland, where they may result in organ damage.

Certain industrial processes give off fumes containing aluminium into the air. Inhalation of these fumes can cause fibrosis of lung tissue. Drugs that contain aluminium interfere with the absorption and excretion of a number of other drugs and should not, therefore, be taken simultaneously.

**alveolitis**

Inflammation and thickening of the walls of the alveoli (the tiny air sacs in the lungs). Alveolitis reduces the elasticity of the lungs during breathing and reduces the efficiency of the transfer of gas between the lungs and the surrounding blood vessels.

**CAUSES**

Alveolitis is commonly caused by an allergic reaction to inhaled dust of animal or plant origin, as in farmer’s lung (caused by spores from mouldy hay), bagassosis (caused by spores from mouldy sugar-cane residue), and pigeon fancier’s lung (caused by particles from bird droppings). This type of alveolitis is known as extrinsic allergic alveolitis.

**Effects of alveolitis**

The alveoli become inflamed and their walls thicken, causing the lungs to become less elastic and less able to transfer oxygen.
Fibrosing alveolitis is an autoimmune disorder (in which the immune system attacks the body’s own tissues). In some cases, it occurs with other autoimmune disorders, such as rheumatoid arthritis or systemic lupus erythematosus.

Radiation alveolitis is caused by irradiation of the lungs and may occur as a rare complication of radiotherapy for lung or breast cancer.

**SYMPTOMS AND DIAGNOSIS**

Alveolitis usually causes a dry cough and breathing difficulty on exertion.

A chest X-ray of a person suffering from alveolitis usually shows mottled shadowing across the lungs. Blood tests may be performed to look for specific antibodies (proteins manufactured by the immune system: see antibody) to an allergen. They may also be performed to look for evidence of an autoimmune disorder (in which the immune system attacks the body’s own tissues). Pulmonary function tests show reduced lung capacity without obstruction to air flow through the bronchi (air passages to the lungs). A lung biopsy (removal of a sample of tissue for microscopic analysis) may be the only way to make a conclusive diagnosis of alveolitis.

**TREATMENT AND OUTLOOK**

For most types of alveolitis, a short course of corticosteroid drugs relieves symptoms, but for fibrosing alveolitis the drugs may need to be taken indefinitely. If the cause of allergic alveolitis is recognized and avoided before lung damage occurs, the effects are not permanent. In fibrosing alveolitis, the damage progresses despite treatment, causing increasing breathing difficulty and, sometimes, respiratory failure.

**alveoloplasty**

Dental surgery that is carried out to remove protuberances and to smooth out other uneven areas from tooth-bearing bone in the jaw. Alveoplasty is performed either under a general anaesthetic (see anaesthesia, dental) or, more usually, under local anaesthetic. The procedure is usually carried out to facilitate the fitting of dentures on people whose alveolar ridge, underlying the gums, would not otherwise be smooth and even enough for dentures to be fitted easily or worn comfortably.

An incision is made in the gum, which is then peeled back to expose the uneven bone. The bone is then either reshaped with large forceps or filed down to the required shape. Finally, the gum is drawn back over the bone and stitched together. Some bruising and swelling of the mouth may occur, but the gum usually heals within two weeks.

**alveolus, dental**

The bony cavity or socket supporting each tooth in the jaw.

**alveolus, pulmonary**

One of millions of tiny, balloonlike sacs at the end of a bronchiole (one of the many small air passages in the lungs) where gases are exchanged during respiration. In each lung, there are approximately 300 million alveoli that are arranged in groups resembling bunches of grapes.

**ANATOMY OF THE ALVEOLI**

These tiny sacs contain capillaries in their thin walls that allow oxygen to be absorbed into the blood.

**Alzheimer’s disease**

A progressive condition in which nerve cells in the brain degenerate and the brain shrinks. Alzheimer’s disease is the most common cause of dementia (a general decline in all areas of mental ability). Its onset is uncommon before the age of 60, but incidence increases steadily with age thereafter.

**CAUSES**

Early onset Alzheimer’s disease, in which symptoms develop before the age of 60, is often inherited as a dominant trait (see genetic disorders). Late onset Alzheimer’s disease is associated with one of the genes that is responsible for the production of the blood protein apolipoprotein E. Genetic factors also result in the abnormal deposition of a protein in the brain called beta amyloid. Other chemical abnormalities include deficiency of the neurotransmitter acetylcholine.

**SYMPTOMS AND SIGNS**

The features of Alzheimer’s disease vary, but there are three broad stages. At first, the affected individual becomes increasingly forgetful; and problems with memory may cause anxiety and depression. Some deterioration in memory is a feature of normal aging, and this alone is not evidence of dementia.

In the second stage of the disease, loss of memory, particularly for recent events, gradually becomes more severe, and there may be disorientation as to time or place. The person’s concentration and numerical ability decline, and there is noticeable dysphasia (inability to find the right word). Anxiety increases, mood changes are unpredictable, and personality changes may occur. If the patient is left unsupervised, he or she may repeatedly wander off.

Finally, confusion becomes profound. There may be symptoms of psychosis, such as hallucinations and delusions. Signs of nervous system disease, such as abnormal reflexes (involuntary actions) and faecal or urinary incontinence, begin to develop.

**DIAGNOSIS**

Alzheimer’s disease is usually diagnosed from the symptoms, but tests including blood tests and CT scanning or MRI (techniques that produce cross-sectional or three-dimensional images) of the brain may be needed to exclude other causes of dementia.

**MRI of the brain in Alzheimer’s disease**

The volume of the brain substance has shrunk markedly, resulting in deep folding of the tissue and enlargement of the fluid-filled brain ventricles.
TREATMENT
The most important aspect of treatment for Alzheimer’s disease is the provision of suitable nursing and social care for sufferers and support for their relatives. Tranquilizer drugs can often improve difficult behaviour and to help with sleep. Treatment with acetylcholinesterase inhibitors, such as rivastigmine and donepezil, may slow the progress of the disease for a time, but will not improve mental ability. Side effects such as nausea and dizziness may occur.

amalgam, dental
A material, consisting of an alloy of mercury with other metals, that is used as fillings for teeth. Amalgam is soft enough to be easily workable by the dentist but sets rapidly into a hard, strong solid (see filling, dental).

amantadine
An antiviral drug that is used in the prevention and treatment of influenza A. Amantadine is also used to help relieve symptoms of Parkinson’s disease.

amaurosis fugax
Brief loss of vision, lasting for seconds or minutes, usually affecting one eye only and caused by the temporary blockage of a small blood vessel in the eye by an embolus (a particle of solid matter such as cholesterol or clotted blood). These emboli are carried in the bloodstream from diseased arteries in the neck or, rarely, the heart. Sufferers typically experience a loss or dimming of vision, in one eye only, rather like a shade being pulled down or up.

Attacks may be infrequent, or they may occur many times a day, which indicates an increased risk of stroke and requires medical investigation.

ambidexterity
The ability to perform manual skills, such as writing or using cutlery, equally well with either hand because there is no definite handedness (preference for the use of one hand in particular). Ambidexterity is an uncommon and often familial trait.

amblyopia
A permanent defect of visual acuity in which there is usually no structural abnormality in the eye. In many cases, there is a disturbance of the visual pathway between the retina and the brain. The term amblyopia is also sometimes applied to toxic or nutritional causes of decreased visual acuity, as in tobacco–alcohol amblyopia.

If normal vision is to develop during infancy and childhood, it is essential that clear, corresponding visual images are formed on both retinas so that compatible nerve impulses pass from the eyes to the brain. If no images are received, normal vision cannot develop. If the images from each eye differ markedly, one will be suppressed to avoid double vision.

CAUSES
The most common cause of amblyopia is squint (a deviation of one eye relative to the other) in young children. Failure to form normal retinal images may also result from congenital (present from birth) cataract (opacity of the lens of the eye), and severe, or unequal, focusing errors, such as when one eye is normal and there is an uncorrected large degree of astigmatism in the other. Toxic and nutritional amblyopia may be the result of damage to the retina and/or the optic nerve.

TREATMENT AND OUTLOOK
The usual treatment for amblyopia due to squint is patching (covering up the good eye to force the deviating eye to function properly). Surgery to place the deviating eye in the correct position might be necessary. Glasses may be needed to correct severe focusing errors. Cataracts may be removed surgically. After the age of eight, amblyopia cannot usually be remedied.

ambulance
A vehicle for transporting sick, injured, or disabled people, usually to hospital, that is staffed by trained personnel who can provide emergency treatment during the journey.

ambulatory ECG
In ambulatory ECG (electrocardiography), a wearable device called a Holter monitor is used to record the electrical activity of the heart by means of electrodes attached to the chest. The monitor is usually worn for at least 24 hours and detects intermittent arrhythmias (abnormal heart rates and rhythms). It is also used to assess the programming of a cardiac pacemaker. The wearer presses a button on the monitor to mark the recording whenever symptoms occur. The recording can be analysed later to determine whether the periods of arrhythmia coincide with the symptoms. In some cases, the patient can send the recording over the telephone by means of telecardiography (transmission of an impulse to a site that is remote from the patient).

amelioration
In medical usage, improvement in the medical condition of a patient.

amelogenesis imperfecta
An inherited condition of the teeth in which the enamel is either abnormally thin or is deficient in calcium. The teeth of affected individuals may be pitted and discoloured (see discoloured teeth) and more susceptible to dental caries (tooth decay) and wear.

amenorrhoea
The absence of menstrual periods. Primary amenorrhoea is defined as failure to start menstruating by the age of 16. Secondary amenorrhoea is the temporary or permanent cessation of periods in a woman who has menstruated regularly in the past.

PRIMARY AMENORRHOEA
The main cause of primary amenorrhoea is the delayed onset of puberty. The delay may not indicate a disorder but, rarely, may result from a disorder of the endocrine system, such as a pituitary tumour, hypothyroidism (underactivity of the thyroid gland), an adrenal tumour, or adrenal hyperplasia. Another rare cause of delayed puberty is Turner’s syndrome, in which one female sex chromosome is missing. In some cases, menstruation fails to take place because the vagina or uterus has been absent from birth. It may also fail to occur because there is no perforation in the hymen (the membrane across the opening of the vagina) to allow blood to escape.

SECONDARY AMENORRHOEA
The most common cause of temporary secondary amenorrhoea is pregnancy. Secondary amenorrhoea may also be caused by hormonal changes that occur as a result of stress, depression, anorexia nervosa, certain drugs, or a pituitary or thyroid disorder. Another possible cause is a disorder of the ovary, such as polycystic ovary (see ovary, polycystic) or an ovarian tumour. Amenorrhoea occurs permanently after the menopause or following a hysterectomy (a surgical operation to remove the uterus).

INVESTIGATION AND TREATMENT
Investigation of amenorrhoea usually involves a physical examination and
**amfobutamone**

A drug used, along with self-help measures, as an aid to stopping smoking. Side effects include a dry mouth and gastrointestinal disturbances.

**amfetamine**

An alternative spelling for amphetamine (see amphetamine drugs). (See also controlled drugs.)

**amiloride**

A potassium-sparing diuretic drug, amiloride is used in combination with loop or thiazide diuretics in the treatment of hypertension (high blood pressure) and the oedema (fluid retention) that results from heart failure (reduced pumping efficiency of the heart) or liver cirrhosis.

**amino acids**

A group of chemical compounds that form the basic structural units of all proteins. Each amino acid molecule consists of amino and carboxyl groups of atoms that are linked to a variable chain or ring of carbon atoms.

Individual amino acid molecules are linked together by chemical bonds (called peptide bonds) to form short chains of molecules called polypeptides. Hundreds of polypeptides are, in turn, linked together (also by peptide bonds) to form a protein molecule. What differentiates one protein from another is the sequence of the amino acids.

There are 20 different amino acids that make up all the proteins in the body. Of these, 12 can be made by the body; they are known as nonessential amino acids because they do not need to be obtained from the diet. The other eight, the essential amino acids, cannot be made by the body and must be obtained in the diet.

The 20 amino acids that make up proteins also occur free within cells and in body fluids. In addition, there are more than 200 other amino acids that are not found in proteins but play an important role in chemical reactions within cells.

**aminoglutethimide**

An anticancer drug used to treat certain types of breast cancer, prostate cancer, and some endocrine gland tumours.

**aminoglycoside drugs**

Aminoglycosides, a type of antibiotic drug, are given by injection and, because their use can damage the inner ear or kidneys, are generally reserved for the treatment of serious infections. Important examples of these drugs are gentamicin and streptomycin, which are also used topically for eye and ear infections.

**aminophylline**

A bronchodilator drug that is used to treat chronic bronchitis, asthma, and, occasionally, heart failure (reduced pumping efficiency of the heart).

Aminophylline relieves breathing difficulty by widening the bronchi (the main air passages to the lungs). It also dilates (widens) blood vessels, thereby improving blood flow from the heart, and increases the production of urine.

Possible side effects of aminophylline include nausea, vomiting, headache, dizziness, and palpitations.

**amiodarone**

An antiarrhythmic drug used in the treatment of various types of arrhythmia (irregular heart rate or rhythm). Long-term use of amiodarone may result in inflammation of the liver, thyroid problems, and damage to the eyes and lungs. For this reason, amiodarone is usually given only when other drugs have failed to be effective.

**amitriptyline**

A tricyclic antidepressant drug with a sedative effect. Amitriptyline is useful in the treatment of depression accompanied by anxiety or insomnia. Possible adverse effects include blurred vision, dizziness, and drowsiness.

**amlodipine**

A calcium channel blocker drug that is used to prevent angina and to treat hypertension (high blood pressure). Possible side effects of amlodipine include headaches and dizziness.

**ammonia**

A colourless, pungent gas that dissolves in water to form ammonium hydroxide, an alkaline solution (see alkali). Ammonia consists of one nitrogen atom linked to three hydrogen atoms. Ammonia is produced in the body and helps to maintain the acid–base balance.

In severe liver damage, the capacity of the liver to convert ammonia to urea is diminished. This leads to a high concentration of ammonia in the blood, which is thought to be a major cause of the impaired consciousness that occurs in liver failure.

**amnesia**

Loss of the ability to memorize information and/or recall information stored in memory. Amnestic conditions affect mainly long-term memory (where information is retained indefinitely) rather than short-term memory (where it is only retained for seconds or minutes).

Many people with amnesia have a memory gap that extends back for some time before the onset of the disorder. This condition, known as retrograde amnesia, is principally a deficit of recall. In the majority of cases, the memory gap gradually shrinks over time.

Some people with amnesia are unable to store new information in the period following the onset of the illness. The resultant gap in memory, known as anterograde amnesia, extends from the moment of onset of the amnesia to the time when the long-term memory resumes (if at all). This memory gap is usually permanent.

**CAUSES**

Amnesia is the result of damage to, or disease of, regions in the brain that are concerned with memory function. Possible causes of such damage are head injury; degenerative disorders such as Alzheimer’s disease and other forms of dementia; infections such as encephalitis; thiamine deficiency in problem drinkers, which leads to Wernicke–Korsakoff syndrome; brain tumours; strokes; and subarachnoid haemorrhage. Amnesia can also occur in some forms of psychiatric illness (in which there is no apparent physical damage to the brain). Some deterioration of memory is a common feature of aging.

**amniocentesis**

A diagnostic procedure in which a small amount of amniotic fluid is withdrawn, using a syringe guided by ultrasound...
scanning, from the amniotic sac (the membrane that surrounds the fetus in the uterus).

WHY IT IS DONE
The amniotic fluid contains fetal cells, which can be subjected to chromosome analysis in order to identify or exclude chromosomal defects, such as Down’s syndrome, or genetic analysis to look for genetic disorders such as haemophilia, cystic fibrosis, and Tay–Sachs disease. The amniotic fluid also contains chemicals; and analysis of the fluid can help to diagnose or exclude developmental abnormalities such as spina bifida. The severity of rhesus incompatibility and the maturity of the fetal lungs can also be checked by amniocentesis.

HOW IT IS DONE
Amniocentesis is usually performed in the 14th to 18th week of pregnancy. It may be performed earlier, but this is technically more difficult a this early stage. The skin of the abdomen is cleaned and a needle is inserted into the amniotic sac; (in all cases, ultrasound scanning is used to avoid contact with the fetus and placenta). An attached syringe removes some fluid for analysis.

COMPLICATIONS
Amniocentesis slightly increases the risk of miscarriage or early rupture of the membranes, and the procedure is therefore recommended only when the fetus is thought to be at increased risk of an abnormality. (See also antenatal care, chorionic villus sampling.)

amnion
One of the membranes that surrounds the fetus in the uterus. The outside of the amnion is covered by another membrane called the chorion.

amniotic fluid
The clear, watery fluid (popularly called the “waters”) that surrounds the fetus in the uterus and is contained within the amniotic sac (a thin, membranous bag). Amniotic fluid cushions the fetus against pressure from the mother’s internal organs, allowing movement.

Amniotic fluid is produced by cells that line the amniotic sac and is constantly circulated. The fetus swallows the fluid, which is absorbed into the fetal bloodstream and then excreted by the kidneys as urine. The fluid is 99 per cent water. The remainder consists of dilute concentrations of the substances found in blood plasma, along with cells and lipids (fats) from the fetus.

Amniotic fluid appears during the first week following conception, and it gradually increases in volume until the tenth week, when it increases very rapidly. After approximately 35 weeks’ gestation, the volume of fluid slowly starts to decline.

In a small number of pregnancies, polyhydramnios (the formation of excessive amounts of amniotic fluid) occurs; less frequently, oligohydramnios (the formation of insufficient fluid) occurs.

amniotic sac
The membranous bag that surrounds the fetus and is filled with amniotic fluid as pregnancy advances. The sac is made up of two membranes, the inner amnion and the outer chorion.

amniotomy
Artificial rupture of the amniotic membranes. Amniotomy, which is popularly known as “breaking of the waters”, is performed for induction of labour.

amoeba
A type of protozoon (see protozoa). An amoeba is a microscopic single-celled organism with an irregular, changeable shape. Amoebae live in moist environments such as fresh water and soil. Some types are parasites of humans, causing diseases such as amoebiasis.

amoebicides
A group of drugs that are used to treat amoebiasis. Examples of amoebicides are diloxanide and metronidazole. The drugs work by killing amoebae (see amoeba) in the intestine and in other body tissues.

amoebiasis
An infection caused by the amoeba Entamoeba histolytica, a tiny single-celled parasite that lives in the human large intestine. Amoebiasis is spread through eating food or drinking water contaminated by human excreta containing cysts of the amoeba.

Once the cysts are swallowed, the cyst walls break down, and the amoebae hatch out to parasitize the large intestine. In the intestine, the amoebae multiply and develop protective capsules, forming new cysts. These cysts are passed out of the body in the faeces and can survive for long periods before the next person acquires them.

SYMPTOMS
Some individuals carry the Entamoeba histolytica parasite in their intestines and excrete cysts without having symptoms. However, some strains of the amoebae invade and ulcerate the intestinal wall, causing diarrhoea and abdominal pain, which may develop into full-blown dysentery.

The amoebae may spread through the bloodstream to the liver or, rarely, to the brain or lung, where they cause abscesses. Symptoms of an amoebic liver abscess include weight loss, chills, fever, and painful liver enlargement. Liver abscesses may also sometimes occur in the absence of symptoms.

PREVENTION AND TREATMENT
Travellers to countries where sanitary standards are low can reduce their risk of acquiring amoebiasis by drinking only bottled or thoroughly boiled water and by not eating uncooked vegetables or unpeeled fruit.

Treatment of all forms of amoebiasis is with drugs such as metronidazole or diloxanide. These drugs kill the parasite within a few weeks, leading to complete recovery.

amoebic dysentery
See amoebiasis.

amoxapine
A tricyclic antidepressant drug. Possible adverse effects of amoxapine include a dry mouth, blurred vision, dizziness, drowsiness, abnormal muscular movements, menstrual irregularities, and enlargement of the breasts.
Amoxicillin

A penicillin drug commonly used to treat a variety of infections, including cystitis, bronchitis, and ear and skin infections. Allergy to it causes a blotchy rash and, rarely, fever, swollen mouth and tongue, itching, and breathing difficulty.

Amoxycillin

See amoxicillin.

Amphetamine drugs

COMMON DRUGS

- Dexamfetamine

A group of stimulant drugs used mainly in the treatment of narcolepsy (a rare disorder that is characterized by excessive sleepiness).

HOW THEY WORK

Amphetamine drugs stimulate secretion of neurotransmitters (chemicals released by nerve endings), such as norepinephrine (norepinephrine), which increase nerve activity in the brain and make a person wakeful and alert.

SIDE EFFECTS

In high doses, amphetamines can cause tremor, sweating, anxiety, and sleeping problems. Delusions, hallucinations, high blood pressure, and seizures may also occur. Prolonged use may produce tolerance and drug dependence.

ABUSE

Amphetamines are often abused for their stimulant effect and, for this reason, they are controlled drugs.

Amphotericin

An antifungal drug used to treat candidiasis of the mouth or intestine. The drug is taken as tablets but is also given by intravenous infusion to treat life-threatening systemic (generalized) fungal infections such as cryptococcosis and histoplasmosis.

Side effects, which include vomiting, fever, headache, and, rarely, seizures, may occur with intravenous infusion.

Ampicillin

A penicillin drug commonly used to treat cystitis, bronchitis, and ear infections. Diarrhoea is a common adverse effect. Some people are allergic to ampicillin and suffer from rash, fever, swelling of the mouth and tongue, itching, and breathing difficulty.

Ampoule

A small glass or plastic vessel that can be hermetically sealed to hold liquid substances, in a sterile condition, for injection. Each ampoule usually contains a single dose of a drug.

Amputation, congenital

The separation of a body part (usually a limb, finger, or toe) from the rest of the body, as a result of the blood supply to the part being blocked, in the uterus, by a band of amnion (fetal membrane). At birth, the affected part may be either completely separated, or it may show the marks of the “amniotic band”. (See also limb defects.)

Amputation, traumatic

Loss of a finger, toe, or limb through injury. (See also microsurgery.)

Amylase

An enzyme that is found in saliva and pancreatic secretions (see pancreas). Amylase helps the body to digest dietary starch, breaking it down into smaller components, such as the sugars glucose and maltose.

Amsler chart

A diagnostic tool used by ophthalmologists to detect changes in the retina, particularly those changes that indicate macular degeneration. A typical Amsler chart consists of a grid of black lines on a white background. In an individual with retinal changes, the lines may appear distorted.

Amyl nitrite

A nitrate drug that was once prescribed to relieve angina pectoris (chest pain as a result of impaired blood supply to the heart muscle). Because it frequently causes adverse effects, the drug has now been superseded by other drugs such as glyceryl trinitrate and isosorbide. Amyl nitrite is sometimes abused for its effect of intensifying pleasure during orgasm.

Amyloidosis

An uncommon disease in which a substance called amyloid, composed of fibrous protein, accumulates in tissues and organs, including the liver, kidneys, tongue, spleen, and heart.

CAUSES

Amyloidosis may occur for no known reason, in which case it is known as primary amyloidosis; more commonly,
it is a complication of some other disease, and in such cases it is called secondary. Conditions that may lead to amyloidosis include multiple myeloma (a cancer of bone marrow), rheumatoid arthritis, familial Mediterranean fever, tuberculosis, and other longstanding infections such as chronic osteomyelitis (bone infection). Amyloid is also deposited in the brain in Alzheimer’s disease. Small deposits of amyloid are a normal feature of aging.

SYMPTOMS AND SIGNS
The symptoms of amyloidosis vary, depending on the organs affected and the duration of the condition. Affected organs typically become enlarged. An accumulation of amyloid in the heart may result in arrhythmias (disturbances of the heart rate or rhythm) and heart failure (reduced pumping efficiency of the heart). If the stomach and intestines are affected, symptoms such as diarrhea may develop, and the lining of these organs may become ulcerated. Primary amyloidosis is often characterized by deposits of amyloid in the skin, which appear as slightly raised, waxy spots. Deposits of amyloid in the kidneys may cause kidney failure, which can be fatal.

TREATMENT
There is no treatment for the removal of amyloid deposits. However, it is possible to halt the progression of secondary amyloidosis by treatment of the underlying disorder.

amyotrophic lateral sclerosis
See motor neuron disease.

amyotrophy
Shrinkage or wasting away of a muscle, caused by a reduction in the size of its fibres, leading to weakness. Amyotrophy is usually the result of poor nutrition, reduced use of the muscle (as occurs when a limb is immobilized for a long period), or disruption of the blood or nerve supply to the muscle (as can occur in poliomyelitis or diabetes mellitus). (See also atrophy.)

anabolic steroids
See steroids, anabolic.

anabolism
The manufacture of complex molecules such as fats and proteins from simpler molecules by metabolic (chemical and physical) processes in living cells. (See also catabolism; metabolism.)
anaemia, aplastic
A rare but serious type of anaemia (a reduced level of the oxygen-carrying pigment haemoglobin in the blood). In aplastic anaemia, the red cells, white cells, and platelets in the blood are all reduced in number. The condition is caused by a failure of the bone marrow to produce stem cells, the initial form of all blood cells.

CAUSES
Treatment of cancer with radiotherapy or anticancer drugs can temporarily interfere with the cell-producing ability of bone marrow, as can certain viral infections and other drugs. Long-term exposure to insecticides or benzene fumes may cause more persistent aplastic anaemia; and another recognized cause is a moderate to high dose of nuclear radiation. An autoimmune disorder (in which the immune system attacks the body’s own tissues) is responsible in some cases. Aplastic anaemia sometimes develops for no known reason.

SYMPTOMS
A low level of red blood cells may cause symptoms, such as fatigue and breathlessness, that are common to all types of anaemia. Deficiency of white cells increases susceptibility to infection, resulting in frequent or severe infections; platelet deficiency may lead to a tendency to bruise easily, bleeding gums, and nosebleeds.

anaemia, haemolytic
A form of anaemia (a reduced level of the oxygen-carrying pigment haemoglobin in the blood) caused by premature destruction of red blood cells in the bloodstream (see haemolysis). The bone marrow has the capacity to increase its red cell production approximately six-fold over normal rates. Haemolytic anaemia will result only if the shortening of the lifespan of red blood cells is sufficiently severe to overcome the reserve capacity of the bone marrow.

TYPES AND CAUSES
Haemolytic anaemias can be classified in two ways: if the cause of the haemolysis is an abnormality of the red cells themselves, the condition is usually inherited; if the cause of the haemolysis is outside the cells, the condition is usually acquired later in life.

When haemolysis is due to a defect within the red cells, the underlying problem may be abnormal rigidity of the cell membrane (the thin layer of tissue surrounding each cell). This causes the cells to become trapped, at an early stage of their life-span, in the small blood vessels of the spleen, where they are destroyed by macrophages (cells that ingest foreign particles). Abnormal rigidity may result from an inherited defect of the cell membrane (as in hereditary spherocytosis), a defect of the haemoglobin in the cell (as in sickle-cell anaemia), or a defect of one of the cell’s enzymes. An inherited deficiency of the glucose-6-phosphate dehydrogenase enzyme (see G6PD deficiency) may result in episodes of haemolytic anaemia since the red cells are prone to damage by infectious illness or certain drugs or foods. One variety of G6PD deficiency is most common in Mediterranean countries (see favism).

Haemolytic anaemias due to defects outside the red cells fall into three main groups. First are disorders in which red cells are destroyed by buffeting (by artificial surfaces such as replacement heart valves, abnormal blood-vessel linings, or a blood clot in a vessel, for example). In the second group, the red cells are destroyed by the immune system. Immune haemolytic anaemias may occur if foreign blood cells enter the bloodstream, as occurs in an incompatible blood transfusion, or they may be due to an autoimmune disorder (in which the immune system attacks the body’s own tissues). In haemolytic disease of the newborn, the baby’s red cells are destroyed by antibodies, produced by the mother, crossing the placenta. Thirdly, the red cells may be destroyed by microorganisms in the blood; the most common cause is malaria.

SYMPTOMS
People with haemolytic anaemia may have symptoms common to all types of anaemia, such as fatigue and breathlessness, or symptoms that are specifically due to haemolysis, such as jaundice (caused by an excessive concentration in the blood of bile pigments formed from the destruction of red blood cells).

DIAGNOSIS AND TREATMENT
Diagnosis is confirmed by microscopic examination of the blood (see blood film). Treatment depends on the cause. Some inherited anaemias can be controlled by removing the spleen (see splenectomy). Others, such as G6PD deficiency and favism, can be prevented by avoiding the drugs or foods that precipitate haemolysis. Anaemias due to immune processes can often be controlled by immunosuppressant drugs. Transfusions of red cells are sometimes needed for emergency treatment of life-threatening anaemia.

anaemia, iron-deficiency
The most common form of anaemia (a reduced level of the oxygen-carrying pigment haemoglobin in the blood).
Iron-deficiency anaemia is caused by a deficiency of iron, an essential constituent of haemoglobin.

CAUSES
The commonest cause of iron-deficiency anaemia is iron loss due to heavy or persistent bleeding; the most common cause in women of childbearing age is particularly heavy periods (see menorrhagia). Pregnancy stops menstural losses, but the baby is an even greater drain on maternal iron stores. Other causes include blood loss from the digestive tract due to disorders such as erosive gastritis, peptic ulcer, stomach cancer, inflammatory bowel disease, haemorrhoids, and bowel tumours (see colon, cancer of). Prolonged use of aspirin and other nonsteroidal anti-inflammatory drugs (NSAIDs) can cause gastrointestinal bleeding. In some countries, hookworm infestation of the digestive tract is an important cause of anaemia. Rarely, bleeding may also occur as a result of disorders of the urinary tract (such as kidney tumours or bladder tumours).

Iron deficiency may also be caused or worsened by lack of iron in, or its poor absorption from, the diet. Malabsorption of iron may have various causes, including the removal of part or all of the stomach (see gastrectomy) or coeliac disease (a disorder that impairs digestion).

SYMPTOMS
The symptoms of iron-deficiency anaemia are those of the underlying cause, along with a sore mouth or tongue; and those that are common to all forms of anaemia, such as fatigue, headaches, and breathlessness.

DIAGNOSIS AND TREATMENT
Diagnosis is made from a blood count that reveals the red blood cells to be microcytic (abnormally small). Measurement of the iron levels in the blood confirms the diagnosis but further investigation will be needed to establish the underlying cause. Treatment is given for the underlying cause, along with a course of iron tablets or, very rarely, iron injections in order to build up the depleted iron stores.

anaemia, megaloblastic
A major type of anaemia (a reduced level of the oxygen-carrying pigment haemoglobin in the blood). Megaloblastic anaemia is caused by deficiency of vitamin B12, or another vitamin, folic acid. Either of these deficiencies seriously interferes with the production of red blood cells in the bone marrow. An excess of cells known as megaloblasts (abnormal immature red cells) appears in the marrow. Megaloblasts give rise to enlarged and deformed red blood cells known as macrocytes.

CAUSES
Vitamin B12 deficiency Vitamin B12 is found only in foods of animal origin, such as meat and dairy products. It is absorbed from the small intestine by first combining with intrinsic factor, a chemical produced by the stomach lining. The most common cause of vitamin B12 deficiency is pernicious anaemia in which the stomach lining fails to produce intrinsic factor, usually as a result of an autoimmune disorder (in which the immune system attacks the body’s own tissues). Total gastrectomy (removal of the stomach) also prevents the production of intrinsic factor, and removal of part of the small intestine prevents B12 absorption, as does the intestinal disorder Crohn’s disease. In a minority of cases, vitamin B12 deficiency is due to a vegan diet (which excludes all foods of animal origin).

Folic acid deficiency Folic acid is found mainly in green vegetables and liver. The usual cause of deficiency is a poor diet. It can also be caused by anything that interferes with absorption of folic acid from the small intestine (Crohn’s disease or coeliac disease, for example). Folic acid is required by rapidly dividing cells, as in the fetus. Women are advised to take folic acid supplements before conception and in early pregnancy, although this is to reduce the risk of the fetus having a neural tube defect rather than to prevent anaemia.

SYMPTOMS
Many people with mild megaloblastic anaemia have no symptoms. Others may experience tiredness, a sore mouth and tongue, weight loss, and mild jaundice. If B12 deficiency continues for a long time, additional symptoms as a result of nerve damage, including numbness and tingling in the feet, may develop.

DIAGNOSIS AND TREATMENT
Megaloblastic anaemia is diagnosed by blood tests and confirmed if a bone marrow biopsy (removal of a small sample of marrow for microscopic analysis) reveals the presence of large numbers of megaloblasts.

Megaloblastic anaemia caused by poor diet can be remedied with a short course of vitamin B12 injections or folic acid tablets and the introduction of a normal diet. A lifelong course of vitamin B12 injections or folic acid tablets is required if the underlying cause of malabsorption is incurable.

anaemia, pernicious
See pernicious anaemia.

anaemia, sickle cell
See sickle cell anaemia.

anaerobic
Capable of living, functioning, and growing without oxygen. Many bacteria are anaerobes and thrive in the intestinal canal or in tissue that has a poor supply of oxygenated blood. Some human body cells are capable of limited anaerobic activity. When muscular exertion is so strenuous that oxygen is used faster than the blood circulation can supply it (during sprinting, for example), the muscle cells can temporarily work anaerobically. When this happens, lactic acid is produced as a waste product (instead of the carbon dioxide that is produced from aerobic activity). This acid buildup can cause muscle fatigue and pain, thereby limiting the time for which anaerobic activity can be carried out. Compensation for this anaerobic activity requires oxygen to convert the lactic acid to glucose or to carbon dioxide, which explains the need to continue to breathe rapidly following vigorous exertion. The deficit of oxygen that builds up in the muscles during exercise is known as the oxygen debt.

anaesthesia
The absence of all sensation; insensibility. The term most commonly refers to anaesthesia that is induced artificially for medical purposes.
Two types of anaesthesia may be used: local (see *anaesthesia, local*) and general (see *anaesthesia, general*). A patient given a local anaesthetic remains conscious, and sensation is abolished in only a specific part of the body. A patient under general anaesthesia is rendered unconscious and maintained in this state with a combination of drugs that are either injected into a vein or inhaled.

Damage to nerve tissues by injury or disease can produce anaesthesia in a localized area.

**anaesthesia, dental**

Loss of sensation induced in a patient to prevent pain during dental treatment. Topical anaesthetics (usually using the drug lidocaine (lignocaine) as a cream or spray) are often used on the surface of the gums before injection of a local anaesthetic (see *anaesthesia, local*).

For minor procedures, a local anaesthetic is injected either into the gum at the site being treated or around the nerve a short distance away (a procedure known as a peripheral *nerve block*). For more complicated procedures, such as periodontal (gum) surgery and multiple tooth extractions, general anaesthesia (see *anaesthesia, general*) is carried out.

**anaesthesia, epidural**

See *epidural anaesthesia*.

**anaesthesia, general**

Loss of sensation and consciousness that is induced to prevent the perception of pain throughout the body during surgery. General anaesthesia is also used to abolish muscle tone and cardiovascular reflexes in the patient.

The state of general anaesthesia is produced and maintained by an anaesthetist, who gives combinations of drugs by injection, inhalation, or both. The anaesthetist is also responsible for the pre-anaesthetic assessment and medication of patients, their safety during surgery, and their recovery during the post-anaesthetic period.

**HOW IT IS DONE**

General anaesthesia is usually induced by intravenous injection of a *barbiturate drug*, usually via a *cannula* (a blunt-ended tube), which is left in place in case further drugs need to be given. Anaesthesia is maintained by the inhalation of anaesthetic gases such as *enflurane* or halothane, which may be introduced into the lungs via a face mask or an *endotracheal tube* (a flexible tube passed into the *trachea* through the nose or mouth). During the anaesthetic, blood pressure, pulse, oxygen saturation (see *oximeter*), and other vital signs are monitored continuously. The principal stages in administering, maintaining, and reversing general anaesthesia are shown in the illustrated box.

**POSSIBLE COMPLICATIONS**

General anaesthetics have become much safer and serious complications are now rare. However, the presence of severe pre-existing diseases, such as lung or heart disorders, increase the risks of the procedure. Minor after-effects, such as nausea and vomiting, are usually controlled effectively with *antiemetic drugs*.

**anaesthesia, local**

Loss of sensation induced in a limited region of the body to prevent pain during diagnostic or treatment procedures, examinations, and surgery. Local anaesthesia is produced by administration of drugs that temporarily interrupt the action of pain-carrying nerve fibres.

**HOW IT IS DONE**

Local anaesthetics may be applied topically, before injections or blood tests, as sprays, skin creams, and ointments. These are often used for children. The throat, larynx (voice-box), and respiratory passages can be sprayed with an anaesthetic before *bronchoscopy* (examination of the bronchi, the main airways of the lungs, using a rigid or flexible viewing tube) and the urethra can be numbed with a gel before *cystoscopy* (examination of the urethra and bladder using a rigid or flexible viewing tube).

For minor surgical procedures, such as stitching of small wounds, local anaesthesia is usually produced by direct injection into the area to be treated. To anaesthetize a large area, or when a local injection would not penetrate deeply enough into body tissues, a *nerve block* (in which the local anaesthetic is injected around nerves at a point remote from the area to be treated) may be used. Nerve impulses can also be blocked where they branch off from the spinal cord, as in *epidural anaesthesia*, which is used in childbirth or caudal block, and *spinal anaesthesia*, which is used for surgery on the lower limbs and abdomen.

**POSSIBLE COMPLICATIONS**

Serious reactions are uncommon, but repeated use of topical preparations may cause local allergic rashes.

</table>
The main phases in the administration of a general anaesthetic are induction (bringing about unconsciousness), maintenance (of unconsciousness), and emergence (returning the patient to consciousness). Some of the main stages are shown below. Often, to allow surgical manipulation, a muscle relaxant must be given in addition to anaesthetic gases or injections. Because the relaxant temporarily paralyses the breathing muscles, the patient’s lungs must be ventilated artificially. Modern general anaesthetics have few side effects, and recovery is usually prompt.

1. Before the operation, the anaesthetist talks to and examines the patient to assess his or her fitness for anaesthesia and surgery. He or she also answers any questions the patient may have.

2. The induction agent is usually given via a cannula inserted into a vein. The cannula is left in position so that other drugs can be given rapidly if needed.

3. Sometimes, anaesthesia is induced or maintained with gases delivered by mask. If no muscle relaxant is used, the patient may be able to continue breathing naturally.

4. In other cases, an endotracheal tube is inserted for delivery of the anaesthetic gases. If a muscle relaxant is used, artificial ventilation is necessary.

5. During surgery, the patient is kept at a level of anaesthesia deep enough for him or her to be unaware of the operation. The composition of the gas mixture, and the patient’s heart rate, breathing, blood pressure, temperature, blood oxygenation, and exhaled carbon dioxide are monitored. After surgery, anaesthesia is stopped, and reversal agents are given if necessary.
anaesthesia, spinal

See spinal anaesthesia.

anaesthetics

A term for the group of drugs that produce anaesthesia and for the medical discipline that is concerned with their administration.

An anaesthetist is a specialist who administers anaesthetics. Before a patient goes to the operating theatre, the anaesthetist assesses the condition of the patient’s heart, lungs, and circulation. He or she decides the type and amount of drugs needed to induce and maintain anaesthesia, determines the patient’s position on the operating table, watches for problems, and decides on the action to be taken if an emergency develops. The anaesthetist is also responsible for monitoring the progress of the waking patient, and watching for and treating any post-anaesthetic complications.

anal dilatation

A procedure in which the anus is stretched. Anal dilatation is used to treat conditions in which the anus becomes too tight, such as anal stenosis and anal fissure. It is also used to treat haemorrhoids. Anal dilatation is usually performed under general anaesthesia (see anaesthesia, general).

Anal dilatation, in which the anus dilates in response to local contact, may occur in certain anal disorders or after repeated anal penetration.

anal discharge

The loss of mucus, pus, or blood from the anus. Haemorrhoids, anal fissures (tears), and proctitis (inflammation of the rectum) can all cause anal discharge.

analectic drugs

Drugs that stimulate breathing. Replaced by ventilation, analectic drugs are now seldom used.

anal fissure

A common disorder of the anus that is caused by an elongated ulcer or tear that extends upwards into the anal canal from the anal sphincter (the ring of muscle that surrounds the anal orifice). An anal fissure may be caused by the passage of hard, dry faeces.

There is usually pain during defaecation, and the muscles of the anus may go into spasm. There may also be a small amount of bright red blood on faeces or toilet paper.

The tear often heals naturally over a few days, although spasm of the anal muscles may delay healing. Treatment of recurrent or persistent fissures is usually by anal dilatation (a procedure to enlarge the anus) and a high-fibre diet, including whole-grain products, fruit and vegetables, and plenty of fluids, to help soften the faeces. Surgery to remove the fissure is occasionally necessary.

anal fistula

An abnormal channel connecting the inside of the anal canal with the skin surrounding the anus.

An anal fistula may be an indication of Crohn’s disease, colitis, or cancer of the colon or rectum (see colon, cancer of; rectum, cancer of). In most cases, it is the result of an abscess that develops for unknown reasons in the anal wall. The abscess discharges pus into the anus and out on to the surrounding skin.

An anal fistula is treated surgically by opening the abnormal channel and removing the lining. The operation is performed under a general anaesthesia (see anaesthesia, general). The wound is then left to heal naturally.

analgesia

The loss of or reduction in pain sensation. Analgesia differs from anaesthesia (loss of all sensation) in that sensitivity to touch is still preserved. Analgesia can be induced by the use of analgesic drugs.

analgesic drugs

COMMON DRUGS

**OPiOIDS**

- Co-codamol
- Co-codaprin
- Codeine
- Co-dyramol
- Co-proxamol
- Diamorphine
- Dipipanone
- Fentanyl
- Meptazinol
- Methadone
- Morphine
- Pentazocine
- Pethidine
- Phenazocine
- tramadol

**NSAIDS**

- Aspirin
- Celecoxib
- Diclofenac
- Diflunisal
- Etodolac
- Fenbufen
- Fenoprofen
- Flurbiprofen
- ibuprofen
- Indomethacin
- Ketoprofen
- Ketorolac
- Mefenamic acid
- naproxen
- Piroxicam
- Rofecoxib

**OTHER NONOPIOIDS**

- Nefopam
- Paracetamol

Drugs used to relieve pain. The two main types are nonopioid and opioid analgesics. Nonopioid analgesics are useful for treating mild to moderate pain. They include paracetamol for headache; or toothache and nonsteroidal anti-inflammatory drugs (NSAIDs) such as aspirin and ibuprofen, which can help to relieve mild pain and stiffness in arthritic conditions. Combinations of a weak opioid (such as codeine) with a nonopioid analgesic (such as aspirin) relieve more severe pain. Potent opioids such as morphine can produce tolerance and drug dependence and are used only when other preparations are ineffective.

**HOW THEY WORK**

When body tissues are damaged, they produce prostaglandins (chemicals that trigger the transmission of pain signals to the brain). Except for paracetamol, nonopioid analgesics work by preventing the production of prostaglandin; paracetamol works by blocking the pain impulses within the brain itself, preventing the perception of pain. Opioid analgesics act in a similar way to endorphins (pain-relieving substances formed by the body) by blocking pain impulses at specific sites in the brain and spinal cord.

**SIDE EFFECTS**

Side effects are uncommon with paracetamol; aspirin and most NSAIDs may irritate the stomach lining and cause nausea, abdominal pain, and, rarely, a peptic ulcer. Nausea, drowsiness, constipation, and breathing difficulties may occur with opioid analgesics. The euphoric effect produced by some opioid analgesics have led to their abuse.

**WARNING**

Over-the-counter (nonopioid) analgesic drugs should not be taken for longer than 48 hours, after which time medical advice should be sought. If pain persists, becomes more severe, recurs, or differs from pain previously experienced, a doctor should be consulted. For precautions on specific drugs, see the individual drug entries.

anal phase

A term used in psychoanalytic theory to refer to a stage of a person’s psychosexual development. The anal phase begins at around 18 months of age and lasts for up to two years. (See also genital phase; oral phase.)

anal stenosis

Tightness of the anus, sometimes known as anal stricture. Anal stenosis prevents normal passage of faeces, causing constipation and pain during defaecation.

Anal stenosis may be present from birth or may be caused by a number of conditions in which scarring has occurred, such as anal fissure, colitis, or cancer of the anus. The condition sometimes occurs after surgery on the anus (for example, to treat haemorrhoids).
Anal stenosis is treated by anal dilatation (a procedure that expands or enlarges the anus).

anal stricture
See anal stenosis.

anal tag
A type of skin tag.

analysis, chemical
Determination of the identity of a substance or of the individual chemical constituents of a mixture. Analysis may be qualitative (as in determining whether or not a particular substance is present), or it may be quantitative (that is, measuring the amount or concentration of one or more constituents). (See also assay.)

analysis, psychological
See psychoanalysis.

HOW ANALGESICS WORK

When tissue is damaged (for example, by injury, inflammation, or infection) the body produces prostaglandins. These substances combine with receptors (specific sites on the surface of cells in the brain and spinal cord). As a result, a signal is passed along a series of nerve cells to the brain, where the signal is interpreted as pain by brain cells. Analgesics (except for paracetamol) work either by preventing the production of prostaglandins at the site of damage or by blocking pain impulses in the brain and spinal cord. Paracetamol works by blocking prostaglandin production in the brain, which prevents pain impulses from being transmitted in the brain.

anaphylactic shock
A rare, life-threatening allergic reaction. Anaphylactic shock is a Type I hypersensitivity reaction (see allergy) that occurs in people with extreme sensitivity to a particular substance (an allergen), most commonly insect venom or certain foods or drugs.

When the allergen enters the bloodstream, massive amounts of histamine and other chemicals are released, causing sudden, severe lowering of blood pressure and constriction of the airways. Other symptoms of anaphylactic shock may include abdominal pain, diarrhoea, swelling of the tongue and throat, and an itchy rash.

Anaphylactic shock requires emergency medical treatment. An injection of adrenaline (epinephrine) may be lifesaving. If the person’s breathing or heartbeat has stopped, cardiopulmonary resuscitation should be performed, and antihistamine drugs and corticosteroid drugs may also be given. (See also hyposensitization.)

anastomosis
A natural or artificial communication between two blood vessels or between tubular cavities that may or may not normally be joined.

Natural anastomoses usually occur when small arteries are attached directly to veins without passing through capillaries. Anastomoses occur in the skin where they are used to help control temperature regulation.

A surgical anastomosis is used to create a bypass around a blockage in an artery or in the intestine. They are also used to rejoin cut ends of the bowel or blood vessels. (See also bypass surgery.)

anastrozole
An anticancer drug that is used to treat advanced breast cancer in postmenopausal women.

anatomical snuffbox
A depression on the back of the wrist that is formed between the tendons of the thumb when the thumb is stretched outwards. The anatomical snuffbox is of significance because tenderness in this area is a feature of a fracture of the scaphoid bone.

anatomy
The structure of the body of any living thing, and its scientific study. Human anatomy, together with physiology (the study of the functioning of the body), dates back to ancient Egyptian times and forms the foundation of all medical science. The dissection of human corpses has provided the primary source of information for anatomists.

Anatomy as a scientific study today is subdivided into many branches. These include comparative anatomy (the study of the differences between human and animal bodies), surgical anatomy (the practical knowledge required by surgeons), embryology (the study of structural changes that occur during the development of the embryo and fetus), systematic anatomy (the study of the structure of particular body systems), and cytology and histology (the microscopic study of cells and tissues respectively).

Every anatomical structure is scientifically named in Latin, but today anatomists prefer to use simpler terms,
ANCYLOSTOMIASIS

DESCRIPTIVE TERMS IN ANATOMY

The relative positions and movements of body parts are conventionally described with reference to the "anatomical position" (that is, an upright posture with the eyes and palms facing forwards). In this position, the parts of the body can be described in relation to various geometrical planes.

In radiology, body imaging pictures (such as CT scans and MRI) are often taken in a series of transverse planes through part of the body.

Joint movements

Extension is straightening, and flexion is bending; abduction is moving away from, adduction is moving towards, the midline of the body. Other movements are forms of rotation around an axis.

When taken by women, the drugs can lead to the development of male characteristics, such as facial hair.

androgen hormones

A group of hormones (the male sex hormones) that stimulate virilization (the development of male secondary sexual characteristics such as growth of facial hair, deepening of the voice, and increased muscle bulk).

FORMATION

Androgens are produced by specialized cells in the testes in males and the adrenal glands in both sexes. The ovaries secrete very small quantities of androgens until the menopause. The most active androgen is testosterone (produced in the testes). Androgen production by the testes is controlled by certain pituitary hormones called gonadotrophins. Adrenal androgens are controlled by ACTH, another pituitary hormone.

EFFECTS

Androgens stimulate the appearance, at puberty, of male secondary sexual characteristics such as deepening of the voice and the growth of facial hair. They have an anabolic effect (they raise the rate of protein synthesis and lower the rate at which it is broken down), which increases muscle bulk and accelerates growth. At the end of puberty, androgens cause the long bones to stop growing. They also stimulate the secretion of sebum, which, if excessive, causes acne. In early adult life, androgens promote male-pattern baldness.

DEFICIENCY

Androgen deficiency may occur if the testes are diseased or the pituitary gland fails to secrete gonadotrophins. Typical effects include high-pitched voice, decreased body and facial hair, underdeveloped genitalia, reduced sexual drive, and poor muscle development.

EXCESS

Overproduction of androgens may be the result of adrenal disorders such as adrenal tumours, congenital adrenal hyperplasia (see adrenal hyperplasia, congenital), testicular tumours (see testis, cancer of), or, rarely, androgen-secreting ovarian tumours (see ovary, cancer of).

In men, excess androgens accentuate male physical characteristics; in boys, they cause premature sexual development. In women, excess androgens cause virilization, features of which include increased body hair, deepening of the voice, enlarged clitoris, and amenorrhoea (the absence of menstruation).

anencephaly

Absence of the brain and cranial vault (top of the skull) at birth. Most infants with anencephaly are stillborn or survive for only a few hours. Anencephaly is detectable early in pregnancy by measurement of the maternal alpha-fetoprotein,
An aneurysm forms when pressure from the blood flow causes a weakened artery wall to distend or forces blood through a fissure. Aneurysms can form anywhere in the body, although the most common sites are the aorta and the arteries supplying the brain.

**TYPES AND CAUSES**

The most common cause of an aneurysm is **atherosclerosis**, a condition in which fatty deposits weaken the artery wall. The aorta is the usual site of atherosclerotic aneurysms.

Less commonly, aneurysms may be due to congenital (present from birth) weakness of the artery walls. Most cerebral aneurysms, known as **berry aneurysms** because of their appearance, are congenital. **Marfan syndrome**, an inherited disorder in which the wall of the aorta is defective, is often associated with aneurysms just above the heart. The arterial wall can also be weakened by inflammation, as occurs in **polyarteritis nodosa**. A dissecting aneurysm is one in which the inner layer of the artery wall ruptures, allowing blood to track along the length of the artery and block any branching arteries. Ventricular aneurysms are aneurysms that sometimes develop in the heart wall due to weakening of an area of heart muscle as a result of a heart attack (see **myocardial infarction**).

Some of the common types, sites, and shapes of aneurysm are shown in the illustrated box.

**SYMPTOMS AND SIGNS**

Most aneurysms are symptomless and remain undetected. However, if the aneurysm expands rapidly and causes pain, or is very large, the symptoms are due to pressure on nearby structures. Aneurysms may eventually rupture, cause fatal blood loss, or, in the case of a cerebral aneurysm, loss of consciousness (see **subarachnoid haemorrhage**). A dissecting aneurysm usually causes severe pain, and there is a high risk of the vessel rupturing. Ventricular aneurysms seldom rupture, but they interfere with the pumping action of the heart.

**DIAGNOSIS AND TREATMENT**

Aneurysms of the aorta may be detected by **ultrasound scanning**, and cerebral aneurysms by **CT scanning or MRI**. **Angiography** can provide more detailed information on all types of aneurysm. A ruptured or enlarged aneurysm requires immediate **arterial reconstructive surgery**. (See also **microaneurysm**.)

**angina**

A strangling or constrictive pain. The term angina has become synonymous with the heart disorder **angina pectoris**. Other types of angina include abdominal angina (abdominal pain after eating caused by poor blood supply to the intestines) and Vincent's angina, which is pain caused by inflammation of the mouth (see **Vincent's disease**).

**angina pectoris**

Pain in the chest that is the result of insufficient oxygen being carried to the heart muscle in the blood. The pain of angina pectoris usually occurs when the heart is working harder and requires more oxygen, such as during exercise or at times of stress.

**CAUSES**

Inadequate blood supply to the heart is usually due to **coronary artery disease**, in which the coronary arteries are...
narrowed by atherosclerosis (fat deposits on the artery walls). Other causes include coronary artery spasm, in which the blood vessels narrow suddenly for a short time, aortic stenosis, in which the heart’s aortic valve is narrowed, and arrhythmias (abnormal heart rhythms).

The pain of angina pectoris is brought on by exertion and is relieved by rest. If the pain continues, it may be due to a heart attack (see myocardial infarction). Rarer causes of the pain include severe anaemia, which reduces the blood’s oxygen-carrying efficiency, and polycythaemia, which thickens the blood and causes its flow through the heart muscle to slow down.

SYMPTOMS
The chest pain of angina varies from mild to severe and is often described as a sensation of pressure on the chest. The pain usually starts in the centre of the chest but can spread to the throat, upper jaw, back, and arms (usually the left), or between the shoulderblades. If it develops during sleep or without provocation, it is called unstable angina.

Other possible symptoms of angina pectoris include nausea, sweating, dizziness, and breathing difficulty.

DIAGNOSIS AND TREATMENT
Diagnostic tests usually include an ECG (measurement of the electrical activity of the heart), which may register normal between attacks, and a cardiac stress test (an ECG undertaken while the patient is exercising enough to cause chest pain). Blood tests and coronary angiography (X-ray examination of the blood vessels) may also be performed to look for an underlying cause.

To help control the symptoms of angina pectoris, it is important for the person to stop smoking and to lose weight if necessary. Attacks may be prevented and treated by nitrates, which increase blood flow through the heart muscle. Beta-blocker drugs, calcium channel blockers, lipid-lowering drugs, and antiplatelet drugs may also be prescribed.

Drug treatment can control the symptoms for many years but cannot cure the disorder. If attacks become more severe or more frequent, despite treatment, coronary artery bypass surgery or angioplasty may be necessary.

angina, Prinzmetal’s
A type of unstable angina pectoris (see angina, unstable) in which the attacks of chest pain occur while the body is at rest and are not brought on by exertion.

angina, unstable
A type of angina pectoris (chest pain due to impaired blood supply to the heart muscle) that occurs during sleep or without provocation (such as exertion).

angioedema
A type of reaction caused by allergy. Angioedema is similar to urticaria (hives) and is characterized by large, well-defined swellings, of sudden onset, in the skin, larynx (voice-box), and other areas. If they are left untreated, the swellings may last a number of days.

CAUSES
The most common cause of angioedema is a sudden allergic reaction to a food. Less commonly, the condition may be due to a drug allergy (such as to penicillin), a reaction to an insect bite or sting, or it may occur as a result of infection, emotional stress, or exposure to animals, moulds, pollens, or cold conditions. There is also a hereditary form of angioedema.

SYMPTOMS
Angioedema may cause sudden difficulty in breathing, swallowing, and speaking, accompanied by swelling of the lips, face, and neck, depending on the area of the body affected.

TREATMENT
Severe cases are treated with injections of adrenaline (epinephrine) and may require intubation (a breathing tube inserted via the mouth into the windpipe) or tracheostomy (surgical creation of a hole in the windpipe) to prevent suffocation. Corticosteroid drugs may also be given. In less severe cases, antihistamine drugs may relieve symptoms.

angiogenesis
The growth of new blood vessels. Angiogenesis is the process that enables tumours to grow: cancerous cells produce chemicals (called growth factors) that stimulate new blood vessels to form near the tumour, supplying it with nutrients and oxygen.

angiography
An imaging procedure that enables blood vessels to be seen clearly on X-ray film following the injection of a contrast medium (a substance that is opaque to X-rays). Digital subtraction angiography uses computer techniques to process images and remove unwanted background information. Magnetic resonance angiography (MRA) can produce images of blood vessels without the use of a contrast medium.

WHY IT IS DONE
Angiography is used to detect conditions that alter the appearance of blood vessels, such as an aneurysm (ballooning of an artery) and narrowing or blockage of blood vessels by atherosclerosis (fatty deposits lining artery walls), a thrombus (abnormal clot), or an embolus (fragment of a clot that is carried in the blood). Angiography is also used to detect changes in the pattern of blood vessels that supply organs injured or affected by a tumour.

Carotid angiography (angiography of the arteries in the neck) may be used to...
investigate transient ischaemic attacks (symptoms of stroke lasting for less than 24 hours). Cerebral angiography can be used to detect an aneurysm in the brain or to pinpoint the position of a brain tumour. Coronary angiography, often combined with cardiac catheterization, can identify sites of narrowing or blockage in coronary artery disease.

During angiography, some types of treatment, such as balloon angioplasty (see angioplasty, balloon) and embolization, that sometimes eliminate a previous need for surgery may be carried out. (See also aortography.)

angioplasty, balloon
A technique for widening a narrowed or blocked section of blood vessel by the introduction of a balloon-tipped catheter (flexible tube) into the constricted area of the vessel.

The balloon is inflated to widen the narrowed area, deflated, then removed. Balloon angioplasty is used to increase or restore blood flow in a significantly narrowed artery in peripheral vascular disease and coronary artery disease.

Coronary balloon angioplasty is usually successful in the short term, but narrowing of the affected vessel may recur, requiring repeat treatment. Angioplasty of peripheral vessels is most successful in treating the iliac and femoral arteries in the legs. Results have improved further with the introduction of stents (metal mesh structures), which are inserted into an artery following balloon dilation to help keep the blood vessel open.

angiotensin
The name of two related proteins involved in regulating blood pressure. The first, angiotensin I, is inactive and is formed when renin, which is produced by the kidneys, acts on the substance angiotensinogen. Angiotensin I is then converted to the second, active, form, angiotensin II, by angiotensin-converting enzyme.

Angiotensin II causes narrowing of the small blood vessels in tissues, resulting in increased blood pressure. It also stimulates release (from the adrenal cortex, the outer part of each adrenal gland) of the hormone aldosterone, which also increases blood pressure.

Certain kidney disorders can increase the production of angiotensin II, resulting in hypertension (high blood pressure). Hypertension can be treated with ACE inhibitor drugs, which reduce the formation of angiotensin II, or with angiotensin II antagonists.

angiotensin-converting enzyme
A substance that converts angiotensin I to its active form, angiotensin II. Drugs that reduce the action of angiotensin-converting enzyme are known as ACE inhibitor drugs and are used in the treatment of hypertension (high blood pressure) and heart failure (reduced pumping efficiency of the heart).

angiotensin-II antagonists

**COMMON DRUGS**
- Candesartan
- Irbesartan
- Losartan
- Valsartan

A group of drugs used in the treatment of hypertension (high blood pressure). Angiotensin-II antagonists have a similar action to ACE inhibitor drugs (in that they block the action of angiotensin II) but do not cause the persistent dry cough that is a common side effect of treatment with ACE inhibitors.

angular stomatitis
See stomatitis.

anhedonia
Total loss of the feeling of pleasure from activities that would normally give pleasure. Anhedonia is often one of the common symptoms of depression.
ANHIDROSIS

anhidrosis
Complete absence of sweating. (See also hypohidrosis.)

animal experimentation
The use of live animals in research and safety testing to provide information about animal biology or, by inference, human physiology or behaviour. Animal research has contributed to the development of surgical techniques, such as transplant surgery and drugs, such as vaccines. Due to ethical concerns, however, alternative practices, such as cell cultures, are now used whenever possible.

animals, diseases from
See zoonosis.

anion
An ion of negative charge, such as a chloride ion. (See also electrolyte.)

anisometropia
Unequal focusing power in the two eyes, usually due to a difference in size and/or shape of the eyes, that causes visual discomfort. For example, one eye may be normal and the other affected by myopia (shortsightedness), hypermetropia (longsightedness), or astigmatism (uneven curvature of the cornea). Glasses or contact lenses correct the problem in most cases.

ankle joint
The hinge joint between the foot and the leg. The talus (uppermost bone in the foot) fits between the two bony protuberances formed by the lower ends of the tibia (shinbone) and the fibula (outer bone of the lower leg). Strong ligaments on either side of the ankle joint give it support. The ankle joint allows for up-and-down movement of the foot.

DISORDERS
An ankle sprain is one of the most common injuries. It is usually caused by twisting of the foot over on to its outside edge, which causes overstretching and bruising of the ligaments. Severe sprains can result in tearing of the ligaments, which may need to be repaired surgically. Violent twisting of the ankle can result in a combined fracture and dislocation, known as Pott’s fracture, in which the fibula breaks above the ankle and either the tibia breaks or the ligaments tear, resulting in dislocation of the ankle.

ankylosing spondylitis
An uncommon inflammatory disease affecting joints between the vertebrae of the spine and the sacroiliac joints (the joints between the spine and the pelvis). Ankylosing spondylitis may also affect other large joints, such as those in the hips.

CAUSES ANDINCIDENCE
The cause of ankylosing spondylitis is usually unknown, but in some cases the disease may be associated with colitis (inflammation of the colon) or psoriasis (a skin disease). Ankylosing spondylitis may run in families; and about 90 per cent of people with the condition have the genetically determined histocompatibility antigen (HLA-B27).

SYMPTOMS
Ankylosing spondylitis usually starts with pain and stiffness in the hips and lower back that are worse after resting and are especially noticeable in the early morning. Other, less common, symptoms include chest pain, painful heels due to additional bone formation, and redness and pain in the eyes due to iritis (inflammation of the iris). In time, inflammation in the spine can lead to ankylosis (permanent stiffness and limited movement) and kyphosis (curvature of the spine).

DIAGNOSIS AND TREATMENT
Ankylosing spondylitis can be diagnosed by X-rays and blood tests. There is no cure, but treatment with a programme of exercise and physiotherapy and anti-inflammatory drugs can reduce the pain and limitation of movement. In some cases, DMARDs (see disease-modifying antirheumatic drugs) are also prescribed. To prevent curvature of the spine, patients are taught breathing exercises and exercises to improve posture.

ankylosis
Complete loss of movement in a joint that results from fusion of the bony surfaces. Ankylosis may be caused by degeneration as a result of inflammation, infection, or injury. The condition can also be produced surgically by an operation to fuse a diseased joint to correct deformity or to alleviate persistent pain (see arthrodesis). (See also ankylosing spondylitis.)

annular
A term meaning shaped like a ring. Annular is a description applied to certain body structures, such as ligaments, and, in dermatology, to the appearance of skin rashes, such as ringworm. The term may also be applied to a cancer that encircles an organ.

anodontia
Failure of some or all of the teeth to develop. Anodontia, which can be partial or total, may be due to the absence of tooth buds at birth, or it may be the result of damage to developing tooth buds by infection or other widespread disease. Both primary and permanent teeth may be affected. Partial anodontia is far more common than total.

If only a few teeth are missing, a dental bridge (false teeth that are attached to natural teeth on either side of the gap) can be fitted. If all the teeth are missing, a denture is required. Recently, however, dental implants (see implant, dental) have become the treatment of choice in selected cases (in which the individual has the correct anatomy and bone density).

anomaly
A deviation from what is accepted as normal, especially a birth defect such as a limb malformation.

Anopheles
A genus of disease-transmitting mosquitoes, many species of which are carriers of malaria. (See also mosquito bites.)

anorexia
The medical term for loss of appetite (see appetite, loss of).
**FEATURES OF ANOREXIA NERVOSA**

- Weight loss
- Overactivity and obsessive exercising
- Tiredness and weakness
- Lanugo (babylke) hair on body, thinning of hair on head
- Extreme choosiness over food
- Binge eating
- Induced vomiting
- Use of laxatives to promote weight loss

**anorexia nervosa**

An eating disorder that is characterized by severe weight loss and altered self-image that leads sufferers to believe that they are fat even when they are, in fact, dangerously underweight.

**CAUSES AND INCIDENCE**

The causes of anorexia are unclear, but the condition may be linked to a lack of self-worth that leads to excessive concern over physical appearance. Sufferers may feel that they can have some control over their lives by controlling their eating. Normal dieting may develop into starvation.

Anorexia nervosa most commonly affects teenage girls and young women, but the incidence in young men is rising.

**SYMPTOMS AND SIGNS**

In the early stages, sufferers may be overactive and may exercise excessively. They are obsessed with food, and often make complicated meals for others, but are reluctant to eat socially and avoid eating the meals themselves. As their weight loss continues, they become tired and weak, the skin becomes dry, lanugo hair (fine, downy hair) grows on the body, and normal hair becomes thinner. Starvation leads to amenorrhoea (the absence of menstrual periods) in many women.

Some sufferers of anorexia nervosa have food binges and then make themselves vomit, or take laxative drugs or diuretic drugs, to promote weight loss (see bulimia). Chemical imbalances as a result of starvation, with or without vomiting, can cause potentially fatal cardiac arrhythmias.

**TREATMENT AND OUTLOOK**

Hospital treatment is often necessary and is usually based on a closely controlled feeding programme combined with psychotherapy or family therapy. For some people, antidepressant drugs may be helpful. Many sufferers relapse after treatment, and long-term psychotherapy is required.

- **anorgasmia**
  - Inability to achieve orgasm (see **orgasm, lack of**).
- **anosmia**
  - Loss of the sense of **smell**.
- **anovulatory menstruation**
  - The occurrence of a menstrual cycle during which there is no **ovulation** (release of an egg from the ovary). Anovulatory menstruation is often the result of reduced production of the hormone oestrogen and occurs most commonly at the beginning and the end of reproductive life, in which case it is normal. However, anovulatory menstruation may also be a sign of a hormonal abnormality. (See also **fertility; menstruation**.)
- **anoxia**
  - The total absence of oxygen within a body tissue such as the brain or a muscle. Anoxia causes disruption of cell **metabolism** (chemical activity) and results in cell death unless it is corrected within a few minutes.

  Anoxia is rare, occurring during cardiorespiratory arrest or asphyxiation. It will cause permanent organ damage or even death if not corrected. Hypoxia (the reduction of oxygen supply to a tissue) is a more common problem.

**Antabuse**

A brand name for disulfiram, a drug used to treat alcohol dependence. Antabuse is a powerful deterrent, which, if taken with even a small amount of alcohol, produces extremely unpleasant side effects such as nausea, headache, dizziness, and palpitations.

**antacid drugs**

**COMMON DRUGS**

- Aluminium hydroxide
- Calcium carbonate
- Hydrocortisone
- Magnesium hydroxide
- Sodium bicarbonate

Drugs that are taken to relieve the symptoms of indigestion, heartburn, acid reflux (the regurgitation of stomach acids into the oesophagus), oesophagitis (inflammation of the oesophagus), and **peptic ulcer**.

**HOW THEY WORK**

Antacids usually contain compounds of magnesium or aluminium, which neutralize stomach acid. Some also contain alginates, which protect the oesophagus by reducing acid reflux, or dimeticon, an antifoaming agent, which helps to relieve flatulence.

**SIDE EFFECTS**

Aluminium may cause constipation, and magnesium may cause diarrhoea. These effects can be avoided, however, if a preparation contains both ingredients. Antacids interfere with the absorption of many drugs and should therefore not be taken at the same time as other medications.

**WARNING**

Antacids should not be taken regularly except under medical supervision because they may suppress the symptoms of a more serious disorder or provoke serious complications.

**antagonist**

Having an opposing effect. For example, antagonist drugs counteract the effects of naturally occurring chemicals in the body. (See also agonist.)

**antenatal care**

The care of a pregnant woman and her unborn baby throughout pregnancy to ensure that both are healthy at delivery. Antenatal care involves regular visits to a doctor or midwife, who performs blood and urine tests and abdominal examinations and also monitors blood pressure and fetal growth in order to detect disease or potential problems (see the antenatal screening procedures chart, overleaf).

High-risk pregnancies, in which, for example, the woman suffers from hypertension (high blood pressure) or diabetes (see diabetic pregnancy), require more frequent antenatal visits. In some cases, the woman may be admitted to hospital for closer observation.

Ultrasound scanning is carried out to identify any abnormalities in the fetus. Amniocentesis or chorionic villus sampling may be performed if the fetus is thought to be at increased risk of a chromosomal abnormality or a genetic disorder. Electronic fetal monitoring may be carried out, in order to check the fetal heartbeat, in pregnancies that are high-risk or overdue.
The woman is also advised on general aspects of pregnancy, such as diet, exercise, and techniques to help her with childbirth. (See also childbirth, natural.)

**antepartum haemorrhage**

Bleeding from the vagina after the 28th week of pregnancy.

Antepartum haemorrhage is most commonly due to a problem with the placenta (the organ in the uterus that sustains the developing fetus), such as *placenta praevia* (in which the placenta is positioned too close to the birth canal) or *placental abruption* (detachment of part of the placenta from the wall of the uterus). Bleeding can also be caused by *cervical erosion* or other disorders of the cervix or vagina.

**SYMPTOMS**

The bleeding is often painless but may be accompanied by abdominal pain if the placenta becomes partly separated from the uterus.

Investigation and treatment requires hospital admission. *Ultrasound scanning* is used to diagnose problems with the placenta. In some cases, it is necessary only to keep a careful watch on the condition of the woman and her baby. If the bleeding is severe, the woman is given a *blood transfusion*; the baby may be delivered immediately by *caesarean section*.

**anterior**

Relating to the front of the body. In human *anatomy*, the term is synonymous with *ventral*.

**ANTENATAL SCREENING PROCEDURES**

<table>

**ANTEPARTUM HAEMORRHAGE**

**antibiotic drugs**

A group of drugs that are used to eradicate *worm infestation* of the body. Anthelmintic drugs kill or paralyse worms in the intestines, preventing them from gripping the intestinal wall, and causing them to pass out of the body in the *faeces*.

Possible side effects of anthelmintic drugs include nausea, abdominal pain, rash, headache, and dizziness.

**anthracosis**

An outdated term for coal workers’ *pneumoconiosis*. Anthracosis is a lung disease caused by inhalation of large amounts of coal dust over many years.

**anthrax**

A serious bacterial infection of livestock that occasionally spreads to humans. The most common form of the infection in humans is cutaneous anthrax, which affects the skin. Another form, pulmonary anthrax, affects the lungs and is potentially fatal.

**CAUSES**

Anthrax is caused by *Bacillus anthracis*. This bacterium produces spores that can remain dormant for years in soil and animal products and are capable of reactivation.

Animals become infected by grazing on contaminated land. Infection can occur in humans via a scratch or a sore if materials from infected animals are handled. Pulmonary anthrax occurs as a result of inhaling spores from infected animal fibres.

**SYMPTOMS AND TREATMENT**

In cutaneous anthrax, a raised, itchy, area develops at the site of entry of the spores, progressing to a large blister and finally a black scab, with swelling of the surrounding tissues. Cutaneous anthrax is treatable in its early stages with *antibiotic drugs*. Without treatment, infection may spread to lymph nodes and the bloodstream and may be fatal.
Pulmonary anthrax causes severe breathing difficulty and may be fatal despite intensive treatment.

**antiallergy drugs**

Drugs used to treat or prevent allergic reactions (see allergy). There are several types of antiallergy drug, including **antihistamine drugs**, **leukotriene receptor antagonists**, **sodium cromoglicate**, and **corticosteroid drugs**.

**antianxiety drugs**

A group of drugs that are used to relieve the symptoms of anxiety. Benzodiazepine drugs, buspirone, and **beta-blocker drugs** are the three main types of antianxiety drug, although **antidepressant drugs** are often used. In most cases, the underlying disorder is best treated by counselling, psychotherapy, or other forms of therapy.

Benzodiazepine drugs promote mental and physical relaxation by reducing nerve activity in the brain; they can also be used to treat insomnia but their use for this purpose is avoided because they are addictive; buspirone is less addictive. Beta-blockers reduce only the physical symptoms of anxiety, such as shaking and palpitations, and are not addictive.

**antiarrhythmic drugs**

A group of drugs used to prevent or treat different types of arrhythmia (irregular heartbeat).

A number of drugs are used to prevent intermittent arrhythmias or slow the rate if an arrhythmia is persistent. These include **beta-blocker drugs**, **calcium channel blockers**, **digitalis drugs**, **amiodarone**, **disopyramide**, **flecainide**, **lidocaine** (lignocaine), **mexiteline**, and **procainamide**. Some antiarrhythmic drugs, such as adenosine and bretyllium, may only be used in hospital. They may be given intravenously to treat arrhythmias that are causing symptoms such as breathlessness or chest pain.

**HOW THEY WORK**

The heart’s pumping action is governed by electrical impulses. Some antiarrhythmics alter these impulses within, or on their way to, the heart; others affect the heart muscle’s response to the impulses received.

**SIDE EFFECTS**

Side effects of antiarrhythmic drugs are common, and they often include nausea and a rash. Some can result in tiredness or breathlessness because they reduce the pumping ability of the heart.

**antibacterial drugs**

A group of drugs that are used to treat infection due to bacteria. The term antibacterial was once used to describe only those **antibiotic drugs** that had been produced synthetically rather than naturally. The two terms are now used interchangeably.

**antibiotic drugs**

**COMMON DRUGS**

- **AMINAGLYCOSIDES**: Amikacin, Gentamicin, Neomycin, Netilmicin, Streptomycin, Tobramycin
- **CEPHALOSPORINS**: Cefaclor, Cefadroxil, Cefalexin, Cefamandole, Cefazolin, Cefixime, Cefotaxime, Cefoxitin, Cefpodoxime, Cefradine, Ceftazidime
- **MACROLIDES**: Azithromycin, Clarithromycin, Erythromycin
- **PENICILLINS**: Amoxicillin, Ampicillin, Azlocillin, Aztreonam, Benzylpenicillin, Co-amoxiclav, Co-fluampicil, Flucoxacinil, Imipenem, Phenoxymethylpenicillin
- **TETRACYCLINES**: Doxycycline, Oxytetracycline, Tetracycline
- **OTHERS**: Chloramphenicol, Ciprofloxacin, Colistin, Fusidic acid, Metronidazole, Rifampicin, Spectinomycin, Teicoplanin, Trimethoprim, Vancomycin

A group of drugs used to treat infections caused by bacteria and to prevent bacterial infection in individuals who are immunocompromized. Most of the commonly used antibiotic drugs belong to one of the following classes: **aminoglycosides**, **cephalosporins**, **macrolides**, **penicillins**, and **tetracyclines**. Some antibiotics are effective against only certain types of bacteria; others, which are known as broad-spectrum antibiotics, are effective against a wide range.

**ANTIBIOTIC RESISTANCE**

Some bacteria develop resistance to a previously effective antibiotic drug. This resistance is most likely to occur during long-term treatment. Some alternative antibiotics are available to treat bacteria that have become resistant to the more commonly prescribed drugs.

**SIDE EFFECTS**

Most antibiotic drugs can cause nausea, diarrhoea, or a rash. Antibiotics may disturb the normal balance of “good” bacteria in the body. This can cause problems such as **candidiasis** (thrush), in which there is excess growth of fungus. Some individuals experience a severe allergic reaction to the drugs, resulting in facial swelling, itching, or breathing difficulty.

**WARNING**

Patients should inform their doctor of any previous allergic reaction that they have had to an antibiotic drug.

**antibody**

A protein that is made by certain lymphocytes (white blood cells) to neutralize an **antigen** (foreign protein) in the body. Bacteria, viruses, and other microorganisms contain a number of antigens; antibodies that are formed...
against these antigens help the body to neutralize or destroy the invading microorganisms. Antibodies may also be formed in response to vaccines, thereby giving immunity against certain infections. Antibodies are also known as immunoglobulins.

Inappropriate or excessive formation of antibodies may lead to illness, as in an allergy. Antibodies against antigens in organ transplants may result in rejection of the transplanted organ. In some disorders, antibodies are formed against the body’s own tissues, resulting in an autoimmune disorder.

**antibody, monoclonal**

An artificially produced antibody that neutralizes only one specific antigen (foreign protein).

Monoclonal antibodies are produced in a laboratory by stimulating the growth of large numbers of antibody-producing cells that are genetically identical. In effect, this process enables antibodies to be tailor-made to react with a particular antigen.

Monoclonal antibodies are used in the study of human cells, hormones, microorganisms, and in the development of vaccines. They are also being used in the diagnosis and treatment of some forms of cancer. Genetically engineered monoclonal antibodies are designed to bind to the proteins on the surface of certain cancer cells, marking them out for destruction. The immune system can then recognize these marked cells and destroy them.

**HOW ANTICANCER DRUGS WORK**

Drugs that are used to treat many forms of cancer. Some tumours respond to drug treatment better than others. Anti-cancer drugs are particularly useful in the treatment of lymphomas, leukemias, breast cancer, cancer of the testis (see testis, cancer of), and prostate cancer.

**HOW THEY WORK**

Most anticancer drugs are cytotoxic (they kill or damage cells or prevent them from dividing). Cytotoxic drugs fall into several classes, including alkylating agents, antimitabolites, cytotoxic antibiotics, and taxanes. Cytokines (proteins released by cells in response to the presence of harmful organisms) such as interferon alpha bind to other cells, activating the immune response (see immune system).

In some cases, drug treatment is used alone, but it is often combined with surgery or radiotherapy. Anticancer drugs are often given in combination to maximize their effects. Treatment with cytotoxic drugs is commonly given by injection in short courses repeated at intervals.

**SIDE EFFECTS**

Some cytotoxic drugs cause nausea and vomiting and may cause hair loss and increased susceptibility to infection. Others (such as tamoxifen for breast cancer) are given continuously by mouth for months or years and cause few side effects.

**anticholinergic drugs**

Drugs that are used to treat and prevent abnormal secretions in the mouth and lungs. Anticholinergics block the effects of acetylcholine (e.g. gland secretion of a fluid). Anticholinergic drugs block the stimulatory action of acetylcholine by combining with the acetylcholine receptors. This action produces, for example, muscle relaxation (e.g. in the bladder, intestine, and bronchi) and dries up secretions in the mouth and lungs. Anticholinergic drugs are used to treat COPD and other conditions.

**HOW THEY WORK**

Anticholinergics block the effects of acetylcholine, a chemical released from nerve endings in the parasympathetic autonomic nervous system. Acetylcholine triggers activity in a number of cells. For example, it stimulates muscle contraction, slows the heartbeat, and increases secretions in the mouth and lungs.

**SIDE EFFECTS**

Possible side effects of anticholinergics may include dry mouth, blurred vision, urinary retention, and confusion.

**anticoagulant drugs**

Drugs that are used to treat and prevent abnormal blood clotting, to treat thrombosis, and to prevent and treat

**HOW THEY WORK**

Anticoagulants block the effects of acetylcholine, a chemical released from nerve endings in the parasympathetic autonomic nervous system. Acetylcholine triggers activity in a number of cells. For example, it stimulates muscle contraction, slows the heartbeat, and increases secretions in the mouth and lungs.

**SIDE EFFECTS**

Possible side effects of anticoagulants may include dry mouth, blurred vision, urinary retention, and confusion.
stroke and transient ischaemic attack (symptoms of stroke lasting less than 24 hours). Anticoagulant drugs are also given long-term to prevent abnormal blood clotting after major surgery (especially heart-valve replacement) or during haemodialysis (see dialysis).

The most common anticoagulants are heparin and the newer heparin-derived drugs, such as tinzaparin, all of which have to be given by injection, and warfarin, which is taken orally. Heparin is usually given initially and is then withdrawn when warfarin therapy has become effective.

HOW THEY WORK
Anticoagulant drugs reduce the activity of certain enzymes, known as blood clotting factors, that are needed for the blood to clot. Anticoagulants do not dissolve clots that have already formed, which can be treated with thrombolytic drugs, however they may help to stabilize an existing clot so that it does not brake away causing an embolism (blockage of an artery by a blood clot).

SIDE EFFECTS
Excessive doses of warfarin or its use with other drugs, such as aspirin and alcohol, may increase the risk of unwanted bleeding. Regular monitoring with blood-clotting tests is required.

WARNING
A doctor should always be consulted before any other drug is taken during anticoagulant treatment.

anticonvulsant drugs

COMMON DRUGS
- Carbamazepine
- Clobazam
- Clomethiazole
- Clonazepam
- Diazepam
- Ethosuximide
- Gabapentin
- Lamotrigine
- Lorazepam
- Phenobarbital
- Phenytoin
- Piracetam
- Primidone
- Sodium valproate
- Tiagabine
- Topiramate
- Vigabatrin

A group of drugs used to treat or prevent seizures. Anticonvulsant drugs are used mainly in the treatment of epilepsy, but they are also prescribed to prevent seizures following serious head injury or some types of brain surgery. They may be needed to control seizures in children with a high fever (see convulsions, febrile). Different drugs are effective at treating different types of seizure.

HOW THEY WORK
Seizures are caused by an abnormally high level of electrical activity in the brain. Anticonvulsant drugs have an inhibitory effect that suppresses this excessive electrical activity, thereby preventing its spread throughout areas of the brain. If seizures continue following treatment with an anticonvulsant, two drugs may be used in combination.

SIDE EFFECTS
Anticonvulsants may produce various side effects, including impaired memory, reduced concentration, poor coordination, and fatigue. If the side effects are troublesome, an alternative anticonvulsant can be tried. The dose of an anticonvulsant drug may need to be monitored using blood tests.

WARNING
The dosage of anticonvulsants should not be reduced or the treatment stopped without a doctor being consulted first. The doctor will supervise a gradual reduction in dosage. Stopping the drugs abruptly could cause withdrawal symptoms and a recurrence of the original problem.

antidepressant drugs

COMMON DRUGS

SELECTIVE SEROTONIN REUPTAKE INHIBITORS (SSRIS)
- Citalopram
- Fluoxetine
- Fluvoxamine
- Paroxetine
- Sertraline

TRICYCLICS (TCAS)
- Amitriptyline
- Amoxapine
- Clomipramine
- Dosulepin
- Doxepin
- Imipramine
- Lofezprameine
- Nortriptyline
- Trimipramine

MONOAMINE OXIDASE INHIBITORS (MAOIS)
- Isocarboxazid
- Moclobemide
- Phenelzine

OTHERS
- Flupentixol
- Maprotiline
- Mianserin
- Mirtazapine
- Reboxetine
- Trazodone
- Venlafaxine

Drugs used in the treatment of depression. Most of the commonly used antidepressant drugs belong to one of the following groups: tricyclic antidepressants (TCAs), selective serotonin reuptake inhibitors (SSRIs), and monoamine oxidase inhibitors (MAOIs).

HOW THEY WORK
Normally, brain cells release enough neurotransmitters (chemical messengers) in the brain to stimulate nearby brain cells. Neurotransmitters are constantly being reabsorbed into the brain cells by another chemical, monoamine oxidase. Depression is thought to be due to a reduction in the release of neurotransmitters. TCAs increase the level of the neurotransmitters noradrenaline (norepinephrine) and serotonin by preventing their reabsorption. MAOIs work by blocking the action of monoamine oxidase, which increases neurotransmitter levels. SSRIs only prevent the reabsorption of serotonin.

Antidepressants usually relieve the symptoms of depression, but it often takes two to three weeks for any beneficial effects to be felt. Treatment usually lasts for at least six months; and the dosage is reduced gradually before being stopped altogether.

SIDE EFFECTS
TCAs may cause constipation, a dry mouth, drowsiness, blurred vision, urinary difficulty, and irregular heartbeat. SSRIs may cause nausea, indigestion, loss of appetite, or sexual difficulties but are less dangerous in overdose than other antidepressants. MAOIs may interact with foods and other drugs, although moclobemide is less likely to cause problems.

Antidepressants are not addictive, but abrupt withdrawal of some types can result in physical symptoms and should therefore be avoided.

antidiabetic drugs

COMMON DRUGS

SULPHONYLUREA DRUGS
- Chlorpropamide
- Glibenclamide
- Gliclazide
- Glimepiride
- Glipizide
- Glipizidone
- Tolbutamide

OTHERS
- Acarbose
- Glucagon
- Guar gum
- Insulin
- Insulin lispro
- Metformin
- Repaglinide
- Rosiglitazone

A group of drugs that are used to treat diabetes mellitus, in which a lack of insulin, or resistance to its actions, results in hyperglycaemia (high levels of glucose in the blood). A wide range of antidiabetics are used to keep the blood glucose level as close to normal as possible, thereby reducing the risk of complications such as vascular (blood vessel) disease. Antidiabetic drugs include insulin, which must be administered by injection, and oral hypoglycaemics (see hypoglycaemics, oral), such as glibenclamide and metformin.

HOW THEY WORK
Most antidiabetic drugs promote the uptake of glucose into the body tissues, helping to prevent an excessive rise in blood glucose levels. However, different antidiabetics work in different ways. Acarbose and guar gum reduce or slow the absorption of carbohydrate from the intestines after meals. Repaglinide
ANTIDIARRHOEAL DRUGS

stimulates release of insulin from the pancreas. Rosiglitazone reduces resistance to the effects of insulin in the tissues and may be used together with other hypoglycaemics.

SIDE EFFECTS
Certain antidiabetics may lower the blood glucose level too much, leading to hypoglycaemia (low blood glucose levels). Rarely, these drugs may also cause a decreased blood cell count, a rash, or intestinal or liver disturbances.

Metformin does not cause hypoglycaemia, although treatment with this drug may result in nausea, appetite loss, abdominal distension, and diarrhea. It should not be taken by people with liver, kidney, or heart problems.

antidiarrhoeal drugs
COMMUN DRUGS

ANTISPASTICS

Hyoscyamine

Ménière’s disease, radiotherapy, and certain drugs. Antiemetics are not normally used in the treatment of food poisoning because the body needs to rid itself of harmful substances.

HOW THEY WORK
Antiemetics and anticholinergic drugs reduce vomiting associated with vertigo by suppressing the vomiting reflex (in which the stomach muscles contract to expel the stomach contents), which is triggered by nerve activity in the balance centre of the inner ear. Motility stimulants work by increasing movement through the gastrointestinal tract. The most powerful antiemetics are used to control nausea and vomiting associated with radiotherapy or anticancer drugs and include serotonin antagonists, such as ondansetron, and nabilone. These drugs act on neurotransmitters in the brain.

SIDE EFFECTS
Only certain antiemetics are used to treat vomiting in early pregnancy because some can damage the developing fetus. Many antiemetics can cause drowsiness.

WARNING
Antiemetics should not be taken regularly except on medical advice since they may mask a serious underlying disorder.

antifreeze poisoning
Most antifreeze in the UK contains ethylene glycol, which is poisonous. Most cases of antifreeze poisoning, which is extremely rare, occur as a result of accidental swallowing.

SYMPTOMS
Drinking antifreeze initially produces effects similar to alcohol intoxication, but vomiting, stupor, seizures, and coma may follow; acute kidney failure may occur within 24 to 36 hours.

TREATMENT
Any person believed to have drunk antifreeze requires immediate medical attention. Until such help arrives, small amounts of alcohol (preferably a spirit such as brandy or whisky) should be given, if possible, because alcohol reduces the rate at which antifreeze is metabolized by the body.

Hospital treatment may include removing the antifreeze from the stomach using a stomach pump (see lavage, gastric) and giving diuretic drugs, alcohol, and bicarbonate, intravenously, to correct excess acidity in the body fluids. Haemodialysis (see dialysis) may be required to remove ethylene glycol from the blood and to treat kidney failure.
Antifungal drugs

COMMON DRUGS
- Amorolfine
- Amphotericin
- Benzoyl peroxide
- Clotrimazole
- Econazole
- Fenticonazole
- Fluconazole
- Griseofulvin
- Itraconazole
- Ketoconazole
- Miconazole
- Nystatin
- Sulconazole
- Terbinafine
- Ticlopiroz

A group of drugs used to treat infections caused by fungi. Antifungals are commonly used to treat different types of tinea (including athlete’s foot and scalp ringworm); candidiasis (thrush) and rare infections, such as cryptococcosis, that affect internal organs. Antifungals are available in various forms, including tablets, injections, creams, and pessaries.

HOW THEY WORK
Antifungal drugs work by damaging the cell walls of fungi, causing chemicals essential for normal cell function and growth to escape. The fungal cells are unable to survive without these chemicals.

SIDE EFFECTS
Topical antifungals rarely cause side effects but may occasionally increase skin irritation. Prolonged treatment, by mouth or injection, of serious fungal infections can result in side effects including liver or kidney damage.

Antigen

A substance that can trigger an immune response, resulting in production of an antibody as part of the body’s defence against infection and disease. Many antigens are foreign proteins such as parts of microorganisms and toxins or tissues from another person that have been used in organ transplants. Sometimes, harmless substances (such as pollen) are misidentified by the immune system as potentially harmful antigens, which results in an allergic response (see allergy).

Antihistamine drugs

COMMON DRUGS
- Non-Sedating: Acrivastine, Cetirizine
- Fexofenadine, Loratadine, Mizolastine
- Sedating: Azatidine, Brompheniramine, Chlorphenamine, Clemastine, Dimenhydrinate, Diphenhydramine, Diphenylpyraline, Doxylamine, Promethazine, Triperazine, Tripolidine

A group of drugs that block the effects of histamine, a chemical released during allergic reactions (see allergy).

Antihistamines are used to treat rashes such as urticaria (hives) and to relieve sneezing and a runny nose in allergic rhinitis. They are also sometimes included in cough remedies and cold remedies, and they are used as antiemetic drugs because they suppress the vomiting reflex. Antihistamines are usually taken by mouth but may be given by injection for anaphylactic shock.

HOW THEY WORK
Antihistamine drugs block the effect of histamine on tissues such as the skin, eyes, and nose. Without drug treatment, histamine dilates small blood vessels, resulting in inflammation of the surrounding tissue due to leakage of fluid from the circulation. Antihistamines also prevent histamine from irritating nerve fibres, which causes itching.

SIDE EFFECTS
Many antihistamines cause drowsiness, but newer drugs have little sedative effect. Other uncommon side effects include loss of appetite, nausea, dry mouth, blurred vision, and difficulty in passing urine.

WARNING
A person should not drive or operate potentially dangerous machinery while taking an antihistamine drug unless he or she is certain that the treatment is not causing dizziness, drowsiness, or impaired concentration.

Anti-hypertensive drugs

COMMON DRUGS
- ACE inhibitors: Captopril, Lisinopril, Trandolapril
- Beta-blockers: Atenolol, Betaxolol, Metoprolol, Propranolol, Sotalol
- Calcium channel blockers: Amlodipine, Nifedipine
- Diuretics: Bumetanide, Hydrochlorothiazide
- Central acting hypotensives: Clonidine, Methyldopa
- Nonsteroidal anti-inflammatory drugs: Indomethacin, ibuprofen

A group of drugs that are used in the treatment of hypertension (high blood pressure) to prevent complications such as stroke, heart failure (reduced pumping efficiency of the heart), myocardial infarction (heart attack), and kidney damage. There are several types of antihypertensive, each one working in a different way to lower blood pressure.

HOW THEY WORK
Antihypertensive drugs work in a variety of ways to lower blood pressure. ACE inhibitors and angiotensin-II antagonists act on enzymes in the blood to dilate blood vessels; alpha-blockers block nerve signals that trigger the constriction of blood vessels; beta-blockers reduce the force of the heartbeat, thereby lowering the pressure of blood flow; diuretics increase the amount of salts and water excreted in the urine, thereby reducing blood volume; calcium channel blockers and ACE inhibitors control the size of blood vessels by preventing constriction of arterial wall muscles; and centrally acting hypertensives act on the mechanism in the brain that controls the size of blood vessels.

SIDE EFFECTS
Side effects depend on the type of antihypertensive used, but all types can cause dizziness if the blood pressure falls excessively.

WARNING
The dosage of antihypertensives should not be reduced or the treatment stopped without first consulting a doctor, who will supervise a gradual reduction in dosage. Abrupt cessation of the drug could cause a dangerous rise in blood pressure.

Anti-inflammatory drugs

Drugs that reduce inflammation. The main groups of these drugs are corticosteroid drugs and nonsteroidal anti-inflammatory drugs (NSAIDs). (See also analgesic drugs.)

Antimalarial drugs

Drugs used to treat malaria. One antimalarial drug, chloroquine, is also used to treat arthritis.

Antimotility drugs

See anti-diarrhoeal drugs.

Antimuscarinic drugs

See anticholinergic drugs.

Anti-obesity drugs

A group of drugs that includes appetite suppressants and orlistat, a drug that acts on the gastrointestinal tract to prevent the digestion of fats.
anti-oestrogen drugs
A group of drugs that oppose the action of the hormone oestrogen. The most important of these drugs is tamoxifen, which is used in the treatment of certain breast cancers.

antioxidant
A type of chemical that neutralizes potentially damaging oxidizing molecules known as free radicals (molecules that bind to and destroy body cells).

Some antioxidants occur naturally in the body; others (vitamin C, vitamin E, and beta-carotene, for example) are obtained through food intake or from dietary supplements.

antiperspirant
COMMON DRUGS
• Aluminium chloride

A substance applied to the skin in the form of a lotion, cream, or spray in order to reduce sweating. High concentrations are sometimes used to treat hyperhidrosis (abnormally heavy sweating).

HOW IT WORKS
An antiperspirant reduces the production of sweat by the sweat glands and blocks the ducts that drain sweat on to the surface of the skin.

SIDE EFFECTS
Antiperspirants may cause skin irritation, particularly if they are used on broken skin. (See also deodorants.)

antiphospholipid syndrome
See Hughes’ syndrome.

antiplatelet drugs
COMMON DRUGS
• Abciximab • Aspirin • Dipyridamole
• Clopidogrel • Ticlopidine

Drugs that reduce the tendency of platelets to stick together to form blood clots (see blood clotting) when blood flow in the arteries is disrupted. Antiplatelet drugs reduce the risk of thromboembolism (in which a clot breaks off and is carried in the bloodstream to lodge elsewhere in the body), which can cause potentially fatal disorders such as a myocardial infarction (heart attack) or stroke.

Aspirin and dipyridamole are commonly used antiplatelet drugs. Others, such as ticlopidine, are used specifically to protect against the stroke or formation of blood clots in the coronary arteries in people who have had a stroke or heart attack or have angina.

antipruritic drugs
COMMON DRUGS
ANTIHISTAMINES • Antazoline • Diphenhydramine
• Trimeprazine
CORTICOSTEROIDS • Hydrocortisone
LOCAL ANAESTHETICS • Tetraaine (amethocaine)
• Benzocaine • Lignocaine
EMOLLIENT AND COOLING PREPARATIONS • Aqueous cream • Calamine lotion
• Cold cream • Emulsifying ointment
OTHERS • Colestyramine • Doxepin

Drugs that are used to relieve persistent itching (pruritus), including pruritus that occurs as a result of a specific condition. For example, colestyramine (a lipid-lowering drug) is used to relieve pruritus associated with primary biliary cirrhosis. Antipruritic drugs can be applied as creams and emollients and may contain corticosteroid drugs, antihistamine drugs, or local anaesthetics. Oral antihistamines may also be used to relieve itching.

HOW THEY WORK
Irritation of the skin causes the release of substances, such as histamine, that cause the blood vessels to dilate and fluid to accumulate under the skin, which results in inflammation and itching. Antipruritic drugs work either by reducing inflammation, and therefore itching, or by numbing the nerve impulses that transmit sensation to the brain.

SIDE EFFECTS
Prolonged or heavy use of any antipruritic, especially antihistamine and local anaesthetic creams, may lead to further skin irritation. Oral antihistamines may cause drowsiness. Prolonged use of potent topical corticosteroids may result in permanent skin changes, most commonly thinning of the skin.

antipsychotic drugs
COMMON DRUGS
PHENOTHIAZINES • Chlorpromazine
• Fluphenazine • Levomepromazine (methotrimeprazine) • Pericyazine
• Perphenazine • Pipotiazine • Thioridazine • Trifluoperazine
BUTYROPHENONES • Benperidol • Droperidol
• Haloperidol
OTHERS • Amisulpride • Clozapine
• Flupentixol • Olanzapine • Pimozide • Quetiapine • Risperidone • Zotepine • Zuclopenthixol

A group of drugs used to treat psychoses (mental disorders involving loss of contact with reality), particularly schizo-

phrenia and mania (abnormal elation and overactivity) in bipolar disorder (see manic–depressive illness). Antipsychotic drugs may also be used to sedate people who are suffering from other mental disorders (such as dementia) and who are very agitated or aggressive.

HOW THEY WORK
Most antipsychotic drugs block the action of dopamine, a chemical that stimulates nerve activity in the brain. Antipsychotic drugs include phenothiazine drugs, butyrophenones such as haloperidol, and several new drugs including risperidone.

SIDE EFFECTS
Antipsychotic drugs can cause drowsiness, lethargy, dyskinesia (abnormal muscular movements), and parkinsonism. Other possible side effects include dry mouth, blurred vision, and difficulty in passing urine. However, newer drugs may have fewer side effects when used long term.

antipyrretic drugs
Drugs that reduce fever. Examples of antipyretic drugs include paracetamol, aspirin, and other non-steroidal anti-inflammatory drugs.

antiretroviral drugs
COMMON DRUGS
NUCLEOSIDE REVERSE TRANSCRIPTASE INHIBITORS • Didanosine • Lamivudine • Stavudine
• Zalcitabine • Zidovudine (AZT)
PROTEASE INHIBITORS • Indinavir • Nelfinavir
• Ritonavir • Saquinavir
NON-NUCLEOSIDE REVERSE TRANSCRIPTASE INHIBITORS • Efavirenz • Nevirapine

Drugs that are used to slow or halt the spread of viruses (see retrovirus) in individuals who have HIV infection and AIDS. There are three main types of antiretroviral drug: nucleoside reverse transcriptase inhibitors, non-nucleoside reverse transcriptase inhibitors and protease inhibitors. A combination of antiretroviral drugs from different groups is often used.

HOW THEY WORK
Antiretroviral drugs work by interfering with the action of enzymes used by the virus to produce genetic material.

SIDE EFFECTS
Antiretroviral drugs can have a range of side effects, including nausea, vomiting, diarrhoea, tiredness, and a variety of effects on blood chemistry, particularly those that involve fats. (See also antiviral drugs.)
antirheumatic drugs

COMMON DRUGS

CORTICOSTEROIDS • Dexamethasone
• Hydrocortisone • Methylprednisolone
• Prednisolone • Triamcinolone

GOLD-BASED DRUGS • Auranoﬁn • Sodium aurothiomalate

IMMUNOSUPPRESSANTS • Azathioprine
• Cyclophosphamide • Ciclosporin
• Methotrexate

NSAIDS • Aspirin • Celecoxib • Diclofenac
• Etodolac • Felbinac • Ibuprofen • Ketoprofen
• Mefenamic acid • Meloxicam • Naproxen
• Piroxicam

OTHERS • Chloroquine • Hydroxychloroquine
• Penicillamine • Sulfasalazine

A group of drugs that are used to treat rheumatoid arthritis and types of arthritis that are the result of other autoimmune disorders (in which the immune system attacks the body’s own tissues) such as systemic lupus erythematosus. Anti-rheumatic drugs affect the disease process and may, therefore, limit joint damage, unlike NSAIDs (see nonsteroidal anti-inﬂammatory drugs), which only relieve pain and stiffness. The most commonly used antirheumatic drugs are corticosteroid drugs, immunosuppressant drugs, chloroquine, penicillamine, gold, and sulfasalazine.

HOW THEY WORK

Different types of antirheumatic drug work in different ways, by suppressing either the production or the activity of lymphocytes (white blood cells). All anti-rheumatics reduce inﬂammation caused by the autoimmune reaction and slow down the degeneration of the cartilage that lines the joints.

SIDE EFFECTS

Many antirheumatic drugs can have serious side effects, and treatment, other than with NSAIDs, is therefore given only under specialist medical supervision.

antiseptics

Chemicals that are applied to the skin in order to destroy bacteria and other microorganisms, thereby preventing sepsis (infection). Antiseptics (the use of antiseptics to prevent infection) is not the same as asepsis, which is the creation of a germ-free environment (see aseptic technique). Antiseptics are milder than disinfectants, which decontaminate inanimate objects but are too strong to be used on the body.

Antiseptic fluids are generally used for bathing wounds; antiseptic creams are applied to wounds before they are dressed. Common antiseptics are chlorhexidine, cetrimide, hexachlorophene, and compounds containing iodine.

antiserum

A preparation containing antibodies (proteins manufactured by the immune system, see antibody) that combine with specific antigens (foreign proteins), usually components of microorganisms, leading to the deactivation or destruction of the microorganisms.

Antiserum is usually used, along with immunization, as an emergency treatment when an individual has been exposed to a dangerous infection, such as rabies, and has not previously been immunized against it. The antiserum helps to provide some immediate protection against the infective microorganisms while full immunity is developing. Such measures are not as effective in preventing disease as earlier (pre-exposure) immunization, however.

antischocial personality disorder

Impulsive, destructive behaviour that often disregards the feelings and rights of others. People who have an antisocial personality lack a sense of guilt and cannot tolerate frustration. They may have problems with relationships and are frequently in trouble with the law.

Behaviour therapy and various forms of psychotherapy may help to improve social integration. In general, the effects of the condition decrease with age.

antispasmodic drugs

COMMON DRUGS

• Atropine • Dicycloverine • Hyoscine
• Mebeverine

A group of drugs that relax spasm in smooth (involuntary) muscle in the wall of the intestine or bladder. Antispasmodic drugs are used in the treatment of irritable bowel syndrome and irritable bladder.

HOW THEY WORK

Some antispasmodic drugs have an anticholinergic action (that is, they work by blocking the action of acetylcholine, a neurotransmitter chemical released from nerve endings that stimulates muscle contraction). Others work by direct action on smooth muscle.

SIDE EFFECTS

Possible side effects of antispasmodic drugs include a dry mouth, blurred vision, and difficulty in passing urine. (See also anticholinergic drugs.)

antithyroid drugs

COMMON DRUGS

• Carbimazole • Iodine • Propylthiouracil

A group of drugs that are used to treat hyperthyroidism, in which the thyroid gland is overactive. They may be used as the sole treatment for hyperthyroidism or may be given prior to thyroid surgery.

HOW THEY WORK

Carbimazole and propylthiouracil work primarily by interfering with production of thyroid hormones by the thyroid gland. Radioactive iodine works by destroying part of the thyroid tissue in people with hormone-secreting thyroid nodules.

SIDE EFFECTS

Side effects of carbimazole and propylthiouracil include nausea, headaches, mild gastrointestinal disturbances, dizziness, joint pain, itching, and rash. Carbimazole can suppress white blood cell production. Iodine can cause hypersensitivity reactions resembling coryza (nasal symptoms of the common cold).

antitoxin

Any of a variety of commercially prepared substances containing antibodies (proteins manufactured by the immune system) that can combine with and neutralize the effect of a specific toxin that has been released into the bloodstream by particular bacteria (such as those that cause tetanus and diphtheria).

Antitoxins are usually given by injection into a muscle. Occasionally, an antitoxin may cause an allergic reaction (see allergy); rarely, it may cause anaphylactic shock (a severe allergic reaction requiring emergency treatment).

antitussive drugs

Drugs that suppress or relieve a cough (see cough remedies).

antivenom

A specific treatment for bites or stings inflicted by venomous animals such as snakes, spiders, and scorpions.

Antivenom is prepared by the inoculation of animals, such as horses, with venom from a particular poisonous animal, thereby provoking the production of antibodies (proteins manufactured by the immune system) that neutralize the poisons in the venom. A preparation of these antibodies can be produced from samples of the animal’s blood.

Antivenoms are given by intravenous injection and may cause allergic reactions (see allergy).
antiviral drugs

COMMON DRUGS

ANTIRETROVIRALS • Didanosine • Efavirenz
• Indinavir • Lamivudine • Nelfinavir
• Nevirapine • Ritonavir • Saquinavir
• Stavudine • Zalcitabine • Zidovudine

OTHERS • Aciclovir • Amantadine • Cidofovir
• Famciclovir • Foscarnet • Ganciclovir
• Idoxuridine • Inosine pranobex • Interferon
• Penciclovir • Ribavirin • Valaciclovir
• Zanamivir

Anus

Drugs used in the treatment of infection by viruses. No drugs have been developed that can eradicate viruses completely, and at present immunization is the most effective way of preventing serious viral infections. However, antiviral drugs can reduce the severity of some viral infections (most notably herpes, influenza, viral hepatitis, and cytomegalovirus infections), particularly in people who have reduced immunity. Advances have also been made in the treatment of HIV infection (see antiretroviral drugs).

HOW THEY WORK

Most antiviral drugs destroy viruses by disrupting the chemical processes necessary for the virus to grow and multiply within a cell. Some antivirals actually prevent viruses penetrating the cells.

SIDE EFFECTS

Side effects of antiviral drugs used in the treatment of HIV infection and AIDS may include nausea, diarrhoea, and tiredness. These drugs may also affect blood chemistry, leading to conditions such as anaemia (a reduced level of the oxygen-carrying pigment haemoglobin in the blood).

Most other antivirals rarely cause side effects. Antiviral creams may cause skin irritation and those given by mouth or injection may lead to nausea, dizziness, and rarely, in prolonged treatment, to kidney damage.

Antral irrigation

Irrigation (flushing out) of the maxillary antrum, one of the nasal sinuses. More commonly known as a sinus washout, antral irrigation is used to treat persistent sinusitis. The procedure is performed less often nowadays since the introduction of nasal endoscopy, (examination of the nasal cavity using a flexible viewing tube).

Anuria

Complete cessation of urine output. Anuria may be caused by a severe mal-function of the kidneys, but a much more common cause is a complete blockage of the flow of urine as a result of enlargement of the prostate gland (see prostate, enlarged), a bladder tumour, or a bladder or kidney stone in the (see calculus, urinary tract). Failure of the kidneys to produce urine may be due to oxygen depletion as a result of reduced blood flow through the kidneys, as occurs in shock, or to severe kidney damage caused by a disease such as glomerulonephritis.

Anuria requires urgent investigation to establish the cause and to allow treatment (such as rehydration or removal of the blockage) to begin. Treatment of the cause may restore urine production, but any delay can result in permanent kidney damage, leading to uraemia (excess urea and other waste products in the blood).

Anus

The end of the alimentary tract through which faeces are expelled from the body. The anus is an extension of the rectum as it passes downwards and backwards through the pelvic floor.

The orifice at the end of the anal canal is open only during defaecation; at other times it is kept closed by the muscles of the anal sphincter. These muscles are arranged in two layers: the internal sphincter, which cannot be controlled voluntarily, and the external sphincter, which can be relaxed at will for defaecation. Disorders of the anus include anal cancer (see anus, cancer of) and imperforate anus (see anus, imperforate). (See also digestive system.)

Anus, cancer of

A rare cancer of the skin of the anus. Possible early signs of anal cancer are the development of swelling or an ulcer at the anus, accompanied by bleeding and discomfort. Treatment is by surgical removal and/or radiotherapy.

Anus, imperforate

A rare congenital (present from birth) abnormality in which the anal opening is missing or covered over. The severity of the condition varies from complete absence of the anal canal to only a layer of skin covering the anal opening.

Treatment is with surgery. In severe cases, a colostomy may be needed initially before definitive surgery to construct an anus. Where surgery simply involves removal of a layer of skin over the anal opening, anal dilation (a procedure to enlarge the anus) may be required for several months afterwards.

Anxiety

An unpleasant emotional state that ranges from mild unease to intense fear. Anxiety is a normal response to stressful situations and prepares the mind and body to respond effectively. However, anxiety that occurs without reason may be a symptom of an anxiety disorder or another psychological disorder such as depression.

Symptoms

A variety of physical symptoms are associated with anxiety. The most common include palpitations (a more forceful or faster heartbeat), chest pains, a feeling of tightness in the chest, and a tendency to overbreathe (see hyperventilation). Muscle tension leads to headaches and back pains.

Gastrointestinal symptoms of anxiety include dry mouth (see mouth, dry), bloating, diarrhoea, nausea, and difficulty in swallowing. Other symptoms

Antiretrovirals

See antiretroviral drugs.
include lightheadedness, sweating, pallor, blushing, and a frequent need to urinate or defecate.

People with anxiety may have a constant feeling that something bad is going to happen. They may fear illness or worry about the health and safety of family and friends. Fear of losing control is also common. Anxiety often leads to increasing dependence on others, irritability, a sense of fatigue, and frustration. Inability to relax may lead to difficulty in sleeping.

TREATMENT
People suffering from anxiety may be helped by counselling or psychotherapy. If there is an underlying disorder, such as depression, treatment with antidepressant drugs can help. Antianxiety drugs are used for short-term control of symptoms but are avoided for long-term treatment because they are addictive.

anxiety disorders
A group of mental illnesses, including several specific syndromes, in which symptoms of anxiety are the principal feature. Anxiety disorders are common and mainly affect young adults.

TYPES
In generalized anxiety disorder, the affected individual suffers from persistent tension and apprehension that has no specific focus or cause, together with physical or psychological symptoms that disrupt normal activity. Panic disorder is characterized by sudden and recurrent attacks of extreme, unreasonable fear and anxiety. Phobias are irrational fears, such as the fear of open spaces or of spiders, that lead to avoidance of certain situations or objects. Post-traumatic stress disorder is a form of anxiety that develops following a stressful or traumatic event and obsessive–compulsive disorder is a condition in which a person’s obsessions and fears lead them to carry out repetitive, ritualized acts.

TREATMENT
Counselling, psychotherapy, and group or individual cognitive–behavioural therapy are used to treat anxiety disorders. Antidepressant drugs are often used, and antianxiety drugs (especially benzodiazepine drugs) may be used for short-term treatment but are addictive.

anxiolytics
See antianxiety drugs.

aorta
The main artery of the body, which supplies oxygenated blood to all other parts. The aorta arises from the left ventricle (the main pumping chamber of the heart) and arches up over the heart before descending, behind it, through the chest cavity. It terminates in the abdomen by dividing into the two common iliac arteries of the legs. The aorta is thick-walled and has a large diameter to cope with the high pressure and large volume of blood passing through it.

DISORDERS
The aorta, like other arteries, can become narrowed as a result of atherosclerosis (fat deposits on its walls), which may cause hypertension (high blood pressure). Coarctation of the aorta (in which the aorta is abnormally narrow at birth) and aortitis (inflammation of the aorta wall) are examples of aorta-specific disorders. Both aortitis and atherosclerosis may result in an aortic aneurysm (ballooning of the aorta wall), which may require surgery. (See also arteries, disorders of; circulatory system.)

aortic incompetence
Leakage of blood through the aortic valve (one of the heart valves), resulting in a backflow of blood from the aorta into the left ventricle (the heart’s main pumping chamber).

CAUSES
Failure of the aortic valve to close properly may be due to a congenital (present from birth) abnormality in which the valve has two leaflets (flaps) rather than three. The valve leaflets can be destroyed by infective endocarditis (inflammation of the membrane lining the heart). Long-term hypertension can sometimes cause the root of the aorta to stretch so that the valve does not close properly.

Aortic incompetence is also associated with ankylosing spondylitis (a disorder that affects the spine), and Marfan syndrome, a congenital disorder of connective tissues. Rheumatic fever, which is now rare, may damage the valve, causing a combination of aortic stenosis (narrowing of the aortic valve) and incompetence. In addition, aortic incompetence may occur in untreated syphilis.
AORTIC STENOSIS

LOCATION AND STRUCTURE OF THE AORTA

From its origin at the left ventricle, the aorta passes upwards, curves behind the heart, and runs downwards, passing through the thorax (chest) and into the abdomen, where it terminates by dividing into two common iliac arteries. The aorta is thick-walled and large in diameter (about 2.5 cm at its origin) to cope with the high pressure and large volume of blood that passes through it. The thick walls of the aorta have an elastic quality that helps to even out the peaks and troughs of pressure that occur with each heartbeat.

SYMPTOMS AND SIGNS
Aortic incompetence may not cause symptoms; it is sometimes found during a routine medical examination when the doctor hears a murmur (abnormal heart sound) over the front of the chest wall to the left of the sternum (breastbone).

The heart compensates for the backflow of blood into the left ventricle by working harder, until the combination of hypertrophy (muscle thickening) and dilatation (ballooning) of the left ventricle wall eventually leads to heart failure (reduced pumping efficiency of the heart); this causes breathing difficulty and oedema (a buildup of fluid).

DIAGNOSIS AND TREATMENT
A chest X-ray, ECG (measurement of the electrical activity of the heart), and echocardiography (imaging of the heart structures by measuring the pattern of reflection of sound waves from them) may be carried out to diagnose aortic incompetence. A cardiac catheter (flexible tube that is inserted into the heart via blood vessels) can be used to demonstrate the degree of stenosis (see catheterization, cardiac).

Heart-valve surgery may be needed to widen or replace the damaged valve.

aortic stenosis
Narrowing of the opening of the aortic valve (one of the heart valves), causing obstruction of blood flow into the circulation. Aortic stenosis makes the heart work harder and causes the muscle in the wall of the left ventricle (the main pumping chamber of the heart) to thicken. Narrowing of the valve also reduces the amount of blood flowing into the coronary arteries (the main arteries that supply the tissues of the heart with oxygen-rich blood).

CAUSES
The most common cause of aortic stenosis is deposition of calcium on the aortic valve. This deposition is usually associated with arteriosclerosis (fatty deposits). Aortic stenosis may also be the result of a congenital (present from birth) abnormality.

SYMPTOMS AND SIGNS
Aortic stenosis may not cause any symptoms; it is sometimes found during a routine medical examination when the doctor hears a murmur (an abnormal heart sound) over the front of the chest wall to the right of the sternum (breastbone) and sometimes up into the neck. Symptoms, when they do occur, include fainting, lack of energy, chest pain on exertion as a result of angina pectoris, and breathing difficulties. Other features, which occur at a late stage, include a weak pulse and cardiomegaly, (enlargement of the heart).

DIAGNOSIS AND TREATMENT
A chest X-ray, an ECG (measurement of the electrical activity of the heart), and echocardiography (imaging of the heart structures by measuring the pattern of reflection of sound waves from them) may be carried out to diagnose aortic incompetence. A cardiac catheter (flexible tube that is inserted into the heart via blood vessels) can be used to demonstrate the degree of stenosis (see catheterization, cardiac).

Heart-valve surgery may be needed to widen or replace the damaged valve.

aortitis
Inflammation of the aorta (the main artery of the body). Aortitis is a rare condition that occurs in people with arteritis (inflammation of the arteries) or untreated syphilis and in some people with ankylosing spondylitis (a disorder affecting the spine).

Aortitis may cause part of the aorta to widen and its walls to become thinner. This may lead to an aneurysm (ballooning of the artery), which may burst and cause severe, sometimes fatal, blood loss. Aortitis may also damage the ring around the aortic valve in the heart, leading to aortic incompetence (a condition which allows the backflow of blood into the heart), which may eventually result in heart failure (reduced pumping efficiency of the heart).

aortography
An imaging technique that enables the aorta (the main artery of the body) and its branches to be seen clearly on X-ray film following injection of a contrast medium (a substance that is opaque to X-rays) into the aorta.

HOW AND WHY IT IS DONE
The contrast medium is usually injected into the aorta through a fine catheter (a flexible plastic tube) that is inserted either into the femoral artery at the groin, the brachial artery on the inside of the elbow, or directly into the aorta within the lower abdomen.

Aortography is used if surgery is needed to treat an aneurysm (ballooning of the aorta).

apathy
The absence of feelings that is often associated with a lack of energy. Healthy people may be described as apathetic, but true apathy is a feature of certain
mental illnesses, such as schizophrenia. An affected person fails to take interest in everyday activities and tends to be inactive and lacking in volition (drive).

aperient
A mild laxative drug.

apex
The tip or uppermost surface of an organ or structure, such as the lungs or the heart. The apex of a tooth is the tip of its root.

apex beat
A normal heartbeat felt through the chest wall. As the heart contracts, its tip hits the chest wall and the beat can be felt between the fifth and sixth ribs on the left side of the chest. The apex beat is displaced when the heart is enlarged.

Apgar score
A system devised by Virginia Apgar, an American anaesthetist, to assess the condition of a newborn baby and help to direct appropriate care. Five features (breathing, heart rate, colour, muscle tone, and reflex to stimulation) are scored one minute, and again five minutes, after birth.

aphakia
The absence of the lens from the eye. Aphakia may be congenital (present from birth), may result from surgery (for example, cataract surgery), or may be due to a penetrating injury.

Aphakia causes severe loss of focusing in the affected eye and requires correction by implanting a lens or with contact lenses or glasses.

aphasia
Complete absence of previously acquired language skills caused by a brain disorder that affects the ability to speak and write, and/or comprehend and read. Related disabilities that may occur as a feature of aphasia are alexia (word blindness) and agraphia (writing difficulty).

CAUSES
Language function in the brain lies in the dominant cerebral hemisphere (see cerebrum). Two particular areas in this hemisphere, Broca’s and Wernicke’s areas, and the pathways connecting the two, are important in language skills. Damage to these areas, which most commonly occurs as a result of stroke or head injury, can lead to aphasia.

TYPES AND SYMPTOMS
Broca’s aphasia causes difficulty in expressing language. Speech is laboured and normal rhythm is lost, but the few words uttered tend to be meaningful. Writing may also be impaired.

Wernicke’s aphasia causes difficulty in language comprehension. Speech is fluent but its content is disturbed, with errors in word selection and grammar. Writing is also impaired, and spoken and/or written language may not be understood.

In associative aphasia, comprehension is normal, and the affected individual can write and speak. However, he or she is unable to repeat what has been heard and cannot read aloud.

Global aphasia comprises the total, or near total, inability to speak, write, or understand language.

Nominal aphasia is restricted to difficulty in naming objects or in finding words, although the sufferer may be able to choose the correct word from several offered.

In jargon aphasia, an affected individual cannot form grammatical sentences and utters meaningless phrases composed of jumbled words or neologism.

TREATMENT AND OUTLOOK
Some recovery from aphasia is usual following a stroke or head injury, but the more severe the aphasia, the less the chances of recovery. Speech therapy is the main treatment. (See also aphonia; dysarthria; dysphasia; dysphonia; speech; speech disorders.)

apheresis
A procedure in which blood is withdrawn from a donor or patient and reinfused after one or more selected components have been separated and removed. For example, in plasmapheresis, antibodies (proteins manufactured by the immune system) that are causing a disease (such as Guillain–Barré syndrome or Goodpasture’s syndrome) are removed; in leukapheresis, white blood cells (see lymphocyte) are removed either to reduce their number or to harvest them for use in a blood transfusion.

aphonia
Complete loss of the voice, which may result from surgery to the larynx (voice-box) or may be temporary, sudden in onset, and due to emotional stress. In aphonia, the vocal cords fail to meet as normal when an individual tries to speak, although they may come together when the person coughs.

There is no particular treatment for aphonia, but in the temporary form of the condition, the sufferer’s voice usually returns as suddenly as it disappeared. (See also dysphonia.)

aphrodisiac
Any substance that is thought to stimulate erotic desire and enhance sexual performance. Aphrodisiacs are named after Aphrodite, the Greek goddess of love, beauty, and fertility.

For centuries, various substances (most notably oysters and rhinoceros horn) have been used as aphrodisiacs. In fact, no substance has a proven aphrodisiac effect.

aphthous ulcer
See ulcer, aphthous.

apical
A term used to describe the position of structures that are found at the apex (tip) of particular organs and structures, including the lungs and heart.

apicectomy
The surgical removal of the tip of a tooth root in order physically to eliminate an infection or an infected cyst at the root tip. The procedure was once performed as part of root-canal treatment but is now used less often because root-canal treatment alone usually achieves the desired result.

aplasia
Absent or severely reduced growth and development of any organ or tissue. For example, in bone marrow aplasia, the rate of cell division in the bone marrow is reduced, leading to insufficient blood-cell production (see anaemia, aplastic). Some birth defects, such as stunted limbs (see phocomelia), occur as a result of incomplete tissue formation during prenatal development.

aplastic anaemia
See anaemia, aplastic.

apnoea
Cessation of breathing that can occur either temporarily (for a few seconds or up to a minute or two) or for a prolonged period.

CAUSES
Breathing is an automatic process that is controlled by the respiratory centre in the brainstem (a stalk of nerve tissue linking the brain to the spinal cord). The respiratory centre sends nerve impulses that regulate contraction of the diaphragm and muscles in the chest wall, thereby controlling the rate and depth of breathing. Failure of this centre to maintain normal breathing is known as central apnoea. The condition may occur in babies, particularly those who are premature, and can be detected by an apnoea alarm. Central apnoea can also be the result of damage to the brainstem (following a stroke or head injury, for example).

In obstructive apnoea, breathing is prevented by a blockage in the airway. The most common type is sleep apnoea, in which blockage of the upper airway occurs repeatedly during sleep.

Deliberate temporary apnoea occurs in breath-holding attacks. Another type of apnoea occurs in Cheyne–Stokes respiration, in which cycles of deep, rapid breathing alternate with episodes of breathing stoppage.

TREATMENT
Treatment depends on the cause; in newborn babies, apnoea resolves itself as they mature. In cases of stroke or head injury, artificial ventilation may be necessary, temporarily, until recovery occurs.

apocrine gland
A gland that discharges cellular material in addition to the fluid that it secretes. The term apocrine is usually applied to the type of sweat glands that appear in hairy areas of the body after puberty. (See also eccrine gland.)

apocrinitis
Inflammation of the apocrine glands, which are located in the armpit, groin, and perineum.

apolipoprotein
Any of a group of proteins that are constituents of lipoproteins, the carriers of fat in the bloodstream. Apolipoproteins are also involved in the growth and repair of nerve tissues.

apomorphine
A drug that is used in the treatment of Parkinson’s disease. Nausea and vomiting are common side effects of apomorphine at the start of treatment.

aponeurosis
A wide sheet of tough, fibrous tissue that acts as a tendon by attaching a muscle to a bone or a joint.

apophysitis
An outgrowth of bone at the site of attachment of a tendon to bone. Inflammation may occur, as in Osgood–Schlatter disease.

apoplexy
An outdated term for a stroke.

apoptosis
The natural process of programmed cell death. Apoptosis occurs in embryonic development, when the shaping of body parts is taking place, and continues throughout life in the constant cycle of death and renewal of body cells. Failure of apoptosis is implicated in the development of cancers.

apotrichy
An outdated term for a pharmacist.

LAPAROSCOPIC APPENDICECTOMY
Surgery to remove the appendix can be carried out, under general anaesthesia, either conventionally or laparoscopically. Laparoscopic appendicectomy takes approximately an hour, which is three times as long as conventional surgery, but recovery is quicker.

Procedure
Three or four tiny incisions are made in the abdominal wall, and a laparoscope, instruments, and suction tubes are inserted. The appendix is then clamped, tied off, and removed.
appendage
An additional piece of tissue that is attached to a main structure. An auricular appendage is a small tag of tissue attached near the ear that may be present from birth.

appendicectomy
Surgical removal of the appendix to treat acute appendicitis (inflammation of the appendix).

WHY IT IS DONE
Appendicectomy is performed to prevent an inflamed appendix bursting and causing peritonitis (inflammation of the peritoneum, the lining of the abdominal cavity) or an abdominal abscess.

HOW IT IS DONE
The two methods of appendicectomy are conventional appendicectomy and minimally invasive surgery. Conventional surgery involves making a hole in the abdominal wall that is large enough for the surgeon’s instruments and finger-tips to be introduced. In minimally invasive surgery, three or four small holes are made in the abdominal wall; a laparoscope (viewing instrument) that incorporates a video camera is inserted into one of the openings, and instruments and suction tubes into the others. In both types of operation, the appendix is identified, clamped, tied off at its base, and removed.

If the appendix has burst, the infected area of the abdominal cavity is washed out with saline and drained via a tube inserted into one of the incisions. Antibiotic drugs may also be given to prevent peritonitis.

COMPLICATIONS AND OUTLOOK
Possible complications are infection of the incision wound, an abscess at the site from which the appendix was removed, or localized peritonitis.

In the absence of complications, normal physical activities can usually be resumed within two to three weeks.

appendicitis
Acute inflammation of the appendix (a narrow, finger-shaped tube that branches off the large intestine), which is a common cause of abdominal pain and peritonitis (inflammation of the lining of the abdominal cavity).

CAUSE AND SYMPTOMS
The cause of appendicitis is usually not known, but the condition is sometimes caused by obstruction of the appendix by a lump of faeces. The closed end of the appendix beyond the obstruction becomes inflamed, swollen, and infected. This may lead to gangrene (tissue death) in the appendix wall, which may perforate (burst).

The first symptom is usually vague discomfort around the navel. Within a few hours, this develops into severe, more localized pain, which is usually most intense in the lower right-hand side of the abdomen. Symptoms may differ if the appendix is not in the most common position. For example, if the appendix impinges on the ureter, the urine may become bloodstained.

DIAGNOSIS AND TREATMENT
Diagnosis may be difficult because the symptoms of appendicitis are similar to those of many other abdominal disorders. Sometimes a laparotomy (surgical investigation of the abdomen) is necessary in order to confirm or exclude a diagnosis of appendicitis.

The usual treatment for appendicitis is appendicectomy, which is often performed endoscopically (see minimally invasive surgery).

COMPLICATIONS
If treatment is delayed, an inflamed appendix may burst, releasing its contents into the abdomen. At this point, the pain ceases abruptly, but the perforation leads to peritonitis. In some cases, the omentum (fold of peritoneum that covers the intestines) envelops the inflamed appendix; this prevents the spread of infection but may result in a localized abscess around the appendix.

appendix
A small, narrow tube that projects out of the caecum (the first part of the colon) at the lower right-hand side of the abdomen. The appendix may lie behind or below the caecum, or in front of or behind the ileum (part of the small intestine).

The appendix has no known function, but it contains a large amount of lymphoid tissue, which provides a defence against localized infection. The position of an individual’s appendix partly determines the symptoms produced by acute appendicitis (inflammation of the appendix).

appendix abscess
An abscess (a collection of pus) that may form after the rupture of an inflamed appendix (see appendicitis).

appetite
A desire for food; a pleasant sensation that is felt in anticipation of eating. Appetite is distinct from hunger, which is a disagreeable feeling caused by the need for food.

Appetite, which is regulated by two parts of the brain (the hypothalamus and cerebral cortex), is learned by enjoying a variety of foods that smell, taste, and look good. It combines with hunger to ensure that the right amount of a wide range of foods is eaten in order to stay healthy. (See also appetite, loss of.)

appetite, loss of
Loss of appetite, known medically as anorexia, is usually temporary and due to an emotional upset or minor illness. Persistent loss of appetite may be a symptom of a more serious underlying physical or psychological disorder and requires investigation by a doctor.

CAUSES
In adolescents and young adults, loss of appetite may be due to anorexia nervosa (an eating disorder) or to drug abuse, particularly of amphetamine drugs. Depression or anxiety may result in loss of appetite at any age.

Possible physical causes of appetite loss include a stroke (damage to part of the brain caused by an interruption to its blood supply), a brain tumour, or a
head injury that has damaged the hypothalamus or cerebral cortex (the parts of the brain that control appetite). Other physical causes include intestinal disorders, such as gastritis (inflammation of the stomach lining, which is common in problem drinkers), stomach cancer, a gastric ulcer, and liver disorders such as hepatitis. Many infectious diseases, such as influenza, can also lead to loss of appetite.

Between the ages of about two and four, some children go through a period of refusing food. If there are no other symptoms, this phase should be regarded as a normal part of a child’s development.

For an otherwise healthy person, a period of two or three days without food is not harmful, provided that plenty of nonalcoholic fluids are drunk. A doctor should always be consulted, however, if there are other health problems (particularly diabetes mellitus) or if regular medication is being taken.

All cases of appetite loss that last for more than a few days should be investigated by a doctor. Appetite generally returns to normal once any underlying illness has been treated. (See also appetite stimulants.)

appetite stimulants
Various tonics and remedies that have been traditionally prescribed to stimulate the appetite. None are proven to be effective.

Some drugs, such as corticosteroid drugs, may stimulate the appetite when used to treat unrelated disorders.

appetite suppressants
A group of drugs that reduce the desire to eat. Sibutramine is the only appetite suppressant now commonly prescribed. Appetite suppressants may be used in the treatment of severe obesity, along with dieting and exercise, when serious attempts at dieting and exercise have previously failed to bring about sufficient weight loss.

HOW THEY WORK
Sibutramine works by inhibiting the reuptake of noradrenaline (norepinephrine) and serotonin.

SIDE EFFECTS
Common side effects of sibutramine include constipation, a dry mouth (see mouth, dry), insomnia, nausea, palpitations, hypertension (high blood pressure), headache, anxiety, sweating, and disturbance of the sense of taste.

The use of sibutramine is strictly controlled and is limited to a maximum of one year.

apparatus
See orthodontic apparatus.

apraxia
The inability to carry out purposeful movements despite normal muscle power and coordination. Apraxia is caused by damage to nerve tracts in the cerebrum (the main mass of the brain) that translate the idea for a movement into an actual movement. People with apraxia usually know what they want to do but are unable to recall from memory the sequence of actions necessary to achieve the movement. Damage to the cerebrum may be caused by a head injury, an infection, a stroke (damage to part of the brain caused by interruption to its blood supply), or a brain tumour.

TYPES
Apraxia takes various forms, and each is related to damage in different parts of the brain. Ideomotor apraxia is the inability to carry out a spoken command to make a certain movement, but to make the same movement unconsciously at other times. In sensory apraxia, a person may not be able to use an object due to loss of ability to recognize its purpose.

Agraphia (difficulty in writing) and aphasia (severe difficulty in expressing language) are special forms of apraxia.

OUTLOOK
Recovery from apraxia is highly variable and is dependent on the cause. Lost skills may need to be relearned.

APUD cell tumour
A growth composed of cells that produce various hormones. APUD (amine precursor uptake and decarboxylation) cells occur in different parts of the body. Some tumours of the thyroid gland, pancreas, and lungs are APUD cell tumours, as are carcinoid tumours (tumours of the intestine or lung, see carcinoid syndrome) and pheochromocytoma (a type of adrenal tumour).

aqueous cream
An emollient preparation that is commonly used to treat dry, scaly, or itchy skin in conditions such as eczema.

aqueous humour
A watery fluid that fills the front chamber of the eye, behind the cornea (the transparent front part of the eyeball).

arachidonic acid
One of the fatty acids in the body that are essential for growth.

arachis oil
Peanut or ground-nut oil. Arachis oil is used in enemas to lubricate and soften impacted faeces and to make bowel movements easier. It can also be applied to the scalp, followed by shampooing, in the treatment of cradle cap.

arachnodactyly
A term for long, thin, spiderlike fingers and toes. Arachnodactyly sometimes occurs spontaneously but is also characteristic of Marfan syndrome, an inherited connective tissue disease.

arachnoiditis
A rare condition that is characterized by chronic inflammation and thickening of the arachnoid mater, which is the middle of the three meninges (membranes) that cover the brain and spinal cord.

The cause of arachnoiditis is often unknown. However, the condition may develop following an episode of meningitis (inflammation of the meninges) or a subarachnoid haemorrhage (a type of brain haemorrhage). It may also be a feature of syphilis or ankylosing spondylitis (a disorder affecting the spine). Arachnoiditis may also result from injury or certain medical procedures.

Symptoms may include headache, epileptic seizures, blindness, or difficulty with movements due to increased muscle tension. There is no effective treatment for arachnoiditis.

arachnoid mater
The middle of the three layers of membrane (see meninges) that cover the brain and spinal cord.

arbovirus
Any of the many viruses transmitted by a member of the arthropod group of animals, including insects, mites, and ticks. (See also insects and disease; mites and disease; ticks and disease).

ARC
An abbreviation for AIDS-related complex. (See also AIDS.)

arcus senilis
A grey-white ring near the edge of the cornea (the transparent front part of the eyeball) overlying the iris (the coloured part of the eye).
Arcus senilis
The arcus senilis is the lighter ring that overlies the edge of the iris (the coloured part of the eye).

Arcus senilis, which is caused by degeneration of fatty material in the cornea, develops gradually during adult life. The ring never spreads to the centre and does not affect eyesight. The development of the condition in early adulthood may be associated with an abnormally high level of fats in the blood (see hyperlipidaemia).

areola
The pigmented circular area surrounding the nipple. The term is also used to describe an inflamed area around a pimple (see pustule).

Aricept
A brand name for donepezil, an acetylcholinesterase inhibitor used to treat Alzheimer’s disease.

aromatherapy
A form of complementary medicine that uses aromatic oils extracted from plants to treat a wide range of disorders. Practitioners claim that aromatherapy is particularly effective in treating stress-related and psychosomatic conditions.

The oil is applied in small quantities through massage; it may also be inhaled, incorporated into creams or lotions, or, very occasionally, taken internally. There is no conclusive scientific evidence of the benefits.

arousal
The awakening of a person from unconsciousness or semiconsciousness. The term is also used to describe any state of heightened awareness, such as that caused by sexual stimulation or fear. Arousal is regulated by the reticular formation in the brainstem.

arrhenoblastoma
A rare tumour of the ovary that occurs in young women. The tumour is noncancerous, but it secretes androgens (male sex hormones) that cause virilization (development of male characteristics). Treatment of arrhenoblastoma is by surgical removal of the affected ovary.

**Arrhythmia, cardiac**
An abnormality of the rhythm or the rate of the heartbeat. Arrhythmias are the result of a disturbance in the electrical impulses within the heart (see Cardiac arrhythmia box, below). Any isolated irregular beat is known as an ectopic heartbeat. Ectopic beats do not necessarily indicate the presence of an abnormality, however.

**TYPES**
Arrhythmias can be divided into two main groups: tachycardias, in which the rate of the heartbeat is faster than normal, and bradycardias, in which the rate is slower. The rhythm may be regular, with each beat of the atria (upper chambers, see atrium) being followed by one beat of the ventricles (lower chambers).

**CARDIAC ARRHYTHMIA**
Any disorder that interferes with the generation or transmission of impulses through the heart’s electrical conducting system (below) can lead to a disturbance of cardiac rate or rhythm. These ECG recordings show two kinds of arrhythmia: sinus bradycardia and atrial fibrillation.

**Sinus bradycardia**
The heart rate is slow, but the rhythm normal, with each atrial beat (small rise) followed by a ventricular beat (spike). Sinus bradycardia is common in athletes but can also be caused by hypothyroidism.

**Atrial fibrillation**
The atrial beat rapidly and irregularly. Ventricular beats (spikes) do not follow each atrial beat and are irregularly spaced. This arrhythmia is common in the elderly and in people with hyperthyroidism.

**Tachycardias** In sinus tachycardia, the rate is raised, the rhythm is regular, and the beat originates in the sinoatrial node (see pacemaker). Supraventricular tachycardia is faster and the rhythm is regular. It may be caused by an abnormal electrical pathway that allows an impulse to circulate continuously in the heart and take over from the sinoatrial node. A rapid, irregular beat that originates in the ventricles is known as a ventricular tachycardia. In atrial flutter, the atria beat regularly and very rapidly, but not every impulse reaches the ventricles, which beat at a slower rate. Uncoordinated, fast beating of the atria is known as atrial fibrillation and produces totally irregular ventricular beats. Ventricular fibrillation is a form of cardiac arrest in which the heart does not pump blood because the ventricles are twitching very rapidly in a disorganized manner.

**Bradycardias** Sinus bradycardia is a slow, regular beat. In heart block, the conduction of electrical impulses through the
heart muscle is either partially or completely blocked, leading to a slow, irregular heartbeat. Periods of bradycardia may alternate with periods of tachycardia due to a fault in impulse generation (see sick sinus syndrome).

**CAUSES**
A common cause of arrhythmia is **coronary artery disease**, in which the coronary arteries are narrowed by **atherosclerosis** (fat deposits on the artery walls), particularly when following **myocardial infarction** (heart attack). Some tachycardias are the result of a **congenital** (present from birth) defect in the heart's conducting system.

**SYMPTOMS**
An arrhythmia may be felt as palpitations, in which the individual becomes aware of an abnormally rapid heartbeat. However, in some cases, arrhythmias cause fainting and dizziness as a result of reduced blood flow to the brain, or chest pain and breathlessness if there is a reduction in blood flow to the lungs. These may be the first symptoms.

**DIAGNOSIS**
Arrhythmias are diagnosed by an **ECG**, which shows the pattern of electrical activity within heart muscle. If the arrhythmia is intermittent, a continuous recording may need to be made using an **ambulatory ECG**.

**TREATMENT**
Treatments for arrhythmias include **anti-arrhythmic drugs**, which prevent or slow tachycardias. With an arrhythmia that has developed slowly, it may be possible to restore normal heart rhythm by using electric shock to the heart (see **defibrillation**).

Repeated attacks of tachycardia can sometimes be treated by radio frequency ablation (the removal of dead or diseased tissue) of the heart's abnormal conduction pathway. This may be carried out during cardiac catheterization (see **catheterization, cardiac**). In some cases, a pacemaker can be fitted to restore normal heartbeat by overriding the heart's abnormal rhythm.

**arrowroot**
A starchy substance that is obtained from the roots of the West Indian plant **Maranta arundinacea**. Arrowroot was traditionally used an an easily digestible invalid or baby food, being either mixed to a paste with milk or water or used as an ingredient in biscuits.

**arsenic**
A poisonous metallic element that occurs naturally in its pure form and various compounds. Arsenic poisoning, which is now rare, once occurred as a result of continuous industrial or pesticide exposure.

**arterial reconstructive surgery**
An operation to repair arteries that are narrowed, blocked, or weakened.

**WHY IT IS DONE**
Arterial reconstructive surgery is most often performed to repair arteries that have been narrowed by **atherosclerosis** (fatty deposits on artery walls). It is also used to repair **aneurysms** (ballooning of arteries) and arteries damaged as a result of injury.

**HOW IT IS DONE**
A narrowed or blocked section of artery, particularly a coronary artery, can be bypassed by sewing in a length of vein above and below the constricted area. Elsewhere in the body, the affected section is commonly replaced using an artificial tube or a section of vein. (See also **angioplasty, balloon; coronary artery bypass; endarterectomy**.)

**arteries, disorders of**
Disorders of the arteries may take the form of abnormal narrowing (which reduces blood flow and may cause tissue damage), complete obstruction (which may cause tissue death), or abnormal widening and thinning of an artery wall (which may cause rupture of the blood vessel).

**TYPES**
**Atherosclerosis**, in which fat deposits build up on the lining of artery walls, is the most common arterial disease. It can involve arteries throughout the body, including the brain (see **cerebrovascular disease**), heart (see **coronary artery disease**), and legs (see **peripheral vascular disease**). Atherosclerosis is the main type of **arteriosclerosis**, a group of disorders that cause thickening and loss of elasticity of artery walls.

**Hypertension** (high blood pressure) is another common cause of thickening and narrowing of arteries. Hypertension predisposes people to coronary artery disease and increases the risk of a **stroke or kidney failure**.

**Arteritis** is inflammation of artery walls that causes narrowing and sometimes blockage.

**Aneurysm** is ballooning of an artery wall caused by the pressure of blood flowing through a weakened area.

**Thrombosis** occurs when a thrombus (blood clot) forms in a blood vessel, causing obstruction of the blood flow.

An **embolism** is blockage of an artery by a fragment of blood clot or other material travelling in the circulation.

**Raynaud’s disease** is a disorder in which there is intermittent spasm of small arteries in the hands and feet, usually precipitated by the cold.

**arteriography**
An alternative name for **angiography**, an X-ray technique for imaging arteries.

**arteriole**
A blood vessel that is a branch from an **artery** and which branches further to form **capillaries**. Arterioles have muscular walls, and their nerve supply enables them to be narrowed or widened to meet the blood-flow needs of tissues they supply.

**arteriopathy**
Any disorder of an artery (see **arteries, disorders of**).

**arterioplasty**
Surgical repair of an artery (see **arterial reconstructive surgery**).

**arteriosclerosis**
A group of disorders that cause thickening and loss of elasticity of artery walls. **Atherosclerosis** is the most common type of arteriosclerosis, and the two terms are often used synonymously.

Other types are **medial arteriosclerosis** (in which muscle and elastic fibres in larger arteries are replaced by fibrous tissue) and **Monckeberg’s arteriosclerosis** (in which there are calcium deposits in the arterial lining).

**arteriovenous fistula**
An abnormal communication directly between an artery and a vein. An arteriovenous fistula may be present at birth or may result from injury. A fistula can also be created surgically for easy access to the bloodstream, as occurs in **dialysis**.

If the fistula is close to the skin surface it may cause a small, pulsating swelling. If several are present in the lungs, uptake of oxygen into the blood
may be impaired, resulting in cyanosis (blue skin colour) and breathing difficulty on exertion.

An isolated fistula that is causing symptoms can often be cut away and the ends of the blood vessels stitched closed. However, if there are many fistulas, surgery is not practicable.

**Arteritis**

Inflammation of an artery wall, which causes narrowing or complete blockage of the affected artery, reduced blood flow, and, in some cases, thrombosis and tissue damage.

**Types**

There are several types of arteritis. Buerger’s disease is an arteritis that affects the limbs, causing pain, numbness, and, in severe cases, gangrene. Polyarteritis nodosa, a serious autoimmune disorder (in which the immune system attacks the body’s own tissues), can affect arteries in any part of the body, especially the heart and kidneys. Temporal arteritis affects arteries in the scalp over the temples and may also affect the retinal artery in the eye. Takayasu’s arteritis is thought to be an autoimmune disorder. This rare type of arteritis usually affects young women and involves the arteries that branch from the aorta into the neck and arms.

**Artery**

A blood vessel that carries blood away from the heart. Systemic arteries carry blood that has been pumped from the left ventricle (lower chamber) of the heart to all other parts of the body except the lungs. The largest systemic artery is the aorta, which emerges from the left ventricle; other major systemic arteries branch off from the aorta. The pulmonary arteries carry blood from the right ventricle to the lungs.

**Structure**

Arteries are tubes with thick, elastic, muscular walls able to withstand the high pressure of blood flow, to which they are subjected on each heartbeat. The structure of arteries helps to even out the peaks and troughs of blood pressure caused by the heartbeat, so that the blood is flowing at a relatively constant pressure by the time it reaches the smallest blood vessels (arterioles, which branch directly off the arteries and connect to the even smaller capillaries). The pulmonary arteries are thinner-walled than systemic arteries and contain blood at a lower pressure. (See also arteries, disorders of.)

**Arthralgia**

Pain in the joints or in a single joint. (See also arthritis; joint.)

**Arthritis**

Inflammation of one or more joints that is characterized by pain, swelling, and stiffness. Arthritis can vary in severity from a mild ache and joint stiffness to severe pain and, subsequently, deformity of the joints.

**Types and Causes**

There are several different types of arthritis, each having different characteristics. The most common type is osteoarthritis, which most often involves the knees, hips, and hands. It usually affects middle-aged and older people because it results principally from wear and tear on the joints. Cervical osteoarthritis is a form of osteoarthritis that affects the joints in the neck.

Rheumatoid arthritis is a damaging autoimmune disorder (in which the immune system attacks the body’s own tissues) that causes inflammation in the joints and other body tissues such as the pericardium (the membrane covering the heart), the lungs, and the eyes. The disorder has different effects in children (see juvenile chronic arthritis).

Ankylosing spondylitis is another persistent type of arthritis that initially affects the spine and the joints between the base of the spine and the pelvis. Other tissues, such as the eyes, may also be affected. Eventually, the disorder may cause the vertebrae (the bones of the spine) to fuse.

Reactive arthritis typically develops in susceptible people following an infection, most commonly of the genital tract or intestines.

Gout and pseudogout are types of arthritis in which crystals are deposited in a joint, causing swelling and pain.

Septic arthritis is a relatively rare condition that can develop when infection enters a joint either through a wound or from the bloodstream.

**Diagnosis**

Diagnosis of particular types of arthritis is made from blood tests and, in some cases, microscopic examination of fluid from the affected joint. X-rays or MRI (a technique that produces cross-sectional or three-dimensional images of body structures) can indicate the type and extent of joint damage.

**Treatment**

Physiotherapy and exercises can help to minimize the effects of arthritis, and there are specific treatments for certain types (antibiotic drugs for septic arthritis, for example).

In severe cases, one or more of the diseased joints may require arthroplasty.
(replacement of a joint with an artificial substitute) or arthrodesis (fusion of the bones in a joint).

**arthrodesis**
A surgical procedure in which the two bones in a diseased joint are fused to prevent the joint from moving, which relieves pain in the affected area.

**HOW AND WHY IT IS DONE**
Arthrodesis is performed if a joint is painful or unstable and other treatments, such as drugs or arthroplasty (replacement of the joint with an artificial substitute), have failed or are inappropriate.

Arthrodesis of a small joint, such as a finger joint, may be carried out under local anaesthesia (see anaesthesia, local). Otherwise, a general anaesthetic (see anaesthesia, general) is used. In most cases, cartilage (smooth, shock-absorbing tissue) is removed from the ends of the two bones, along with a surface layer of bone from each. The two ends are then joined so that they will fuse when fresh bone cells grow. The bones may need to be kept in position with plates, rods, or screws; a bone graft may also be carried out in some cases.

In arthrodesis of the knee or ankle joints, additional immobilization of the joint (by transfixing it with pins inserted through the skin) may be necessary to keep the area stable until healing is complete.

**RECOVERY AND OUTLOOK**
Complete union of the bones can take up to six months but may be much quicker. In some cases the bones fail to fuse, but fibrous tissue usually fills the gap between them and is strong enough to provide the same effect and strength as bone fusion.

Following arthrodesis, no movement can take place in the affected joint, unlike after arthroplasty. However, the advantage of arthrodesis over arthroplasty is that, once it has been performed, it requires no regular surveillance or further care; and the patient can be reasonably confident that the problem with the joint has been resolved permanently.

**arthrography**
A diagnostic technique in which the interior of a damaged joint is X-rayed following the injection of a radiopaque (visible on X-ray) solution. The procedure is gradually being replaced by MRI, ultrasound scanning, and arthroscopy.

**arthrogyrosis**
See contracture.

**arthropathy**
A medical term for any disease or disorder that involves the joints. (See also diabetic arthropathy.)

**arthroplasty**
Replacement of a joint or part of a joint by metal or plastic components. A hip replacement is one of the most common operations of this type, as is a knee-joint replacement. Replacement of other joints, such as the finger (see finger-joint replacement), shoulder, and elbow, is also common.

**arthroscopy**
Inspection through an endoscope (a viewing tube) of the interior of a joint, usually for diagnostic purposes.

**WHY IT IS DONE**
Arthroscopy is most often used to diagnose disorders of the knee joint but can also be used in other joints such as the shoulder, hip, or wrist. The procedure allows the surgeon to see the surface of the bones, the ligaments, the cartilages, and the synovial membrane. Specimens can be taken for examination.

Some surgical procedures that used to involve making a large incision, such as removal of damaged cartilage, repair of ligaments, and shaving of the patella...
(kneecap), are now usually performed arthroscopically. Arthroscopic surgery substantially reduces the amount of recovery time required.

**Artro tec**
The brand name of an antirheumatic drug containing diclofenac and misoprostol.

**articulation**
The junction point of two or more bones (see joint).

**artificial feeding**
See feeding, artificial.

**artificial heart**
See heart, artificial.

**artificial insemination**
A form of assisted conception in which semen is introduced artificially into the uterus, instead of by sexual intercourse, with the aim of inducing conception and pregnancy.

**TYPES**
There are two types of artificial insemination: AIH, artificial insemination with the semen of the woman’s male partner; and AID, insemination with a donor’s sperm. AIH is usually for couples who are unable to have intercourse, or if the man has a low sperm count or a low volume of ejaculate. AIH is also used when a man’s semen has been stored prior to his having treatment (such as chemotherapy) that has made him sterile. AID is available to couples if the man is infertile or a carrier of a genetic disease. It may also be used by a woman who wants children but has no male partner.

**HOW IT IS DONE**
Artificial insemination is carried out at centres that are specially staffed and equipped to obtain, test, and store semen, to carry out the insemination, and to give counselling before and after the procedure. Semen donors are screened for a wide variety of physical and mental disorders.

Insemination is performed by injecting a sample of semen into the woman’s cervix using a small syringe. The procedure is timed to coincide with her natural ovulation (the development and release of an egg from the ovary), or it may be combined with treatment to stimulate ovulation.

**artificial kidney**
The common name for the machine used in dialysis.

**artificial limb**
See prosthesis.

**artificial respiration**
See rescue breathing.

**artificial rupture of membranes**
See amniotomy.

**artificial saliva**
A preparation used to relieve a persistently dry mouth, which may be a side effect of certain drugs or radiotherapy or may be due to Sjögren’s syndrome (an autoimmune disorder in which the immune system attacks the body’s own tissues). Artificial saliva, as a spray, gel, or pastilles, is formulated to resemble natural saliva as closely as possible.

**artificial sweeteners**
Synthetic substitutes for sugar that are used by people on slimming diets and by the food industry.

Saccharin and aspartame are often recommended for use in calorie-controlled diets. They are, however, of questionable value because the appetite compensates for the lack of calories from sugar, therefore other foods are eaten to maintain the calorie intake.

**artificial tears**
Preparations that are used to supplement tear production in disorders, such as keratoconjunctivitis sicca, that cause dry eye and to relieve irritation.

**arytenoid**
One of two pyramid-shaped cartilages that form part of the larynx (voice-box).

**asbestos-related diseases**
A variety of diseases that are caused by inhalation of asbestos fibres. Asbestos is a fibrous mineral formerly used as a heat- and fire-resistant insulating material. There are three main types of asbestos fibre: white, which is widely used, blue, and brown. Blue and brown are the most dangerous types of asbestos. The use of all types is now carefully controlled.

**TYPES**
In asbestosis, widespread fine scarring occurs in the lungs. The disease causes breathlessness and a dry cough, eventually leading to severe disability and death. Asbestosis develops mostly in industrial workers who have been heavily exposed to asbestos. The period from initial exposure to development of the disease is usually at least 20 years. Diagnosis is by chest X-ray. Asbestosis increases the risk of developing lung cancer.

**Mesothelioma** is a cancerous tumour of the pleura (the membrane surrounding the lungs) or the peritoneum (the membrane lining the abdominal cavity). In the pleura, mesotheliomas cause pain and breathlessness; in the peritoneum they cause enlargement of the abdomen and intestinal obstruction. The condition cannot be treated and usually leads to death within one or two years. The average interval between initial exposure to asbestos and death is between 20 and 30 years. Mesothelioma affects people who have been exposed to blue or brown asbestos.

Diffuse pleural thickening is a condition in which the outer and inner layers of the pleura become thickened, and excess fluid may accumulate in the cavity between them. This combination restricts the ability of the lungs to expand, resulting in shortness of breath. The condition may develop even after short exposure to asbestos.

**asbestosis**
See asbestos-related diseases.

**ascariasis**
Infestation with the roundworm Ascaris lumbricoides, which lives in the small intestine of its human host. Ascariasis is common worldwide, especially in the tropics. One or several worms may be present, but symptoms usually only occur with heavy infestation.
The person becomes infested by swallowing the eggs, which hatch into larvae in the intestine. The larvae travel in the blood through the wall of the intestine to the lungs, up the windpipe, and are swallowed back into the small intestine. There they become adult worms.

**CAUSES**
The parasite that causes ascariasis is a pale, cylindrical, tapered roundworm, which reaches between 15 and 35 cm in length in its adult form.

Ascariasis is spread by ingestion of worm eggs, usually from food grown in soil that has been contaminated by human faeces. In some dry, windy climates, airborne eggs may be swallowed after being blown into the mouth.

**SYMPTOMS**
Light infestation may cause no symptoms, although mild nausea, abdominal pain, and irregular bowel movements may occur. A worm may be passed via the rectum, or it may be vomited. A large number of worms may compete with the host for food, leading to malnutrition and anaemia, which, in children, can retard growth.

**TREATMENT**
The worm infestation is treated with anthelmintic drugs, such as levamisole, which usually bring about complete recovery. The worms are passed out of the body via the rectum some days after the drug is taken.

**ascites**
Excess fluid in the peritoneal cavity, the space between the two layers of the peritoneum (the membranes that line the inside of the abdominal wall and cover the abdominal organs).

**CAUSES**
Ascites may occur in any condition that causes generalized oedema (excessive accumulation of fluid in the body tissues), such as in congestive heart failure, nephrotic syndrome, and cirrhosis of the liver. Ascites may occur in cancer if metastases (secondary growths) from a cancer elsewhere in the body develop in the peritoneum. The condition also occurs if tuberculosis affects the abdomen.

**SYMPTOMS**
Ascites causes abdominal swelling and discomfort. Additionally, it may cause breathing difficulty as a result of pressure on, and the immobilization of, the diaphragm, the sheet of muscle that separates the thorax (the chest) from the abdomen.

**DIAGNOSIS**
The doctor diagnoses the cause of ascites by removing and analysing a sample of ascitic fluid via a sterile needle inserted through the abdominal wall.

**TREATMENT**
The underlying cause is treated if possible. Diuretic drugs, particularly spironolactone, are often used to treat ascites associated with cirrhosis. If the ascites is causing discomfort or breathing difficulty, fluid can be drained from the peritoneal cavity.

**ascorbic acid**
The chemical name for vitamin C.

**ASCITES**
Excess fluid in the peritoneal cavity, the space between the two layers of the peritoneum (the membranes that line the inside of the abdominal wall and cover the abdominal organs). Light infestation may cause no symptoms, although mild nausea, abdominal pain, and irregular bowel movements may occur. A worm may be passed via the rectum, or it may be vomited. A large number of worms may compete with the host for food, leading to malnutrition and anaemia, which, in children, can retard growth.

**CAUSES**
Ascites may occur in any condition that causes generalized oedema (excessive accumulation of fluid in the body tissues), such as in congestive heart failure, nephrotic syndrome, and cirrhosis of the liver. Ascites may occur in cancer if metastases (secondary growths) from a cancer elsewhere in the body develop in the peritoneum. The condition also occurs if tuberculosis affects the abdomen.

**SYMPTOMS**
Ascites causes abdominal swelling and discomfort. Additionally, it may cause breathing difficulty as a result of pressure on, and the immobilization of, the diaphragm, the sheet of muscle that separates the thorax (the chest) from the abdomen.

**DIAGNOSIS**
The doctor diagnoses the cause of ascites by removing and analysing a sample of ascitic fluid via a sterile needle inserted through the abdominal wall.

**TREATMENT**
The underlying cause is treated if possible. Diuretic drugs, particularly spironolactone, are often used to treat ascites associated with cirrhosis. If the ascites is causing discomfort or breathing difficulty, fluid can be drained from the peritoneal cavity.

**aspartame**
An artificial sweetener used in some foods and drugs.

**Asperger’s syndrome**
A developmental disorder that is usually first recognized in childhood because of stilted speech, difficulties with social interactions, and very specialized interests. Intelligence is normal or high.

Asperger’s syndrome is one of a group of conditions known as pervasive developmental disorders; it is considered to be an autism spectrum disorder (a developmental disorder characterized by obsessive behaviour and impaired com-
munition and social skills). Special educational support may be necessary, often within mainstream education. Asperger’s syndrome is a lifelong condition.

**aspergillosis**

An infection caused by inhalation of spores of aspergillus, a fungus that grows in decaying vegetation. Aspergillus is harmless to healthy people but may proliferate in the lungs of people with **tuberculosis**. It can also worsen the symptoms of asthma and may produce serious, even fatal, infection in people with reduced immunity, such as those taking **immunosuppressant drugs**.

**aspermatagonia**

*See* azoospermia.

**asphyxia**

The medical term for suffocation. Asphyxia may be caused by the obstruction of a large airway, usually by a foreign body (see choking), by insufficient oxygen in the surrounding air (as occurs when, for example, a closed plastic bag is put over the head), or by poisoning with a gas, such as carbon monoxide, that interferes with the uptake of oxygen into the blood.

The person initially Breaths more rapidly and strongly to try to overcome the lack of oxygen in the blood. There is also an increase in heart rate and blood pressure.

First-aid treatment is by clearing the airway of obstruction followed by rescue breathing. Untreated asphyxia leads to death within a few minutes.

**aspiration**

The withdrawal of fluid or cells from the body by suction. The term also refers to the act of accidentally inhaling a foreign body, usually food or drink. If consciousness is impaired, for example by a head injury or excess alcohol intake, aspiration of the stomach contents is common.

Aspiration biopsy is the removal of cells or fluid, using a needle attached to a syringe, for examination. Aspiration biopsy is commonly used to obtain cells from a fluid-filled cavity (such as a breast cyst). The procedure is also used to obtain cells from the bone marrow (see bone marrow biopsy), or from internal organs, when a fine needle is guided to the site of the biopsy by **CT scanning** or **ultrasound scanning**. (See also aspiration pneumonia.)

**aspiration pneumonia**

A form of pneumonia that results from accidental inhalation of vomit. Aspiration pneumonia usually occurs in people whose cough reflex is not functioning, such as those who have drunk excessive amounts of alcohol, taken certain illegal drugs, or suffered a head injury.

**aspirin**

A nonopioid analgesic drug (painkiller) that may be given in tablet or suppository form to treat disorders such as headache, menstrual pain, and muscle discomfort. Aspirin has an anti-inflammatory action. It also reduces fever and is included in some cold remedies.

In small doses, aspirin reduces the stickiness of platelets (blood particles involved in clotting). This has led to its use in preventing thrombosis (abnormal blood clots) in people at risk of developing stroke or myocardial infarction (heart attack) and as an initial treatment of chest pain that may be due to myocardial infarction. Aspirin may also reduce the risk of colon cancer and slow the progress of dementia.

In children, aspirin can cause Reye’s syndrome, a rare but serious brain and liver disorder. For this reason, it should not be given to children under the age of 16 years, except on the advice of a doctor. Aspirin may cause irritation of the stomach lining, resulting in indigestion or nausea. Prolonged use may cause bleeding from the stomach due to gastric erosion (disruption of the stomach lining) or peptic ulcer.

**Aspro**

A brand name for aspirin.

**assay**

The analysis or measurement of a substance to determine its presence or effects. A qualitative assay determines whether or not a substance is present, whereas a quantitative assay determines the actual amount present.

Biological assays (known as bioassays) measure the response of an animal or organ to particular substances. Assays can be used, for example, to test the effects of a drug or to measure hormone levels. (See also immunoassay, radioimmunoassay.)

**assisted conception**

Treatment for infertility involving techniques that assist the fertilization and implantation of eggs.

**association area**

One of a number of areas in the cortex (outer layer) of the brain that are concerned with higher levels of mental activity. Association areas interpret information received from sensory areas and prompt appropriate responses, such as voluntary movement.

**associative aphasia**

Also known as conductive aphasia, a form of aphasia (loss of language skills, including comprehension and/or speech production) in which comprehension is normal, and the affected individual can write and speak, but he or she is unable to repeat what has been heard and cannot read aloud. Associative aphasia is caused by damage to a localized area in the brain, often as a result of a stroke.

**astereognosis**

The inability to recognize objects by touch when they are placed in the hand, even though there is no defect of sensation in the fingers or difficulty in holding the object. Astereognosis is either left- or right-sided; tactile recognition is normal on the other side. If both sides are affected, the condition is called tactile agnosia.

Astereognosis and tactile agnosia are caused by damage to parts of the cerebrum (the main mass of the brain) that are involved in recognition by touch. The conditions may occur as a result of a stroke or a head injury.

**asthenia**

An outdated term for loss of strength and energy (see weakness).

**asthenia, neurocirculatory**

*See* cardiac neurocirculatory.

**asthma**

A lung disease in which there is intermittent narrowing of the bronchi (airways), causing shortness of breath, wheezing, and a cough. The illness often starts in childhood but can develop at any age. At least one child in seven suffers from asthma, and the number affected has increased dramatically in recent years. Childhood asthma may be outgrown in about half of all cases.

During an asthma attack, the muscle in the walls of the airways contracts, causing narrowing. The lining of the airways also becomes swollen and inflamed, producing excess mucus that can block the smaller airways.
Breathlessness and wheezing in asthma are caused by narrowing of the bronchioles (small airways in the lungs). Asthma can be triggered by a wide variety of stimuli, including exercise, infection, pollen, and dust, which would have no effect on non-asthmatic people.

Inflammation of the linings of these bronchioles results in increased production of sputum (phlegm), which makes the obstruction worse. A dry cough often develops as the sufferer attempts to clear the airways.

**TREATMENT OF AN ASTHMA ATTACK**

Attacks are treated by inhalation of a bronchodilator drug from an inhaler. For a severe attack, a nebulizer can be used to dispense the drug as fine mist through a face mask or mouthpiece. Babies, young children, or any adults who are unable to coordinate their breathing, require a spacer.

**Effect of asthma on the lungs**

- **Healthy bronchiole**: Inhalation of the bronchodilator widens the bronchiole and improves airflow.
- **Obstructed bronchiole**: Before treatment, the airflow is obstructed by a narrowing of the bronchiole.

**Seasonal asthma**

When symptoms occur only during a few months, the cause is likely to be allergy to pollen or spores.

**Types and Causes**

In some people, an allergic response triggers the swelling and inflammation in the airways. This allergic type of asthma tends to occur in childhood, and it may develop in association with the allergic skin condition, eczema or certain other allergic conditions such as hay fever (see rhinitis, allergic). Susceptibility to these conditions frequently runs in families.

Some substances are known to trigger attacks of allergic asthma (see allergens). These include pollen, house-dust mites, mould, feathers, and dander (tiny scales) and saliva from furry animals such as cats and dogs. Rarely, certain foods, such as milk, eggs, nuts, and wheat, provoke an allergic asthmatic reaction. Some people with asthma are sensitive to aspirin, and taking it may trigger an attack.

When asthma starts in adulthood, there are usually no identifiable allergic triggers. The first attack is sometimes brought on by a respiratory tract infection, stress, or anxiety.

In some cases, a substance that is inhaled regularly in the workplace can result in the development of asthma in a previously healthy person. This is known as occupational asthma, and it is one of the few occupational lung diseases that are still increasing in incidence.

There are currently about 200 substances used in the workplace that are known to trigger symptoms of asthma, including glues, resins, latex, and some chemicals, especially isocyanate chemicals used in spray painting. However, occupational asthma can be difficult to diagnose because a person may be regularly exposed to a particular trigger substance for weeks, months, or even years before the symptoms of asthma begin to appear.

Factors that can provoke attacks in a person with asthma include cold air, exercise, smoke, and occasionally emotional factors such as stress and anxiety. Although industrial pollution and exhaust emission from motor vehicles do not normally cause asthma, they do appear to worsen symptoms in people who already have the disorder. Pollution in the atmosphere may also trigger asthma in susceptible people.

**Symptoms**

Asthma attacks can vary in severity from mild breathlessness to respiratory failure. The main symptoms are wheezing, breathlessness, dry cough, and a tightness in the chest. In a severe attack, breathing becomes increasingly difficult, resulting in a low level of oxygen.
in the blood. This causes cyanosis (a bluish discoloration) of the face, particularly of the lips. Left untreated, such attacks can be fatal.

**TREATMENT**

There is no cure for asthma, but attacks can be prevented to a large extent if a particular allergen can be identified and consequently avoided.

Treatment involves inhaled bronchodilator drugs (sometimes known as relievers) to widen the airways, thereby relieving symptoms. When symptoms occur frequently, or are severe, inhaled corticosteroids are also prescribed. These drugs (also known as preventers) are used continuously to prevent attacks by reducing inflammation in the airways.

Other drug treatments include sodium cromoglicate and nedocromil sodium, both of which are useful in the prevention of exercise-induced asthma. The use of a leukotriene receptor antagonist in combination with a corticosteroid drug may enable the required dose of corticosteroid to be reduced. Theophylline or the inhaled anticholinergic drug ipratropium bromide may also be used as bronchodilators. An asthma attack that has not responded to treatment with a bronchodilator needs immediate assessment and treatment in hospital.

**asthma, cardiac**

Breathing difficulty in which bronchospasm (narrowing of the airways) and wheezing occur as a result of fluid accumulation in the lungs (pulmonary oedema). Cardiac asthma is usually due to reduced pumping efficiency of the left side of the heart (see heart failure) and is not true asthma. Treatment is with diuretic drugs or other drugs for heart failure.

**astigmatism**

A condition in which the front surface of the cornea does not conform to the normal “spherical” curve, even though the eye is perfectly healthy. Because the cornea is unevenly curved, it refracts (bends) the light rays that strike it to differing degrees. The lens is then unable to bring all the rays into focus on the light-sensitive retina. A minor degree of astigmatism is normal and does not require correction. More severe astigmatism causes blurring of lines at a certain angle and does require correction.

**TREATMENT**

Correction may be achieved by using special “cylindrical” glasses that can be framed at a precise angle; contact lenses that can give an even spherical surface for focusing; or by undergoing laser treatment on the cornea.

**astringents**

**COMMON DRUGS**

+ Aluminium acetate + Potassium permanganate + Silver nitrate + Zinc sulphate

Substances that cause tissue to dry and shrink by reducing its ability to absorb water. Astringents are widely used in antiperspirants and to promote healing of broken or inflamed skin. They are also used in some eye or ear preparations. Astringents may cause burning or stinging when applied.

**astrocytoma**

A type of cancerous brain tumour. Astrocytomas are the most common type of glioma, a tumour that arises from the glial (supporting) cells within the nervous system.

Astrocytomas most commonly develop in the cerebrum (the main mass of the brain) and are classified in four grades (I to IV) according to their rate of growth and malignancy. A grade I astrocytoma is a slow-growing tumour that may spread widely throughout the brain but may be present for many years before causing symptoms. The most severe and fast-growing type is called glioblastoma multiforme (a grade IV astrocytoma).

Symptoms are similar to those of other types of brain tumour. Diagnostic tests include CT scanning or MRI. Treatment is with surgery as well as, in some cases, radiotherapy.

**asylum**

An outdated term for an institution that provides care for the mentally ill.

**asymptomatic**

A medical term meaning without symptoms (indications of illness noticed only by the patient). For example, hypertension (high blood pressure) is often asymptomatic and is usually discovered during a routine blood pressure test and diabetes mellitus is often diagnosed from a routine blood or urine test.

Most disorders have no symptoms in their early stages. In the case of cancer, much effort has been made to devise screening tests for the detection of tumours at their early, asymptomatic, stage. (See also sign.)
CAUSES
Obstruction of a bronchus or bronch-iole may be caused by the accumulation of mucus. This buildup of mucus most commonly occurs in a baby at birth; in people with asthma; following an abdominal or chest operation that has made coughing difficult because of pain; in certain infections such as pertussis (whooping cough) in children or chronic bronchitis (inflammation of the bronchi) in adults.
Obstruction may also result from an accidentally inhaled foreign body, a tumour in the lung, or enlarged lymph nodes (which occur in tuberculosis, some other lung infections, or certain forms of cancer) exerting pressure on the airway. The collapsed lung may become infected.
SYMPTOMS
The main symptom of atelectasis is shortness of breath. There may also be a cough and chest pain, depending on the underlying cause.
DIAGNOSIS AND TREATMENT
Atelectasis can be diagnosed by chest X-ray, and treatment is aimed at removing the cause of the blockage. The treatment may include physiotherapy or bronchoscopy, a procedure that involves removal of the blockage using a rigid or flexible viewing tube (see endoscopy). If the obstruction can be removed, the lung should reinflate normally.

ateno(lo)l
A beta-blocker drug that is commonly used to treat hypertension (high blood pressure), angina pectoris (chest pain caused by an impaired blood supply to the heart muscle), and certain types of arrhythmia (irregular heartbeat) in which the heart beats too rapidly.

atheroma
Fatty deposits on the inner lining of an artery that occur in atherosclerosis and restrict blood flow. The deposits are also known as atheromatous plaques.

atherosclerosis
The accumulation of cholesterol and other fatty substances (lipids) in the walls of arteries, causing the arteries to narrow. Atherosclerosis can affect arteries in any area of the body and is a major cause of stroke, heart attack (see myocardial infarction), and poor circulation in the legs.
The arteries become narrowed when fatty substances carried in the blood accumulate on the inside lining of the arteries and form yellow deposits known as atheromatous plaques. These deposits restrict the blood flow through the arteries. In addition, the muscle layer of the artery wall becomes thickened, which narrows the artery even further. Platelets (tiny blood cells that are responsible for blood clotting) may collect in clumps on the surface of the deposits and initiate the formation of blood clots. A large clot may completely block the artery, resulting in the organ it supplies being deprived of oxygen. A complete blockage in a coronary artery can cause a sudden, often fatal, heart attack.

CAUSES
The risk of developing atherosclerosis is determined largely by the level of cholesterol in the bloodstream, which depends on dietary and genetic factors. Atherosclerosis is more common in developed countries, where most people eat a diet high in fat. Some disorders such as diabetes mellitus can be associated with a high cholesterol level, regardless of diet.

SYMPTOMS
Atherosclerosis usually produces no symptoms in its early stages. As the condition progresses, symptoms occur as a result of reduced, or total absence of, blood supply to the organs supplied by the affected arteries.

Partial blockage of the coronary arteries (which supply the heart muscle) may produce symptoms such as the chest pain of angina pectoris. Narrowing of the arteries supplying blood to the brain may cause transient ischaemic attacks (symptoms and signs of a stroke that last for less than 24 hours) and episodes of dizziness.

ARterial degeneration in atherosclerosis
Atherosclerosis is narrowing of the arteries due to plaques of atheroma on their inner linings. The plaques are composed mainly of fats, deposited from the bloodstream, that disrupt normal blood flow through the artery. Men are affected earlier than women because premenopausal women are protected by natural oestrogen hormones.

Risk factors
- Cigarette smoking
- Hypertension
- Male gender
- Obesity
- Physical inactivity
- Diabetes mellitus
- Heredity
- High cholesterol

Micrograph of artery in atherosclerosis
The artery shown here has an atheromatous (fibrous and fatty) plaque deposit on its inner wall. The lumen (channel) has been narrowed, disrupting blood flow.

Atherosclerotic artery
A deposit of atheromatous plaque disrupts normal blood flow through the artery at the point where it branches. This occurs because of the greater level of turbulence in this area.
Intermittent claudication (a cramplike pain on walking) is often the first symptom of atherosclerosis in the leg arteries. If the condition is associated with an inherited lipid disorder (see hyperlipidaemias), fatty deposits may develop on tendons or as visible lumps under the skin.

**DIAGNOSIS AND TREATMENT**

Blood flow through an artery can be investigated by angiography (X-rays after injection of a radiopaque substance) or Doppler ultrasound scanning.

The best treatment for atherosclerosis is to prevent it from progressing by the maintenance of a healthy lifestyle. This includes adoption of a low-fat diet, not smoking, regular exercise, and maintenance of the recommended weight for height. These measures lead to a reduced risk of developing significant atherosclerosis.

Those individuals found to have high blood cholesterol levels but who are otherwise in good health will be advised to adopt a low-fat diet. They may also be given drugs that decrease blood cholesterol levels (see lipid-lowering drugs).

For those people who have had a heart attack, research has shown that there may be a benefit in lowering blood cholesterol levels, even if the level is within the average range for healthy people.

People with atherosclerosis and those at risk may be prescribed a drug such as aspirin to reduce the risk of blood clots forming on the damaged artery lining.

Surgical treatment of atherosclerosis, such as coronary angioplasty (see angioplasty, balloon), may be recommended for those people thought to be at high risk of severe complications. If blood flow to the heart is severely obstructed, a coronary artery bypass may be carried out to restore blood flow.

**athetosis**

A disorder of the nervous system that is characterized by involuntary slow, writhing movements, most often of the face, head, neck, and limbs. These movements commonly include facial grimacing, with contortions of the mouth. There may also be difficulty in balancing and walking.

Athetosis tends to be combined with chorea (involuntary irregular, jerky movements). Both athetosis and chorea arise from damage to the basal ganglia, clusters of nerve cells in the brain that control movement.

Causes of athetosis include brain damage prior to or at birth (see cerebral palsy), encephalitis (brain infection), degenerative disorders such as Huntington’s disease, or as a side effect of phenothiazine drugs or levodopa. If drug treatment is the cause of the condition, the abnormal movements may stop when the drug is withdrawn.

**athlete’s foot**

A common condition in which the skin between the toes becomes itchy and sore and may crack, peel, or blister.

**athlete’s foot**

The typical appearance of athlete’s foot is of fissuring in the cleft between the fourth and fifth toes. There is usually an annoying itch.

**CAUSES**

Athlete’s foot is usually the result of a fungal infection known medically as tinea pedis, but the condition may also be caused by bacteria.

Because the fungi thrive in humid conditions, athlete’s foot is more common in people with particularly sweaty feet and those who wear shoes and socks made from synthetic fibres, which do not absorb sweat.

**TREATMENT**

Self-treatment with topical antifungal drugs is usually effective and should be combined with careful washing and drying of the feet.

**atlas**

The topmost cervical vertebra in the human spine. The atlas is attached to and supports the skull. A pivot joint attaching the atlas to the second cervical vertebra, the axis, allows the atlas to rotate, thereby turning the head from side to side.

**atony**

Loss of tension in a muscle, so that it is completely flaccid. Atony can occur in some nervous system disorders or after injury to nerves. For example, the arm muscles may become atonic after injury to the brachial plexus (nerve roots in the neck passing into the arm).

**atopic eczema**

Atopic eczema is the most common form of eczema (an inflammatory skin condition). It usually begins in infancy but may flare up during adolescence and adulthood. The cause of atopic eczema is unknown, but people with atopy (a predisposition to allergic reactions) are more susceptible.

**atopy**

A predisposition to various allergic reactions (see allergy). Atopic individuals have a tendency to suffer from one or more allergic disorders, such as asthma, eczema, urticaria (nettle rash), and allergic rhinitis (hay fever).

The mechanism that underlies the predisposition is unclear, but atopy seems to run in families.

**ATP**

An abbreviation for the compound adenosine triphosphate, the principal energy-carrying chemical in the body. (See also ADP; metabolism.)

**atresia**

Congenital (present from birth) absence or severe narrowing of a body opening or tubular organ due to a failure of development in the uterus. Examples are biliary atresia, in which the bile ducts between the liver and duodenum are absent; oesophageal atresia, in which the oesophagus comes to a blind end; and anal atresia (see anus, imperforate), in which the anal canal is shut off. Most forms of atresia require surgical correction early in life.

**atrial fibrillation**

A type of abnormality of the heartbeat (see arrhythmia, cardiac) in which the atria (see atrium), the upper chambers of the heart, beat irregularly and very rapidly. The ventricles (the heart’s lower chambers) also beat irregularly but at a slower rate. As a result, the pumping ability of the heart is reduced.

**CAUSES**

Atrial fibrillation can occur in almost any longstanding heart disease, but it is most often associated with heart-valve disorders or coronary artery disease.

**SYMPTOMS AND SIGNS**

Sudden onset of atrial fibrillation can cause palpitations (awareness of a fast
angina pectoris (chest pain as due to impaired blood supply to the heart muscle), or breathlessness. The inefficient pumping action of the heart reduces the output of blood into the circulation. Blood clots may form in the atria and may enter the bloodstream and lodge in an artery (see embolism).

**DIAGNOSIS AND TREATMENT**

Diagnosis of atrial fibrillation is confirmed by an ECG, which shows the electrical activity of the heart.

Digoxin or beta-blocker drugs may be given to control the heart rate. If the atrial fibrillation is of recent onset, it may be reversed by defibrillation (the application of a short electric shock to the heart). In most cases, anticoagulant drugs or aspirin are also given to reduce the risk of an embolism occurring.

**atrial flutter**

A type of abnormality of the heartbeat (see arrhythmia, cardiac) in which the atria (see atrium), the upper chambers of the heart. Atrial natriuretic peptide is released into the bloodstream in response to swelling of the atrial muscle due, for example, to heart failure or hypertension (high blood pressure).

Atrial natriuretic peptide increases the amount of sodium excreted in the urine. Sodium draws water out with it, which decreases the volume of the blood, thereby reducing blood pressure.

Children who have congenital (present from birth) heart disorders that result in heart disease (see heart disease, congenital) possess high levels of atrial natriuretic peptide. Following successful surgery to correct the heart abnormality, the levels of atrial natriuretic peptide fall.

**atrial septal defect (ASD)**

A congenital (present from birth) heart abnormality (see heart disease, congenital) in which there is a hole in the dividing wall (see septal defect) between the heart’s two upper chambers, or atria (see atrium).

**atrioventricular block**

A type of heart block.

---

**atrioventricular node**

A small knot of specialized muscle cells in the right atrium (upper chamber) of the heart. Electrical impulses from the sinoatrial node (a cluster of muscle cells that act as the heart’s natural pacemaker) pass through the atrioventricular node and along conducting fibres to the ventricles (the lower chambers of the heart), causing them to contract and pump blood around the body.

**atrium**

Also known as an auricle, either of the two (right and left) upper chambers of the heart. The atria open directly into the ventricles (the lower chambers of the heart). Deoxygenated blood from the body enters the right atrium through the venae cavae. Oxygenated blood from the lungs enters the left atrium through the pulmonary veins.

**attachment**

An affectionate bond between individuals, especially between a parent and child (see bonding) or between a person and an object, such as a young child and a security blanket.

The term attachment is also used to refer to the site at which a muscle or tendon is attached to a bone.

**attempted suicide**

See suicide, attempted.

**attention deficit hyperactivity disorder (ADHD)**

A behavioural disorder in which a child has a consistently high level of activity and/or difficulty in attending to tasks. Attention deficit hyperactivity, or hyperkinetic, disorder affects up to five per cent of children in the UK.

The disorder, which is more common in boys, should not be confused with the normal boisterous conduct of a healthy child. Children with ADHD show abnormal patterns of behaviour over a period of time. An affected child is likely to be constantly restless, unable to sit still for more than a few moments, inattentive, and impulsive.
CAUSES
The causes of ADHD are not fully understood, but the disorder often runs in families, which suggests that genetic factors may be involved. ADHD is not, as popularly believed, a result of poor parenting or abuse.

SYMPTOMS AND SIGNS
Symptoms of the condition develop in early childhood, usually between the ages of three and seven, and may include the inability to finish tasks; inability to concentrate in class; a short attention span; difficulty in following instructions; a tendency to talk excessively, frequently interrupting other people; difficulty in waiting or taking turns; inability to play alone, quietly; and physical impulsiveness.

Children with ADHD may have difficulty in forming friendships. Self-esteem is often low because an affected child is frequently scolded and criticized.

TREATMENT AND OUTLOOK
Treatment of ADHD includes behaviour modification techniques, both at home and at school. In some children, avoidance of certain foods or food additives seems to reduce symptoms. In severe cases, stimulant drugs, usually methylphenidate, may be prescribed. Paradoxically, the use of stimulant drugs in the treatment of ADHD reduces hyperactivity and improves concentration.

In general, the condition improves by adolescence but may be followed by antisocial behaviour and drug abuse or substance abuse.

attenuated
A term used to refer to microorganisms that have been treated to reduce their ability to cause disease. Attenuated organisms are used in some vaccines.

atypical
A term used to describe something that is not the usual type or that does not fit into the usual pattern. The atypical presentation of a disease or disorder is one in which the early symptoms and signs differ from those that normally occur, which may make diagnosis of the condition more difficult.

audiogram
A graph that is produced as a result of audiometry (measurement of the sense of hearing). An audiogram shows the hearing threshold (the minimum audible decibel level) for each of a range of sound frequencies.

audiology
The study of hearing, especially impaired hearing.

audiometry
Measurement of the sense of hearing. The term audiometry often refers to hearing tests in which a machine is used to produce sounds of a defined intensity (loudness) and frequency (pitch), and in which the hearing in each ear is measured over the full range of normally audible sounds. (See also impedance audiometry.)

auditory nerve
The part of the vestibulocochlear nerve (the eighth cranial nerve) concerned with hearing. The auditory nerve is also known as the acoustic nerve.

aura
A peculiar “warning” sensation that precedes or marks the onset of a migraine attack or a seizure in epilepsy.

A migraine attack may be preceded by a feeling of elation, excessive energy, or drowsiness; thirst or a craving for sweet foods may develop. A migraine may also be heralded by flashing lights before the eyes, blurred or tunnel vision, or difficulty in speaking. There may also be weakness, numbness, or tingling in one half of the body. As these symptoms subside, the migraine headache begins.

An epileptic aura may occur as a distorted perception, such as a hallucinatory smell or sound or a sensation of movement in a part of the body. One type of attack (in people who have temporal lobe epilepsy) is often preceded by a vague feeling of discomfort in the upper abdomen, sometimes followed by borborygmi (rumbling or gurgling bowel sounds, and by a sensation of fullness in the head).

auranofin
A gold preparation used as an anti-rheumatic drug in the treatment of rheumatoid arthritis. Unlike other gold preparations, which are given as intramuscular injections, auranofin can be taken by mouth.

auricle
Another name for the pinna, the external flap of the ear. The term is also used to describe the earlike appendages of the atria (the upper chambers of the heart, see atrium).

auriscope
Also called an otoscope, an instrument for examining the ear.

auscultation
A procedure that involves listening to sounds within the body, using a stethoscope, to assess the functioning of an organ or to detect disease.

AUSCULTATION OF THE HEART
To listen to the heart, the doctor places the stethoscope on the chest at four points which correspond to the location of the heart valves. With the patient either sitting up, lying in a semi-reclining position, or lying on his or her left side, the doctor listens for any abnormality in the rate and rhythm of the heartbeat and for a heart murmur or other abnormal heart sound that may indicate a heart defect.

AUSCULTATION OF THE LUNGS
When listening to the lungs, the doctor places the stethoscope on numerous areas of the chest and back. The patient breathes normally, and then takes deep breaths, so that the doctor can compare the sounds on the right and left sides. Abnormal breath sounds may indicate pneumonia, bronchitis, and pneumothorax (in which air enters the space between the pleura, the membranes lining the outside of the lungs and the inside of the chest cavity). Cracking or bubbling sounds (known as crepitations) are caused by fluid in the lungs; wheezing sounds result from spasm of the airways, usually as a result of asthma. Pleurisy (inflammation of the pleura) causes a scratching sound as inflamed areas of the lung rub together.

The doctor may also test for vocal resonance by asking the patient to whisper something. The sound is louder if there is pus in the lung due to a condition such as pneumonia.

AUSCULTATION OF THE BLOOD VESSELS
Blood vessels near the skin surface (usually the carotid artery in the neck, the abdominal aorta, or the renal artery) may be listened to for bruits (sounds made by turbulent or abnormally fast blood circulation). Bruits occur when blood vessels are narrowed (for example by fatty deposits in atherosclerosis) or widened (by an aneurysm, for example). They may also be present if heart valves have been narrowed or damaged (for example by endocarditis).

AUSCULTATION OF THE ABDOMEN
The abdomen is auscultated for borborygmi (loud rumbling, gurgling sounds that make the abdomen growl).
that are made by the movement of air and fluid in the intestine), and also for abnormal bowel sounds that may indicate intestinal obstruction (see intestine, obstruction of).

**autism**
A rare condition in which an affected person has difficulty with social relationships, communication, and with imagination, together with repetitive patterns of behaviour. Autism is more common in boys. The condition is, by definition, evident before the age of 30 months and is usually apparent in the first year of life. The precise causes of autism are unknown.

**SYMPTOMS AND SIGNS**
Autistic children often seem normal for the first few months of life, before becoming increasingly unresponsive to parents or other stimuli. The child fails to form relationships, avoids eye contact, and has a preference for playing alone. Extreme resistance to change of any kind is an important feature of the condition, which can make it very difficult to teach the autistic child new skills.

Rituals develop in play, and there is often attachment to unusual objects or obsession with one particular idea. Delay in speaking is common and most autistic children have a low IQ. Other behavioural abnormalities may include walking on tip-toe, rocking, self-injury, screaming fits, and hyperactivity.

Appearance and coordination are normal. Some autistic people have an isolated special skill, such as musical ability or an outstanding rote memory.

**TREATMENT AND OUTLOOK**
There is no cure for autism, which is a lifelong condition. Special schooling, support and counselling for the families, and, sometimes, behaviour therapy (such as to reduce violent self-injury) can be helpful. Medication is useful only for specific problems, such as hyperactivity.

The outlook depends on the intelligence and language ability of the individual. The majority of autistic people need special care.

**autism spectrum disorders**
A range of developmental disorders that are characterized by obsessive behaviour and impaired communication and social skills (see Asperger’s syndrome; autism). Autism spectrum disorders are usually diagnosed during childhood.

**autoantibody**
An antibody (a protein that is manufactured by the immune system) that reacts against the body’s own cells (see autoimmune disorders).
**autoclave**
A piece of apparatus that produces steam at high pressure within a sealed chamber; the heat of the water vapour destroys microorganisms. Autoclaving is often used in hospitals for the sterilization of surgical equipment.

**autograft**
Tissue that has been transplanted from one part of an individual’s body to another (see grafting). Autografting is often used to treat severe burns.

**autoimmune disorders**
Any of a number of disorders caused by a reaction of the body’s immune system against its own cells and tissues. Such disease-producing processes, known as hypersensitivity reactions, are similar to the reactions that occur in allergy, except that in autoimmune disorders the hypersensitivity response is to the body itself rather than to an external substance.

**CAUSES**
The immune system normally distinguishes “self” from “nonself”. Some lymphocytes (a type of white blood cell) are capable of reacting against self, but these lymphocytes are generally suppressed. Autoimmune disorders occur when there is interruption of the normal control process, allowing such lymphocytes to escape from suppression, or when there is alteration in a particular body tissue meaning that it is no longer recognized as self and is attacked.

**SOURCES**
Bacteria, viruses, and drugs may play a role initiating an autoimmune disorder in someone who already has a genetic (inherited) predisposition, but in most cases the trigger is unknown.

**TYPES**
Autoimmune processes can have various results, such as the destruction of a particular type of cell or tissue, stimulation of an organ into excessive growth, or interference in an organ’s function.

Autoimmune disorders are classified into organ-specific and non-organ-specific types. In organ-specific disorders, the autoimmune process is directed mainly against one organ. Examples include Hashimoto’s thyroiditis (thyroid gland), pernicious anaemia (stomach), Addison’s disease (adrenal glands), and type 1 diabetes mellitus (pancreas).

In non-organ-specific disorders, autoimmune activity is towards a tissue, such as connective tissue, that is widespread in the body. Examples of such disorders are systemic lupus erythematosus and rheumatoid arthritis.

**TREATMENT**
Initial treatment for any autoimmune disorder is to reduce the effects of the disease by, for example, replacing hormones, such as insulin, that are not being produced.

In cases in which the disease is having widespread effects, treatment is also directed at diminishing the activity of the immune system while maintaining the body’s ability to fight disease. Corticosteroid drugs are most commonly used for this purpose but may be combined with other immunosuppressant drugs.

**autologous blood transfusion**
See blood transfusion, autologous.

**automatism**
A state in which behaviour is not controlled by the conscious mind. An individual carries out activities without being aware of doing so, and later he or she has no clear memory of what happened. Episodes of automatism start abruptly and are usually no more than a few minutes in duration.

Automatism is uncommon and may be a symptom of temporal lobe epilepsy, dissociative disorders (psychological illness in which a particular mental function is lost), drug or alcohol intoxication, or hypoglycaemia (low blood sugar levels).

**autonomic nervous system**
Also called the involuntary nervous system, the part of the nervous system that controls the involuntary activities of a variety of body tissues, including blood vessels, organs, and glands. The autonomic nervous system consists of a network of nerves divided into the sympathetic and parasympathetic nervous systems.

The two systems act in conjunction and normally balance each other. However, during exercise or at times of stress, the activity of the sympathetic system predominates, while during sleep the parasympathetic system exerts greater control.

**SYMPATHETIC NERVOUS SYSTEM**
The sympathetic nervous system comprises two chains of nerves that pass from the spinal cord throughout the body tissues. Into these tissues, the nerve endings release the neurotransmitters (chemical messengers) adrenaline (epinephrine) and noradrenaline (norepinephrine). The sympathetic nervous system also stimulates the release of adrenaline from the adrenal glands.

In general, the actions of the sympathetic nervous system heighten activity in the body. This activity is known as the fight-or-flight response. Among the most important effects produced are the acceleration and strengthening of the heartbeat, widening of the airways, widening of the blood vessels in muscles and narrowing of those in the skin and abdominal organs (in order to increase the blood flow through the muscles), and the inducement of sweating. In addition, the activity of the digestive system is decreased and the pupils are dilated.

**PARASYMPATHETIC NERVOUS SYSTEM**
The parasympathetic nervous system is composed of a chain of nerves that passes from the brain and another that leaves the lower spinal cord. The nerves are distributed to the same tissues that are supplied by the sympathetic nerves. The parasympathetic nerves release the neurotransmitter acetylcholine, which has the opposite effect to those of adrenaline and noradrenaline.

The parasympathetic system is concerned mainly with everyday functions such as digestion and excretion.
The autonomic nervous system (also known as the involuntary nervous system) is responsible for controlling the involuntary body functions, such as sweating, digestion and heart rate.

The autonomic nervous system is divided into two separate systems: the sympathetic nervous system and the parasympathetic nervous system. The sympathetic system is primarily concerned with preparing the body for action; it predominates at times of stress or excitement. The sympathetic system stimulates functions such as heart-rate and sweating and dilates the blood vessels to the muscles so that more blood is diverted to them. Simultaneously, it subdues the activity of the digestive system. In contrast, the parasympathetic nervous system is concerned mainly with the body's everyday functions such as digestion and the excretion of waste products, this system dominates during sleep. The parasympathetic system slows the heart rate and stimulates the organs of the digestive tract. Most of the time, activity is balanced between the two systems, with neither dominating. Both of the systems play an important part in sexual arousal and orgasm in both men and women.
**EFFECT OF DRUGS**

Certain disorders can be treated by administration of drugs that affect the autonomic nervous system. *Anticholinergic drugs*, for example, block the effect of acetylcholine, which can reduce muscle spasms in the intestine. *Beta-blocker drugs* block the action of adrenaline (epinephrine) and noradrenaline (norepinephrine) on the heart, thus slowing the rate and force of the heartbeat.

**autopsy**

A postmortem examination of the body, including the internal organs, which is usually undertaken to determine the precise cause of death. An autopsy is sometimes required by law.

When the cause of death is known and there are no legal requirements for an autopsy to be carried out, hospitals and/or doctors may seek the next-of-kin’s permission to perform an autopsy in order to advance knowledge of the disease that caused death, thereby helping in the care of future patients with the same condition. Relatives are free to refuse such consent.

**autoregulation**

Processes occurring within the body that maintain ideal conditions for normal function. Such processes include the distribution of blood between different organs, and balance of the body’s salt and water content.

**autosomal disorders**

See *genetic disorders*.

**autosomal**

Any chromosome that is not a sex chromosome. Of the 23 pairs of chromosomes in each human cell, 22 pairs are autosomes.

**autosuggestion**

Putting oneself into a receptive hypnotic-like state as a means of stimulating the body’s ability to heal itself. The idea that symptoms could be relieved merely through attitude was put forward by the Frenchman Emile Coué at the end of the nineteenth century.

Although, autosuggestion enjoyed only brief popularity, some techniques used today are based on its premise. For example, in one method used to control anxiety symptoms, people are taught muscular relaxation techniques (see biofeedback) and learn to summon up calming imagery or pleasant thoughts.

**avascular**

A term meaning without blood vessels.

**avascular necrosis**

Cell death in body tissues as a result of damage to the blood vessels that supply the area.

**aversion therapy**

An outdated form of *behaviour therapy* in which unpleasant stimuli, such as electric shocks, are administered at the same time as an unwanted behaviour in an attempt to alter behavioural patterns. Other forms of therapy are now generally considered to be more appropriate.

**aviation medicine**

The medical speciality concerned with the physiological effects of air travel, such as the effects of reduced oxygen, pressure changes, and accelerative forces, as well as with the causes and treatment of medical problems that may occur during a flight. Aviation medicine includes assessment of the fitness of the aircrew, and sometimes of passengers, to fly, the management of medical emergencies in the air, the consequences of special types of flights (such as in helicopters and spacecraft), and the investigation of aircraft accidents.

**AIR TRAVEL-RELATED PROBLEMS**

Increasing altitude causes a fall in air pressure and with it a fall in the pressure of oxygen. Hypoxia (a seriously reduced oxygen concentration in the blood and tissues) is a threat to anyone who flies at altitude. Aviator’s decompression sickness has the same causes as the related condition that affects scuba divers but it is not normally a risk for passengers on regular flights. Rapid decompression (a sudden drop in air pressure) in civil aircraft is extremely rare, but passengers and crew are provided with oxygen masks for use in emergencies while the aircraft descends to a safe altitude.

Hypoxia or, more commonly, anxiety during flight can lead to hyperventilation (overbreathing), in which increased breathing results in excess loss of carbon dioxide. This loss alters the body’s acidity and gives rise to symptoms such as tingling around the mouth, muscle spasms, and lightheadedness. If such symptoms develop, the treatment is to rebreathe air from a paper bag held over the nose and mouth, which reduces the loss of carbon dioxide.

The changes in altitude or cabin pressure during a flight affect the body’s gas-containing cavities, principally the middle ears, the facial sinuses, the
lungs, and the intestines. When pressure drops during ascent, the volume of gas in these cavities increases and usually escapes freely. On descent, the gas volume decreases as pressure outside the body rises. Unless preventative measures are taken, this may cause pain and, rarely, damage (see barotrauma).

There is increasing concern about the risk of developing deep vein thrombosis (see thrombosis, deep vein) during air travel. The condition may be caused by long periods of sitting in one position or compression of the tissues, both of which occur during long-haul flights.

The accelerative forces experienced by civil aircraft passengers are mild, even during take-off and landing, and no medical precautions are necessary. Military aircraft pilots, on the other hand, may experience severe accelerations and must wear special suits and use a reclined seat to prevent pooling of blood in the feet, which would cause immediate loss of consciousness.

Motion sickness usually causes fewer problems during air travel than during road or sea travel. Passengers who are prone to motion sickness may benefit from taking an anti-motion sickness preparation.

Air travel allows the rapid crossing of several time zones within a short period of time, which can affect sleep-waking cycles, causing jet-lag.

**AVIATION MEDICINE SPECIALISTS**

Most large airlines have doctors who are specially trained in aviation medicine who are responsible for the healthcare of the airline staff. The doctors also give advice on the transportation of sick passengers, the provision of training and equipment to deal with illness during flight, and the maintenance of airline hygiene.

**avitaminosis**

See hypovitaminosis.

**Avloclor**

A brand name for chloroquine, a drug that is used to prevent and treat malaria. Avloclor is also used in the treatment of some rheumatic disorders, such as rheumatoid arthritis.

**avulsed tooth**

A tooth that has become completely dislodged from its socket following an injury. If the tooth is kept clean and moist (ideally by being stored in milk, saliva, or contact-lens solution), is not otherwise washed, and treatment is sought immediately, reimplantation (see reimplantation, dental) may be possible.

**avulsion**

The tearing away of a body structure from its point of attachment. Avulsion may be due to an injury, for example excessive contraction of a tendon may avulse a small piece of bone at its attachment point. Avulsion may also be performed as part of a surgical procedure, as in the surgical removal of varicose veins.

**axilla**

The medical name for the armpit.

**axis**

The second cervical vertebra in the human spine. The axis is attached by a pivot joint to the atlas, the topmost vertebra, which in turn is attached to the base of the skull. The pivot joint allows the head to turn to either side.

**axon**

The thin, elongated part of a neuron (nerve cell) that conducts nerve impulses. Many axons in the body are covered with a fatty myelin sheath.

**Ayurvedism**

See Indian medicine.

**azathioprine**

An immunosuppressant drug used to treat severe rheumatoid arthritis and other autoimmune disorders (in which the immune system attacks the body’s own tissues). The drug is also used to prevent organ rejection after transplant surgery. Azathioprine may be injected or given in tablet form. Side effects include increased susceptibility to infection.

**azelaic acid**

A topical (applied to the skin) drug that is used to treat mild to moderate acne.

**azithromycin**

A macrolide antibiotic drug used to treat infections of the skin, chest, throat, and ears. Azithromycin is also used to treat genital infections due to chlamydia (see chlamydial infections).

**azoosperma**

The absence of sperm from semen, causing infertility in males. Azoosperma may be caused either by a congenital (present from birth) disorder or by one that develops later in life. It can also occur following a vasectomy.

**CAUSES**

Congenital azoosperma may be due to a chromosomal abnormality such as Klinefelter's syndrome (the presence of an extra sex chromosome); failure of the testes to descend into the scrotum; absence of the vasa deferentia (ducts that carry sperm from the testes to the seminal vesicles, where it is stored prior to ejaculation); or cystic fibrosis (a genetic disease of the lungs and pancreas that may also cause defects of the vasa deferentia).

In some males, azoosperma may be the result of hormonal disorders affecting the onset of puberty. Another cause is blockage of the vasa deferentia, which may follow a sexually transmitted infection, tuberculosis, or surgery on the groin. Azoosperma can also be the result of damage to the testes. This can follow radiotherapy, treatment with certain drugs (for example, anticancer drugs), prolonged exposure to heat, or the effects of occupational exposure to toxic chemicals. In some cases, production of sperm ceases permanently for no known reason.

**TREATMENT AND OUTLOOK**

If the cause is treatable (with hormones to bring on puberty or surgery to unblock ducts closed by infection, for example), sperm production may restart. However, in some cases the testes will have been permanently damaged.

**AZT**

The abbreviation for azidothymidine, the former name for zidovudine.

**aztreonam**

An antibiotic drug used to treat some types of meningitis and infections by certain types of bacteria, including Pseudomonas.

**azygous**

A term meaning not paired. Azygous describes a structure such as the heart, which does not have a twin organ on the opposite side of the body. The azygous vein drains blood from the abdomen and chest and travels along the right side of the spine.
babesiosis
A general term covering a number of diseases that are caused by the Babesia genus of protozoa (single-celled parasites). Babesiosis is mainly a disease of animals; it may affect sheep, cattle, horses, and other domestic animals. Babesiosis can be transmitted from animals to humans by tick bites, producing symptoms similar to those of malaria.

Treatment is with the antimalarial drug quinine and an antibiotic drug. (See also ticks and disease.)

Babinski’s sign
A reflex movement in which the big toe bends upwards when the outer edge of the sole of the foot is scratched. In babies, Babinski’s sign is a normal reflex action. In adults, Babinski’s sign is an indication of damage to, or disease of, the brain or the spinal cord.

baby blues
A common name for a mild form of depression that sometimes occurs in women after childbirth. The baby blues almost always disappear without treatment but can occasionally develop into a more serious depressive illness (see postnatal depression).

baby teeth
Also known as milk teeth, an alternative term for the first teeth (see primary teeth).

bacillary dysentery
A type of dysentery (infection of the intestinal tract) caused by bacteria of the Shigella genus (see shigellosis).

bacille Calmette-Guérin
See BCG vaccination.

bacilli
Rod-shaped bacteria. Bacilli (singular: bacillus) are responsible for causing a variety of diseases, including infectious diseases such as tuberculosis, tetanus, typhoid fever, pertussis (whooping cough), and diphtheria.

bacitracin
A type of antibiotic drug used in combination with other drugs to treat infections of the eyes and skin. Bacitracin is most commonly applied as an external skin preparation or as eye-drops.

back
The area between the shoulders and buttocks. The back is supported by the spinal column (see spine), which is bound together by ligaments (bands of tough, fibrous tissue) and supported by muscles that also help to control posture and movement.

DISORDERS
Back problems are numerous and may be the result of a variety of factors affecting the spine. They can be related to disorders of bones, muscles, ligaments, tendons, nerves, and joints in the spine, all of which can cause back pain. (See also spine disorders box.)

background radiation
The small amounts of natural radiation that emanate from such sources as rocks and the soil.

back pain
Most people suffer from back pain at some time in their lives. In many cases, no exact diagnosis is made because the pain gets better with rest and because analgesic drugs (painkillers) are used before any tests, such as X-rays, are carried out. In such cases, doctors may use the term “nonspecific back pain” to describe the condition.

CAUSES
Nonspecific back pain is one of the largest single causes of working days lost through illness in the UK. The people most likely to suffer from back pain are those whose jobs involve a lot of heavy lifting and carrying or those who spend long periods sitting in one position or bending awkwardly. Overweight people are also more prone to back pain—they back their load and they tend to have weaker abdominal muscles, which usually help to provide support to the back.

Nonspecific back pain is thought to be caused by a mechanical disorder affecting one or more structures in the back. This may be a ligament strain, a muscle tear, damage to a spinal facet joint, or disc prolapse (slipped disc).

In addition to pain from a damaged structure, spasm of surrounding muscles will cause pain and tenderness over a wider area. This can result in temporary scoliosis (an abnormal sideways curvature of the spine).

Abnormalities of a facet joint and prolapse of an intervertebral disc can both cause sciatica (pain in the buttock and down the back of the leg into the foot). This condition is the result of pressure on a sciatic nerve root as it leaves the spinal cord. Coughing, sneezing, or straining will increase the pain. Pressure on the sciatic nerve can also cause a pins-and-needles sensation in that leg as well as weakness in muscles that are activated by the nerve. Rarely, pain may radiate down the femoral nerve at the front of the thigh.

Osteoarthritis in the joints of the spine can cause persistent back pain. Ankylosing spondylitis (an inflammatory disorder in which arthritis affects the spine) causes back pain and stiffness with loss of back mobility. Coccydynia (pain and tenderness at the base of the spine) may occur after a fall in which the coccyx has struck the ground, during pregnancy, or spontaneously for unknown reasons.

Fibrositis is a term that is sometimes used to describe pain and tenderness in muscles, which may affect the back. Fibrositis is often worse in cold and damp weather and is occasionally associated with feeling generally unwell. Unlike other causes of back pain, fibrositis is not accompanied by muscle spasm or restriction of back movement.

It often improves when treated with nonsteroidal anti-inflammatory drugs.

Pyelonephritis can cause back pain as well as pain and tenderness in the loin, fever, chills, and pain when passing urine. Cancer in the spine can cause persistent back pain that disturbs sleep and is not relieved by rest.

SELF-HELP
People with back pain and sciatica are usually advised to remain as mobile as possible. Sleeping on a firm mattress and taking analgesic drugs can help to relieve pain. However, if pain persists, is very severe, or is associated with weakness in a leg or bladder control problems, immediate medical advice should be sought.

INVESTIGATION
Examination of the back may show tenderness in specific areas or loss of back mobility. Weakness or loss of sensation in the legs implies pressure on a nerve root, which needs prompt investigation.

X-rays of the spine may reveal narrowing between the intervertebral discs; osteoarthritis; osteoporosis; ankylosing
Most people experience back pain at some time in their lives, but in most cases it is not serious and the problem corrects itself before investigation takes place. However, some kinds of back pain can be related to a specific disorder. The most common sites affected by back pain are shown in this diagram.

**BACLOFEN**

A muscle-relaxant drug that blocks nerve activity in the spinal cord. Baclofen is used to relieve muscle spasm and stiffness caused by injury to either the brain or spinal cord, by neurological disorders such as multiple sclerosis, or by a stroke. The drug does not cure the underlying disorder but helps to facilitate movement and allows physiotherapy to be more effective. The drug is taken in either tablet or liquid form. Side effects of baclofen may include drowsiness and muscle weakness. These effects can be reduced if the dose of the drug is increased gradually under medical supervision until the desired degree of relaxation is achieved.

**bacteraemia**

The presence of bacteria in the bloodstream. Bacteraemia commonly occurs for a few hours after minor surgical operations and dental treatment and may also occur in infections such as tonsillitis. The immune system, the body’s natural defence mechanism, usually prevents the bacteria from multiplying and causing damage. However, in people with abnormal heart valves (due to conditions such as a congenital defect or scarring from rheumatic fever), the bacteria may cause endocarditis (inflammation of the heart lining and valves). If bacteraemia affects a person whose immune system is weakened by illness or major surgery, septicemia (an infection of the blood) may develop.

**bacteria**

Single-celled microorganisms that are invisible to the naked eye. The singular form of the term is bacterium. Abundant in the air, soil, and water, most bacteria are harmless to humans. Some, such as those that live in the intestine, are beneficial and help to break down food for digestion.

**BACK PAIN**

Most people experience back pain at some time in their lives, but in most cases it is not serious and the problem corrects itself before investigation takes place. However, some kinds of back pain can be related to a specific disorder. The most common sites affected by back pain are shown in this diagram.

**DISEASE-CAUSING TYPES**

Disease-causing bacteria are known as pathogens and are classified, according to shape, into three main groups: cocci (spherical); bacilli (rod-shaped); and spirochaetes or spirilla (spiral-shaped).

Among the wide range of diseases caused by cocci are pneumonia, tonsillitis, bacterial endocarditis (inflammation of the lining inside the heart), meningitis (inflammation of the membranes surrounding the brain and spinal cord), toxic shock syndrome, and various disorders of the skin.

Diseases that are caused by bacilli include tuberculosis, pertussis (whooping cough), typhoid fever, diphtheria, tetanus, salmonellosis, shigellosis (bacillary dysentery), legionnaires’ disease, and botulism.

Bacteria from the third, and smallest, group, the spirochaetes, are responsible for causing syphilis, yaws, leptospirosis, and Lyme disease.

**GROWTH AND MOVEMENT**

The bacteria that colonize the human body thrive in warm, moist conditions.

**Common types of bacteria**

- **Staphylococcus**
  - (causes boils)
- **Streptococcus**
  - (causes sore throat)
- **Salmonella typhi**
  - (causes typhoid fever)
- **Spirochaete**
  - (causes syphilis)
Some of these bacteria are aerobic (they need oxygen to grow and multiply) and are therefore most commonly found on the skin or within the respiratory system. Others are anaerobic, thriving where there is no oxygen, deep within tissue or wounds.

Some types of bacteria are naturally static; if they move around the body at all, they do so only when carried in currents of air or fluid. However, there are also highly motile types of bacteria, such as salmonella, which move through fluids by lashing with their whiplike tails (known as flagella) and can anchor themselves to other cells with filamentous threads called pili.

REPRODUCTION
Bacteria reproduce by simple cell division, which can occur every few minutes in ideal conditions (exactly the right temperature and sufficient nourishment for all cells). Some bacteria multiply by each producing a spore (a single new bacterium). Spores, which are protected by a tough membrane, can survive high temperatures, dry conditions, and lack of nourishment.

HOW BACTERIA ENTER THE BODY
Bacteria can enter the body through the lungs if they are inhaled in infected droplets spread by coughs and sneezes. The digestive tract may become infected if contaminated food is eaten. Some bacteria cause diseases, such as sexually transmitted infections, by entering the genitourinary system.

Bacteria can also penetrate the skin in various ways: through hair follicles; by way of superficial cuts and abrasions; through burns; and via deep, penetrating wounds.

HOW BACTERIA CAUSE DISEASE
Some bacteria release poisons (toxins) that are harmful to human cells. The toxins either destroy the cell or disrupt its chemical processes. Less commonly, certain types of bacteria directly enter, and multiply within, body cells, causing tissue damage as they spread.

THE BODY’S DEFENCES
The body’s first defences against disease-causing bacteria are the skin and the mucous membranes lining the respiratory tract, the digestive tract, and the genitourinary system. The eyes are protected by an enzyme in tears and the stomach secretes hydrochloric acid, which kills many of the bacteria found in food and water.

If bacteria pass through these barriers, the body’s immune system responds by sending various types of white blood cell to seek and destroy the bacteria. Immunity can also be generated by immunization. This involves injecting a weakened form of the bacterium or its poison into the body to stimulate an immune response. Immunization is now routine for a number of conditions, including diphtheria, tetanus, and some forms of meningitis.

TREATMENT OF BACTERIAL DISEASES
The immune response is sometimes enough to bring about recovery, and mild bacterial infections may not need any treatment. However, antibiotic drugs are the main form of treatment for more severe infections. Superficial infected wounds may be treated with antiseptics.

Some bacteria, such as MRSA, are now becoming resistant to treatment with antibiotics. In these circumstances, bacterial infections can be difficult or even impossible to treat and may be life-threatening. (See also infectious disease.)

bacterial endocarditis
See endocarditis.

bacterial food poisoning
See food poisoning.

bacterial vaginosis
An infection of the vagina that causes a greyish-white discharge and itching. The disorder is due to excessive growth of bacteria that normally live in the vagina. Bacterial vaginosis occurs most commonly in sexually active women and is treated with antibiotic drugs.

bactericidal
A term that is used to describe any substance that kills bacteria. (See also antibiotic drugs; bacteriostatic.)

bacteriology
The study of bacteria, particularly of the types that cause disease. Bacteriology includes techniques used to isolate and identify bacteria from specimens such as a throat swab or urine. Bacteria are identified by their appearance under a microscope, including their response to stains (see Gram’s stain; staining), and by the use of culture. Testing for sensitivity to antibiotic drugs may be performed.

bacteriostatic
A term used to describe a substance that stops the growth or multiplication of bacteria but does not kill them. (See also antibiotic drugs; bactericidal.)
bacteriuria
The presence of bacteria in the urine. It is common for small, harmless numbers of bacteria to be found in the urine of healthy people. Bacteriuria is of significance only if more than 100,000 bacteria are present in each millilitre of urine, or if 100 white blood cells (pus cells) per millilitre of urine are present (which is an indication of the body's response to the infection).

Bacteroides
A genus of anaerobic (capable of living without oxygen) bacilli (rod-shaped bacteria) that normally inhabit the intestines. One particular type, Bacteroides fragilis, is commonly found in abdominal wound infections and in the blood when the intestines are diseased.

bad breath
See halitosis.

bagassosis
An occupational disease affecting the lungs of workers who handle mouldy bagasse (the fibrous residue of sugar-cane after juice extraction). Bagassosis is one cause of allergic alveolitis, a reaction of the lungs to inhaled dust containing fungal spores. Symptoms develop four to five hours after inhalation of the dust and may include shortness of breath, wheezing, fever, headache, and cough; typically, they last for about 24 hours. Repeated exposure to dust may lead to permanent lung damage. Protective measures taken by industry have made the disease rare.

Baker's cyst
A firm, fluid-filled lump behind the knee. A Baker's cyst occurs as a result of increased pressure in the knee joint due to a buildup of fluid. Such a buildup is a feature of disorders such as rheumatoid arthritis. The cyst is created by a backward ballooning-out of the synovial membrane covering the knee joint.

Most Baker's cysts are painless, and some disappear spontaneously, sometimes after many months. Occasionally, a cyst may rupture, causing fluid to seep down between the layers of the calf muscles. This can produce pain and swelling in the calf that may mimic a deep vein thrombosis (see thrombosis, deep vein).

Diagnosis of a Baker's cyst is confirmed by ultrasound scanning. Treatment is rarely needed, but in a few cases surgery may be performed.

balance
The ability to remain upright and move without falling over. Keeping one's balance is a complex process that relies on a constant flow of information to the brain about body position. The integration of all of this information, and continual instructions from the brain, enable the body to make the changes needed to maintain balance.

The brain receives data on body position from various sources: the eyes; the sensory organs (called proprioceptors) in the skin, muscles, and joints; and the three semicircular canals of the labyrinth of the inner ear. The part of the brain called the cerebellum collates this information and sends instructions to muscles to contract or relax to maintain balance.

DISORDERS
Balance can be affected by various disorders, particularly inner-ear disorders such as labynrinthitis (inflammation of the ear's labyrinth) and Ménière's disease (an abnormally high pressure of fluid in the labyrinth). Less commonly, otitis media (a disorder of the middle ear) may disturb balance.

Damage to nerve tracts in the spinal cord that carry information from position sensors in the joints and muscles to the brain can also impair balance. This damage to the nerves may result from spinal tumours, circulatory disorders, nerve degeneration due to deficiency of vitamin B₁₂, or, rarely, tabes dorsalis (a complication of syphilis). A tumour or stroke that affects the cerebellum in the brain may cause clumsiness of the arms and legs as well as other features of impaired muscular coordination.

ball-and-socket joint
A highly mobile joint, such as the shoulder or hip.

ballismus
Violent jerking and twitching of the limbs that is caused by brain damage within the area below the thalamus (a structure that relays sensory information). In most cases, only one side of the body is affected, in which case the condition is known as hemiballismus.

balloon angioplasty
See angioplasty, balloon.

ballottement
A technique occasionally used during a physical examination (see examination, physical) to check the position of an organ, particularly in a fluid-filled area of the body. It involves flicking or tapping the area with the fingers, causing the organ to move up and down. The technique was once widely used to confirm pregnancy; when the wall of the uterus is tapped, the fetus moves away and floats back with a responding tap.

balloon catheter
A flexible tube with a balloon at its tip, which, when inflated, keeps the tube in place or applies pressure to an organ or vessel. One type of balloon catheter is

---

**BALLOON CATHETER**

- Sterile water tube to inflate balloon
- Irrigation tube for fluid to wash out bladder
- Tube to drain urine from bladder
- Inflatable balloon filled with water
- Hole through which urine enters

---

baldness
See alopecia.
used to drain urine from the bladder (see catheterization, urinary). Balloon catheters are sometimes used to expand narrowed arteries (see angiplasty, balloon). They may also be used to control bleeding from widened veins in the lower part of the oesophagus (known as oesophageal varices) before surgery.

**balm**
A soothing or healing medicine applied to the skin.

**balsam**
An aromatic oily liquid that is obtained from various evergreen trees. Balsam is an antiseptic substance and was once also widely used in remedies for respiratory disorders.

**bambuterol**
A bronchodilator drug that is taken orally for the relief of asthma.

**bandage**
A strip or tube of fabric used to keep dressings in position, to apply pressure, to control bleeding, or to support a sprain or strain. Roller and tubular bandages are the type most widely used. Tubular gauze bandages require a special applicator and are used mainly for areas that are awkward to bandage, such as a finger. Triangular bandages are used to make slings. (See also wounds.)

**banding**
A procedure for treating haemorrhoids (piles) that are large or are causing particular discomfort. Using a special instrument, a doctor places a rubber band around the base of the haemorrhoid, which causes it to shrink and, eventually, to fall off. Banding is virtually painless and the procedure can be performed in a doctor’s surgery.

**barber’s itch**
See sycosis barbae.

**barbiturate drugs**
COMMON DRUGS
- Amobarbital
- Butobarbital
- Secobarbital
- Thiopental

A group of sedative drugs that work by depressing activity within the brain. Barbiturate drugs include thiopental, which is very short-acting and is used to induce anaesthesia (see anaesthesia, general), and phenobarbital, which is long-acting and is sometimes used as an anticonvulsant drug in the treatment of epilepsy. In the past, barbiturates were widely used as anxiety drugs and sleeping drugs, but they have been largely replaced by benzodiazepine drugs and other nonbarbiturates. Because barbiturates are habit-forming and are widely abused for their sedative effect, they are now classed as controlled drugs.

**HOW THEY WORK**
The sedative action of barbiturate drugs is produced by the drug molecules blocking the conduction of stimulatory chemical signals between the nerve cells of the brain and reducing the ability of the cells to respond. Barbiturates, especially phenobarbital, also reduce the sensitivity of brain cells to abnormal electrical activity.

**POSSIBLE SIDE EFFECTS**
The possible adverse effects of barbiturate drugs include excessive drowsiness, staggering gait, and, in some cases, excitability. An overdose of barbiturates can be fatal, particularly when taken in combination with alcohol, which dangerously increases their depressing effect on the brain (including suppression of the respiratory centre).

Barbiturates are likely to produce drug dependence if used for longer than a few weeks, and withdrawal effects, such as sleeplessness and twitching, may then occur when treatment is stopped.

**Bardet–Biedl syndrome**
A very rare genetic disorder characterized by learning difficulties, retinopathy (an eye defect), obesity, polydactyly (the presence of extra fingers or toes) and hypogonadism (underactivity of the testes or ovaries).

**barium sulphate**
A salt that is used in solution as a contrast medium in X-ray examinations of the intestinal tract (see barium X-ray examinations). Barium is opaque to X-rays and is used to view the outline of hollow internal organs, which would otherwise not be visible.

**barium X-ray examinations**
Procedures used to detect and follow the progress of some disorders of the gastrointestinal tract. Because barium (a metallic element) is opaque to X-rays, it is used to outline organs, such as the stomach, which are not normally visible on an X-ray image. Barium sulphate mixed with water is passed into the part of the tract requiring examination before X-rays are taken. In some cases, barium X-ray examinations can be used as an alternative to endoscopy (internal examination using a rigid or flexible viewing tube), although endoscopy is often the preferred form of investigation.

Barium X-rays may be single- or double-contrast. Single-contrast X-rays use barium sulphate alone. The barium fills the section of the tract under examination and provides an outline image that shows up any prominent abnormalities. In double-contrast barium X-rays, the barium forms a thin film over the inner surface of the tract and the tract is subsequently filled with air so that any small surface abnormalities can be seen.

**TYPES OF EXAMINATION**
Various types of barium X-ray examination are used to investigate different parts of the gastrointestinal tract. A barium swallow involves drinking a solution of barium; this procedure is used to investigate the swallowing mechanism or the oesophagus. A barium meal is carried out to look at the lower oesophagus, stomach, and duodenum.

A barium follow-through examination can be used to investigate disorders of the small intestine; after barium has been swallowed, a series of X-rays are taken at intervals as the barium travels down the oesophagus to the intestine. A barium enema can be used to investigate disorders of the large intestine and the rectum; the barium is introduced into the body through a tube inserted in the rectum.

Any barium that remains in the intestine may be a cause of constipation. For this reason, it is important to ensure that a patient has a high-fibre diet and drinks plenty of water following a barium examination, until all the barium has passed through. (See also Barium X-ray procedures box, overleaf.)

**barotrauma**
Damage or pain, mainly affecting the middle ear and the facial sinuses, that is caused by changes in surrounding air pressure. Air travellers are at the greatest risk of barotrauma, but scuba divers face similar problems.

**CAUSE**
Aircraft cabin pressure decreases as the plane ascends and increases as it descends. As the aircraft ascends, the ears may seem to “pop” as the air in the middle ear expands and is expelled via the eustachian tubes, which connect the middle ear to the back of the throat. On descent, the higher pressure may push the eardrum inwards and cause pain.
BARIUM X-RAY PROCEDURES

Barium X-ray examinations are used to reveal abnormalities or disorders within the upper and lower gastrointestinal tract. Barium swallows are used to investigate the oesophagus, and barium meals are used for the examination of areas such as the stomach and duodenum. The large intestine is examined by means of a barium enema.

BARIUM SWALLOW/MEAL

Barium swallows and meals are used to investigate the upper gastrointestinal tract. No food or drink is permitted for six to nine hours beforehand. At the examination, the patient swallows a glass of barium mixed with a flavoured liquid, or is given a piece of bread or a biscuit soaked in barium if a disorder of the swallowing mechanism is being investigated.

Taking the X-ray
The radiographer takes X-ray pictures while the patient swallows. For a barium swallow, the patient stands; for a barium meal, the patient lies on the table in different positions; for a barium follow-through, the patient lies on the right side and X-rays are taken at intervals until the barium has progressed through the small intestine.

BARIUM ENEMA

A barium enema is carried out for examination of the large intestine and rectum. In order for an examination to be successful, the large intestine needs to be as empty and clean as possible because faeces can obscure or simulate a polyp or tumour. For this reason, the patient’s intake of food and fluids is sometimes restricted for a few days before the examination, and laxatives are given to make sure that the bowel is empty prior to the procedure.

The procedure
The radiographer or radiologist introduces the barium into the patient’s intestine via a tube inserted into the rectum. The patient lies on his or her left side while the barium is infused. He or she then turns on to the other side, front, and back, and X-rays are taken.

Single-contrast result
In single-contrast barium enemas, the section of intestine to be examined is filled with liquid barium. Because barium is opaque to X-rays, it provides an outline image that shows up prominent abnormalities such as narrowing.

Double-contrast result
In double-contrast, barium and air are introduced into the tract. The barium forms a film on the tract’s inner surface only, providing an image of small surface abnormalities that would not be visible using single-contrast.
SYMPTOMS
Minor pressure damage in the middle ear may cause pain, hearing loss, and tinnitus (ringing in the ears) for a few days; damage in the facial sinuses may also cause pain, and possibly a discharge of mucus or blood. Symptoms usually wear off within hours or days, but treatment may be needed if they worsen or persist. Large changes in pressure can rupture the eardrum (see eardrum, perforated).

PREVENTION
Barotrauma can be avoided by vigorous swallowing or by forcibly breathing out with the mouth closed and the nose pinched, which is known as the Valsalva manoeuvre. This action serves to equalize the internal and external pressures in the middle ear and sinuses.

If the eustachian tubes are blocked, as commonly occurs with a cold, use of a nasal spray containing a decongestant drug is recommended shortly before the descent of the aircraft. Anyone with a severe head cold should avoid air travel if possible. Infants should be breast- or bottle-fed during descent to encourage swallowing. (See also aviation medicine; scuba-diving medicine.)

Mechanism of barotrauma
The diagram above shows the location of the middle ear and the pressure changes that occur when the eustachian tube is blocked and there is an increase in surrounding air pressure.

barrel chest
A prominent, rounded chest that is sometimes the result of lung distension in people with longstanding emphysema (enlarged air sacs in the lungs). Lung distention leads to an increase in distance between the front and back of the chest, thereby resulting in a change in the shape of the chest wall. (See also pulmonary disease, chronic obstructive.)

Barrett’s oesophagus
A complication of long-term gastrooesophageal reflux (see acid reflux), in which the cells that line the lower part of the oesophagus are replaced by cells that are normally found in the stomach. People with Barrett’s oesophagus are at increased risk of developing cancer of the oesophagus (see oesophagus, cancer of). The condition may be monitored regularly by endoscopy (internal examination using a viewing instrument) of the oesophagus.

barrier cream
A cream that is used to protect the skin against the effects of irritant substances and excessive exposure to water. (See also sunscreens.)

barrier method
A method of preventing pregnancy by blocking the passage of sperm to the uterus (see contraception, barrier methods of). An example of a barrier method is the use of a condom or a diaphragm.

barrier nursing
The nursing technique by which a patient with an infectious disease is prevented from infecting other people (see isolation). In reverse barrier nursing, a patient with reduced ability to fight infections (for example, because of an immunodeficiency disorder or following certain types of surgery) is protected against outside infection. (See also aseptic technique.)

bartholinitis
An infection of the Bartholin’s glands at the entrance to the vagina. The disorder, which may be due to a sexually transmitted infection such as gonorrhoea, causes an intensely painful red swelling at the opening of the gland ducts. Treatment is with antibiotic drugs, analgesic drugs, and warm baths.

Bartholinitis sometimes leads to the formation of an abscess (see Bartholin’s abscess) or a painless cyst, known as a Bartholin’s cyst, which may become infected. Abscesses are drained under general anaesthesia (see anaesthesia, general). Recurrent abscesses or infected cysts may require surgery to convert the duct into an open pouch (see marsupialization) or remove the gland completely.

Bartholin’s abscess
The formation of pus in one or both of the Bartholin’s glands, which are located on either side of the vulva (the folds of flesh that surround the opening of the vagina). Bartholin’s abscesses develop as a result of bacterial infection of the glands (see Bartholin’s glands).

Bartholin’s glands
A pair of oval, pea-sized glands whose ducts open into the vulva (the folds of flesh that surround the opening of the vagina). During sexual arousal, the Bartholin’s glands secrete a fluid that lubricates the vulval region. Infection of these glands causes Bartholin’s abscess or the development of a Bartholin’s abscess.

Basal cell carcinoma
A type of skin cancer, also known as a rodent ulcer or BCC, that occurs most commonly on the face or neck, but can affect any part of the body. The cells of the tumour closely resemble, and are possibly derived from, cells in the basal (innermost) skin layer.

Basal cell carcinoma is caused by skin damage from the ultraviolet radiation in sunlight. Fair-skinned people over the age of 50 are most commonly affected by this form of cancer; dark-skinned people are protected by the larger amount of melanin (a pigment that absorbs ultraviolet radiation) in their skin. The incidence of basal cell carcinoma is much higher among people living in sunny climates, especially those who have outdoor occupations; in parts of the US and Australia, over half the white population has had a basal cell carcinoma by the age of 75.
SYMPTOMS
The majority of basal cell carcinomas occur on the face, often at the side of an eye or on the nose. It starts as a small, flat nodule and grows slowly, eventually breaking down at the centre to form a shallow ulcer with raised edges.

Diagnosis is confirmed through a biopsy (removal of a small sample of cells for microscopic analysis). Without treatment, the tumour gradually invades and destroys the surrounding tissues, but it virtually never spreads to other parts of the body.

TREATMENT
Treatment of basal cell carcinoma is usually with surgery (or in some cases radiotherapy) and is often completely successful. Plastic surgery may also be required, however, depending on the size and site of the tumour.

PREVENTION
The risk of developing this form of skin cancer can be reduced by avoiding over-exposure to strong sunlight, by using sunscreens, and by wearing protective clothing such as sun hats. People who have previously had a basal cell carcinoma may develop further tumours and should be especially alert to any new changes in their skin. (See also melanoma, malignant; squamous cell carcinoma; sunlight, adverse effects of.)

basal ganglia
Paired nerve cell clusters deep within the cerebrum (the main mass of the brain) and the upper part of the brainstem. The basal ganglia play a vital part in producing smooth, continuous muscular actions and in stopping and starting movement. Any disease or degeneration affecting the basal ganglia and their connections may lead to the appearance of involuntary movements, trembling, and weakness, as occur in Parkinson’s disease.

basal metabolic rate (BMR)
The rate at which energy is used by the body just to maintain vital functions. Such vital functions include breathing, circulation, and digestion. (See also energy requirements; metabolism.)

base
See alkali.

basement membrane
The thin membrane that lies directly beneath the epithelium (the layer of cells that covers surfaces of the body and lines most hollow structures within it). The basement membrane is composed of protein fibres and carbohydrates.

base pair
Part of a DNA molecule comprising two chemicals known as nucleotide bases that are linked together by means of hydrogen bonds. A base pair forms one “run” of the DNA “ladder”. There are only two possible pairings of the four bases: guanine always pairs with cytosine and adenine with thymine. The sequence of base pairs in each DNA chain provides the code for the activities of the cell (see genetic code). (See also nucleic acids.)

basic life support
Resuscitation techniques that may be performed by a first aider (see rescue breathing; cardiopulmonary resuscitation). If basic life support measures fail to restore a normal heartbeat and spontaneous breathing, advanced life support must then be administered by trained medical personnel.

basilar membrane
A membrane within the cochlea (the inner ear structure containing the receptor for hearing). Sound waves cause the basilar membrane to vibrate, stimulating sensory hair cells to send electrical signals to the brain.

basophil
A type of white blood cell that plays a part in inflammatory and allergic reactions.

Batten’s disease
One of a group of hereditary metabolic diseases (see metabolism, inborn errors of) to which Tay–Sachs disease also belongs. In Batten’s disease, abnormal fatty substances accumulate in the cells of the nervous system, causing progressive dementia, worsening seizures, and loss of vision. Symptoms of the condition usually first appear during early childhood.

There is no known treatment for Batten’s disease, which is generally fatal during childhood.

Bazin’s disease
A rare disorder, mainly affecting young women, in which tender swellings develop under the skin in the calves. In most cases no cause can be found, although Bazin’s disease may sometimes be linked to tuberculosis.

B-cell
See B-lymphocyte.

BCG vaccination
A vaccine that gives immunity against tuberculosis. The BCG vaccine is prepared from an artificially weakened strain of bovine (cattle) tubercle bacilli, the rod-shaped bacteria that are responsible for causing tuberculosis. The letters BCG stand for “bacille Calmette–Guérin”, after the two men who developed the tuberculosis vaccine.

WHY IT IS DONE
The BCG vaccine is given to people who are at risk of tuberculosis and to those whose tuberculin test is negative, indicating that they are likely to have no immunity to the disease. People at risk include health workers, contacts of people with tuberculosis, and immigrants from countries where there is a high rate of tuberculosis. Infants born to immigrants in this category are immunized, without having a tuberculin test, within a few days of birth. The vaccine is also recommended for children aged 10 to 14 years for whom the tuberculin test is negative.

HOW IT IS DONE
The vaccine is usually injected into the upper arm. About six weeks later, a small pustule appears. This normally heals completely, leaving a small scar, but can occasionally develop into a chronic ulcer (open sore).

Becker’s muscular dystrophy
A type of muscular dystrophy.

beclometasone
A corticosteroid drug that is used in the treatment of asthma and hay fever (see rhinitis, allergic). When prescribed as a nasal spray, beclometasone controls the symptoms of these conditions by reducing inflammation and the production of mucus in the lining of the nose. Prescribed as an inhaler for the treatment of asthma, the drug reduces inflammation of the airways, thereby controlling wheezing and coughing.

Beclometasone is often given with bronchodilator drugs in the management of asthma. A severe asthma attack may require the dose to be increased. The action of beclometasone is slow, however, and its full effect takes several days to occur. Possible adverse effects of the drug include hoarseness, throat irritation, and, on rare occasions, fungal infections in the mouth.
Beclometasone is also prescribed in the form of a cream or as an ointment to treat inflammation of the skin resulting from eczema.

**beclomethasone**
The former name for the corticosteroid drug beclometasone.

**Beconase**
A brand name for a nasal spray that contains the corticosteroid drug beclometasone. Beconase is used to treat hay fever (see rhinitis, allergic) and also some other nasal allergies.

**Becotide**
A brand name for an inhaled form of the corticosteroid drug beclometasone that is used to treat asthma.

**becquerel**
A unit of radioactivity (see radiation units).

**bed bath**
A method of washing a bedridden person. A small area is washed and dried at a time, while the rest of the body is kept covered to prevent chilling.

**bedbug**
A flat, wingless, brown insect that is about 5 mm long and 3 mm wide. Bedbugs live in furniture and furnishings, especially in beds and carpets, emerging at night to feed on humans by sucking their blood. Bedbugs are not known to transmit disease, but their bites are itchy and they may develop into sores that become infected.

**bedpan**
A metal, plastic, or fibre container into which a patient can defaecate or urinate without getting out of bed.

**bed rest**
A term used to describe periods spent in bed. Bed rest is sometimes part of the treatment for certain illnesses, such as rheumatic fever, and for some types of injury, such as a fractured vertebra.

Prolonged bed rest carries risks such as muscle wasting, bedsores, and development of blood clots in the legs. Bed rest was once considered an essential part of the treatment of many common conditions, but it is now avoided when possible. Patients are usually encouraged to be mobile as soon as they are able following illness or surgery.

**bedridden**
A term used to describe a person who is unable to leave bed due to illness or injury. People most likely to be bedridden are the very elderly, the terminally ill, and those paralysed as the result of an accident.

**bedsore**
Also known as a decubitus ulcer or pressure sore, an ulcer that forms on the skin of patients who are unconscious or immobile. Common sites for bedsores include the shoulders, elbows, lower back, hips and buttocks, knees, ankles, and heels.

CAUSES
Bedsores may develop following a stroke or spinal injuries that result in loss of sensation. Incontinence (see incontinence, urinary), if it results in constantly wet skin, may also be a causative factor.

SYMPTOMS
Bedsores start as red, painful areas that become purple before the skin starts to break down, producing open sores. At this stage, the sores may become infected and take a long time to heal.

TREATMENT AND PREVENTION
Deep, chronic ulcers may require treatment with antibiotic drugs and, in some cases, plastic surgery. Good nursing care, including changing the patient’s position regularly, skin care, protection of vulnerable areas, and use of cushions and special mattresses, should prevent bedsores from developing in most cases.

**bedwetting**
The common name for poor bladder control at night (see enuresis, nocturnal).

**bee stings**
See insect stings.

**behavioural problems in children**
Behavioural problems range from mild and short-lived periods of unacceptable behaviour, which are common in most children, to more severe problems such as conduct disorders and refusal to go to school. Behavioural problems may occasionally occur in any child; specialist management is called for when the problems become frequent and disrupt school and/or family life. Some behavioural problems can occur whatever the family or home situation of the child. In some cases, however, stressful external events, such as moving home or parental divorce, may produce periods of problem behaviour.

Behavioural problems that are common in young children include sleeping problems, such as waking repeatedly in the night. In toddlers, breath-holding attacks, tantrums, separation anxiety, and head-banging are problems best dealt with by a consistent and controlled approach. Problems with toilet-training...
are usually avoided if the training is delayed until the child is physically and emotionally ready.

In children between the ages of four and eight years, minor behavioural problems, such as thumb-sucking and nail-biting, clinginess, bedwetting (see enuresis, nocturnal), and disruption during the night due to nightmares, are so common as to be almost normal. Such problems are best dealt with by using a positive approach that concentrates on rewarding good behaviour. In most cases, the child grows out of the problem, but medical help from a child guidance counsellor or a child psychiatrist may occasionally be needed.

behaviourism
An American school of psychology founded by John Broadus Watson early in the 20th century. He argued that, because behaviour, rather than experience, was all that could be observed in others, it should constitute the sole basis of psychology.

behaviour therapy
A collection of techniques, based on psychological theory, that are used to change abnormal behaviour or to treat anxiety. Behaviour therapy is based on two main ideas: that repeated exposure to a feared experience under safe conditions will render it less threatening, and that desirable behaviour can be encouraged by using a system of rewards, often self-administered.

**TYPES**
Specific behaviour therapy techniques include exposure therapy (also known as desensitization), flooding, response prevention, and modelling.

**Exposure therapy** A technique that is commonly used to treat phobic disorders, such as agoraphobia (a fear of open spaces and/or public places), animal phobias, and fear of flying. It consists of exposing the patient to the cause of the anxiety in stages: for example, the therapist may accompany an agoraphobic patient on a short journey. At the same time, the patient is taught to cope with anxiety symptoms by using relaxation techniques. The intensity of the exposure is increased, until eventually, he or she is able to deal with the full situation.

**Flooding** In flooding, the patient is confronted directly and for a lengthy period with the anxiety-provoking stimulus. He or she is supported by the therapist until the fear is reduced. This technique can be emotionally traumatic and is now used less commonly.

**Response prevention** The patient is prevented from carrying out an obsessive task. For example, someone with a handwashing compulsion is prevented from carrying out the washing rituals. This technique is used in combination with other methods.

**Modelling** In this approach, the therapist acts as a model for the patient, performing the anxiety-provoking activity first, and encouraging the patient to copy.

**behaviour, types A and B**
Behaviours characteristic of two personality types described in the early 1970s, when studies were performed to examine the behaviour patterns of people with coronary artery disease.

It was proposed that a particular behaviour pattern (called Type A) was associated with increased vulnerability to stress-related illnesses, such as hypertension (high blood pressure). Type A personalities are said to feel constantly under pressure to perform many tasks at the same time, and to be competitive and self-critical. They are also impatient and easily irritated by others. In contrast to this, people with Type B personalities are said to be calmer and more relaxed.

**Behçet’s syndrome**
A rare, multisystem disorder with recurrent mouth ulcers and genital ulcers and inflammation of the eyes, skin, joints, blood vessels, brain, and intestines.

The cause of Behçet’s syndrome is unknown, but the disorder is strongly associated with HLA-B51, a genetically determined histocompatibility antigen. It affects twice as many men as women. Treatment of Behçet’s syndrome is often difficult and may involve corticosteroid drugs and immunosuppressant drugs. The condition often becomes long term.

**belching**
The noisy return of air from the stomach through the mouth. Swallowing air is usually an unconscious habit, which may result from eating or drinking too much and/or too quickly. Occasionally, belching may help to alleviate discomfort caused by indigestion.

**belladonna**
An extract of the deadly nightshade plant that has, since ancient times, been used medicinally. Belladonna contains alkaloids (substances containing nitrogen), such as atropine, that are used as antispasmodic drugs to treat gastrointestinal disturbances. (See also anticholinergic drugs.)

**Bell’s palsy**
The most common form of facial palsy (facial muscle weakness).

**Bence–Jones protein**
An abnormal protein found in the urine of people with multiple myeloma, which is a cancer affecting one type of cell in the bone marrow.

**bendrofluazide**
The former name for the diuretic drug bendroflumethiazide.

**bendroflumethiazide**
A thiazide diuretic drug that is used to treat hypertension (high blood pressure) and heart failure.

**bends**
The nonmedical term for decompression sickness. The term is used especially to refer to the severe bone and joint pains that are a common symptom in divers who rise to the surface too rapidly.

**benign**
A term used to describe a disease that is relatively harmless. When used to refer to tumours, benign means noncancerous tumours that do not invade or destroy local tissues and do not spread to other sites within the body.

**benign prostatic hyperplasia (BPH)**
A medical term for noncancerous enlargement of the prostate gland (see prostate, enlarged).

**Bennett’s fracture**
A fracture of the base of the thumb, which is often accompanied by partial dislocation of the joint.

**benorilate**
A nonsteroidal anti-inflammatory drug (NSAID) that contains aspirin and paracetamol. Benorilate is mainly used to relieve joint pain and stiffness in osteoarthritis and rheumatoid arthritis. Side effects of benorilate are not usually serious, but the aspirin in the drug may cause nausea, indigestion, or bleeding from the stomach lining.

**benorylate**
The former spelling of the nonsteroidal anti-inflammatory drug benorilate.
benzalkonium chloride
A preservative that is widely used in eye-drops and products such as cosmetics and mouth washes.

benzocaine
A local anaesthetic (see anaesthesia, local) commonly used as an ingredient in over-the-counter preparations for relieving the pain of conditions such as mouth ulcers and sore throat.

benzodiazepine drugs
COMMON DRUGS
SLEEPING DRUGS • Flunitrazepam • Flurazepam • Loprazolam • Lorazepam • Nitracepame • Temazepam
SEDATIVES • Alprazolam • Clorazepate • Oxazepam

A group of sedative drugs given for short periods either as sleeping drugs for insomnia or to control the symptoms of anxiety (see tranquilizer drugs). Common benzodiazepine drugs include diazepam, which is used as a tranquilizer, and nitrazepam, which is used to relieve insomnia. Benzodiazepine drugs are also used in the management of alcohol withdrawal and in the short-term control of an epileptic seizure.

HOW THEY WORK
Benzodiazepine drugs promote sleep and relieve anxiety by interfering with chemical activity in the brain and nervous system. This reduces the communication between nerve cells and depresses brain activity.

POSSIBLE ADVERSE EFFECTS
Adverse effects of benzodiazepines include excessive daytime drowsiness, dizziness, and forgetfulness. Unsteadiness and slowed reactions may also occur. If taken with alcohol, benzodiazepines may increase the alcohol’s effect to a dangerous extent.

After as little as two weeks, users of a benzodiazepine drug may become psychologically and physically dependent on the drug. For this reason, most doctors are now reluctant to prescribe the drugs unless they are absolutely necessary, and then only for a maximum of three weeks.

When benzodiazepine treatment is stopped suddenly, withdrawal symptoms, such as anxiety, restlessness, and nightmares may occur. People who have been taking benzodiazepine drugs long term need to have them gradually withdrawn over the course of several months to prevent withdrawal symptoms. Benzodiazepines are sometimes abused for their sedative effects.

benzyl peroxyde
An antiseptic agent used in the treatment of acne and fungal skin infections (see fungal infections). In acne, benzyl peroxide also works by removing the surface layer of skin, thereby unblocking sebaceous glands.

benzylpenicillin
A type of penicillin drug that is given by injection.

bereavement
The emotional reaction following the death of a loved one. The expression of grief is individual to each person, but there are recognized stages of bereavement, each of which is characterized by a particular attitude.

STAGES OF BEREAVEMENT
In the first stage of bereavement, which may last from three days to three months, there is often a feeling of numbness and an unwillingness to recognize the death. These emotions are defence mechanisms against admitting, and therefore accepting, the loss and the associated pain. Often, the reality of the death does not penetrate completely at this time, and many people continue to behave as though the dead person were still alive. Hallucinations, in which the deceased person is seen or sensed, are a common experience among the recently bereaved. This sensation can be quite comforting for some people, but others may find it disturbing.

Once the numbness wears off, the person may be overwhelmed by feelings of anxiety, anger, and despair that can develop into a depressive illness (see depression). Gastrointestinal disturbances, insomnia, malaise, agitation, and tearfulness are also common.

Gradually, but usually within two years, the bereaved person adjusts to the loss and begins to look more towards the future. This process can involve periods of pain and despair, alternating with periods of enthusiasm and interest.

SUPPORT AND COUNSELLING
Family and friends can often provide the support a bereaved person needs. Outside help is sometimes required and may be given by a social worker, health visitor, member of the clergy, or self-help group. For some people, when depression, apathy, and lethargy impede their chances of recovery, specialized counselling or psychotherapy is necessary. (See also stillbirth.)

beriberi
A nutritional disorder resulting from a lack of thiamine (vitamin B₁) in the diet. Thiamine, found in wholemeal cereals, meat, green vegetables, potatoes, and nuts, is essential for the metabolism of carbohydrates. Without it, the brain, the nerves, and the muscles (including the heart muscle) are not able to function properly. In developed countries, the illness is seen only in people who are starving or those who have an extremely restricted diet, such as alcoholics.

SYMPTOMS AND SIGNS
There are two forms of the illness: “dry” and “wet” beriberi. In dry beriberi, thiamine deficiency mainly affects the nerves and skeletal muscles. The symptoms include numbness, a burning sensation in the legs, and muscle wasting. In severe cases, the affected person becomes virtually paralysed, emaciated, and bedridden.

In wet beriberi, the main problem is heart failure (the inability of the heart to maintain efficient pumping of blood around the body). This in turn causes oedema (swelling caused by fluid accumulation) in the legs and sometimes also in the trunk and face. Other symptoms of wet beriberi include poor appetite, rapid pulse, and breathlessness. Without treatment, heart failure worsens and can lead to death.

TREATMENT
Beriberi is treated with thiamine, given either orally or by injection, which usually brings about a complete cure. A permanent improvement in diet is also required to prevent recurrence.

Bernard–Soulier syndrome
A genetic disorder in which platelets (the blood cells responsible for initiating blood clotting) do not function properly. The syndrome is characterized by abnormal bleeding in the skin and internal organs.

berry aneurysm
An abnormal swelling that occurs at the junction of arteries supplying the brain. Berry aneurysms are usually due to a congenital (present at birth) weakness in the artery wall. They may occasionally rupture, which results in a subarachnoid haemorrhage. (See also aneurysm; intracranial aneurysm.)
berylliosis
An occupational disease that is caused by the inhalation of dust or fumes containing beryllium, a metallic element that is used in high-technology industries such as nuclear energy, electronics, and aerospace. Short exposure to high concentrations of beryllium may lead to an episode of severe pneumonitis (lung inflammation). Exposure over a number of years to smaller concentrations may lead to permanent damage to the lungs and the liver.

Treatment with corticosteroid drugs can reduce damage to the lungs. In most cases, the introduction of safe working practices prevents exposure to dangerous levels of beryllium.

Best's disease
A genetic disorder in which the macula (part of the light-sensitive retina at the back of the eye) is abnormal. The disorder is congenital (present from birth) and results in progressive loss of vision.

beta-blocker drugs

**COMMON DRUGS**

**CARDIOSELECTIVE**

- Atenolol + Betaxolol
- Bisoprolol + Celiprolol + Metoprolol

**NONCARDIOSELECTIVE**

- Acebutolol + Carvedilol
- Labetolol + Nadolol + Oxprenolol + Pindolol
- Propranolol + Sotalol + Timolol

A group of drugs, also known as beta-adrenergic blocking agents, prescribed principally to treat heart and circulatory disorders such as angina pectoris (pain in the chest due to an insufficient supply of blood to the heart muscle) and hypertension (high blood pressure). The drugs block the effects of the sympathetic nervous system, which releases adrenaline (epinephrine) and noradrenaline (norepinephrine) at nerve endings known as beta receptors.

There are two types of beta receptor: beta1 and beta2. Beta1 receptors are present mainly in the heart and beta2 are found in the lungs, blood vessels, and elsewhere in the body. Certain beta-blockers (such as atenolol, bisoprolol and metoprolol) are termed cardioselective and, because they act mostly on beta1 receptors, are used principally to treat heart disease such as angina, hypertension, and cardiac arrhythmia (abnormal heartbeat). These drugs are sometimes given following a myocardial infarction (heart attack) in order to reduce the likelihood of further damage to the heart muscle.

**HOW BETA-BLOCKERS WORK**

Beta-blockers block specific sites on body tissues where neurotransmitters (chemicals released from nerve endings) bind. These sites are called beta receptors, and there are two types: beta1 receptors, found in heart tissue, and beta2 receptors, found in the lungs, blood vessels, and other tissues. At these receptors, two chemicals, adrenaline (epinephrine) and noradrenaline (norepinephrine), are released from nerve endings in the sympathetic nervous system, the part of the involuntary nervous system that enables the body to deal with stress, anxiety, and exercise. These neurotransmitters bind to beta receptors to increase the force and speed of the heartbeat, to dilate the airways to increase air flow to the lungs, and to dilate blood vessels.

Cardioselective beta-blockers bind predominantly to beta1 receptors; noncardioselective beta-blockers bind to both types. Beta-blockers slow the heart rate and reduce the force of contraction of heart muscle. These effects can be used to slow a fast heart rate and regulate abnormal rhythms.

Beta-blockers prevent attacks of angina pectoris by reducing the work performed by the heart muscle and therefore the heart’s oxygen requirement. High blood pressure is reduced because the rate and force at which the heart pumps blood into the circulation is lowered.

The effect of blocking beta receptors on muscles elsewhere in the body is to reduce the muscle tremor of anxiety and an overactive thyroid gland. Beta-blockers may help to reduce the frequency of migraine attacks by preventing the dilation of blood vessels surrounding the brain, which is what causes the headache. In glaucoma they lower pressure in the eye by reducing fluid production in the eyeball.
Other types of beta-blocker, such as oxprenolol, propranolol, and timolol, may be given to prevent migraine attacks by acting on blood vessels in the head. They are also used to reduce the physical symptoms of anxiety and to control the symptoms of thyrotoxicosis (an over-active thyroid gland). Beta-blockers such as timolol are sometimes given in the form of eye-drops to treat glaucoma; they work by lowering the fluid pressure within the eyeball. (See also the illustrated box.)

POSSIBLE ADVERSE EFFECTS
Beta-blocker drugs may reduce an individual’s capacity for strenuous exercise. They may worsen the symptoms of asthma, bronchitis, or other forms of lung disease. They may also reduce the flow of blood to the limbs, causing cold hands and feet. In addition, sleep disturbance and depression can be side effects of beta-blockers. Anyone taking beta-blockers should not suddenly stop; a severe recurrence of previous symptoms and a significant rise in blood pressure may result.

betahistine
A drug that is used in the treatment of the inner-ear disorder Ménière’s disease. Betahistine reduces the frequency and severity of the characteristic attacks of nausea and vertigo.

beta interferon
A type of interferon (a protein produced naturally by body cells) sometimes used in the treatment of multiple sclerosis.

beta-lactam antibiotics
A group of antibiotic drugs that includes the penicillins and the cephalosporins. Beta-lactam antibiotics work by altering chemical activity in bacteria, thereby killing them.

beta-lactamase
An enzyme, also known as lactamase, that inactivates antibiotic drugs such as penicillins. Bacteria that are able to produce this enzyme are therefore resistant to treatment with these kinds of antibiotic drugs.

betamethasone
A corticosteroid drug that is used in the treatment of inflammation. Betamethasone is applied to the skin as a cream to treat contact dermatitis and eczema. The drug is also prescribed as nasal spray to treat allergic rhinitis (hay fever) and is taken by mouth to treat some cases of asthma and arthritis.

Adverse effects of betamethasone are unlikely with short-term use. However, prolonged topical use of the drug can cause thinning of the skin and may aggravate any infection that has developed. Taken orally over a prolonged period or in high doses, betamethasone can cause adverse effects typical of other corticosteroid drugs.

betel nut
The seed of the tropical palm Arecaceae, which, when chewed, acts as a stimulant and digestant. Betel nut is commonly used throughout India and Southeast Asia.

Betnovate
A brand name for the corticosteroid drug betamethasone, which is used in topical preparations.

bezafibrate
A lipid-lowering drug used to reduce blood cholesterol levels.

bezoar
A ball of food and mucus, vegetable fibre, hair, or other indigestible material that is composed of hair, may form in the stomachs of children or emotionally disturbed adults who nibble at, or pull out and swallow, their hair.

Symptoms include loss of appetite, constipation, nausea and vomiting, and abdominal pain. If trichobezoars pass into the intestines, they may cause a blockage (see intestine, obstruction of). Bezoars can be removed by endoscopy (a procedure in which a flexible viewing tube is passed down the digestive tract) or by conventional surgery.

bi-
A prefix meaning two or twice, as in bilateral (two-sided).

bicarbonate of soda
See sodium bicarbonate.

biceps muscle
The name that is given to any muscle that originates as two separate parts, which then fuse. The term biceps muscle is commonly used to refer to the biceps brachii muscle of the upper arm, which bends the arm at the elbow and rotates the forearm. Another example of a biceps muscle is the biceps femoris muscle, located at the back of the thigh, which bends the leg at the knee and extends the thigh.

bicorne
The term that is used to describe an abnormally shaped uterus (womb) that divides into two halves in its upper part. Bicornuate literally means “having two horns”.

bicusp di
A term meaning to have two cusps (curved, pointed structures). Bicuspid describes certain heart valves and is used as an alternative name for a premolar tooth (see teeth).

bifocal
A spectacle lens with two different focal lengths. Glasses that have bifocal lenses make corrections both for close and for distant vision. (See also myopia; hypermetropia.)

biguanides
Oral hypoglycaemic drugs (see hypoglycaemics, oral) used in the treatment of type 2 (non-insulin-dependent) diabetes mellitus. Metformin, which is the only available type of biguanide drug, reduces the production of glucose...
(sugar) in the liver and also increases the uptake of glucose by the body’s cells. (See also antidiabetic drugs.)

bilateral

A term that means affecting both sides of the body, or affecting both organs if they are paired (for example, both ears in bilateral deafness).

bile

A greenish-brown alkaline liquid that is secreted by the liver. Bile carries away waste products formed in the liver and also helps to break down fats in the small intestine for digestion.

The waste products in bile include the pigments bilirubin and biliverdin, which give bile its greenish-brown colour; bile salts, which aid in the breakdown and absorption of fats; and cholesterol. Bile passes out of the liver through the bile ducts and is then concentrated and stored in the gallbladder. After a meal, bile is expelled and the duodenum (the first section of the small intestine) via the common bile duct. Most of the bile salts are later reabsorbed into the bloodstream to be recycled by the liver into bile. Bile pigments are excreted in the faeces. (See also biliary system; colestyramine.)

bile duct

Any of the ducts through which bile is carried from the liver to the gallbladder and then on to the duodenum (the first section of the small intestine).

The bile duct system forms a network of tubular canals. Canaliculi (small canals) surround the liver cells and collect the bile. The canaliculi join together to form ducts of increasing size. The ducts emerge from the liver as the two hepatic ducts, which join within or just outside the liver to form the common hepatic duct. The cystic duct branches off to the gallbladder; from this point the common hepatic duct becomes the common bile duct and leads into the duodenum. (See also biliary system.)

bile duct cancer

See cholangiocarcinoma.

bile duct obstruction

A blockage or constriction of a bile duct (see biliary system). Obstruction of a bile duct results in the accumulation of bile in the liver (cholestasis) and jaundice (yellowing of the skin and the whites of the eyes) due to a buildup of bilirubin (bile pigment) in the blood. Prolonged obstruction of the bile duct can lead to secondary biliary cirrhosis, which is a serious form of liver disease.

CAUSES

The most common cause of bile duct obstruction is gallstones. Other causes include a tumour affecting the pancreas (see pancreas, cancer of) and cancer that has spread from elsewhere in the body. Cholangiocarcinoma (cancer of the bile ducts) is a rare cause of a blockage. Bile duct obstruction is known to be a rare side effect of certain drugs. It may also be caused by cholangitis (inflammation of the bile ducts), trauma (such as injury during surgery), and, rarely, by flukes or worms.

SYMPTOMS

Bile duct obstruction causes “obstructive” jaundice, which is characterized by pale-coloured faeces, dark urine, and a yellow skin colour. There may also be itching. Other symptoms of bile duct obstruction depend on the cause of the blockage; for example, there may be abdominal pain (with gallstones) or weight loss (with cancer).

TREATMENT

Treatment depends on the cause, but surgery is sometimes necessary. Gallstones may be removed by means of ERCP (an X-ray procedure that uses a viewing tube called an endoscope with instruments attached to it).

bilharzia

Another name for the tropical parasitic disease schistosomiasis.

biliary atresia

A rare congenital disorder in which some or all of the bile ducts fail to develop or develop abnormally. As a result, bile is unable to drain from the liver (see cholestasis). Unless the atresia can be treated, secondary biliary cirrhosis (a serious liver disorder) will develop and may prove fatal. Symptoms include jaundice, usually beginning a week after birth, and the passing of dark urine and pale faeces. Treatment is by surgery to bypass the ducts. If this fails, or if the jaundice recurs, a liver transplant is required.

biliary cirrhosis

An uncommon form of liver cirrhosis that results from problems with the bile ducts. There are two types of biliary cirrhosis. One is an autoimmune disorder and is known as primary biliary cirrhosis. Secondary biliary cirrhosis occurs as a result of a longstanding blockage. In both types of the condition, liver function is impaired due to cholestasis (accumulation of bile in the liver).

Primary biliary cirrhosis principally affects middle-aged women and seems to be linked with a malfunction of the immune system. In this disorder, the bile ducts within the liver become inflamed and are destroyed. Symptoms include itching, jaundice (a yellowish discoloration of the skin and the whites of the eyes), an enlarged liver, and sometimes abdominal pain, fatty diarrhoea, and xanthomatosis (deposits of fatty material under the skin). Osteoporosis may also develop. Symptoms of liver cirrhosis and liver failure may occur after a few years. Drugs can be used to minimize complications and to relieve symptoms such as itching, but a liver transplant is the only cure.

Secondary biliary cirrhosis results from prolonged bile duct obstruction or biliary atresia (abnormal bile ducts). Symptoms and signs include abdominal pain and tenderness, liver enlargement, fevers and chills, and sometimes blood abnormalities. Treatment is the same as for bile duct obstruction.

biliary colic

A severe pain in the upper right quadrant of the abdomen that is usually caused by the gallbladder’s attempts to expel gallstones or by the movement of a stone in the bile ducts. The pain may be felt in the right shoulder (see referred pain) or may penetrate to the centre of the back. Episodes of biliary colic often last for several hours and may recur, particularly after meals.

Injections of an analgesic drug and anti-spasmodic drug may be given to relieve the colic. Tests such as cholecystography or ultrasound scanning can confirm the presence of gallstones, in which case cholecystectomy (surgical removal of the gallbladder) may be performed.

biliary system

The organs and ducts in which bile is formed, concentrated, and carried from the liver to the duodenum (the first part of the small intestine). Bile is secreted by liver cells and collected by a network of bile ducts that carry the bile out of the liver via the hepatic duct. The cystic duct branches off the hepatic duct and leads to the gallbladder, where the bile is concentrated and stored. Beyond this
junction, the hepatic duct becomes the common bile duct, which opens into the duodenum at a controlled orifice known as the ampulla of Vater. The presence of fat in the duodenum following a meal prompts the secretion of a hormone that opens the ampulla of Vater. This causes contraction of the gallbladder, which squeezes stored bile into the duodenum.

The main disorders affecting the biliary system are gallstones, congenital biliary atresia and bile duct obstruction. (See also gallbladder, disorders of.)

**biliiousness**
A condition in which bile is brought up to the mouth from the stomach. Biliiousness is also used as a nonmedical term for nausea and vomiting.

**bilirubin**
The main pigment in bile. Bilirubin is produced by the breakdown of haemoglobin, the pigment in red blood cells. Very high levels of bilirubin cause the yellow pigmentation of jaundice. Products formed from the breakdown of bilirubin make faeces brown.

**Billings’ method**
A technique (also known as the mucus inspection method) in which a woman notes changes in the characteristics of mucus produced by her cervix. The technique is employed to predict ovulation for the purposes of contraception or family planning.

**Billroth’s operation**
A type of partial gastrectomy in which the lower part of the stomach is surgically removed. Previously used in the treatment of peptic ulcers, the operation
is now rarely performed due to the introduction of newer, less invasive treatment, often using antibiotic drugs.

**Binet test**
The first intelligence test that attempted to measure higher mental functions rather than more primitive abilities. The Binet test was devised in 1905.

**binge–purge syndrome**
An alternative term for the eating disorder bulimia.

**bio-**
A prefix describing a relationship to life, as in biology, the science of life.

**bioavailability**
The proportion of a drug that reaches the target organs and tissues, usually expressed as a percentage of the dose administered. Intravenous administration of a drug results in 100 per cent bioavailability because the drug is injected directly into the bloodstream. Drugs taken orally have a much lower bioavailability. Preparations that have equal bioavailabilities are described as bioequivalent. (See also drug.)

**biochemistry**
A science that studies the chemistry of living organisms, including human beings. The human body is made up of millions of cells that require nutrients and energy, and which grow, multiply, and die. The chemical processes that are involved in providing these cells with energy, eliminating their wastes, repairing damage, promoting cell growth, and causing both normal and abnormal cell division are all studied by biochemists, the specialists in the field.

Life is maintained by a huge number of chemical reactions that are carried out inside cells. These reactions link together in a complex way and together make up the metabolism of the body. The reactions that produce energy and breakdown food and body structures are termed catabolism; those that build up body structures and store food are termed anabolism. Overall regulation of these chemical processes is a principal function of hormones which are secreted into the bloodstream by the endocrine glands; regulation of individual reactions is carried out by enzymes (substances that promote biochemical reactions).

Certain vital chemical processes take place in every single cell in the body. Other, more specific, chemical processes are confined to specialized cells that make up the tissues of particular organs. For example, liver cells store and chemically modify the digestion products of food; kidney cells help to control the amounts of various substances (such as certain minerals) in the blood, as well as regulating the total amount of fluid in the body.

A constant interchange of substances occurs between the cell fluids and the blood and urine. Biochemists can learn a great deal about the chemical changes occurring inside the body’s cells by regularly taking, and comparing, precise measurements of the various minerals, gases, enzymes, hormones, and proteins in the different fluids of the body.

Such biochemical tests may be used to make, or to confirm, a diagnosis, as well as to screen for a particular disease and to monitor its progress. The most commonly used biochemical tests are performed on blood; such tests include liver function tests and kidney function tests. Biochemical tests can also be performed on urine (see urinalysis) as well as on all other body fluids.

**bioengineering**
See biomechanical engineering.

**biofeedback training**
A technique in which a person uses information about a normally unconscious body function, such as blood pressure, to gain conscious control over that function. This training may help to treat stress-related conditions, including certain types of hypertension (high blood pressure), anxiety, and migraine.

**HOW IT IS DONE**
The doctor connects the patient to a recording instrument that can measure one of the unconscious body activities, such as blood pressure, heart rate, muscle tension, the quantity of sweat on the skin, brain waves, or stomach acidity. The patient receives information (feedback) on the changing levels of these activities from changes in the instrument’s signals, for example a flashing light or sound changing tone.

After some experience with the technique, the person starts to become aware of how he or she is feeling whenever there is a change of signal. By using relaxation techniques, the person learns to change the signals by conscious control of the function. Once acquired, control can be exercised without the instrument.

**biological clock**
A popular term for the inherent timing mechanism that supposedly controls physiological processes and cycles in living organisms. (See also biorhythms.)

**biology**
The scientific study of all living organisms, including animals, plants, and microorganisms (single-celled organisms). Biology involves the study of the structure and functions of living organisms, their relationships with other organisms, and the ways in which they interact with their environment. (See also biochemistry; microbiology.)

**biomechanical engineering**
A discipline that applies engineering methods and principles to the body to explain how it functions and to treat disorders. Applications include the design of artificial joints and heart valves, pacemakers, and kidney dialysis machines.

**biopsy**
A diagnostic test involving the removal of small amounts of tissue or cells from the body for microscopic examination. A biopsy is an accurate method of diagnosing many illnesses, including cancer. Microscopic examination of tissue (see histology) or of cells (see cytology) usually gives a correct diagnosis.

**HOW IT IS DONE**
There are several types of biopsy. In excisional biopsy, the whole abnormal area is removed for study. Incisional biopsy involves cutting away a small sample of skin or muscle for analysis. In a needle biopsy, a needle is inserted through the skin and into the organ or tumour to be investigated. Aspiration biopsy uses a needle and syringe to remove cells from a lump (see box). Guided biopsy uses ultrasound scanning or CT scanning to locate the area of tissue to be biopsied and follow the progress of the needle. In endoscopic biopsy, an endoscope (viewing tube) is passed into the organ to be investigated and an attachment is used to take a sample from the lining of accessible hollow structures such as the lungs, stomach, and bladder. In an open biopsy, a surgeon opens a body cavity to reveal a diseased organ or tumour and removes a sample. Prompt analysis, in some cases by frozen section (in which the tissue is frozen and thinly sliced), can enable the surgeon to decide whether to remove the entire diseased area immediately.
ASPIRATION BIOPSY

1 A fine needle attached to a syringe is inserted into the lump, and fluid or cells are sucked out to be examined under a microscope. The syringe can be held in a device that withdraws the plunger. Usually no anaesthetic is necessary, but local anaesthetic may be sometimes be used.

2 Before examination any fluid may be spun at high speed in a centrifuge and a small amount placed on a slide.

3 The cells are then fixed (preserved) and finally stained for viewing. The cytologist examines individual cells for abnormalities, paying particular attention to the size, shape, and structure of the nucleus.

OBTAINING RESULTS
Biopsy samples are analysed by staining; dyes are used to show up structures or identify constituents such as antibodies or enzymes. Tissue may be tested with specific antibodies in the investigation of infection and inflammation. In some cases, a tissue culture (cultivation of tissue cells in a growing medium) may be required. (See also endometrial biopsy; excision; kidney biopsy; liver biopsy.)

biorhythms
A term used to describe physiological functions that vary in a rhythmic way (for example, the menstrual cycle, which repeats approximately every 28 days in fertile women).

Most biorhythms are based on a daily, or circadian (24-hour), cycle. Our bodies are governed by an internal clock, which is itself regulated by hormones (chemicals released into the circulation by endocrine glands). Periods of sleepiness and wakefulness may be affected by the level of melatonin secreted by the pineal gland in the brain. Release of melatonin is stimulated by darkness and suppressed by light. Cortisol, a hormone that is secreted by the adrenal glands, also reflects sleeping and waking states, being low in the evening and high in the morning.

When the normal regular division between night and day is distorted by air travel to a distant time zone, the body’s internal clock is disrupted and the result is jet-lag.

biosynthesis
The formation of chemical compounds by a living organism.

biotechnology
The use of living organisms such as bacteria in industry and science (for example, in drug production).

bioterrorism
The use of disease-causing organisms as an act of violence and intimidation. Examples of such organisms are anthrax spores and the smallpox virus.

biotin
A vitamin of the B complex (see vitamin B complex) that is essential for the breakdown of fats.

biphosphonate drugs
See biphosphonate drugs.

bipolar disorder
An illness, commonly known as manic-depressive illness, that is characterized by swings in mood from severe depression to overexcitability and vice versa.

bird-fancier’s lung
A form of allergic alveolitis (inflammation of the lungs) caused by inhalation of dust particles from bird droppings. The disease is also sometimes known as pigeon-fancier’s lung.

birth
See childbirth.

birth canal
The passage through the pelvis, running from the cervix (the neck of the womb) to the vaginal opening, through which the baby passes during childbirth.

birth control
Limitation of the number of children born, either to an individual or within a population. Family planning allows men and women to choose if and when to have children; contraception can prevent unwanted pregnancies.

birth defects
Abnormalities that are obvious at birth or detectable early in infancy. Also called congenital defects, they encompass both minor abnormalities, such as birthmarks, and serious disorders such as spina bifida (failure of the spinal column to close properly). Birth defects may occur as the result of a variety of factors, but in most cases no obvious cause can be found.

CHROMOSOME DEFECTS
Some children are born with more or fewer than the normal 23 pairs of chromosomes (threadlike structures in the cell nuclei that carry the genetic information for normal development). Down’s syndrome, a condition in which there is an extra copy of one of the chromosomes, is one of the most common chromosomal abnormalities.

GENETIC OR HEREDITARY DEFECTS
These may be inherited from one or both parents (see gene; genetic disorders). Genetic defects obvious at birth include albinism (lack of normal pigmentation in the skin, hair, and eyes) and achondroplasia (abnormally short stature).

DRUGS AND OTHER HARMFUL AGENTS
Certain drugs and chemicals (known as teratogens) can damage the fetus if the mother takes or is exposed to them during early pregnancy. Teratogenic drugs include thalidomide (now rarely prescribed) and isotretinoin, which is used in the treatment of severe acne. Alcohol can affect the development of the brain and face (see fetal alcohol syndrome).

IRRADIATION
Irradiation of the embryo at an early stage of development, for example, if a woman is X-rayed before she is aware of her pregnancy, can cause abnormalities.

INFECTIONS
If a woman contracts certain infections during pregnancy, there is a chance that
they may cause birth defects. For example, rubella (German measles) in early pregnancy can cause fetal abnormalities, including deafness, cataract (clouding of the lens of the eye), and heart disease. Toxoplasmosis (infection with a parasite found in cats’ faeces), can also be passed on to the fetus, causing damage to the eyes, liver, and other organs.

**OTHER COMMON DEFECTS**
Abnormalities in the embryo’s development can damage the brain and spinal cord, causing defects such as spina bifida and hydrocephalus (a buildup of fluid in the brain). In congenital heart disorders (see heart disease, congenital), there is a structural abnormality in the heart that may interfere with normal blood flow. Cleft lip and palate result from a failure of the two sides of the fetal face and palate to join completely.

**DETECTION**
Ultrasound scanning and blood tests during pregnancy can identify women at high risk of having a baby with a birth defect. Further tests such as chorionic villus sampling, amniocentesis, or fetoscopy may then be carried out.

**PREVENTION**
Some birth defects can be prevented, or the risks minimized; for example, by rubella immunization before pregnancy or avoiding teratogens during pregnancy.

**birthmark**
An area of discoloured skin that is present at birth, or appears very soon afterwards. Birthmarks include moles, freckles, and other types of melanocytic naevi (a variety of flat, brown to blue-grey skin patches), strawberry marks (bright red, usually protuberant areas), and port-wine stains (purple-red, flat, often large areas). The latter two are types of haemangiomata (malformation of blood vessels). Strawberry marks often increase in size in the first year, but most disappear after the age of nine. Port-wine stains seldom fade, but some of them can be reduced by laser treatment during adulthood.

**birthpool**
A pool of warm water in which a woman can sit to help relieve pain during labour (see childbirth).
**immunoglobulin**, if there is any possibility that the animal could be infected with the rabies virus. (See also bites, human; insect bites; snake bites; spider bites; venomous bites and stings.)

**bites, human**
Wounds that are caused by one person biting another. Human bites rarely result in serious tissue damage or blood loss; but infection from any microorganisms in the mouth is likely, particularly if the bite is deep. For example, there is a risk of tetanus infection, and transmission of hepatitis B, herpes simplex, and HIV through a human bite is a theoretical hazard.

**Bitot’s spots**
Grey, foamy patches that appear on the conjunctiva (the mucous membrane covering the front of the eye). Bitot’s spots, which are made up of keratinized (horny) cells, are associated with vitamin A deficiency.

**black death**
The medieval name for bubonic plague, which in past epidemics killed 50 per cent of its victims. One feature of the disease is bleeding under the skin, causing bluish-black bruises, hence the name.

**black eye**
A dark discoloration of the skin around the eye, usually following an injury. The discoloration is due to blood collecting under the skin (see bruise). Because the skin around the eye is loose and thin, bruising is darker than on other parts of the body. A cold compress held over the eye can help to relieve the discomfort.

**blackhead**
Also called a comedo, a semi-solid, black-capped plug of keratin and sebum that blocks the outlet of a sebaceous (oil-forming) gland in the skin. Blackheads occur most commonly on the face, chest, shoulders, and back, and they are associated with increased sebaceous gland activity. They are one of the features of most types of acne.

**blackout**
A common term for loss of consciousness (see fainting).

**black teeth**
See discoloured teeth.

**blackwater fever**
An occasional, life-threatening complication of falciparum malaria (the most dangerous form of malaria). Symptoms include loss of consciousness, fever, vomiting, and very dark urine (due to pigment from destroyed red blood cells being filtered into the urine).

**bladder**
The hollow, muscular organ situated in the lower abdomen that acts as a reservoir for urine. The bladder lies within,

---

**ANATOMY OF THE BLADDER**

The bladder is a hollow organ that holds urine. It is situated behind the pubic bone and is protected by the pelvis. The ureters carry urine to the bladder from the kidneys. When the sphincter at the lowest part of the bladder is relaxed, urine is passed into the urethra and out of the body.

---

**Intravenous urography**
This special X-ray technique shows clearly the position of the bladder in the pelvis.
and is protected by, the pelvis. The average adult bladder can hold about 0.5 litres of urine before the need to pass urine is felt.

The bladder walls consist of muscle and an inner lining. Two tubes called ureters carry urine to the bladder from the kidneys. At the lowest point of the bladder is the opening into the urethra (outflow tube), known as the bladder neck. This is normally kept closed by a ring of muscle (the urethral sphincter).

**FUNCTION**

The bladder’s function is to collect and store urine until it can be expelled from the body. Full control over bladder function takes several years to develop. In infants, emptying of the bladder is an entirely automatic, or reflex, reaction. When the bladder fills with urine and is stretched beyond a certain point, nerve signals are sent to the spinal cord. Signals from the spinal cord then cause the urethral sphincter to relax and the principal bladder muscle to contract, thereby expelling urine via the urethra.

Children develop complete bladder control at varying ages. Most are dry at night by the age of five years, but some take longer (see enuresis, nocturnal).

Defective bladder function, leading to problems such as incontinence (see incontinence, urinary) and urinary retention, can have a variety of causes. (See also bladder disorders box.)

**bladder cancer**

See bladder tumours.

**bladder outflow obstruction**

See prostate, enlarged; urinary retention.

**bladder tumours**

Growths originating in the inner lining of the bladder. Papillomas (small wart-like growths) often recur and eventually become cancerous. Other, more malignant, growths may extend not only into the bladder cavity, but also through the bladder wall to involve nearby organs, such as the colon, rectum, prostate gland, or uterus. Bladder cancer is more common in smokers and workers in the dye and rubber industries.

**SYMPTOMS**

Haematuria (blood in the urine) is the main symptom of bladder cancer. A tumour may obstruct the point at which a ureter enters the bladder, causing back pressure and pain in the kidney region, or the urethral exit, causing difficulty in passing, or retaining, urine.

**DIAGNOSIS AND TREATMENT**

Bladder tumours are diagnosed using cystoscopy (passage of a viewing tube up the urethra into the bladder) and biopsy (tissue sampling for microscopic analysis) of the abnormal area.

If they are small, the tumours can be treated by heat or removed surgically. Tumours tend to recur within the bladder, so regular follow-up cystoscopy is usually necessary. Bladder tumours that have spread through the bladder wall may be treated by radiotherapy or by the removal of part or all of the bladder.

**DISORDERS OF THE BLADDER**

The most important causes of bladder problems are infection, tumours, calculi (stones), and impairment of the bladder’s nerve supply.

**Infection**

Bacterial infection of the bladder, which causes inflammation of the bladder wall (see cystitis), is particularly common in women. The short female urethra makes it relatively easy for bacteria to enter from outside the body. In men, infection is usually associated with obstruction of urine flow from the bladder by, for example an enlarged prostate gland (see prostate, enlarged) or bladder tumours.

**Tumours**

Bladder tumours may be cancerous or noncancerous and are more common in men than in women. They are usually painless in the early stages, the first symptoms being blood in the urine (see haematuria) or urinary retention, in which the bladder cannot be emptied. All bladder tumours need careful follow-up because, left untreated, noncancerous bladder tumours may become cancerous.

**Calculi**

Bladder stones (see calculus, urinary tract) are mostly caused by the crystallization of substances, such as calcium, in the urine. They mainly affect men and usually result from a longstanding urinary tract infection and/or incomplete emptying of the bladder.

**Nerve impairment**

Damage to the nerves controlling the bladder can prevent normal bladder function and lead either to incontinence (see incontinence, urinary) or to urinary retention. The most common cause is spinal-cord injury or tumours. Bladder control can be affected by nerve degeneration in conditions such as diabetes mellitus, multiple sclerosis, or dementia.

**Other disorders**

An unstable or irritable bladder is a common condition, particularly in women, in whom the bladder wall is especially sensitive to being stretched. Weakness of the muscles at the bladder neck, causing stress incontinence, is also common in women, particularly after childbirth. Tension or anxiety can cause frequent urination. In children, delayed bladder control (see enuresis, nocturnal) is most often due to delayed maturation of the nervous system. Injury to the bladder is rare but may occur if the pelvis is fractured when the bladder is full.

**Blalock shunt**

A surgical procedure in which a connection is made between one of the two subclavian arteries (which normally deliver oxygen-rich blood to the neck and arms) and one of the pulmonary arteries (which carry blood from the right side of the heart to the lungs for oxygenation). The shunt is used as a temporary treatment for congenital heart disorders, such as tetralogy of Fallot, in which oxygen-depleted blood is diverted back to the heart before it reaches the lungs. The shunt redirects the blood to the lungs, where it is oxygenated, before being sent back to the body. This shunt is usually temporary and is intended to allow time for the child to grow and develop other treatments or procedures, such as surgery to correct the heart defect, to become possible. Blalock shunts are performed by a cardiac surgeon and typically involve opening the chest and operating on the heart and blood vessels.

**INVESTIGATION**

Various methods are used to investigate bladder disorders. Urinary tract infection is diagnosed by tests on a sample of urine. The bladder can be viewed directly by cystoscopy (insertion of a viewing tube). Ultrasound scanning is often performed, particularly if stones are suspected. X-ray procedures include micturating cystourethrography, which normally shows only the bladder and urethra, and intravenous urography, which shows the whole urinary tract except the urethra. Urodynamics, which may involve X-rays, are studies carried out to investigate bladder control problems. Cystometry measures bladder capacity in relation to pressure.
oxygen-depleted blood to the lungs. The improved blood oxygen levels allow the child to survive and grow until corrective surgery is possible.

**bland diet**
An easily digested diet that is free from possible irritants to the digestive tract, such as spicy foods and raw vegetable fibre. A bland diet is often advised following abdominal surgery or for people with gastrointestinal disorders.

**blast cell**
An immature cell that later develops into a specialized cell. For example, white blood cells begin as blast cells in the bone marrow and eventually form different types of mature white blood cells that are then released into the bloodstream. The presence of certain blast cells may indicate illness. For example, blast cells are found in the blood in acute leukaemia (see leukæmia, acute). (See also stem cell.)

**blast injury**
Tissue damage due to the effects of blast waves generated by an explosion. The eardrums and digestive tract are particularly at risk; the air within the ear and hollow parts of the gut transmits the waves in all directions, often resulting in severe damage.

**blastocyst**
A cell cluster that develops from a fertilized ovum and grows into an embryo (see fertilization).

**blastomycosis**
A type of fungal infection that can affect the lungs and other internal organs.

**bleaching, dental**
A cosmetic procedure for lightening certain types of discoloured teeth, including nonvital “dead” teeth. The surface of the affected tooth is painted with oxidizing agents and then exposed to ultraviolet light. A home procedure, consisting of trays loaded with bleaching material, is also available but is slower.

**bleb**
Another term for a blister.

**bleeding**
Loss of blood from the circulatory system, which may be caused by damage to the blood vessels or by a bleeding disorder. Bleeding may be visible (external) or concealed (internal). Rapid loss of more than 10 per cent of the blood volume can cause symptoms of shock, with fainting, pallor, and sweating.

The speed with which blood flows from a cut depends on the type of vessel damaged: blood usually oozes from a capillary, flows from a vein, and spurts from an artery. If an injury does not break open the skin, the blood collects around the damaged blood vessels just beneath the skin and forms a bruise.

Any lost blood that mixes with other body fluids such as sputum (phlegm) or urine will usually be noticed quite readily; bleeding from the lining of the digestive tract may make vomit or faeces appear darker than usual. Internal bleeding may not be discovered until severe anaemia develops.

**bleeding disorders**
A group of conditions characterized by bleeding in the absence of injury or by abnormally prolonged and excessive bleeding following injury. Bleeding disorders are the result of defects in the mechanisms by which bleeding is normally stopped: the coagulation of blood, the plugging of damaged blood vessels by platelets (the smallest type of blood cell), and the constriction of blood vessels (see blood clotting).

Defects in the coagulation system tend to cause deep bleeding into the gastrointestinal tract, muscles, and joint cavities. Defects of the platelets or blood vessels usually cause superficial bleeding into the skin, the gums, or the lining of the intestine or the urinary tract.

**COAGULATION DEFECTS**
These disorders are usually due to a deficiency of or abnormality in the enzymes (coagulation factors) that are involved in blood clotting. Clot formation is very slow and the clots are weak and do not seal blood vessels securely. Coagulation defects may be congenital (present at birth) or may be acquired later in life.

**Conagenal**
The main congenital coagulation defects are haemophilia, Christmas disease, and von Willebrand’s disease. In all of these, one coagulation factor is either absent from the blood or present only in small amounts. Haemophilia and Christmas disease are similar disorders, resulting from deficiencies of two different coagulation factors: factor VIII and factor IX respectively. Inheritance of these disorders is sex-linked (see genetic disorders) and normally only males are affected. Von Willebrand’s disease is an inherited disorder in which there is a platelet and a factor VIII defect; it affects both sexes about equally.

Individuals with one of these disorders may suffer from bruising, internal bleeding, abnormally heavy menstrual periods, and excessive bleeding from wounds. In severe cases, there may be recurrent bleeding into joints, such as the knee.

**Acquired** Acquired defects of blood coagulation factors may develop at any age due to severe liver disease, digestive system disorders that prevent the absorption of vitamin K (which is needed to make certain coagulation factors), or the use of anticoagulant drugs.

Disseminated intravascular coagulation (DIC) is an acquired disorder that is complex and serious. It may be the result of an underlying infection or of a cancerous tumour. In this condition, platelets accumulate and clots develop within small blood vessels; coagulation factors are used up faster than they are able to be replaced, and severe bleeding may result.

**Tests and treatment** Coagulation disorders are investigated by blood-clotting tests. If such a disorder is severe, it is treated by replacing the missing factor. Factors are extracted from fresh blood or from fresh frozen plasma, or genetically engineered factors may be used. Paradoxically, anticoagulants are sometimes used to suppress excess clotting activity in DIC, which results in a reduction in bleeding.

**PLATELET DEFECTS**
Bleeding may occur if there are too few platelets in the blood, a condition called thrombocytopenia. The main feature of this disorder is surface bleeding into the skin and gums, and there are multiple small bruises.

Occasionally, the platelets are present in normal numbers but function abnormally, causing bleeding. Platelet defects may be inherited, they may be associated with the use of certain drugs (including aspirin), or arise as a complication of certain bone marrow disorders such as leukaemia. Platelets can be destroyed by autoimmune disorders that may have been triggered by an infection or by drug treatment.

Platelet defects are investigated by blood tests. Bleeding due to a lack of platelets may be treated with intravenous platelet transfusions. In some cases, oral corticosteroid drugs are prescribed.
BLOOD VESSEL DEFECTS
In rare cases, abnormal bleeding is the result of a blood-vessel defect or scurvy (a disorder that is caused by a deficiency of vitamin C). Elderly people and patients on long-term courses of corticosteroid drugs may suffer mild abnormal bruising due to loss of skin support to the smallest blood vessels. Treatment is rarely required in these cases.

bleeding, dysfunctional uterine
Abnormal bleeding from the uterus (womb) with no obvious cause. (See also menorrhagia).

bleeding gums
See gingivitis.

bleeding, occult
Bleeding that is not obvious to the naked eye (such as that which occurs within the intestine) and that may be detected only by tests. (See also occult blood, faecal).

bleeding time
An assessment of the functioning of platelets (the tiny cell fragments within the blood that play a vital role in blood clotting) by measuring the speed at which they form plugs to stem bleeding from damaged blood vessels. Two small cuts are made in the forearm and the time taken for the bleeding from these cuts to stop is recorded.

blepharitis
Inflammation of the eyelids, with redness, irritation, and scaly skin at the lid margins. Blepharitis may cause burning and discomfort in the eyes and eyelids or crusts on the lashes. The condition is common, tends to recur, and is sometimes associated with dandruff of the scalp or eczema. Severe blepharitis may lead to corneal ulcers. In many cases, treatment of associated dandruff with an antifungal shampoo will result in improvement of the blepharitis.

blepharoplasty
A cosmetic operation to remove drooping, wrinkled skin from the upper and/or lower eyelids. Blepharoplasty is usually performed under local anaesthetic (see anaesthesia, local).

blepharospasm
Prolonged, involuntary contraction of one of the muscles controlling the eyelids, causing them to close. It may be due to photophobia (abnormal sensitivity of the eyes to light), to damage to the cornea (the transparent dome that forms the front part of the eyeball), or to dystonia (abnormal muscle rigidity), for which botulinum toxin (a muscle relaxant) treatment is highly effective.

blind loop syndrome
A condition in which a redundant area or dead end (blind loop) in the small intestine becomes colonized with bacteria. The bacteria break down bile salts, which are necessary for the absorption of fat and certain vitamins. This results in poor absorption of fats and abnormal faeces. Blind loop syndrome may result from surgery or a stricture (narrowing) in the intestine as a result of a disorder such as Crohn’s disease. It is characterized by steatorrhoea (pale yellow, foul-smelling, fatty, bulky faeces that are difficult to flush away), tiredness, and weight loss. Antibiotic drug treatment is usually effective, but the condition may recur if the underlying abnormality cannot be corrected.

blindness
Inability to see. Definitions of blindness and partial sight vary. In the UK, blindness is defined as a corrected visual acuity of 3/60 or less, or a visual field of no more than 20 degrees, in the better eye.

CAUSES
Loss of vision may result from injury to, or disease or degeneration of, the eyeball; the optic nerve or the nerve pathways that connect the eye to the brain; or the brain itself.

Blepharoplasty involves the removal of a crescent-shaped section of skin and underlying fat from each eyelid.

Appearance before (top) and after (bottom)
the optic nerve, which may be caused by diabetes mellitus, hypertension, a tumour, injury, or temporal arteritis (inflammation of arteries in the scalp); optic neuritis (inflammation of the optic nerve that may occur in multiple sclerosis); the toxic (poisonous) effects of certain chemicals; and certain nutritional deficiencies.

**Brain** Nerve impulses from the retina eventually arrive in a region of the cerebrum (the main mass of the brain) called the visual cortex. Blindness can result if there is pressure on the visual cortex from a brain tumour or a brain haemorrhage, or if the blood supply to the visual cortex has been reduced following a stroke.

**DIAGNOSIS AND TREATMENT** It is frequently possible to detect the cause of blindness by direct examination of the eye, using such techniques as ophthalmoscopy, slit-lamp examination, and tonometry. The conduction of nerve impulses can be measured by means of evoked responses. Treatment of blindness depends on the underlying cause. If the loss of vision cannot be corrected, the patient may then be registered as legally blind or partially sighted, and will become eligible for certain benefits and services. (See also eye; vision, loss of.)

**blind spot**

The small, oval-shaped area on the retina of the eye where the optic nerve leaves the eyeball. The area is not sensitive to light because it has no light receptors (nerve endings responsive to light). The blind spot can also be used to describe the part of the visual field in which objects cannot be detected.

**blister** A collection of fluid beneath the outer layer of the skin that forms a raised area. The fluid is serum that has leaked from blood vessels in underlying skin layers after minor damage; it provides protection for the damaged tissue. Common causes of blisters are burns and friction. Blisters may also occur in some skin diseases, including eczema, epidermolysis bullosa, impetigo, erythema multiforme, pemphigus, pemphigoid, and dermatitis herpetiformis, and in some types of porphyria. Small blisters develop in chickenpox, herpes zoster (shingles), and herpes simplex. Blisters are generally best left intact; large or unexplained blisters need medical attention.

**bloating** Distension of the abdomen, commonly due to wind in the stomach or intestine (see abdominal swelling).

**blocked nose** See nasal congestion; nasal obstruction.

**blocking** The inability to express true feelings or thoughts, usually due to emotional or mental conflict. In Freudian-based psychotherapy, blocking is thought to result from the repression of painful emotions in early life. A very specific form of thought blocking occurs in schizophrenia: trains of thought are persistently interrupted involuntarily to be replaced by unrelated new ones.

**blood** The red fluid that circulates in the body’s veins, arteries, and capillaries. Blood is pumped by the heart via the arteries to the lungs and all other tissues and is then returned to the heart in veins (see circulatory system). Blood is the body’s transport system and also plays an important role in the defence against infection. An average adult has about 5 litres of blood.

Almost half the blood’s volume consists of blood cells, including red blood cells (erythrocytes), which carry oxygen to the tissues; white blood cells (leukocytes), which defend the body against infection; and platelets (thrombocytes), which are involved in blood clotting. The rest of the blood volume is made up of plasma, a watery, straw-coloured fluid containing proteins, sugars, fats, salts, and minerals.

Nutrients are transported in the bloodstream to the tissues after absorption from the intestinal tract or after release from storage depots such as the liver. Waste products, including urea and bilirubin, are carried in the plasma to the kidneys and liver respectively.

Plasma proteins include fibrinogen, which is involved in blood clotting; immunoglobulins (also called antibodies) and complement, which are part of the immune system; and albumin. Hormones are also transported in the bloodstream to their target organs.

**blood–brain barrier** A system of tight, impermeable junctions between the cells that form the walls of the capillaries (tiny blood vessels) within the central nervous system. The blood–brain barrier has a protective function; it allows only certain substances and drugs in the bloodstream to gain access to the central nervous system, especially to the brain.

**blood cells** Cells, also called blood corpuscles, that are present in blood for most or part of their lifespan. They include red blood cells (which make up about 45 per cent of the volume of normal blood), white blood cells, and platelets. All blood cells are made in the bone marrow by a series of divisions from a single type of cell called a stem cell.

**RED BLOOD CELLS** These cells are also known as RBCs, red blood corpuscles, or erythrocytes. They transport oxygen from the lungs to the tissues (see respiration).

**Formation** Red blood cells are formed from stem cells in the bone marrow by a process called erythropoiesis, which takes about five days. Their formation requires an adequate supply of nutrients, including iron, amino acids, and the vitamins B12 and folic acid. The rate at which RBCs are formed is influenced by a hormone called erythropoietin, which is produced by the kidneys.

Immature red blood cells that have just been released into the bloodstream from the bone marrow are called reticulocytes; within two to four days, these develop into mature cells.

**Structure and function** In 1 ml of blood there are approximately 5 million red blood cells (which make up about 45 per cent of the volume of normal blood), white blood cells, and platelets. All blood cells are made in the bone marrow by a series of divisions from a single type of cell called a stem cell.

**blood–brain barrier** A system of tight, impermeable junctions between the cells that form the walls of the capillaries (tiny blood vessels) within the central nervous system. The blood–brain barrier has a protective function; it allows only certain substances and drugs in the bloodstream to gain access to the central nervous system, especially to the brain.

**blood cells** Cells, also called blood corpuscles, that are present in blood for most or part of their lifespan. They include red blood cells (which make up about 45 per cent of the volume of normal blood), white blood cells, and platelets. All blood cells are made in the bone marrow by a series of divisions from a single type of cell called a stem cell.

**RED BLOOD CELLS** These cells are also known as RBCs, red blood corpuscles, or erythrocytes. They transport oxygen from the lungs to the tissues (see respiration).

**Formation** Red blood cells are formed from stem cells in the bone marrow by a process called erythropoiesis, which takes about five days. Their formation requires an adequate supply of nutrients, including iron, amino acids, and the vitamins B12 and folic acid. The rate at which RBCs are formed is influenced by a hormone called erythropoietin, which is produced by the kidneys.

Immature red blood cells that have just been released into the bloodstream from the bone marrow are called reticulocytes; within two to four days, these develop into mature cells.

**Structure and function** In 1 ml of blood there are approximately 5 million red blood cells (which make up about 45 per cent of the volume of normal blood), white blood cells, and platelets. All blood cells are made in the bone marrow by a series of divisions from a single type of cell called a stem cell.
Blood is pumped around the body in veins and arteries, transporting oxygen from the lungs to the tissues and carbon dioxide from the tissues to the lungs. Blood also carries nutrients such as sugars, fats, and proteins that have been absorbed from the intestine and hormones produced by a variety of glands. Waste products that are released from cells are carried in the blood to be broken down in the liver or excreted from the kidneys.

White blood cells
These cells protect the body against infection and fight it when it occurs. They are bigger than red blood cells but fewer in number. Each of the three main types (granulocytes, monocytes, and lymphocytes) plays a different role in dealing with infection.

Platelets
The smallest type of blood cell produced in the bone marrow. They play an important role in blood clotting.

**BLOOD CELLS**

**CONSTITUENTS OF BLOOD**

Blood cells, each of which is disc-shaped, about 0.0075 mm in diameter, and thicker around the edge than at the centre. This shape gives each cell a relatively large surface area, which helps it absorb and release oxygen molecules, and allows it to distort as it squeezes through narrow blood vessels. The surface structure of red blood cells varies slightly among individuals, and this provides the basis for classifying blood into groups (see blood groups).

RBCs are packed with large quantities of haemoglobin, a pigmented protein that contains iron. Haemoglobin binds (combines chemically) with oxygen to form oxyhaemoglobin, which carries oxygen to body tissues. Oxyhaemoglobin is responsible for the bright red coloration of oxygenated blood, which flows mainly through the arteries. Most venous blood is darker because it contains the unbound (deoxygenated) form of haemoglobin.

Every RBC also contains enzymes (substances that promote biochemical reactions), minerals, and sugars that provide energy for the cell’s metabolism (chemical processes) and maintain its shape, structure, and elasticity.

**Aging and destruction** The normal lifespan of RBCs in the circulation is about 120 days. As they age, their internal chemical machinery wears out, they lose elasticity, and they become trapped in small blood vessels in the spleen and other organs; they are then destroyed by a type of white blood cell called a macrophage. Most of the components of haemoglobin molecules are reused, but some are broken down to form the waste product bilirubin.

**Disorders** Abnormalities can occur in the rate at which RBCs are produced or destroyed; in their numbers; and in their shape, size, and haemoglobin content, all of which may cause forms of anaemia and polycythaemia (see blood disorders box).

**WHITE BLOOD CELLS**

These are also called WBCs, white blood corpuscles, or leukocytes. They protect the body against infection and fight infection when it occurs. White blood cells are bigger than red blood cells (up to 0.015 mm in diameter) but are far less numerous (about 7,500 per ml of blood). They generally spend a shorter part of their lifespan than red blood cells in the blood itself. The three main types of WBC are granulocytes (also called polymorphonuclear leukocytes), monocytes, and lymphocytes.

**Granulocytes** Granulocytes are further classified as neutrophils, eosinophils, or basophils, each type having a specific role. The most important are neutrophils, which isolate and destroy invading bacteria. Neutrophils remain in the blood for only about six to nine hours before moving through blood-vessel walls into tissues. Eosinophils play a part in allergic reactions and increase in numbers in response to certain parasitic infections. Basophils are involved in inflammatory and allergic reactions.

**Monocytes** These cells also play an important role in the immune system.
Abnormalities can occur in any of the components of blood: in red blood cells, white blood cells, platelets, and the numerous constituents of plasma.

There are various types of anaemia (a reduced level of the oxygen-carrying pigment haemoglobin in the blood), which is by far the most common blood disorder. Some abnormalities of the blood are inherited; others may be the result of various diseases, such as cancer, or be caused by poisoning by infective organisms, toxins, or drugs.

**Genetic disorders**
Some blood disorders are inherited (genetic) and are present from birth (congenital). Such disorders include sickle cell anaemia and thalassaemia, in which the red blood cells are abnormally fragile, and haemophilia, in which there is a deficiency of one of the blood clotting factors.

**Nutritional disorders**
Heavy or persistent blood loss, most commonly as a result of menstruation, may mean that iron (an essential component of the red cell pigment haemoglobin) is lost faster than it can be replaced in the diet (see anaemia, iron-deficiency). Deficiencies of the vitamins B₁₂ or folic acid interfere with the production of red blood cells in bone marrow and give rise to abnormally large, deformed red blood cells (see blood, anaemia, megaloblastic).

**Cancer**
There are various types of bone marrow cancer, all of which affect the blood. Leukaemia causes an overgrowth of abnormal white blood cells and destroys healthy bone marrow. In polycythaemia, too many red blood cells are produced. Another bone marrow cancer, multiple myeloma, can cause an excess of certain proteins in the blood plasma. Secondary deposits that have spread from cancers elsewhere in the body may also involve the bone marrow.

**Clotting disorders**
Defects in the blood platelets and in blood clotting mechanisms may lead to bleeding disorders, such as haemophilia and disseminated intravascular coagulation (DIC). Liver disease may cause deficiencies of some clotting factors. Unwanted clot formation (see thrombosis) may have any of a variety of causes, such as a mutation in the gene that controls production of a clotting factor (see factor V, for example) or use of oral contraceptives. People with Hughes’s syndrome are also at increased risk of thrombosis.

**Other disorders**
Blood poisoning may be caused by the multiplication of bacteria in the blood (see septicaemia) or by the toxins released by bacteria (see toxaemia). Poisoning can also be caused by toxins such as carbon monoxide and lead.

Some drugs can cause blood abnormalities. For example, thiazide diuretic drugs may depress the production of white blood cells and/or platelets; methotrexate may interfere with red cell production; and too high a dose of anticoagulant drugs can cause abnormal bleeding.

Albumin, which is an important protein in blood plasma, may become deficient as a result of either liver or kidney disease.

**INVESTIGATION**
Blood disorders are investigated principally by various blood tests, such as blood count, blood film, and blood-clotting tests. Levels of vitamins and minerals, such as iron, may also be measured. In some cases, a bone marrow biopsy may also be required.

They circulate in the bloodstream for about one to three days. Lymphocytes Lymphocytes are usually formed in the lymph nodes, rather than in the bone marrow. They play an important role in the immune system, roving throughout the body between the bloodstream, the lymph nodes, and the channels between lymph nodes. Lymphocyte cells may survive for anywhere between three months and ten years.

There are two principal types of lymphocyte: T-lymphocytes (or T-cells) and B-lymphocytes (or B-cells). T-lymphocytes are responsible for delayed hypersensitivity reactions (see allergy) and are also involved in protection against cancer. T-lymphocytes manufacture chemicals, called lymphokines, which affect the functioning of other cells. T-lymphocytes can be classified according to their surface marker proteins. For example, T-lymphocytes with CD4 surface marker proteins are particularly important in monitoring HIV infection. In addition, T-lymphocytes moderate the activity of B-lymphocytes, which form the antibodies that can act to prevent a second attack of certain infectious diseases.

**Disorders**
The leukaemias are blood disorders in which there is uncontrolled overproduction of white blood cells in the bone marrow. Other disorders arise when white blood cells are not produced in sufficient numbers.

**Platelets**
Platelets, which are also called thrombocytes, are the smallest type of blood cell (0.002 mm to 0.003 mm in diameter). There are about 250,000 of them per cubic mm of blood. Like other blood cells, they originate in the bone marrow. Platelets survive in the blood for about nine days.

**Function**
Platelets circulate in the blood in an inactive state until brought into action by certain circumstances, when they begin to stick to blood-vessel walls and to each other. These activities play an important part in blood cloting, which helps wounds to heal. However, the accumulation of platelets can, occasionally, lead to the formation of clots in blood vessels (see thrombosis).

**BLOOD CELLS IN DIAGNOSIS**
The numbers, shapes, and appearance of the various types of blood cell are of great value in the diagnosis of disease (see blood count; blood film).
**BLOOD CLOT**

**HOW BLOOD CLOTS**

Clotting describes the solidification of blood anywhere in the body. Clotting occurs almost immediately at the site of a cut and helps to limit blood loss by sealing damaged blood vessels. However, if abnormal clotting occurs in major blood vessels, a heart attack, stroke, or other disorder may occur. The clotting process has two main parts – platelet activation and the formation of fibrin filaments.

1. Platelets are activated by coming into contact with damaged blood vessel walls, where they become sticky and then clump at the site of injury and adhere to the damaged blood-vessel wall.
2. Chemicals released by the platelets and damaged tissues stimulate coagulation factors within the blood to form filaments of fibrin at the site of injury.
3. The fibrin filaments enmesh the platelets along with red and white blood cells.
4. Once the cut blood vessel is plugged by the mass of fibrin, platelets, and red and white blood cells, the fibrin filaments contract to form a solid clot.

**ANTICLOTTING MECHANISMS**

There are several anticlotting mechanisms that prevent the formation of unwanted blood clots. These mechanisms include prostacyclin (a prostaglandin), which prevents platelet aggregation (the first stage of blood clotting), and plasmin, which breaks down fibrin (see fibrinolysis). Blood flow washes away active coagulation factors; and the liver deactivates excess coagulation factors.

**CLOTTING DEFECTS**

Defects in blood clotting may result in bleeding disorders. Excessive clotting, or thrombosis, may be due to an inherited increase or defect in a coagulation factor (see factor V); the use of oral contraceptives; a decrease in the level of enzymes that inhibit coagulation; or sluggish blood flow through a particular area. Treatment is usually with anticoagulant drugs such as heparin or warfarin.

**blood clot**

See thrombus.

**blood clotting**

The process of blood solidification. Blood clotting is important in stemming bleeding from damaged blood vessels. However, blood clots can also form inside major blood vessels, leading to a myocardial infarction (heart attack) or to a stroke (see thrombosis).

**CLOTTING MECHANISM**

When a blood vessel is damaged, it constricts immediately to reduce blood flow to the area. The damage sets off a series of chemical reactions, leading to the formation of a clot to seal the injury. First, platelets around the injury site are activated, becoming sticky and adhering to the blood-vessel wall. The activated platelets then release chemicals that, in turn, activate coagulation factors. These factors, together with vitamin K, act on fibrinogen, a substance found in blood, converting it to fibrin. Strands of fibrin form a kind of meshwork, which traps red blood cells to form a clot.

**blood count**

A test, also called full blood count, that measures the haemoglobin concentration and the numbers of red blood cells, white blood cells, and platelets in 1 cu. mm of blood. The proportion of various white blood cells is measured and the size and shape of the red and white cells is also noted.

A blood count is the most commonly performed blood test and is important for diagnosing anaemia or confirming the presence of an infection to which cells in the blood have responded. It is also used to diagnose disorders such as leukaemia and thrombocytopenia (abnormally low platelet levels).

About 1 to 2 ml of blood is required for a blood count, which is usually performed by an automatic analyser.

**blood-clotting tests**

Laboratory tests used to screen for and diagnose bleeding disorders. Such disorders usually result from deficiencies or abnormalities of blood coagulation factors or of platelets (see blood clotting). The tests are also used to monitor treatment with anticoagulant drugs; excessive doses of these drugs could cause bleeding. (See also international normalized ratio.)
blood culture
A laboratory test performed on a sample of blood to determine the presence of microorganisms such as bacteria. (See also culture.)

blood donation
The process of giving blood for use in blood transfusion. Blood donors give up to 500 ml of blood (about one-tenth of total blood volume), usually about twice a year. Donated blood is routinely tested for a range of infectious agents, such as hepatitis B and hepatitis C, and antibodies to HIV. After being classified into blood groups, the blood is stored in a blood bank, either whole or separated into its components (see blood products).

Apheresis is a specific type of blood donation in which only a particular component of blood (such as plasma, platelets, or white blood cells) is withdrawn from the donor.

blood film
A test that involves smearing a drop of blood on to a glass slide for examination under a microscope. The blood film is stained with dyes to make the blood cells show up clearly.

The test allows the shape and appearance of blood cells to be checked for any abnormality, for example the sickle-shaped red blood cells characteristic of sickle cell anaemia. The relative proportions of the different types of white blood cells can also be counted. This examination, known as a differential white cell count, may be helpful in diagnosing infection or leukaemia. Blood films are also used in diagnosing infections in which the parasites can be seen inside the red blood cells; an example of such an infection is malaria.

Blood film tests are usually carried out together with a full blood count.

blood gases
Measurement of the concentrations of oxygen and carbon dioxide in the blood. The acidity–alkalinity (pH) and bicarbonate levels are also measured. The test is carried out on a sample of blood that has been taken from an artery, usually at the wrist or the groin. It is useful in diagnosing and monitoring respiratory failure. Bicarbonate and acidity reflect the acid–base balance of the body, which may be disturbed in conditions such as diabetic ketoacidosis, aspirin poisoning, hyperventilation (overbreathing), or repeated vomiting.

Blood oxygen can also be monitored continuously without the need to take blood samples by using an oximeter.

blood glucose
The level of glucose in the blood. Abnormally high blood glucose (sometimes called blood sugar) levels may be an indication of diabetes mellitus. (See also hyperglycaemia; hypoglycaemia.)

blood glucose monitoring
A method of analysing a person’s blood glucose (sugar) levels that requires only a drop of blood taken from a pinprick on the fingertip. The blood is applied to a test strip, which has an area impregnated with a chemical that reacts with the glucose in the blood sample. The glucose level is shown either by a visible colour change on the strip or by placing the strip in a digital meter. People with diabetes mellitus must perform regular blood glucose monitoring tests to monitor their blood glucose control. (See also hyperglycaemia; hypoglycaemia.)

blood groups
Systems of classifying blood according to the different antigens (marker proteins) on the surface of red blood cells (RBCs) and the antibodies in the blood plasma. The antigens affect the ability of the RBCs to provoke an immune response. The two principal blood grouping systems used are the ABO system and the rhesus system.

ABO GROUPS
In this system, the presence or absence of two types of antigen (A and B) on the surface of the red blood cells determines a person’s blood group. People with the A antigen (blood group A) have anti-B antibodies; people with the B antigen (blood group B) have anti-A antibodies; those with both antigens (blood group AB) have neither type of antibody; and those with neither antigen (blood group O) have both types of antibody.

RHESUS FACTORS
The rhesus system involves several antigens, the most important of which is called factor D. People with this factor are Rh-positive; those without it are Rh-negative. The importance of the Rh group relates mainly to pregnancy in Rh-negative women because, if the baby is Rh-positive, the mother may form antibodies against the baby’s blood (see rhesus incompatibility).

USES
Blood group typing is essential for safe blood transfusion. The ABO and rhesus groups are used to categorize blood stored in blood banks, so that donor blood that is compatible with that of the patient can be selected before transfusion takes place.

Because a person’s blood group is inherited, identification of blood group may be used in paternity testing. Genetic analysis allows identification of the blood of a criminal suspect with virtual certainty (see genetic fingerprinting).

blood level
The concentration of a given substance in the blood plasma or serum that may be measured by blood tests.

blood loss
See bleeding.

blood poisoning
A common name for septicaemia with toxæmia, a life-threatening illness that is caused by multiplication of bacteria and formation of toxins in the bloodstream. Septicaemia may occur as a complication of an infection in an organ or tissue. In some infective conditions, septic shock may be caused by toxins that are released by bacteria. Treatment for blood poisoning is with antibiotic drugs and intensive therapy for shock. (See also bacteraemia.)

blood pressure
The pressure exerted by the flow of blood through the main arteries. The pressure at two different phases is measured. Systolic, the higher pressure, is
created by the contraction of the ventricles of the heart. Diastolic, the lower pressure, is recorded during relaxation of the ventricles between heartbeats; it reflects the resistance of all the small arteries in the body and the load against which the heart must work. The pressure wave that is transmitted along the arteries with each heartbeat is easily felt as the pulse.

Blood pressure is measured using a sphygmomanometer and is expressed as millimetres of mercury (mmHg). Blood pressure varies with age, between individuals, and at different times in the same individual. A healthy young adult usually has a blood pressure reading, at rest, of about 120/80 (120 mmHg systolic and 80 mmHg diastolic pressure). A sustained level of high blood pressure is called hypertension; abnormally low pressure is termed hypotension.

**blood products**

Donated blood (see blood donation) that is separated into its components: red cells, white cells, platelets, and plasma. Each blood product has a specific lifespan and use in blood transfusion. Packed red cells (blood that has most of the plasma removed) are used to treat individuals with some forms of chronic anaemia and babies with haemolytic disease of the newborn. Washed red cells (with white blood cells and/or plasma proteins removed) are used when a person requires repeated transfusions since there is less risk of an allergy to any of the blood components developing.

Platelets may be given through transfusions for those people who have blood-clotting disorders. Patients who have life-threatening infections may be treated with granulocytes, a type of white blood cell. Fresh frozen plasma is used to correct many types of bleeding disorder because plasma contains all the clotting factors. Plasma substitutes may be used to treat shock that has occurred as a result of severe blood loss, until sufficient compatible whole blood becomes available. Purified albumin preparations are used for people who have nephrotic syndrome and chronic liver disease.

Concentrates of blood clotting factors VIII and IX are used in the treatment of the conditions haemophilia and Christmas disease. Immunoglobulins (also called antibodies), which are extracted from blood plasma, can be given by injection (see immunoglobulin injection) to protect those people who are unable to produce their own antibodies or have already been exposed to an infectious agent. Immunoglobulins may also be given to provide short-term protection against hepatitis A. Immunoglobulins are given in large doses to treat certain autoimmune disorders.

**blood smear**

See blood film.

**blood sugar**

See blood glucose.

**blood test, haematological**

Analysis of a sample of blood to provide information about its cells and proteins and the chemicals, gases, antigens, and antibodies it contains. Haematological blood tests are used to check respiratory function, the immune system, the metabolism, hormonal balance, and the health of the major organs. The tests look at the numbers, appearance, shape, and size, of blood cells and assess the function of clotting factors in the blood.

**blood transfusion**

The infusion of large volumes of blood or of blood products directly into the bloodstream to remedy severe blood loss or to correct chronic anaemia. In an exchange blood transfusion, nearly all of the recipient’s blood is replaced by donor blood.

**how it is done**

Before a transfusion, a sample of the recipient’s blood is taken to identify his or her blood group, which is then matched with suitable donor blood. The donor blood is transfused into an arm vein through a plastic cannula (a tube with a smooth tip). Usually, each unit (about 500 ml) of blood is given over one to four hours; in an emergency, 500 ml may be given within a couple of minutes. The blood pressure, body temperature, and pulse of the patient are monitored during the procedure.

**complications**

If mismatched blood is accidentally introduced into the circulation, antibodies in the recipient’s blood may cause the donor cells to burst, leading to shock or kidney failure. Less severe reactions can produce fever, chills, or a rash. Reactions can also occur as the result of an allergy to a particular component of the transfused blood.

The risk of infection is extremely small. All blood used for transfusion is carefully screened for a number of infectious agents, including HIV (the AIDS virus) and hepatitis B and hepatitis C.

In elderly or in severely anaemic patients, blood transfusion can overload the circulation, leading to heart failure. In patients with chronic anaemia who need regular transfusions over the course of many years, excess iron may accumulate (a condition called haemosiderosis) and damage organs such as the heart, liver, and pancreas. Treatment with the drug desferrioxamine to remove excess iron may be needed in this case.
blood transfusion, autologous
The use of a person’s own blood, which had been donated at an earlier time, for blood transfusion. Autologous transfusion eliminates the slight but serious risk of contracting an infectious illness from contaminated blood. Another advantage is that there is no risk of a reaction occurring as a result of incompatibility between donor and recipient blood.

Up to 2.5 litres of a person’s blood can be removed and stored in several sessions up to three days before planned surgery. There must be at least four days between each session. Blood may also be taken during surgery. The blood is filtered and returned to the body.

blood transfusion, incompatible
A blood transfusion in which the recipient’s blood and the donor’s blood are mismatched. As a result, antibodies that are present in the recipient’s circulation lead to destruction of the transfused red blood cells. This can have serious consequences, including kidney failure and occasionally even death. Careful cross-matching of blood in the laboratory make incompatible transfusions rare.

blood vessels
A general term for arteries, veins, and capillaries (see circulatory system).

Bloom’s syndrome
A genetic disorder that is most commonly found among people of East European Jewish descent. Physical characteristics of the syndrome include short stature, a butterfly-shaped red rash on the face, and photosensitivity (an abnormal reaction to sunlight). Individuals with Bloom’s syndrome may also be at increased risk of certain cancers, such as leukemia.

blue baby
An infant with a cyanotic (bluish) complexion, especially visible on the lips and tongue, caused by a relative lack of oxygen in the blood. This is usually due to a structural defect of the heart or the major arteries leaving the heart. Such defects may need to be corrected surgically (see heart disease, congenital).

blue bloater
An outdated term to describe a person with bluish lips and tongue and oedema (a buildup of fluid in the tissues). The cause is long-term lung damage that has led to heart failure (see pulmonary disease, chronic obstructive).

blue naevus
A type of naevus (skin blemish) with a dark blue or black coloration and a clearly defined border. Blue naevi are noncancerous and they are made up of a collection of pigment-producing cells called melanocytes.

blurred vision
Indistinct, or fuzzy, visual images. Blurred vision, which should not be confused with double vision (diplopia), can occur in one eye or both, for episodes of varying lengths of time, and can develop gradually or suddenly. The usual cause of longstanding blurred vision is a refractive error such as astigmatism (unequal curvature of the front of the eye), hypermetropia (longsightedness), or myopia (shortsightedness), all of which can be corrected by glasses or contact lenses. After the age of 40, presbyopia (reduced ability to focus on near objects) becomes more common.

Vision may also be blurred or impaired as a result of damage, disease, or abnormalities of parts of the eye or its connections to the brain. Blurred vision as a result of disease is most commonly caused by cataract or retinopathy.

blushing
Brief reddening of the face, and sometimes the neck, caused by widening of the blood vessels close to the skin’s surface. Blushing is often an involuntary reaction to embarrassment. In some women, blushing is a feature of the hot flushes that occur during the menopause. Flushing of the face also occurs in association with carcinoid syndrome.

B-lymphocyte
A type of white blood cell, also referred to as a B-cell. B-lymphocytes play a vital part in the immune system, the body’s natural defence mechanism, by producing antibodies (special proteins) to find and destroy harmful microorganisms.

body contour surgery
Surgery that is performed to remove excess fat, skin, or both, from various parts of the body, especially from the abdomen, the thighs, and the buttocks. One of the most commonly used operations is abdominal wall reduction, also called abdominoplasty, which involves removing excess skin and fat from the abdominal area.

To minimize scarring, a less invasive procedure, such as suction liposuction (liposuction), may be performed. In this operation, a rigid hollow tube is inserted through a small incision in the skin and is used to break up large areas of fat. The fat can then be sucked out through the instrument.

All body contour surgery carries a risk of complications, including wound infection. Minor irregularities and some dimpling of the skin commonly occur following liposuction.

body dysmorphic disorder
A psychiatric disorder in which a person suffers intense anxiety about an imagined defect in part of his or her body.

body image
A person’s perception of the different parts of his or her own body.

body mass index (BMI)
An indicator of healthy body weight. BMI is calculated by dividing weight in kilograms by the square of height in metres. The normal range is 20 to 25.

body odour
The smell caused by the action of bacteria on sweat. It is most noticeable in the armpits and around the genital area, where the apocrine glands contain proteins and fatty materials favourable to bacterial growth.

body temperature
See temperature.

boil
An inflamed, pus-filled area of skin, usually an infected hair follicle. A more severe and extensive form of boil involving several hair follicles is known as a carbuncle. The usual cause of a boil is infection with the bacterium Staphylococcus aureus. Recurrent boils may occur in people with known or unrecognized diabetes mellitus or in those with other conditions in which general resistance to infection is impaired.

The use of a person’s own blood, which had been donated at an earlier time, for blood transfusion. Autologous transfusion eliminates the slight but serious risk of contracting an infectious illness from contaminated blood. Another advantage is that there is no risk of a reaction occurring as a result of incompatibility between donor and recipient blood.

Up to 2.5 litres of a person’s blood can be removed and stored in several sessions up to three days before planned surgery. There must be at least four days between each session. Blood may also be taken during surgery. The blood is filtered and returned to the body.

A blood transfusion in which the recipient’s blood and the donor’s blood are mismatched. As a result, antibodies that are present in the recipient’s circulation lead to destruction of the transfused red blood cells. This can have serious consequences, including kidney failure and occasionally even death. Careful cross-matching of blood in the laboratory make incompatible transfusions rare.

A general term for arteries, veins, and capillaries (see circulatory system).

A genetic disorder that is most commonly found among people of East European Jewish descent. Physical characteristics of the syndrome include short stature, a butterfly-shaped red rash on the face, and photosensitivity (an abnormal reaction to sunlight). Individuals with Bloom’s syndrome may also be at increased risk of certain cancers, such as leukemia.

An infant with a cyanotic (bluish) complexion, especially visible on the lips and tongue, caused by a relative lack of oxygen in the blood. This is usually due to a structural defect of the heart or the major arteries leaving the heart. Such defects may need to be corrected surgically (see heart disease, congenital).

An outdated term to describe a person with bluish lips and tongue and oedema (a buildup of fluid in the tissues). The cause is long-term lung damage that has led to heart failure (see pulmonary disease, chronic obstructive).

A type of naevus (skin blemish) with a dark blue or black coloration and a clearly defined border. Blue naevi are noncancerous and they are made up of a collection of pigment-producing cells called melanocytes.

Indistinct, or fuzzy, visual images. Blurred vision, which should not be confused with double vision (diplopia), can occur in one eye or both, for episodes of varying lengths of time, and can develop gradually or suddenly. The usual cause of longstanding blurred vision is a refractive error such as astigmatism (unequal curvature of the front of the eye), hypermetropia (longsightedness), or myopia (shortsightedness), all of which can be corrected by glasses or contact lenses. After the age of 40, presbyopia (reduced ability to focus on near objects) becomes more common.

Vision may also be blurred or impaired as a result of damage, disease, or abnormalities of parts of the eye or its connections to the brain. Blurred vision as a result of disease is most commonly caused by cataract or retinopathy.

Brief reddening of the face, and sometimes the neck, caused by widening of the blood vessels close to the skin’s surface. Blushing is often an involuntary reaction to embarrassment. In some women, blushing is a feature of the hot flushes that occur during the menopause. Flushing of the face also occurs in association with carcinoid syndrome.

A type of white blood cell, also referred to as a B-cell. B-lymphocytes play a vital part in the immune system, the body’s natural defence mechanism, by producing antibodies (special proteins) to find and destroy harmful microorganisms.

The abbreviation for body mass index.

The abbreviation for basal metabolic rate.

A brand-name blood glucose monitoring test strip for analysing the blood glucose level in diabetes mellitus. The strip is sensitive to blood glucose levels ranging from 1 mmol to 44 mmol.

Surgery that is performed to remove excess fat, skin, or both, from various parts of the body, especially from the abdomen, the thighs, and the buttocks. One of the most commonly used operations is abdominal wall reduction, also called abdominoplasty, which involves removing excess skin and fat from the abdominal area.

To minimize scarring, a less invasive procedure, such as suction liposuction (liposuction), may be performed. In this operation, a rigid hollow tube is inserted through a small incision in the skin and is used to break up large areas of fat. The fat can then be sucked out through the instrument.

All body contour surgery carries a risk of complications, including wound infection. Minor irregularities and some dimpling of the skin commonly occur following liposuction.

A psychiatric disorder in which a person suffers intense anxiety about an imagined defect in part of his or her body.

A person’s perception of the different parts of his or her own body.

An indicator of healthy body weight. BMI is calculated by dividing weight in kilograms by the square of height in metres. The normal range is 20 to 25.

The smell caused by the action of bacteria on sweat. It is most noticeable in the armpits and around the genital area, where the apocrine glands contain proteins and fatty materials favourable to bacterial growth.

See temperature.

An inflamed, pus-filled area of skin, usually an infected hair follicle. A more severe and extensive form of boil involving several hair follicles is known as a carbuncle. The usual cause of a boil is infection with the bacterium Staphylococcus aureus. Recurrent boils may occur in people with known or unrecognized diabetes mellitus or in those with other conditions in which general resistance to infection is impaired.
bonds may be delayed if a baby is premature or ill and has to be separated from his or her parents immediately after birth (for example, by being placed in an incubator).

**Bonding, Dental**

Techniques that use plastic resins and acrylic or porcelain veneers to repair, restore, or cosmetically improve the teeth. Dental bonding may sometimes be used as an alternative to crowning (see crown, dental) and can also be used to protect the teeth.

**Bone**

The structural material of the skeleton that provides a rigid framework for the muscles and protects certain organs of the body. In combination with the joints and the muscles, the bones form the locomotor system.

**Structure**

Bone consists of several layers. The surface has a thin covering known as the periosteum, a membrane that contains a network of blood vessels and nerves. Beneath the periosteum is an inner shell of hard (also called compact or cortical) bone composed of columns of bone cells (osteocytes and osteoblasts). Each column has a central hollow (haversian canal) that is important for the nutrition, growth, and repair of the bone. The direction of the haversian canals corresponds with the mechanical forces acting on the bone.

Inside the hard shell, bone has a central meshlike structure (which is known as spongy, cancellous, or trabecular bone). The cavity in the center of certain bones, and the spaces in spongy bone, contain bone marrow, in which the red blood cells, platelets, and most of the white blood cells are formed.

**Growth**

Bone is continuously reabsorbed by osteoclasts and replaced by osteoblasts. The osteoblasts encourage deposition of calcium phosphate on the protein framework of the bone; the osteoclasts remove it. The actions of these cells are controlled by growth hormone, secreted by the pituitary gland, the sex hormones oestrogen and testosterone, the adrenal hormones, the thyroid hormone thyroxine, and parathyroid hormone. These hormones also work to maintain the level of calcium in the blood.

Most bones begin to develop in the embryo during the fifth or sixth week of pregnancy, at which time they take the form of cartilage. This cartilage begins to be replaced by hard bone, in a process known as ossification, at around the seventh or eighth week of pregnancy; this process is not complete until early adult life. At birth, many bones consist mainly of cartilage, which ossifies later in life. The epiphyses (the growing ends of the long bones) are separated from the bone shaft (diaphysis) by the epiphyseal plate. Some bones in the body, such as certain skull bones, do not develop from cartilage, and these are known as membranous bones.

**Bone Abscess**

A localized collection of pus in a bone (see osteomyelitis).

**Bone Age**

A measure of skeletal maturity used to assess physical development in children. X-rays, which show how much bones have grown in a particular body area, are used to determine bone age. (See also age.)

**Bone Cancer**

Malignant growth in bone. Bone cancer may originate in the bone itself (primary bone cancer) or, more commonly, may occur as a result of cancer spreading from elsewhere in the body (secondary, or metastatic, bone cancer).

**Primary Bone Cancer**

Cancers that originate in the bone are rare; the type of primary bone cancer that occurs most often is osteosarcoma. Other types include chondrosarcoma and fibrosarcoma. Cancers can also start in the bone marrow, but these are not usually considered to be bone cancers (see multiple myeloma and leukaemia). The treatment of primary bone cancer will depend on the extent to which the disease has spread. If it remains confined to bone, it may be possible to remove the cancer and fill the defect with a bone graft. In other cases, amputation may be recommended. Radiotherapy or chemotherapy, or both, may also be needed.

**Secondary Bone Cancers**

The cancers that spread most readily to form secondary bone cancer are those of the breast, lung, prostate, thyroid, and kidney. These bone metastases occur commonly in the spine, pelvis, ribs, and skull. Pain is usually the main symptom. Affected bones are abnormally fragile and may fracture easily. Bone cancer that affects the spine may cause collapse or crushing of vertebrae, damaging the...
spinal cord and causing weakness or paralysis of one or more limbs.

Secondary bone cancers from the breast and prostate gland may respond to treatment with hormone antagonists. In other cases, local treatment with radiotherapy is often effective in relieving pain caused by the tumour.

bone conduction
A method of transmitting sound that is tested during investigation into the cause of impaired hearing.

A vibrating tuning fork is held next to the ear. The base of the fork is then placed against the bone behind the ear. If the deafness is the result of an outer- or middle-ear problem (conductive deafness), the sound will be heard better when the tuning fork is held behind the ear. The bone transmits sound directly to the inner ear, bypassing the outer and middle ear. (See also deafness; hearing tests.)

bone cyst
An abnormal cavity in a bone. Bone cysts typically develop at one end of a long bone and may be discovered only by chance after a fracture at the site of the cyst. Minor surgery to scrape out the cyst and fill the cavity with bone chips usually cures the condition; many small cysts do not actually require treatment.

bone density
The compactness of bone tissue in relation to its volume. A decrease in bone density is a normal part of aging. However, excessive loss of bone density (see osteoporosis) can lead to fractures. An increase in bone density (see osteosclerosis) occurs in some disorders, such as osteopetrosis and Paget’s disease. Bone density is measured by densitometry, a technique that uses low-dose X-rays.

bone graft
A surgical operation in which small pieces of bone are taken from one part of the body in order to repair or replace abnormal or missing bone elsewhere. The bone graft eventually dies, but it acts as a scaffold upon which strong new bone grows.

Bone is most commonly taken from the iliac crests (upper parts of the hip bones). They contain a large amount of inner, spongy bone, which is very useful for getting grafts to “take”. Other common sources are the ribs (for curved bone) and the ulna in the forearm.

bone imaging
Techniques for providing pictures that show the structure or function of bones. X-ray images are commonly used for diagnosing fractures and injuries. More detailed information is provided by tomography, CT scanning, or MRI, which can show tumours, infections, and the effects of diseased bone on the surrounding tissues. Radionuclide scanning detects areas in the skeleton in which there is high bone-cell activity. This type of scanning is used mainly to determine whether cancer has spread to the bones.

bone marrow
The soft fatty tissue found in bone cavities; it may be red or yellow. Red bone marrow is present in all bones at birth and is the factory for most blood cells. During the teens, red bone marrow is gradually replaced in some bones by less active yellow marrow. In adults, red marrow is confined principally to the spine, sternum, (breastbone), pelvis (hip bones), ribs, scapulae (shoulderblades), clavicles (collarbones), and skull bones.

Stem cells within the red marrow are stimulated to form blood cells by the hormone erythropoietin. Yellow marrow is composed mainly of connective
Bone is affected by the same types of disorders as other body tissues, but its hard, rigid structure makes for extra complications. If a bone receives a direct blow or suffers from repeated stress, it may fracture. If it becomes infected (due to osteomyelitis or a bone abscess, for example), the resulting inflammation may interfere with the blood supply, leading to death of part of the bone.

**Genetic disorders**
Several inherited conditions may affect bone growth; these include achondroplasia and osteogenesis imperfecta. Such disorders often result in short stature.

**Nutritional disorders**
Lack of calcium and vitamin D in the diet may result in rickets in children and osteomalacia in adults; in both conditions the bones become soft and lose their shape.

**Hormonal disorders**
If the pituitary gland produces excess growth hormone before puberty, this results in excessive growth of the bones and other organs, leading to gigantism. Excess parathyroid hormone may lead to bone cysts. Osteoporosis (loss of bone density) is common in women following the menopause, when oestrogen levels fall.

**Tumours**
Several different types of cancerous and noncancerous growth can arise from bone (see bone cancer and bone tumour). In addition, the bones are a common site for secondary tumours (metastases) that have spread from cancerous tumours elsewhere in the body.

**Other disorders**
Paget’s disease involves thickening of some areas of the bones, while other areas become spongy.

**Bone marrow biopsy**
A procedure to obtain a sample of cells from the bone marrow (an aspiration biopsy) or a small core of bone with marrow inside (a trephine biopsy). The sample is usually taken, under local anaesthesia, from the sternum (breastbone) or iliac crests (upper part of the hip-bones). Microscopic examination gives information on the development of the blood components and on the presence of cells foreign to the marrow. It is useful in the diagnosis of many blood disorders, including leukaemia and anaemia. It can also show whether bone marrow has been invaded by lymphoma or cells from other tumours.

**Bone marrow transplant**
The technique of using normal red bone marrow to replace cancerous, defective, or diseased bone marrow in a patient. In autologous bone marrow transplantation (BMT), healthy marrow is taken from a donor with a very similar tissue-type to the recipient’s (often a brother or sister). In autologous BMT, the patient’s own healthy bone marrow is harvested while his or her disease is in remission and is reinfused at a later time. Generally, BMT is used only in the treatment of serious, potentially life-threatening blood and immune system disorders, including aplastic anaemia (see anaemia, aplastic), sickle cell anaemia, and leukaemia.

An alternative treatment is stem-cell transplantation, in which cells from the umbilical cord of a newborn baby or the bloodstream of an adult are transplanted instead of bone marrow.

**Bone resorption**
Loss of bone tissue. Bone resorption and the laying down of new bone tissue are continuous processes. With increasing age, resorption exceeds new bone formation, and the bone tissue gradually becomes thinner. However, in certain disorders (for example, osteoporosis), resorption takes place more rapidly and to a greater extent, causing weakening of bone and increased risk of fractures.

**Bone tumour**
A bone swelling that may be cancerous (see bone cancer) or noncancerous. The most common type of noncancerous bone tumour is an osteochondroma.
Normal bone marrow is used to replace malignant or defective marrow. In the allogeneic procedure, healthy marrow is taken from a donor. In the autologous procedure, the patient’s own healthy marrow is used.

Finding a donor
The more siblings one has, the greater the chance of finding a donor. With three or more siblings, the chances are good.

1. Before transplantation, all the recipient’s bone marrow is destroyed by treatment with drugs or radiation. Destroying the marrow kills any cancer cells.

2. Using general anaesthesia, bone marrow is aspirated from the donor’s iliac crests and/or sternum. Up to one litre is removed. The transplanted marrow grows quickly to occupy the bone spaces.

3. After aspiration, the bone marrow is transfused intravenously into the patient. The bone marrow cells find their way through the circulation into the patient’s marrow cavities, where they start to grow.

Sites of bone marrow
Red or yellow in colour, bone marrow is a soft, fatty tissue found in the cavities of bones. In newborn babies, red bone marrow is present in all bones; during the teen years, most is replaced by yellow marrow. The marrow used for transplants is red.

Donor aspiration
With the donor lying face down, a hollow aspiration needle, which has a stylet (a thin, sharp lance) within it, is introduced into the bone (iliac crests). The stylet is then removed. Bone marrow is sucked out through the cortex into a syringe connected to the needle.
Other types of bone tumour are *osteoma* and *chondroma* (see *chondromatosis*). Treatment is needed only if the tumour becomes large or causes symptoms by pressing on other structures. In such cases, it can be removed by surgery. Osteoclastoma (also called a giant cell tumour), which usually occurs in the arm or leg of a young adult, is tender and painful and has to be removed.

**booster**

A follow-up dose of *vaccine*, given to reinforce or prolong immunity after an initial course of *immunization*.

**borborygmi**

The medical name for *bowel sounds* that are audible without a stethoscope.

**borderline personality disorder**

A personality disorder that falls between neurotic and psychotic levels. Mood changes are often rapid and inappropriate. Angry outbursts are common, as are impulsive, self-damaging acts such as gambling or suicide attempts.

**Bordetella pertussis**

A species of *bacteria* that may infect the human respiratory tract and is responsible for causing *whooping cough*.

**Bornholm disease**

One of the various names for epidemic *pleurodynia*, an infectious viral disease that is characterized by severe chest pains and fever.

**Borrelia**

A genus of spiral-shaped *bacteria* transmitted through tick bites (see *ticks and disease*). *Borrelia* species cause *relapsing fever* (an infectious disease characterized by recurrent bouts of fever) and also *Lyme disease*.

**bottle-feeding**

Infant feeding using a milk preparation usually based on modified cow’s milk. This formula milk contains similar proportions of protein, fat, lactose (milk sugar), and minerals to those in human milk, but it lacks the protective antibodies that are present in breast milk. Vitamins are added.

In some cases, medical problems in the mother or child may make *breast-feeding* impossible or undesirable, in which case bottle-feeding is recommended. However, bottle-fed babies are at higher risk of gastrointestinal infections than breast-fed babies and may be more likely to develop allergic disorders. (See also *feeding, infant*.)

**Botox**

A brand name for the drug *botulinum toxin*, which is used to treat muscle spasm in conditions such as *cerebral palsy*. Botox is also used for cosmetic reasons to reduce the appearance of wrinkles in the skin.

**botulinum toxin**

A potentially lethal toxin produced by the bacterium *Clostridium botulinum* (see *botulism*). In tiny doses, botulinum toxin is used as a *muscle-relaxant drug* to control muscle spasms in some disorders (see *blepharospasm; facial spasm*). It is also increasingly used for cosmetic purposes; when injected into facial muscles, botulinum toxin temporarily reduces wrinkles.

**botulism**

A rare but serious form of poisoning caused by eating improperly canned or preserved food contaminated with a toxin produced by the bacterium *Clostridium botulinum* (see *botulism*). In tiny doses, botulinum toxin is used as a *muscle-relaxant drug* to control muscle spasms in some disorders (see *blepharospasm; facial spasm*). It is also increasingly used for cosmetic purposes; when injected into facial muscles, botulinum toxin temporarily reduces wrinkles.

**bowel**

A common name for the large and/or small *intestines*.

**bowel disorders**

Any disorder that affects the *intestine*. Common bowel disorders are *inflammatory bowel disease* and *irritable bowel syndrome* (IBS). (See also *intestinal disorders box; intestine, cancer of; intestine, obstruction of; intestine, tumours of*.)

**bowel movements, abnormal**

See *faeces, abnormal*.

**bowel sounds**

Sounds made by the passage of air and fluid through the *intestine*. Absent or abnormal bowel sounds may indicate a disorder. Those that are audible without a stethoscope are known as borborygmi and are a normal part of the digestive process, but they may be exaggerated by anxiety and some intestinal disorders.

**Bowen’s disease**

A rare skin disorder that is characterized by the formation of a flat patch of red, scaly skin, most commonly on the face or the hands. Bowen’s disease may become cancerous.

Treatment involves surgical removal of the diseased skin, or its destruction by freezing or *cauterization*.

**bowleg**

An outward curving of bones in the legs that results in wide separation of the knees when the feet are together. Bowlegs are common in very young children, and they are a normal part of development. In most cases, the curve straightens as the child grows. If the bowing is severe, is on one side only, or persists beyond the age of three, a doctor should be consulted. Surgery may be needed. Rarely, leg deformity is a result of bone disease, particularly *rickets* (a vitamin D deficiency) in children.
**Bowman’s capsule**
A cup-shaped membrane within the kidney’s **nephron** containing a **glomerulus** (a cluster of tiny blood vessels called capillaries). Here, blood is filtered into the kidney tubule.

**BP**
The abbreviation for **blood pressure**.

**brace, dental**
See **orthodontic appliances**.

**brace, orthopaedic**
An appliance worn to support part of the body or hold it in a fixed position. A brace may be used to correct or halt the development of a deformity, to aid mobility, or to relieve pain. (See also **caliper splint; corset; splint**.)

**brachial artery**
The **artery** that runs down the inner side of the upper arm, between the armpit and the elbow.

**brachialgia**
Pain or stiffness in the arm that is often accompanied by pain, tingling and/or numbness of the hands or fingers, and weak hand grip. It may be a symptom of underlying disorders such as **frozen shoulder** or nerve compression from **cervical osteoarthritis**.

**brachial plexus**
A group of large nerve trunks formed from nerve roots of the lower part of the cervical spine (in the neck) and upper part of the thoracic spine (in the chest). These nerve trunks divide into the musculocutaneous, axillary, median, ulnar, and radial nerves, which control muscles in and receive sensation from the arm and the hand. Injuries to the brachial plexus can cause loss of movement and sensation in the arm.

In severe injuries, there may be damage to both the upper and the lower nerve roots of the brachial plexus, producing complete paralysis of the arm. The paralysis may be temporary if the stretching was not severe enough to tear nerve fibres. It may be possible to repair nerve roots that have been torn by nerve grafting, which is a **microsurgery** procedure, but if a nerve root has become separated from the spinal cord, surgical repair will not be successful. Apart from injuries, the brachial plexus may be compressed by the presence of a **cervical rib** (extra rib).

**brachytherapy**
A type of **radiotherapy**.

**bradycardia**
An abnormally slow heart rate. Most people have a heart rate of between 60 and 100 beats per minute. Many athletes and healthy people who exercise regularly and vigorously have slower rates. In others, bradycardia may indicate an underlying disorder such as **hypothyroidism** or **heart block**. Bradycardia may also occur as a result of taking **beta-blocker drugs**. Profound or sudden bradycardia may cause a drop in blood pressure that results in fainting (see **vasovagal attack**).

**bradykinin**
A **polypeptide** (protein molecule) that forms naturally in the blood as part of the inflammatory process. Bradykinin is a powerful vasodilator (it causes the widening of blood vessels). Bradykinin also allows fluid to leak from the blood vessels; stimulates pain receptors; and causes contraction of the smooth muscle in internal organs such as the lungs or intestines.

**Braille**
A system of embossed dots, now accepted for all written languages, that enables blind people to read and write. The system is based on six raised dots, which can be combined in different ways to form symbols.

There are two types of Braille. In grade I, each symbol represents an individual letter or punctuation mark. In grade II, which is the more widely used, symbols represent common letter combinations or words.

**brain**
The major organ of the **nervous system**, located in the **cranium** (skull). The brain receives, sorts, and interprets sensations from the nerves that extend from the **central nervous system** (brain and spinal cord) to the rest of the body; it initiates and coordinates nerve signals involved in activities such as speech, movement, thought, and emotion.

An adult brain weighs about 1.4 kg and has three main structures: the **brainstem**; the **cerebellum**; and the largest part, the **cerebrum**, which consists of left and right hemispheres.

**CEREBRUM**
Each hemisphere in the cerebrum has an outer layer called the cortex, consisting of grey matter, which is rich in nerve-cell bodies and is the main region in the brain for conscious thought, sensation, and movement. Beneath the cortex are tracts of nerve fibres called white matter, and, deeper within the hemispheres, are the **basal ganglia** (paired nerve cell clusters). The surface of each of the hemispheres is divided by fissures (sulci) and folds (gyri) into distinct lobes (occipital, frontal, parietal, and temporal lobes), named after the skull bones that overlie them. A thick band of nerve fibres called the corpus callosum connects the hemispheres.

The cerebrum encloses a central group of structures including the **thalamus** and the **hypothalamus**, which has close connections with the **pituitary gland**. Encircling the thalamus is a complex of nerve centres called the **limbic system**. These structures act as links between parts of the cerebrum and the brainstem lying beneath the thalamus.

**BRAINSTEM AND CEREBELLUM**
The brainstem is concerned mainly with the control of vital functions such as breathing and blood pressure. The cerebellum at the back of the brain controls balance, posture, and muscular coordination. Both of these regions operate at a subconscious level.

**MENINGES AND CEREBROSPINAL FLUID**
The brain and spinal cord are encased in three layers of membranes known as **meninges**. Cerebrospinal fluid circulates between these membrane layers and within the four main brain cavities, which are known as **ventricles**. This fluid helps to nourish and cushion the brain.

**BLOOD SUPPLY**
The brain as a whole has an extensive blood supply. Blood comes from a circle of arteries fed by the internal **carotid arteries** (which run up each side of the front of the neck to enter the base of the skull) and from two vertebral arteries that run parallel to the spinal cord. The brain receives about 20 per cent of the blood from the heart’s output.

**brain abscess**
A collection of pus, surrounded by inflamed tissues, within the brain or on its surface. The most common sites are the frontal and temporal lobes of the **cerebrum** in the forebrain.

Brain abscesses may occur after a head injury, but most cases result from the spread of infection from elsewhere in the body, such as the middle ear or the sinuses. Another cause of a brain
STRUCTURE OF THE BRAIN

The brain has three main parts: the brainstem (an extension of the spinal cord), the cerebellum, and the cerebrum, much of which consists of the two large cerebral hemispheres. Each hemisphere consists of an outer layer, or cortex, which is rich in nerve cells and called grey matter, and inner areas rich in nerve fibres, called white matter. The surface of each hemisphere is thrown into folds called gyri, separated by fissures called sulci. The two hemispheres are linked by a thick band of nerve fibres, the corpus callosum. Deep within the forebrain are various central structures, which include the thalamus, hypothalamus, basal ganglia, and pituitary gland.

The brain has the consistency of jelly and, in adults, weighs about 1.4 kg. It is protected by membranous coverings (known as meninges) within the skull.

Special areas
Some areas of the brain are associated with specific functions – for example, the occipital lobe with vision and the cerebellum with balance and coordination. Touch and pressure sensation is perceived within the postcentral gyrus. Muscle movements are controlled from the precentral gyrus; speech is controlled from an area in the frontal lobe of the dominant hemisphere.

IMAGING THE BRAIN

CT scanning
CT scans produce images as “slices” through the head. The scan above shows bleeding into the brain tissue (a cerebral haemorrhage).

Angiography
This technique makes blood vessels clearly visible. The angiogram above shows the carotid artery and its branches.

Magnetic resonance imaging
MRI produces three-dimensional or cross-sectional images. This MRI shows a tumour (the white area to the right of centre) in the cerebellum.
abcess is an infection following a penetrating brain injury. Multiple brain abscesses may occur as a result of blood-borne infection, most commonly in patients with a heart-valve infection (see endocarditis).

Symptoms of a brain abscess include headache, drowsiness, vomiting, visual disturbances, fever, and seizures. There may also be other symptoms, such as speech disturbances, that are due to local pressure. Treatment is with anti-biotic drugs and surgery. A craniotomy may be needed to open and drain the abscess. Untreated, brain abscesses can cause permanent damage and can be fatal. Despite treatment, scarring can cause epilepsy in some cases.

**brain contusion**

Bruising of the brain accompanied by loss of consciousness, which occurs as the result of an injury. (See also brain damage; concussion.)

**brain damage**

Degeneration or death of nerve cells and tracts within the brain that may be localized to a particular area of the brain or may be diffuse.

**DISORDERS OF THE BRAIN**

Defects and disorders of the brain have numerous causes, including infection, injury, brain tumour, or a lack of blood or oxygen (see hypoxia). Brain cells destroyed by injury or disease cannot be replaced, so any resulting loss in function can be difficult to reverse.

Because the brain is encased within the skull, any space-occupying tumour, brain abscess, or haematoma (large blood clot) creates raised pressure, which can impair the function of the whole brain.

Brain disorders that are localized in a small region may affect a specific function, such as speech (see aphasia). However, more often, damage is more diffuse and the symptoms can be varied and numerous.

The brain may also be damaged by a blow to the head (see head injury).

**Congenital defects**

Some brain disorders are congenital (present from birth) due to genetic or chromosomal disorders, as in Down’s syndrome. Structural defects during fetal development include hydrocephalus (water on the brain) and anencephaly (congenital absence of the brain).

**Impaired blood and oxygen supply**

Brain cells can survive only a few minutes without oxygen. A reduced supply may occur at birth, causing cerebral palsy. Later in life, choking or arrest of breathing and heartbeat can cause hypoxia (oxygen lack).

From middle age onwards, cerebro-vascular disease, which impairs the blood supply to one or more regions of the brain, is the most important cause of brain disorders. If an artery within the brain becomes blocked or ruptures, leading to haemorrhage, the result is a stroke.

**Infection**

Encephalitis (infection within the brain) may be due to a virus. Meningitis (infection of the membranes surrounding the brain) is generally due to bacterial infection. Creutzfeldt–Jakob disease is a rare, fatal brain disease associated with an infective agent called a prion, which, in some cases, has been linked with bovine spongiform encephalopathy (BSE), a disease in cattle.

**DIFFUSE DAMAGE**

One of the most common causes of diffuse brain damage is prolonged cerebral hypoxia (an insufficient supply of oxygen to the brain), which may occur in a baby during a difficult birth. Other causes of diffuse damage to the brain tissue include cardiac arrest (cessation of the heartbeat), respiratory arrest (cessation of breathing), drowning, certain types of poisoning, and status epilepticus (prolonged seizures). Diffuse damage may also occur gradually as a result of exposure to environmental pollutants, such as lead or mercury compounds (see Minamata disease), or if nerve-cell poisons build up in the brain, as occurs in untreated phenylketonuria. Other possible causes of diffuse brain damage include brain infections such as encephalitis.

**LOCALIZED DAMAGE**

Localized brain damage may occur as the result of a head injury, stroke (damage to part of the brain caused by an interruption to its blood supply), brain tumour, or brain abscess. At birth, a raised blood level of bilirubin (see haemolytic disease of the newborn) can cause local damage to the basal ganglia deep within the brain. This leads to a condition called kernicterus. Brain damage that occurs before, during, or after birth may result in cerebral palsy.

**OUTCOME**

Diffuse damage to the brain may result in learning difficulties and severe physical disability. Localized brain damage may cause specific deficits in brain function, such as disturbances of movement or speech (see speech disorders). Nerve cells and tracts in the brain and spinal cord cannot repair themselves once they have been damaged, but some return of function may be possible with training, as patients learn to use other parts of the brain. (See also Structure of the brain box.)

**brain death**

The irreversible cessation of all functions of the brain, including those of the brainstem. (See also death.)

**brain failure**

See brain syndrome, organic.

**brain haemorrhage**

Bleeding within or around the brain caused either by injury or by the spontaneous rupture of a blood vessel. There

**Degenerative disorders**

Multiple sclerosis is a progressive disease of the brain and spinal cord. Degenerative brain diseases include Alzheimer’s disease and Parkinson’s disease.

**Other disorders**

Emotional or behavioural disorders are often called psychiatric illnesses, but the distinction between these and neurological disorders is unclear. In many illnesses, such as depression and schizophrenia, there may be an underlying disturbance of brain chemistry.

**INVESTIGATION**

Procedures used to investigate brain disorders and function include tests of reflexes and of mental and physical abilities. Electrical activity may be measured with an EEG. Physical abnormalities can be found using brain imaging techniques such as angiography, CT scanning, or MRI.
are four possible types of brain haemorrhage: subdural, extradural, subarachnoid, and intracerebral (see the illustrated box). Extradural and subdural haemorrhages are usually caused by a blow to the head (see head injury). Subarachnoid and intracerebral haemorrhages tend to occur spontaneously due to rupture of aneurysms or small blood vessels in the brain.

**brain imaging**

Techniques that can provide pictures of the brain. Brain imaging techniques are used to detect injury or disease of the brain and include X-rays, angiography, CT scanning, MRI (magnetic resonance imaging), PET (positron emission tomography) scanning, and SPECT (single photon emission CT).

**INVESTIGATION OF BRAIN STRUCTURE**

CT scanning gives images of the brain substance; it provides clear pictures of the ventricles (fluid-filled cavities) and can reveal tumours, blood clots, strokes, aneurysms, and abscesses.

MRI (magnetic resonance imaging) produces very detailed images of the brain’s structure. This technique is also used to detect patches of abnormal brain tissue, as seen in multiple sclerosis.

Angiography involves the injection of a contrast medium that shows up the blood vessels in the brain on X-ray. It is used to investigate aneurysms and other circulatory disorders.

**INVESTIGATION OF BRAIN FUNCTION**

PET and SPECT scanning are specialized forms of radionuclide scanning that use small amounts of radioactive material to provide information about brain function as well as structure. They enable blood flow and metabolic activity in the brain to be measured.

Functional magnetic resonance imaging (fMRI) can be used to determine which parts of the brain are activated by different sensations or activities, such as sight or movement of the fingers. This technique is used to assess how the brain is working.

Ultrasound scanning, through the fontanelles (holes where the skull bones have yet to fuse), can detect bleeding in the brain only in premature or very young babies; ultrasound waves cannot penetrate the bones of a mature skull.

**brainstem**

A stalk of nerve tissue that forms the lowest part of the brain and links with the spinal cord. The brainstem acts partly as a highway for messages travelling between other parts of the brain and spinal cord. It also connects with 10 of the 12 pairs of cranial nerves (which emerge directly from the underside of the brain) and controls basic functions such as breathing, vomiting, and eye reflexes. Brainstem activities are below the level of consciousness, and they operate mainly on an automatic basis.

**STRUCTURE**

The brainstem is composed of three main parts: the midbrain, pons, and medulla. Attached to the back of the brainstem is a separate part of the brain, the cerebellum, which is concerned with balance and coordinated movement. Running longitudinally through the middle of the brainstem is a canal; this widens in the pons and medulla to form the fourth ventricle (cavity) of the brain, which contains the circulating cerebrospinal fluid.

**Midbrain** The midbrain is the smallest section of the brainstem. This part contains the nuclei (nerve-cell centres) of the third and fourth cranial nerves, which control eye movements and the size and reactions of the pupil. It also contains cell groups, such as the substantia nigra, involved in smooth coordination of limb movements.

**Pons** The pons contains thick bundles of nerve fibres that connect with the cerebellum. It also houses the nuclei for the fifth to eighth cranial nerves, and relays sensory information from the ear, face, and teeth, as well as the signals that move the jaw, adjust facial expressions, and produce some eye movements.

**Medulla** The medulla resembles a thick extension of the spinal cord. It contains the nuclei of the ninth to 12th cranial nerves, by which it receives and relays taste sensations from the tongue and
relays signals to muscles involved in speech and in tongue and neck movements. The medulla also contains the “vital centres” (groups of nerve cells that regulate the heartbeat, breathing, blood pressure, and digestion (information on which is relayed via the 10th cranial nerve (see vagus nerve)).

**Reticular formation** Throughout the brainstem are numerous nerve-cell groups known collectively as the reticular formation. This network alerts the higher brain centres to sensory stimuli that may require a conscious response. Our sleep/wake cycle is controlled by the reticular formation.

**DISORDERS**

The brainstem is susceptible to the same disorders that afflict the rest of the central nervous system (see brain, disorders of). Damage to the medulla’s vital centres is rapidly fatal; damage to the reticular formation may cause coma. Damage to specific cranial nerve nuclei can sometimes lead to specific effects. For example, damage to the seventh cranial nerve (the facial nerve) leads to facial palsy. Degeneration of the substantia nigra in the midbrain is thought to be a cause of Parkinson’s disease.

**brain syndrome, organic**

Disorder of consciousness, intellect, or mental functioning that is of organic (physical), as opposed to psychiatric, origin. Possible causes include degenerative diseases, most notably Alzheimer’s disease; infections; certain drugs; or the effects of injury, stroke, or tumour.

**SYMPTOMS**

Symptoms of acute organic brain syndrome range from mild confusion to stupor or coma. They may also include disorientation, memory loss, hallucinations, and delusions (see delirium). In the chronic form, there is a progressive decline in intellect, memory, and behaviour (see dementia). Treatment is more likely to be successful with the acute form. In chronic cases, irreversible brain damage may already have occurred. (See also psychosis.)

**brain tumour**

An abnormal growth in or on the brain. Although they are not always cancerous, all brain tumours are serious due to the buildup of pressure they cause within the brain and the compression of adjoining brain areas, both of which may occur as the tumour grows and expands. Expansion of a brain tumour within the rigid skull may also result in damage to the normal tissue that surrounds the tumour.

**TYPES**

Brain tumours may be primary growths arising directly from tissues within the skull or metastases (secondary growths) that have spread via the bloodstream from cancerous tumours elsewhere in the body, particularly from those in the lung or breast.

The cause of primary brain tumours is not known. About 60 per cent are gliomas (which are frequently cancerous), and arise from the brain tissue. Other primary tumours include meningiomas, which arise from the meningeal membranes covering the brain; acoustic neuromas, which arise from the acoustic nerve; and pituitary tumours, which arise from the tissue of the pituitary gland. Most of these tumours are noncancerous, but their relatively large size can cause local tissue damage.

Some types of primary brain tumour affect mainly children. These include two types of glioma called medulloblastoma and cerebellar astrocytoma. Primary brain tumours virtually never spread (metastasize) outside the central nervous system.

Secondary growths (metastases) are always cancerous and may be found in more than one organ.

**SYMPTOMS**

Compression of brain tissue or nerve tracts near the tumour may cause muscle weakness, loss of vision, or other sensory disturbances, speech difficulties, and epileptic seizures.

The presence of a growing tumour can increase pressure within the skull, causing headache, visual disturbances, vomiting, and impaired mental functioning. Hydrocephalus (excess fluid in the brain) may occur if the circulation of cerebrospinal fluid is obstructed by the tumour.

**DIAGNOSIS AND TREATMENT**

Many different brain imaging techniques may be used to locate the site of a brain tumour and to establish its size and the extent of its spread.

In some cases, complete removal of a brain tumour may be possible using guidance from MRI scanning during surgery. In such cases, the patient may be cured. However, many cancerous growths are inaccessible or too extensive for removal. In cases where a tumour cannot be completely removed, as much as possible of it will be cut away to relieve pressure.

For primary and secondary tumours, radiotherapy or anticancer drugs may also be given. Corticosteroid drugs are often prescribed temporarily to reduce the size of a tumour and any associated swelling of brain tissues.

**brain**

The fibrous outer covering of grain that cannot be digested. The fibre is used as a bulk-forming laxative to prevent constipation (see fibre, dietary).

**branchial disorders**

Disorders due to abnormal development, in an embryo, of the branchial arches (paired segmented ridges of tissue in each side of the throat). Such disorders include branchial cyst and branchial fistula.

A branchial cyst is a soft swelling, containing fluid that may be either clear or puslike, that appears on the side of the neck in early adulthood. Treatment of a branchial cyst is usually with surgical removal.

A branchial fistula occurs between the back of the throat and the external surface of the neck, where it appears as a small hole, usually noted at birth. A hole in the neck that does not extend to the back of the throat is a branchial cleft sinus. A branchial fistula or cleft sinus may discharge mucus or pus and may be removed surgically.

**brash, water**

See waterbrash.

**Braxton Hicks’ contractions**

Short relatively painless contractions of the uterus during pregnancy. They may be felt in late pregnancy and are sometimes mistaken for labour pains.

**BRCA 1 and BRCA 2**

Two of the abnormal genes that are thought to be responsible for inherited breast cancer. Women with these genes may also have an increased risk of ovarian cancer (see ovary, cancer of).

**breakbone fever**

A tropical viral illness, which is also called dengue, that is spread by mosquitoes. The symptoms include high fever and severe joint and muscle pain.

**breakthrough bleeding**

Bleeding or staining (“spotting”) from the vagina between menstrual periods in women taking an oral contraceptive.
The bleeding is most common during the first few months of taking the pill and is caused by incomplete suppression of the monthly buildup of the endometrium (lining of the uterus). (See also vaginal bleeding.)

breast
Either of the two mammary glands, which, in women, provide milk to nourish a baby and are secondary sexual characteristics. The male breast is an immature version of the female breast.

DEVELOPMENT AND STRUCTURE
At puberty, a girl’s breasts begin to develop: the areola (the circular area of pigmented skin around the nipple) swells and the nipple enlarges. This is followed by an increase in glandular tissue and fat.

The adult female breast consists of between 15 and 20 lobes of milk-secreting glands embedded in fatty tissue. The ducts of these glands have their outlet in the nipple. The areolar skin contains sweat glands, sebaceous glands, and hair follicles. Bands of fine ligaments determine the breast’s height and shape.

The size, shape, and general appearance of a woman’s breasts may vary throughout the menstrual cycle, during pregnancy and lactation, and following the menopause.

BREAST FUNCTION
During pregnancy, the hormones oestrogen and progesterone, which are secreted by the ovaries and placenta, cause the milk-producing glands in the breasts to develop and to become active. These two hormones also cause the nipples to enlarge.

Just before and immediately after childbirth, the glands in the breast produce a watery fluid known as colostrum. The production of this fluid is replaced by milk production a few days later. Milk production and release are stimulated by the hormone prolactin.

breast abscess
A collection of pus in the mammary gland, usually in a woman who is lactating (producing milk). Breast abscesses develop if acute mastitis (inflammation of the breast) is not treated promptly and occur most commonly during the month after a woman’s first delivery.

The initial symptoms of a breast abscess are the same as those of acute mastitis. The abscess develops in one area, which becomes very firm, red, and extremely painful. Treatment involves antibiotic drugs and repeated aspiration (withdrawal by suction) of the pus using a needle and syringe. In rare cases, surgical drainage may be needed.

breast awareness
A woman’s familiarity with the appearance and feel of her breasts, which allows her to recognize both normal and abnormal changes. Doctors recommend that women develop “awareness” in order to improve the chances of detecting breast cancer at an early stage. (See also breast self-examination.)

breastbone
The common name for the sternum, the front part of the thorax (chest).

breast cancer
A cancerous tumour of the breast. Breast cancer is the most common type of cancer in nonsmoking women and the second most common type, after lung cancer, in women who smoke. One woman in every 12 who live to old age will develop breast cancer at some point in her life. Breast cancer can also rarely develop in men. The advancement of techniques for early diagnosis and treatment of breast cancer has improved overall survival rates.

CAUSES
Current theories regarding the causes of breast cancer are focused on hormonal and genetic influences. However, the principal risk factor is age, with a woman’s chances of developing the disease doubling every ten years of her life.

The incidence of breast cancer is known to be raised in women whose menstrual periods began at an early age and in those whose menopause was late to commence. The risk is also higher in women who did not have children or those who had their first child late in life. Women whose mothers or sisters have had breast cancer are also at an increased risk. Diet may also play a part; breast cancer is more common in countries in which the typical diet contains a lot of fat. Studies have shown that hormone replacement therapy (HRT) slightly increases the chances of developing breast cancer; the risk increases with the length of time that HRT has been taken.

THE FEMALE BREAST
The breast is made up of lobes of glands set in fatty tissue, the ducts of which have their outlet at the nipple. The areola contains sweat glands, sebaceous glands, and hair follicles.
Breast cancer in women under the age of 50 may be linked to genetic factors and various genes, including BRCA 1 and BRCA 2, have been identified. These genes seem to account for some of the breast cancers that occur within families. Women with one or more relatives who have developed the disease in their 30s or 40s may wish to seek specialist genetic advice.

SYMPTOMS AND SIGNS
The first sign of breast cancer is often a painless lump. However, it is important to note that nine out of ten breast lumps are not cancerous. Other symptoms of breast cancer may include a dark discharge from the nipple, retraction (indentation) of the nipple, and an area of dimpled, creased skin over the lump. In the majority of cases, only one breast is affected.

An abnormality may sometimes be detected during a routine mammography, which is offered every three years to all women between the ages of 50 and 65.

INVESTIGATION AND TREATMENT
If a lump is detected in the breast, an imaging procedure, such as mammography or ultrasound scanning, will be carried out. Cells will then be collected from the lump by needle aspiration (withdrawal by suction) or biopsy (surgical removal of a small sample of tissue for analysis).

A small cancerous tumour that is not thought to have spread outside the breast is removed surgically, along with a surrounding margin of normal tissue. Lymph nodes in the armpit are usually removed at the same time. Larger cancers may require mastectomy (surgical removal of the whole breast). Surgery can be combined with or followed by mammoplasty (breast reconstruction) to help reduce the psychosexual impact of the disease.

Any further treatment depends on the size of the tumour; whether or not there is evidence of spread to the lymph nodes; and the sensitivity of the tumour cells to hormones, which is assessed in the laboratory using a technique known as oestrogen receptor testing. The woman’s age and whether or not she has gone through the menopause are also significant factors in determining appropriate treatment.

After surgery, most women have a course of radiotherapy to any remaining breast tissue and to the armpit, and/or chemotherapy (treatment with anticancer drugs). Tamoxifen, an oral anti-oestrogen drug, is commonly prescribed for five years following surgery for breast cancer to reduce the risk of recurrence. Women who are approaching the menopause may be offered treatment to bring on an early menopause if the tumour is oestrogen-sensitive.

Secondary tumours in other parts of the body, which may be present at the time of the initial diagnosis or may develop years after apparently successful treatment, are treated with anticancer drugs and hormones.

OUTLOOK
A complete cure or years of good health can usually be expected after treatment for early breast cancer. Regular check-ups are required to detect recurrence or the development of a new cancer in the other breast. Mammograms should be performed periodically for this reason. If the cancer recurs, it can be controlled, sometimes for years, by drugs and/or radiotherapy. (See also breast self-examination.)

breast cyst
A fluid-filled lump that forms within the milk-producing tissue of the breast. Breast cysts most commonly affect women in their 30s and 40s, especially in the years leading up to the menopause. A lump can be diagnosed as a cyst by ultrasound scanning, a mammography, or by withdrawing fluid from it with a syringe and needle (see aspiration), which usually results in the lump disappearing. About half of all women with a breast cyst will develop future cysts. Any new breast lump should be seen by a doctor to confirm the diagnosis.

breast enlargement surgery
A type of mammoplasty.

breast-feeding
The natural method of infant feeding during the period between birth and weaning. Human milk contains the ideal balance of nutrients for a baby and provides valuable antibodies (proteins made by the immune system) against infections. For the first few days after birth, the breasts produce a watery fluid known as colostrum. Milk flow is stimulated by the baby’s sucking and is usually established in three to four days.

Breast-feeding problems may occur as a result of engorged breasts and cracked nipples or if the baby has problems sucking; a breast-feeding advisor may be able to help with these difficulties. Breast-feeding can sometimes cause an infection (see mastitis) that leads to a breast abscess. In such cases, treatment with antibotic drugs may mean that it is possible to continue breast-feeding.

breast implant
An artificial structure surgically introduced into the breast to increase its size (see mammoplasty).
**breast lump**

Any mass, swelling, or cyst that can be felt in the breast tissue. At least 90 per cent of lumps are noncancerous; the rest are cancerous (see *breast cancer*).

Many women have generally lumpy breasts, with the lumps more obvious before a period. Once known as fibrocystic disease or fibroadenosis, this is now considered to be a variation of normal. Lumpy breasts do not increase the risk of breast cancer, but any new or distinct lump should be medically assessed. In a young woman, a single lump is likely to be a noncancerous fibroadenoma. This growth is usually round, firm, and rubbery, causes no pain, and can be moved about beneath the skin. In an older woman, a lump is more likely to be a noncancerous, fluid-filled breast cyst.

Breast awareness and regular breast self-examination may help to detect any changes. Treatment depends on the cause and type of lump. Cysts can be drained in a simple outpatient procedure. Other lumps may need to be removed surgically.

**breast pump**

A device that is used to draw milk from overfull breasts during lactation (see *breast-feeding*). A breast pump may also be used to express milk for future use or to feed a baby who is unable to suckle.

**breast reconstruction**

See *mammoplasty*.

**breast reduction**

See *mammoplasty*.

**breast self-examination**

A visual and manual examination carried out by a woman to detect lumps and other changes in her breasts that might be a sign of early *breast cancer*.

To carry out self-examination, the breasts should be checked in a mirror for any dimpling of the skin, changes in the appearance of the nipples, or changes in breast size and shape. Then, placing one arm behind the head, and using small, circular movements, the breast should be gently but firmly pressed. The entire breast, armpit area, and nipple should be examined.

By performing regular self-examination, a woman is able to familiarize herself with the appearance and feel of her breasts (see *breast awareness*); any abnormal changes should be reported to a doctor without delay.

---

**breast tenderness**

Soreness or tenderness of the breasts, frequently accompanied by a feeling of fullness. Breast tenderness is extremely common. In most women it is cyclical, varying in severity in response to the hormonal changes of the menstrual cycle. The breasts are usually most tender before a period (see *premenstrual syndrome*). The condition tends to affect both breasts and may be aggravated by stress or caffeine. Breast tenderness may also be noncyclical, caused by muscle strain or mastitis. During lactation, it may be due to engorgement of the breasts with milk. Rarely, tenderness may be due to a *breast cyst* or to *breast cancer*. Examination by a doctor will exclude any underlying problems.

Women with large breasts are more likely to suffer from both cyclical and noncyclical breast tenderness.

Cyclical tenderness may be relieved by reduced caffeine intake, relaxation exercises for stress, a well-fitting bra, or weight loss to reduce breast size. If these measures do not work, hormonal treatment may be recommended.

**breath-holding attacks**

Periods during which a toddler holds his or her breath, usually as an expression of pain, frustration, or anger. The child usually becomes red or even blue in the face after a few seconds, and may faint. Breathing quickly resumes as a natural reflex, ending the attack. Breath-holding does not cause damage and is usually outgrown.

**breathing**

The process by which air passes into and out of the lungs to allow the blood to take up oxygen and dispose of carbon dioxide.
Breathing is controlled by the respiratory centre in the brainstem. On inhalation, the diaphragm contracts and flattens. The intercostal muscles (between the ribs) contract and pull the ribcage up and out. The resulting increase in volume in the chest cavity causes the lungs to expand, and the reduced pressure draws air into the lungs. On exhalation, the chest muscles and diaphragm relax, causing the ribcage to sink and the lungs to contract, squeezing air out.

In normal, quiet breathing, less than a tenth of the air in the lungs passes out to be replaced by the same amount of fresh air (the tidal volume). This new air mixes with the stale air (the residual volume) already held in the lungs. The normal breathing rate for an adult at rest is 13 to 17 breaths per minute. (See also respiration.)

**breathing difficulty**

Laboured or distressed breathing that includes a change in the rate and depth of breathing or a feeling of breathlessness. Some degree of breathlessness is normal after exercise, particularly in unfit or overweight people. Breathlessness at rest is always abnormal and is usually due to disorders that affect the airways (see asthma), lungs (see pulmonary disease, chronic obstructive), or cardiovascular system (see heart failure). Severe anxiety can result in breathlessness, even when the lungs are normal (see hyperventilation). Damage to the breathing centre in the brainstem due to a stroke or head injury can affect breathing. This may also happen as a side effect of certain drugs. Ventilator assistance is sometimes needed.

At high altitudes, the lungs have to work harder in order to provide the body with sufficient oxygen (see mountain sickness). Breathlessness may occur in severe anaemia because abnormal or low levels of the oxygen-carrying pigment haemoglobin means that the lungs need to work harder to supply the body with oxygen. Breathing difficulty that intensifies on exertion may be caused by reduced circulation of blood through the lungs. This may be due to heart failure (reduced pumping efficiency of the heart), pulmonary embolism (blockage of blood vessels in the lungs by clots), or pulmonary hypertension (increased pressure in the arteries in the lungs).

Breathing difficulty due to air-flow obstruction may be caused by chronic bronchitis, asthma, an allergic reaction, or lung cancer. Breathing difficulty may also be due to inefficient transfer of oxygen from the lungs into the bloodstream. Temporary damage to the lung tissue may be due to pneumonia, pneumothorax (collapsed lung), pulmonary oedema (fluid in the lung), or pleural effusion (fluid around the lung). Permanent lung damage may be due to emphysema, a condition in which the small air sacs in the lungs are destroyed.

Chest pain (for example, due to a broken rib) that is made worse by chest or lung movement can make normal breathing difficult and painful, as can pleurisy (inflammation of the membrane that lines the lungs and chest cavity). Pleurisy is associated with pain in the lower chest and often in the shoulder tip on the affected side.

Abnormalities of the skeletal structure of the thorax (chest), such as severe scoliosis or kyphosis, may cause difficulty in breathing by impairing the normal movements of the ribcage.

**breathing exercises**

Techniques for learning to control the rate and depth of breathing. They aim to teach people to inhale through the nose, while expanding the chest, and then to exhale fully through the mouth, while contracting the abdominal muscles. The exercises are used after chest surgery and for people with chronic obstructive pulmonary disease (see pulmonary disease, chronic obstructive), who often tend to have difficulty breathing effectively. Breathing exercises can also help people with anxiety disorders and may also help to relieve the symptoms of asthma.

In yoga, deep, rhythmic breathing is used to achieve a state of relaxation. During childbirth, breathing exercises can relax the mother and may also help to control the contractions of the uterus and reduce pain. (See also physiotherapy.)

**breathing stoppage**

The cessation of breathing (see apnoea). Breathing may be stopped by an airway obstruction, by damage to the brainstem...
breathlessness
A feeling of laboured breathing. Breathlessness is a normal response to exercise or exertion, but may also be caused by some underlying disorders (see breathing difficulty).

breath test
A procedure used to check for infection of the digestive tract by Helicobacter pylori, the bacterium associated with peptic ulcers. The test involves drinking a substance that can be broken down by the bacterium. The breakdown process produces a chemical that passes into the bloodstream and is then breathed out. A machine detects the substance’s presence in the breath, confirming infection with the bacterium.

breech delivery
A birth in which the fetus presents buttocks first. Many fetuses lie in a breech position before week 32 of pregnancy, but most of them turn by week 36. The three per cent that do not turn may be in one of three types of breech presentation: in a complete breech, the fetus is curled up; in a frank breech, the fetus’s legs are extended and the feet are close to the face; in a footling breech, one or both feet are positioned over the cervix. In many twin pregnancies, one twin is in a breech position.

A mother whose fetus is in a breech presentation may be offered a procedure to turn the fetus around after week 36 of pregnancy, because this usually makes birth easier. In some breech deliveries, a caesarean section may be recommended.

bridge, dental
False teeth attached to natural teeth on either side of a gap left by one or more missing teeth (see the illustrated box). Adhesive bridges, which are attached to, but do not damage, the teeth on either side of the gap are now available in certain situations. (See also denture.)

Bright’s disease
An alternative name for the kidney disorder glomerulonephritis.

Briquet’s syndrome
An alternative name for somatization disorder, a psychiatric illness.

brittle bones
Bones with an increased tendency to fracture. They are a feature of osteoporosis and may occur in people who are taking corticosteroid drugs, are immobile, or have certain hormonal disorders. In osteomalacia, the bones are soft and tend both to become deformed and to fracture. The inherited disorder osteogenesis imperfecta is a rare cause of brittle bones and frequent fractures and is usually detected in infancy.

brittle diabetes
A former term for type 1 (insulin-dependent) diabetes mellitus in which it is difficult to maintain blood sugar levels within an acceptable range.

Broca’s area
An area of the cerebral cortex (the outer layer of the brain) that is responsible for speech origination. Damage to Broca’s area may result in aphasia (complete loss of previously acquired language skills).

Brodmann areas
Areas of the cerebral cortex (outer layer of the brain), that are numbered one to 47. Each area contains nerve cells that correspond to specific functions, such as sight, hearing, and movement.

broken leg
See femur, fracture of; fibula; tibia.

broken nose
Fracture of the nasal bones or dislocation of the cartilage that forms the bridge of the nose (see nose, broken).

broken tooth
See fracture, dental.

broken veins
A term that is commonly used to refer to telangiectasia, in which small blood vessels under the surface of the skin enlarge and give the impression of being "broken".

bromides
Substances formerly used as sedative drugs or as anticonvulsant drugs in the treatment of epilepsy. Bromides are no longer used due to their side effects, which include serious disturbance of brain function that may lead to coma.

bromocriptine
A drug used to suppress production of prolactin (a hormone) to treat conditions such as noncancerous pituitary tumours (see prolactinomas; acromegaly). Bromocriptine may also be used to suppress

FITTING A BRIDGE
The most common type of bridge consists of one or more false teeth attached to a crown on each side of a gap. The natural teeth are shaped to receive the crowns, which are then cemented into place.

1 Two complete teeth are missing. A bridge of two false teeth and two crowns can be attached.

2 The two healthy teeth are shaped so that they can receive the crowns on either side of the gap.

3 The bridge, which is mounted on a cast-metal subframe (not shown), is cemented on to the healthy teeth on either side of the gap.

4 The finished bridge is in position, showing the new porcelain teeth; the metal base to which they are cemented is concealed.
bronchial asthma

See asthma.

bronchiectasis

A lung disorder in which one or more bronchi (air passages leading from the trachea) are abnormally widened and distorted, with damaged linings. Bronchiectasis commonly develops during childhood and is once associated with infections such as measles and pertussis (whooping cough). The condition may also be a complication of cystic fibrosis. Bronchiectasis results in pockets of long-term infection within the airways and the continuous production of large volumes of green or yellow sputum (phlegm). Extensive bronchiectasis may cause shortness of breath.

Symptoms are usually controlled with antibiotic drugs and postural drainage, a technique that clears secretions from the lungs. If the condition is confined to one area of lung, surgical removal of the damaged area may be recommended.

bronchiolitis

An acute viral infection of the lungs, mainly affecting babies and young children, in which the bronchioles (the airways branching off the bronchi) become inflamed. A common cause is the respiratory syncytial virus (RSV).

Symptoms of bronchiolitis include rapid breathing, a cough, and fever. No treatment may be necessary but, in severe cases, hospital admission is necessary so that oxygen therapy can be given. If treatment is prompt, recovery is usually within a few days. Antiobiotic drugs may be given to prevent a secondary bacterial infection.

bronchitis

A disorder in which the bronchi, the large air passages to the lungs, are inflamed. Bronchitis results in a cough that may produce considerable quantities of sputum (phlegm) and may be acute or chronic. Both types are more common in smokers and in areas with high atmospheric pollution. (See also bronchitis, acute; bronchitis, chronic.)

bronchitis, acute

A form of bronchitis, usually due to a viral infection, that develops suddenly but often clears up within a few days. Bacterial infection of the airways may be a complication. Smokers, babies, the elderly, and people with lung disease are particularly susceptible. Symptoms include wheezing, shortness of breath, and a cough producing yellow or green sputum. There may also be pain behind the sternum (breastbone) and fever.

Symptoms may be relieved by drinking plenty of fluids and inhaling steam or using a humidifier. Most cases clear up without further treatment, but acute bronchitis may be serious in people who already have lung damage.

bronchitis, chronic

Smoking-induced inflammation of the airways associated with emphysema, in which the air sacs in the lungs are destroyed. The combination of chronic bronchitis and emphysema is known as chronic obstructive pulmonary disease (see pulmonary disease, chronic obstructive). Symptoms include a productive cough and progressive breathlessness.

bronchoconstrictor

A substance that causes narrowing of the airways. Bronchoconstrictors, such as histamine, are released during an allergic reaction (see allergy) and may provoke an asthma attack. The effect can be reversed by a bronchodilator drug.

bronchodilator drugs

COMMON DRUGS

SYMPATHOMIMETICS • Bambuterol • Eformoterol • Ephedrine • Epinephrine • Fenoterol • Salbutamol • Salmeterol • Terbutaline

ANTICHOLINERGICS • Ipratropium bromide • Oxitropium

XANTHINES • Aminophylline • Theophylline

Drugs that widen the bronchioles (small airways in the lungs) to improve air flow and breathing. They are especially used to treat asthma and chronic obstructive pulmonary disease (see pulmonary disease, chronic obstructive), in which the lungs are inflamed and damaged.

TYPES

There are three main types of bronchodilator drug. Sympathomimetics (such as salbutamol) are used primarily for the rapid relief of breathing difficulty. Anticholinergics (such as ipratropium) and xanthines (such as aminophylline) are more frequently used for the long-term prevention of attacks of breathing difficulty. Bronchodilators can be given by inhaler, in tablet form, or, in severe cases, by nebulizer or injection.

SIDE EFFECTS

The main side effects of sympathomimetics are palpitations and trembling. Anticholinergics may cause dry mouth, blurred vision, and, rarely, difficulty in passing urine. Xanthines may cause headaches, nausea, and palpitations.

bronchography

An X-ray procedure used for examining the bronchi, which are the two main air passages of the lungs. Once used to diagnose bronchiectasis (widenng and distortion of the bronchi), this method has now been largely replaced by other imaging techniques, especially CT scanning, and by bronchoscopy.

bronchopneumonia

The most common form of pneumonia. In bronchopneumonia, inflammation is spread throughout the lungs in small patches around the airways; in lobar pneumonia, it is confined to one lobe.

bronchoscopy

Examination of the bronchi, the main airways of the lungs (see bronchus), by means of an endoscope (viewing tube) known as a bronchoscope. Bronchoscopes may be rigid or flexible.

WHY IT IS DONE

Bronchoscopy is performed to inspect the bronchi for abnormalities, such as lung cancer and tuberculosis; to collect samples of mucus; to obtain cells; and to take biopsy samples from the airways or lungs. A bronchoscope with special attachments is used to carry out treatments such as removing inhaled foreign bodies, destroying abnormal growths, and sealing off damaged blood vessels. (See also Bronchoscopy box, overleaf.)

bronchospasm

Temporary narrowing of the bronchi (the air passages to the lungs). Bronchospasm is caused by contraction of the muscles in the walls of the bronchi, by inflammation of the lining of the bronchi, or by a combination of both. Contraction may be triggered by the release of substances during an allergic
reaction (see allergy). When the airways are narrowed, the air is reduced, causing wheezing or coughing. **Asthma** is the most common cause of bronchospasm. Other possible causes include respiratory infection, chronic obstructive pulmonary disease (see pulmonary disease, chronic obstructive), in which the lungs are inflamed and damaged, anaphylactic shock (a potentially life-threatening hypersensitivity reaction), or allergic reaction to chemicals.

**bronchus**
A large air passage in a lung. Each lung has one main bronchus, originating at the end of the trachea (windpipe). This main bronchus divides into smaller branches known as segmental bronchi, which further divide into bronchioles.

**bronchus, cancer of**
See lung cancer.

**bronze diabetes**
An outdated term for haemochromatosis, a rare genetic disorder in which excess amounts of iron are deposited in tissues.

**brown fat**
A special type of fat found in infants and some animals. Located mainly between and around the shoulderblades, brown fat provides energy and helps infants to maintain a constant body temperature.

**Brown–Sequard syndrome**
A combination of symptoms associated with damage to a part of the spinal cord. There is loss of pain and temperature sensation on the opposite side of the body below the damage, and weakness and stiffness of muscles below the damage on the same side of the body.

**brow presentation**
A rare form of malpresentation in which the head of the fetus is bent slightly backwards and its brow lies against the...
mother’s cervix. Vaginal delivery is not possible if this presentation persists throughout labour, and a caesarean section is then required.

**brucellosis**
A rare bacterial infection, caused by various strains of *Brucella*, which may be transmitted to humans from affected cattle, goats, and pigs. The infection may also be transmitted in unpasteurized dairy products.

Brucellosis causes high fever, sweating, poor appetite, joint aches, headache, backache, weakness, and depression. Rarely, severe untreated cases lead to pneumonia or meningitis (inflammation of the membranes surrounding the brain and spinal cord). In long-term brucellosis, bouts of the illness recur over months or years, and the depression can be severe. The disease is treated with antibi oti c drugs.

**bruise**
A discoloured area under the skin caused by leakage of blood from damaged capillaries (tiny blood vessels). The blood initially appears blue or black; as the haemoglobin (the red pigment in blood) breaks down, the bruise turns a yellowish colour.

A bruise that does not fade after about week, that appears for no apparent reason, or that is severe after only minor injury, may indicate a bleeding disorder. (See also black eye; purpura.)

**bruits**
The sounds that are made in the heart, arteries, or veins when the blood circulation becomes turbulent or when it flows abnormally fast. This may happen when blood vessels widen (as in an aneurysm), when they become narrowed by disease (as in arteriosclerosis), or when heart valves are narrowed or damaged (as in endocarditis). Bruits can be heard by a doctor through a stethoscope. (See also carotid bruit.)

**bruxism**
Rhythmic grinding or clenching of the teeth that usually occurs during sleep. The main causes are emotional stress and minor discomfort when the teeth are brought together. Continued bruxism may wear away the teeth.

**BSE**
The abbreviation for bovine spongiform encephalopathy.

**bubo**
An inflamed and swollen lymph node, usually in the groin or armpit. Buboes usually occur as the result of a bacterial infection such as plague or a sexually transmitted infection.

**bubonic plague**
The most common form of plague, characterized by the development of a bubo (a swollen lymph node) in the groin or armpit.

**buccal**
A term that refers to the cheek or mouth. Buccal preparations of some drugs are available. Placed between the cheek and gum, they dissolve and are absorbed directly into the blood circulation.

**buck teeth**
Prominent upper incisors (front teeth) that protrude from the mouth. Orthodontic treatment of buck teeth involves repositioning the teeth with a removable brace (see brace, dental) or a fixed orthodontic appliance.

**Budd–Chiari syndrome**
A rare disorder in which the veins draining blood from the liver become blocked or narrowed. Blood accumulates in the liver, which swells. Liver failure and portal hypertension (raised pressure in the vein carrying blood to the liver) result.

Treatment is aimed at removing the cause of the obstruction, which may be a blood clot, pressure on the veins from a liver tumour, or a congenital (present from birth) abnormality of the veins. In most cases, treatment has only a limited effect and, unless a liver transplant can be carried out, the disease is generally fatal within two years.

**budesonide**
A corticosteroid drug used in the prevention of bronchial asthma attacks. Budesonide is administered using an inhaler. Adverse effects, which include hoarseness, throat irritation and, rarely, fungal infections, can be reduced by rinsing the mouth after administration.

**Buerger’s disease**
A rare disorder, also known as thromboangiitis obliterans, in which the nerves, arteries, and veins in the legs, and sometimes the arms, become severely inflamed. The blood supply to the toes and fingers becomes cut off, eventually causing gangrene (tissue death). Buerger’s disease is most common in men under the age of 45 who smoke heavily.

**buffalo hump**
A lump of fat under the skin on the back of the neck. A buffalo hump may develop following long-term treatment with high doses of corticosteroid drugs or as a result of Cushing’s syndrome.

**building-related illnesses**
Another term for the group of symptoms known as sick building syndrome.

**bulbar palsy**
Weakness of the muscles involved in talking and swallowing, causing slurred speech, hoarseness, difficulty in swallowing, and choking on food and drink. Bulbar palsy may be caused by damage to the muscles’ nerve supply, as in motor neuron disease, or disease of the muscles themselves, as in muscular dystrophy.

**bulimia**
A psychiatric illness that is characterized by bouts of overeating, usually followed by self-induced vomiting or excessive use of laxatives. Most people suffering from bulimia are girls or women between the ages of 15 and 30. In some cases, the symptoms coexist with those of anorexia nervosa.

Repeated vomiting can lead to dehydration and loss of potassium, causing weakness and cramps, and also causes tooth damage due to the gastric acid in vomit. Treatment of bulimia includes supervision and regulation of the person’s eating habits, psychotherapy, and, in some cases, antidepressant drugs (see selective serotonin reuptake inhibitors).

**bulk-forming agent**
A type of antidiarrhoeal drug that absorbs water, making stools less liquid. Bulk-forming agents are also used as laxatives, stimulating bowel movement by softening faeces and increasing their bulk.

**bulla**
A large air- or fluid-filled bubble that is usually found in the lungs or skin. Lung bullae in young adults are usually congenital (present from birth). In later life, lung bullae develop in patients with emphysema, a disorder in which the air sacs in the lungs are gradually destroyed. Skin bullae are large, fluid-filled blisters with a variety of causes, including the bullous disease pemphigus.
bull-neck
Swelling of the neck caused by severely swollen lymph glands, often related to infections in the tonsils and throat. (See also diphtheria.)

bullous pemphigoid
An alternative term for pemphigoid, a skin disease in which large, tense blisters develop.

bumetanide
A powerful, short-acting loop diuretic drug used to treat oedema (accumulation of fluid in tissues) resulting from heart failure, nephrotic syndrome (damage to the kidney’s filtering units), or cirrhosis. It may be given by injection for the emergency treatment of pulmonary oedema (fluid in the lungs). Side effects may include rash and muscle pain.

bundle
Also known as a fascicle, a cluster of nerve or muscle fibres.

bundle branch block
See heart block.

bunion
A thickened pad of tissue or a fluid-filled bursa (sac) overlying a deformed big-toe joint. The underlying cause is an abnormal outward projection of the big toe called a hallux valgus. Small bunions can usually be remedied by wearing well-fitting shoes and a special toe pad to straighten the big toe. Large bunions may require surgery to realign the joint and relieve the pressure.

HOW BUNIONS FORM
A bunion results from the rubbing of a shoe against an abnormal outward projection of the joint at the base of the big toe (a hallux valgus), leading to irritation and inflammation. The joint abnormality is often due to wearing narrow, pointed shoes with high heels, although it can also result from an inherited weakness in the joint.

buphthalmos
A large, prominent eyeball in an infant due to congenital glaucoma (increased pressure inside the eyeball). The condition is usually treated with surgery to reduce the pressure; otherwise, the child’s sight is progressively damaged.

bupivacaine
A long-acting local anaesthetic (see anaesthesia, local) often used as a nerve block during childbirth and in epidural anaesthesia and spinal anaesthesia. Side effects are uncommon, but high doses may cause blood pressure to fall.

bupropion
Another name for amfebutamone, a drug used as an aid to stopping smoking.

Burkitt’s lymphoma
A cancer of lymph tissues (see lymphatic system) characterized by tumours within the jaw and/or the abdomen. The condition almost exclusively affects children living in the low-lying, moist, tropical regions of Africa and New Guinea. Anti-cancer drugs or radiotherapy give a partial or complete cure in about 80 per cent of cases. (See also lymphoma.)

burns
Tissue damage caused by contact with heat, electricity, chemicals, or radiation. Burns are classified, according to the severity of skin damage, as first-, second-, or third-degree (or superficial, partial thickness, or full thickness).

FIRST-DEGREE BURNS
A first-degree burn causes reddening of the skin and affects only the epidermis, (topmost layer of skin). These type of burns usually heal quickly, but the damaged skin may peel away after a day or two. Sunburn is a common example of a first-degree burn.

SECOND-DEGREE BURNS
A second-degree burn extends into, and damages, the dermis (deep layer of skin), sometimes causing the formation of blisters. Because some of the dermis is left to recover, these type of burns usually heal without leaving scars, unless they are very deep.

THIRD-DEGREE BURNS
A third-degree burn destroys the full skin thickness and may extend to the muscle layer beneath the skin. The affected area will look white or charred; if the burn is very deep, muscles and bones may be exposed. Even if very localized, third-degree burns will need specialist treatment and possibly skin grafts to prevent scarring.

ELECTRICAL BURNS
Electrical burns can cause extensive tissue damage with minimal external skin damage. The electric current may cause heart damage.

EFFECTS AND COMPLICATIONS
Extensive first-degree burns (such as sunburn) cause pain, restlessness, fever, and headache, but are not life-threatening. A second- or third-degree burn that affects more than ten per cent of the body surface causes shock, with lowered blood pressure and a rapid pulse, due to massive fluid loss from the burned area. Shock may be fatal if this fluid is not replaced intravenously.

When the skin is burned it can no longer protect the body from contamination by airborne bacteria. The infection of extensive burns may cause fatal complications if effective treatment with antibiotic drugs is not available.

Victims who have inhaled smoke may develop inflammation of the lungs and may need specialist care for burns of the eyes and respiratory passages.

TREATMENT
A burn is covered with a non-stick dressing to keep the area moist. Analgesic drugs are given if necessary and antibiotics are prescribed if there is any infection. For extensive second-degree burns, which may be slow to heal or carry a high risk of infection, a topical antibacterial agent, such as silver sulphadiazine, is used. Third-degree burns always require skin grafts, which are used early to minimize scarring. Extensive burns may require plastic surgery.

burping
Another term for belching.

burr hole
A hole made in the skull by a special drill with a rounded tip (burr). The hole relieves pressure on the brain that often results from bleeding inside the skull, usually due to a head injury. Burr holes may be part of a craniotomy (in which a section of skull is removed for access to the brain) and may be life-saving.
**bursa**
A fluid-filled sac that acts as a cushion at a pressure point, often where a tendon or muscle crosses bone or other muscles. The important bursae are found around the knee, elbow, and shoulder joints.

**bursitis**
Inflammation of a bursa (a fluid-filled sac) causing pain and swelling. Bursitis may result from pressure, friction, or injury to the membrane surrounding a joint, or to infection. Prepatellar bursitis (also known as housemaid’s knee), for example, is the result of prolonged kneeling on a hard surface. Treatment is by avoiding further pressure and by taking nonsteroidal anti-inflammatory drugs. Antibiotic drugs may be necessary if the bursa is infected.

**buserelin**
A synthetic form of the hormone gonadorelin that is used to treat endometriosis (a disease of the lining of the uterus), infertility, and cancer of the prostate.

**butterfly rash**
A skin eruption, also called a butterfly patch, that is characteristic of systemic lupus erythematosus (see rash).

**buzzer and pad system**
A device used to treat bedwetting (see enuresis, nocturnal). A pad that detects moisture is placed in the bed and is attached to a buzzer that sounds when the pad becomes wet with urine. The person is woken up as soon as he or she starts to pass urine and gradually learns to wake up before starting to pass urine.

**bypass operations**
Surgical procedures that are used to bypass blockages or narrowing. The term bypass usually refers to operations on arteries, although blockages in the digestive system can also be treated with bypass operations.

The most common type of bypass operation is coronary artery bypass, which is used to treat coronary artery disease, (a condition in which the arteries have become blocked or narrowed by atherosclerosis). Obstructions can be bypassed by using sections of healthy artery or vein from elsewhere in the body or using tubing made from a synthetic material such as dacron.

Intestinal bypass operations are most often performed to treat cancer patients in whom the tumour is too extensive to be removed surgically. The blocked area is bypassed by joining the sections of bowel above and below the blockage.

**byssinosis**
A lung disease caused by the dust that is produced during the processing of flax, cotton, hemp, or sisal. Byssinosis causes a feeling of tightness in the chest and shortness of breath that may become chronic (of long duration) if exposure to the agent continues. Bronchodilator drugs and other drugs used to treat asthma can relieve the symptoms; good ventilation and equipment such as masks reduce the risk.
cachexia
A condition of severe weight loss and decline in health caused by a serious underlying disease, such as cancer or tuberculosis, or by starvation.

cadaver
A dead human body used as a source of transplant organs or for anatomical study and dissection.

cadmium poisoning
The toxic effects of cadmium, a tinlike metal. Poisoning as a result of inhalation of cadmium fumes is an industrial hazard, the effects of which depend on the duration and severity of exposure. Eating vegetables grown in cadmium-rich soil, or the consumption of food or drink stored in cadmium-lined containers, can also cause poisoning.

Short-term exposure to cadmium may lead to pneumonitis (inflammation of the lungs). Exposure over a long period can lead to urinary tract calculi (stones), kidney failure, or emphysema (a form of permanent lung damage).

caecum
The first section of the large intestine, joining the ileum (the end of the small intestine) to the ascending colon. The appendix projects from the caecum. (See also digestive system).

caesarean section
An operation to deliver a baby from the mother’s uterus through a horizontal or, less commonly, a vertical incision in the abdomen. A caesarean section is performed if vaginal delivery would be difficult or dangerous for the mother or the baby. Increasingly, women who do not want to go through labour are also opting to have the operation.

A caesarean section may be performed using either an epidural anaesthesia or general anaesthesia (see anaesthesia, general). The procedure for performing a caesarean section is shown in the illustrated box (see opposite page).

After the operation, the mother is given analgesic drugs (painkillers) as required. If there are no complications, she and the baby can usually leave hospital about a week after the operation.

café au lait spots
Coffee-coloured patches on the skin that may occur on any part of the body. Café au lait spots are usually oval in shape and may measure several centimetres across. Generally, the presence of a few of these spots is not significant. However, larger numbers of them may be a sign of neurofibromatosis, a hereditary disorder of the sheaths that surround nerve fibres.

cafeine
A stimulant drug that is found in coffee, tea, cocoa, and cola drinks. Caffeine reduces fatigue, improves concentration, makes the heart pump blood faster, and has a diuretic effect.

<table>
<thead>
<tr>
<th>CAFFEINE LEVELS</th>
</tr>
</thead>
<tbody>

<tr>
<td>Cocoa</td>
</tr>
<tr>
<td>Cola</td>
</tr>
</tbody>
</table>

Large quantities of caffeine may produce side effects such as agitation and tremors. A regular high intake may lead to increased tolerance, so that people need to increase their caffeine intake to obtain the equivalent stimulant effect. In people who consume large amounts of caffeine, withdrawal symptoms (see withdrawal syndrome), such as headaches and tiredness, may occur after a few hours without caffeine.

Caffeine may be used in some drug preparations, particularly in combination with analgesic drugs (painkillers) and with ergotamine in preventive treatments for migraine.

calamine
A preparation of zinc oxide and iron oxide that is applied to the skin as an ointment, lotion, or dusting powder to relieve irritation and itching. Calamine has a protective, cooling, and drying effect. It may be combined with a local anaesthetic (see anaesthesia, local), corticosteroid drug, or antihistamine drug.

calcaneal bursitis
Inflammation of the bursa (fluid-filled container) that cushions the calcaneus and prevents friction at the back of the heel (see bursitis). The condition causes pain and swelling but usually clears up with rest and anti-inflammatory drugs.

calcaneus
The heel bone. The calcaneus is one of the tarsal bones and is the largest bone in the foot. The Achilles tendon runs between the back of the calcaneus and the calf muscles; it controls upward and downward movements of the foot.

DISORDERS
The calcaneus may be fractured by a fall from a height on to the heel. Minor fractures do not usually cause problems and can be treated by placing the affected foot and leg in a cast. A more serious fracture, with compression of the bone, may cause permanent damage to the joints involved in turning the foot in and out, leading to pain and stiffness that are aggravated by walking.

The point at which the Achilles tendon joins the calcaneus may become strained by excessive or prolonged stress from the pull of the tendon (in some running injuries, for example). In children, this area may be inflamed and painful (see osteochondrosis) because the bone is still growing.

LOCATION OF THE CALCANEUS
The calcaneus is the largest of the tarsal bones. It projects backwards beyond the leg bones.
A caesarean section allows delivery of a baby through a horizontal or vertical cut in the abdominal and uterine walls. The mother is given epidural anaesthesia, so that she remains conscious during the procedure, or general anaesthesia.

**WHY IT IS DONE**

A caesarean can be elective (planned) in cases of breech presentation; placenta praevia (where the placenta is lying close to or across the cervix); the mother’s ill health; or, most commonly, if there were problems in previous caesareans that still exist (such as the mother having a small pelvis).

Elective caesarean is sometimes requested by the parents for social reasons.

An emergency caesarean is needed in cases of fetal distress (lack of oxygen); unsuccessful induction of labour; or bleeding (such as in placental abruption (premature separation) or placenta praevia).

**HOW IT IS DONE**

1. First, epidural anaesthesia is carried out to temporarily numb the abdomen by deadening the nerves leading to it. A needle is introduced into the epidural space and a catheter is threaded through it. A local anaesthetic is injected down the catheter. A catheter is also inserted into the bladder to empty it.

2. The abdomen is then opened, usually through a horizontal incision made just above the pubic bone. This type of cut heals most effectively. The resulting scar is hardly noticeable and comes below the "bikini line".

3. The amniotic fluid is drained off by suction. The baby is delivered through an incision in the lower part of the uterus. The umbilical cord is cut and the afterbirth removed. The incisions in the uterus and abdomen are then sewn up. The mother is given an injection of ergometrine and oxytocin to make the uterus contract and stop any bleeding.
The tendons of the sole of the foot are fixed under the calcaneus, and the associated muscles are important in supporting the arches of the foot. Inflammation around these tendons (as occurs in plantar fasciitis) causes pain and tenderness under the heel when standing or walking. A calcaneal spur (a bony protrusion) occurs in some people with plantar fasciitis and also, occasionally, in those with healthy feet.

calciferol
A former name for vitamin D₃. This vitamin is now more commonly known as ergocalciferol (see vitamin D).

calcification
The deposition of calcium salts in body tissues. Calcification is part of the normal processes of bone and teeth formation and the healing of fractures. It also occurs in injured muscles, in arteries affected by atherosclerosis, and when blood calcium levels are raised by disorders of the parathyroid glands.

calcification, dental
The deposition of calcium salts in developing teeth. Primary teeth (see eruption of teeth) begin to calcify in a fetus at between three and six months gestation. Calcification of permanent teeth (other than the wisdom teeth) begins between birth and four years.

Certain tooth conditions can cause abnormal calcification. In amelogenesis imperfecta, an enamel disorder (see hypoplasia, enamel), teeth have a thin, grooved covering due to incomplete calcification. Another cause is absorption of high levels of fluoride (see fluorosis) and drugs, such as tetracycline, that are taken in pregnancy.

calcinosclerosis
The abnormal deposition of calcium salts in the skin, muscles, or connective tissues, forming nodules. Calcinosclerosis occurs in connective tissue disorders such as scleroderma. (See also calcification.)

calcipotriol
A derivative of vitamin D that is used in topical treatments for the skin condition psoriasis.

calcitonin
A hormone produced by the thyroid gland that helps to control blood calcium levels by slowing the rate at which calcium is lost from the bones.

WHY IT IS USED
A synthetic form of calcitonin used in the treatment of Paget’s disease, in which the bones grow abnormally and become deformed, causing pain and an increased risk of fracture. Injections of calcitonin can generally halt abnormal bone formation in about a week and can relieve pain within a few months.

Calcitonin is also used in the treatment of hypercalcaemia (abnormally high levels of calcium in the blood), which may be caused by overactivity of the parathyroid glands or by bone cancer. It helps to relieve the nausea and vomiting that result from hypercalcaemia by rapidly reducing the level of calcium circulating in the blood.

SIDE EFFECTS
Calcitonin causes minimal side effects. Gastrointestinal reactions, such as nausea, vomiting, and diarrhoea, usually diminish with continued use.

calcium
The body’s most abundant mineral, calcium is essential for cell function, muscle contraction, the transmission of nerve impulses from nerve endings to muscle fibres, and for blood clotting. Calcium phosphate is the hard, basic constituent of teeth and bones. Dietary sources of calcium include dairy products, eggs, and green, leafy vegetables.

CONTROL OF CALCIUM LEVELS
Vitamin D and certain hormones help to control the overall amount of calcium in the body. They act by regulating the amount of calcium that is absorbed from food and the amount filtered out from the blood by the kidneys and excreted in the urine.

The levels of calcium in the blood are controlled by the actions of two hormones: parathyroid hormone, which is produced by the parathyroid glands, and calcitonin, which is produced by the thyroid gland. When the level of calcium in the blood falls to a low level, the parathyroid glands release more parathyroid hormone, which raises the blood calcium level by helping to release calcium from the enormous reservoir in the bones. When the blood calcium level rises significantly, the thyroid gland releases more calcitonin. This hormone counteracts the effects of parathyroid hormone, thereby lowering the level of calcium in the blood.

DISORDERS OF CALCIUM METABOLISM
Abnormally high levels of calcium in the blood (hypercalcaemia) or abnormally low levels (hypocalcaemia) may seriously disrupt cell function, particularly in muscles and nerves. (See also mineral supplements.)

calcium carbonate
A calcium salt used in some antacid drugs, which can be taken for the treatment of indigestion.

calcium channel blockers
COMMON DRUGS
- Amiodipine
- Diltiazem
- Felodipine
- Isradipine
- Lercanidipine
- Nifedipine
- Verapamil

Drugs used in the treatment of angina pectoris (chest pain due to impaired blood supply to the heart muscle), hypertension (high blood pressure), and certain types of cardiac arrhythmia (irregular heartbeat).

HOW THEY WORK
Calcium channel blockers work by interfering with the movement of calcium across the membranes of muscle cells in blood vessels and in the heart muscle itself. This action decreases the work of the heart in pumping blood, reduces the pressure of blood flow through the body, and improves blood circulation through the heart muscle.

The drugs also slow the passage of nerve impulses through the heart’s internal conduction system, which helps to control certain types of arrhythmia.

SIDE EFFECTS
The side effects of calcium channel blockers are mainly related to their action of increasing the blood flow through tissues. These effects include headaches, swollen ankles, flushing, and dizziness. Adverse effects tend to diminish with continued treatment.

calculus
A hard deposit in the body. Calculus may form on the surface of the teeth (see calculus, dental). Alternatively, it may be a small, hard, crystalline mass that forms in a body cavity from certain substances in fluids such as bile, urine, or saliva. Such calculi (also called stones) can occur in the gallbladder and bile ducts (see gallstones), kidneys, ureters, bladder (see calculus, urinary tract), or in the salivary ducts.

Although some calculi do not cause any symptoms, some can cause severe pain, in which case they may need to be dissolved, shattered, or surgically removed from the body cavity.
calculus, dental
A hard, crust-like deposit, also called tartar, found on the crowns and roots of the teeth. Calculus forms when mineral salts in saliva are deposited in existing plaque, a coating of mucus and debris that forms on the teeth.

TYPES
There are two types of dental calculus. Supragingival calculus is a yellowish or white deposit that forms above the gum margin, on the crowns of teeth in areas close to the openings of salivary gland ducts. Subgingival calculus forms below the gum margin, is more evenly distributed around all the teeth, and is brown or black.

Both types of calculus are hard and are therefore difficult to remove; the subgingival variety may be more difficult to remove because of its location and degree of calcification.

EFFECTS AND TREATMENT
The toxins present in calculus can lead to gum inflammation (see gingivitis), which may progress to destruction of the supporting tissues (see periodontitis). Calculus should be removed on a regular basis by professional scaling. Careful attention to oral hygiene may reduce the recurrence of dental calculus.

calculus, urinary tract
A stone in the kidneys, ureters, or bladder that is formed from crystallized substances in the urine.

TYPES AND CAUSES
Kidney and ureteral stones Most stones that form in the kidneys and ureters are composed of calcium oxalate or other salts crystallized from the urine. These stones may be associated with a diet that is rich in oxalates (which are found, for example, in leafy vegetables and tea); high levels of calcium in the blood due to hyperparathyroidism (over-activity of the parathyroid glands); or chronic dehydration.

Other types of kidney or ureteral stone are associated with gout and certain cancers. Stones that develop in these locations due to chronic urinary tract infection are termed “infective”. Kidney stones that fill the entire network of urine-collecting ducts at the top of the ureter are called “staghorn” calculi, due to their shape.

Bladder stones In developing countries, bladder stones usually occur as a result of dietary deficiencies. In developed countries, they are usually caused by an obstruction to urine flow from the bladder and/or a longstanding urinary tract infection. The composition of the stones is related to the acidity or alkalinity of the urine.

SYMPTOMS
The most common symptom of a stone in the kidney or ureter is renal colic, a severe pain in the back, under the ribs, that often spreads into the groin. This pain may be accompanied by nausea and vomiting. There may also be haematuria (blood in the urine). A bladder stone usually causes difficulty in passing urine.

DIAGNOSIS AND TREATMENT
Investigation of a suspected calculus usually starts with microscopic examination of the urine, which may reveal red blood cells and the presence of crystals. The degree of acidity or alkalinity of the urine may reflect the type of stone involved. The site of a stone can usually be confirmed by intravenous urography. Some stones, particularly those containing calcium, are visible on a plain abdominal X-ray.

Renal colic is treated with bed rest and an analgesic drug (painkiller). With an adequate fluid intake, small stones are usually passed in the urine without causing problems. The first line of treatment for larger stones in the urinary tract is often lithotripsy, a procedure that uses ultrasonic waves or shock waves to disintegrate the stones. Alternatively, cystoscopy can be used to crush and remove stones in the bladder and lower ureter. In some cases, surgery may be needed to remove the stones.

calendar method
A method of contraception, also called the rhythm method, based on abstaining from sexual intercourse around the

<table>
<thead>
<tr>

</tr>
</thead>
<tbody>
<tr>
<td>Calculi form in the urinary tract when certain substances in the urine become overly concentrated. The substances form crystals, which grow into stones. Some stones may be associated with recurrent episodes of urinary tract infection. Symptoms vary according to the site of the stone. Small stones may be passed in the urine and cause no symptoms. Some stones, however, may lodge in a ureter, causing renal colic (a sudden, severe pain in the small of the back that moves towards the groin) and haematuria (blood in the urine). In the bladder, stones may settle over the outlet, which can cause difficulty in passing urine, a poor flow rate, and dribbling. Any obstruction to urine flow may result in rapid kidney damage and acute, severe infection (pyelonephritis).</td>

time of ovulation (the release of an egg from a woman’s ovary). This time is calculated on the basis of the length of her previous menstrual cycles. The calendar method is unreliable because a woman’s menstrual cycle may vary. There are now more scientific and effective contraceptive methods of this type (see contraception, natural methods).

calf muscles
The muscles extending from the back of the knee to the heel. The gastrocnemius muscle starts behind the knee and forms the bulky part of the calf; beneath it lies the soleus muscle which starts at the back of the tibia (shin). These two muscles join to form the Achilles tendon, which connects them to the heel. Contraction of the calf muscles pulls the heel up and is important in walking, running, and jumping.

LOCATION OF CALF MUSCLES

The gastrocnemius muscle and the soleus muscle at the back of the leg join to form the Achilles tendon.

callus
A diffuse growth of new, soft bone that forms as part of the healing process in a fracture. As healing continues, the callus is replaced by harder bone, and the original shape of the bone is restored.

callosity
See callus, skin.

callosum
An orthopaedic device that corrects or controls a deformed leg or supports a leg weakened by a muscular disorder, allowing an affected person to stand and walk. For example, a person who has lost the ability to flex the foot upward and, as a result, drags the toes on the ground with each step can be fitted with a splint that keeps the foot permanently at right angles to the leg, thereby allowing walking.

A caliper splint consists of one or two vertical metal rods attached to leather or metal rings that are worn around the affected limb. A splint extending just below the knee is sufficient to control the position of the ankle. Longer splints may be jointed to allow movement of the knee.

caloris test
A method of finding out whether the labyrinth in the inner ear is diseased. A caloric test may be performed as part of investigations into vertigo (dizziness) and hearing loss.

The outer-ear canal is briefly flooded with water of different temperatures, above and below normal body temperature. This flooding sets up convection currents in the semicircular canals in the inner ear. If the labyrinth is normal, nystagmus (rapid reflex flickering of the eyes) occurs for a predictable period. If the labyrinth is diseased, this response is either absent or reduced. The presence and duration of nystagmus may be observed directly or recorded electrically using electronystagmography.

calorie
A unit of energy. One calorie is the amount of energy that is needed to raise the temperature of 1 gram of water by 1°C. The term “calorie” is also used in medicine and dietetics to mean “kilocalorie”, which is a larger unit of energy equal to 1,000 calories.

Normally, when a person’s calorie intake matches the amount of energy expended, body weight remains constant. If intake exceeds expenditure, weight is usually gained; if expenditure exceeds intake, weight is usually lost. In general, fats contain more calories than proteins or carbohydrates.

Energy can also be measured in joules: 1 calorie equals 4.2 joules. (See also calorimetry, diet and disease.)

calorie requirements
See energy requirements.

calorimetry
The measurement of the calorie (energy) value of foods or the energy expenditure of a person. In direct calorimetry, a small measure of food is burned up inside a sealed container, which is immersed in water. The resultant rise in water temperature is used to calculate the calorie value.

Energy production in humans can be measured by oxygen uptake. Every litre of oxygen taken into the body produces 4.8 kilocalories of energy. The level of energy production is calculated by comparing the percentage of oxygen in air that is inhaled and exhaled.

Calpol
A brand name for paediatric preparations containing the analgesic drug (painkiller) paracetamol.

camouflaging preparations
Creams or powders that are applied to the skin to conceal skin disfigurements, such as birthmarks and scars.

Campbell de Morgan’s spot
A small (1–3 mm), bright red, domed spot, also known as a cherry angioma, that appears on the trunk or limbs. A Campbell de Morgan’s spot is a type of haemangioma (a noncancerous blemish). The spots are harmless. They are
caused by weakening of the walls of capillaries in the dermis (the inner layer of the skin). Campbell de Morgan’s spots are common in adults, especially elderly people.

**Campylobacter**
A group of bacteria that are among the most common causes of gastrointestinal disorders. Campylobacter bacteria are harboured by animals and can be passed on to humans through contaminated food, especially in poultry, causing *food poisoning*. These bacteria also cause a form of *colitis*, an inflammatory disease of the colon.

**canal**
A narrow tubular passage or channel in the body, such as the *ear* canal, which leads from the outer to the middle ear, or the alimentary canal, which is part of the *digestive system*.

**cancer**
Any of a group of diseases that are characterized by the abnormal and unrestrained growth of cells in body organs or tissues. Cancerous tumours can form in any tissue in the body, but they most commonly develop in major organs, such as in the lungs, breasts, intestines, skin, stomach, or pancreas. Cancerous tumours can also develop in the nasal sinuses, the testes or ovaries, or the lips or tongue. Cancers may also develop in the tissues of the bone marrow that form blood cells (see *leukaemia*) and in the lymphatic system, the muscles, or the bones.

Cancers differ from benign (non-cancerous) *neoplasms* (growths) in that they spread and infiltrate surrounding normal tissue. The tumours can cause blockages in hollow organs, such as within the digestive tract. They can also destroy nerves and erode bone. Cancer cells may also spread through the blood vessels or lymphatic system to other organs to form secondary tumours, known as metastases (see *metastasis*).

**CAUSES**
Tumour-forming cells develop when the *oncogenes* (genes controlling cell growth and multiplication) in a cell or cells undergo a series of changes. A small group of abnormal cells develop that divide more rapidly than normal, lack differentiation (they no longer perform their specialized task), and may escape the normal control of hormones and nerves. Possible causes of cancer include environmental factors (such as sunlight and pollutants), alcohol consumption, dietary factors, and, most particularly, smoking, which is responsible for more cancers than any other agent. All of these factors may provoke critical changes within body cells in people who are already susceptible to developing cancer. Susceptibility to certain cancers may be inherited.

**SYMPTOMS**
Cancer symptoms depend on the site of the growth, the tissue of origin, and the extent of the tumour. They may be a direct feature of the growth (for example, lumps or skin changes) or may result from disruption of the function of a vital organ or blockage of a part of the body by the tumour. Unexplained weight loss is a feature of many different types of cancer.

**DIAGNOSIS**
Screening tests (see *cancer screening*) are increasingly being used to detect early signs of certain types of cancer in people who are thought to be at risk. Early detection of cancer optimizes the chance of a cure; for this reason, screening for breast cancer, cancer of the cervix, and intestinal cancer has been adopted in an attempt to reduce the chance of a cure; for this reason, screening for breast cancer, cancer of the cervix, and intestinal cancer has reduced mortality from these tumours. Diagnosis of cancer after symptoms have appeared is based on a physical examination, and confirmed by *biopsy* (removal of a sample of abnormal tissue for microscopic analysis) and imaging tests.

There are four main types of procedure used to detect cancer: cytology (cell) tests, imaging techniques, chemical tests, and direct inspection.

**TREATMENT AND OUTLOOK**
Many cancers are now curable, usually by combinations of surgery, *radiotherapy*, and *anticancer drugs*. For details of a specific type of cancer, refer to the article on that organ (for example, see lung cancer; stomach cancer).

**cancerphobia**
An intense fear of developing cancer, out of proportion to the actual risk, that significantly affects the life of the sufferer. An individual who has cancerphobia may become convinced that symptoms such as headaches, skin problems, constipation, or difficulty in swallowing, are signs of cancer. Patterns of behaviour that are typical of *obsessive–compulsive disorder* (such as prolonged washing rituals) may be adopted in an attempt to reduce the...
CANCER SCREENING

TESTS USED TO DETECT CANCER

<table>
<thead>
<tr>
<th>Cytology tests</th>
<th>Imaging techniques</th>
<th>Chemical tests</th>
<th>Viewing techniques</th>
</tr>
</thead>
<tbody>
<tr>
<td>These tests reveal the presence of abnormal cells. One example is the cervical smear test, an investigation in which cells are scraped from the cervix (neck of the uterus) and examined microscopically to detect potential or early cancer of the cervix. Another example is urine cytology, used to detect bladder cancer. Cells can also be removed from solid lumps; this procedure is often carried out on breast lumps.</td>
<td>Imaging tests can sometimes reveal changes in the appearance of tissue that are suggestive of cancer. One such test is a low-dose X-ray used in mammography to detect early breast cancer. Another is ultrasound scans can detect cancer of the ovary. CT scanning and MRI provide detailed images of internal anatomy and are particularly useful for showing inaccessible areas, such as the brain and the back of the abdominal cavity.</td>
<td>Tests on blood, urine, or faeces can show the presence of substances suggestive of cancer. For example, microscopic amounts of blood in the faeces may be due to cancer of the colon; high blood levels of prostate specific antigen (PSA) are sometimes due to prostate cancer.</td>
<td>Viewing tests involve looking inside a hollow organ using an endoscope (a tube with a viewing lens). They are usually performed only when cancer is already suspected. Examples include colonoscopy, gastroscopy, cystoscopy, and laparoscopy (viewing of the colon, stomach, bladder, and abdominal cavity, respectively).</td>
</tr>
</tbody>
</table>

risk of cancer. Psychotherapy, including behaviour therapy, may be of benefit. (See also phobia.)

cancer screening

Tests that are carried out to detect cancer before symptoms have developed. Cancer screening is used particularly for groups of people who are thought to be susceptible because of their age, occupation, lifestyle, or genetic predisposition. Early detection often increases the chance of a cure. Tests for cancers of the cervix (see cervical smear test), breast (see mammography), bladder, and colon have proved effective in reducing mortality from these conditions.

cancrum

The medical term for canker or ulceration. It mainly refers to the mouth and lips, when the condition is known as cancrum oris. (See also noma.)

candidiasis

Infection by the fungus Candida albicans, also known as thrush or moniliasis. Candidiasis affects areas of mucous membrane in the body, most commonly the vagina and the inside of the mouth. In infants, candidiasis can occur in conjunction with nappy rash.

CAUSES

The fungus is normally present in the mouth and the vagina, but in some situations it may multiply excessively. Candidiasis may occur if antibiotic drugs destroy the harmless bacteria that control the growth of the fungus, or if the body’s resistance to infection is lowered. Certain disorders, for example diabetes mellitus, and the hormonal changes that occur during pregnancy or with oral contraceptives, may also encourage growth of the fungus. Candidiasis can be contracted by having sexual intercourse with an infected partner. The infection is far more common in women than in men.

SYMPTOMS

Symptoms of vaginal infection include a thick, white discharge, genital irritation, and discomfort on passing urine. Less commonly, the penis is infected, usually causing balanitis (inflammation of the head of the penis). Oral candidiasis produces sore, creamy-yellow, raised patches inside the mouth.

Candidiasis may spread from the genitals or mouth to other moist areas of the body. It may also affect the gastrointestinal tract, especially in people with impaired immune systems, such as those taking immunosuppressant drugs or who have HIV (the virus that leads to AIDS).

DIAGNOSIS AND TREATMENT

Candidiasis is diagnosed by examination of a sample taken from the white discharge or from patches.

The condition is treated topically with antifungal drugs such as clotrimazole or with oral antifungals. The drugs are given in the form of creams, vaginal pessaries, or throat lozenges. Treatment of candidiasis is usually successful, but the condition may recur.

Canesten cream

A brand name for the antifungal drug clotrimazole, used to treat fungal infections of the skin and genitals (for example, candidiasis).

canine tooth

See teeth.

cannabis

A preparation that is derived from the hemp plant Cannabis sativa and usually used to produce euphoria and hallucinations (see marijuana).

cannula

A smooth, blunt-ended tube that is inserted into a blood vessel, lymphatic vessel, or body cavity, in order to introduce or withdraw fluids. Cannulas are used for blood transfusions and intravenous infusions and for draining pleural effusions (fluid around the lungs). If necessary, a cannula may be left in place for several days if continuous testing of, or introduction of, fluids is required.

canthus

The anatomical term for the corner of the eye (the angle at which the upper and lower eyelids meet).

capacity, iron-binding

A measure of the level of transferrin, a protein that acts in addition to haemoglobin (the oxygen-carrying pigment in the blood) to bind and transport iron in the blood. Measuring iron-binding capacity may help to establish the cause of anaemia (a reduced level of haemoglobin in the blood).

Transferrin is formed mainly in the liver. The amount produced is determined by the amount of iron that is stored in the body. When iron stores are low, as occurs in iron-deficiency anaemia (see anaemia, iron-deficiency), more transferrin is produced to enable the blood to carry as much iron as possible. The level of transferrin and the iron-binding capacity of the blood are thereby raised, although the level of iron in the body is low.
capacity, vital
The maximum volume of air, usually around 4.5 litres, that can be expelled from the lungs following maximum inhalation. Vital capacity is measured as part of lung function tests (see pulmonary function tests).

cap, cervical
A flexible contraceptive device that is placed directly over the cervix to prevent sperm from entering it (see contraception, barrier methods of).

cap, duodenal
See duodenal cap.

Capgras’ syndrome
The delusion (false belief) that a relative or friend has been replaced by an identical impostor. Capgras’ syndrome, also known as the “illusion of doubles”, is seen most frequently in patients with paranoid schizophrenia but can also occur in some organic brain disorders (see brain syndrome, organic) and affective disorders.

capillary
Any of the vessels that carry blood between the smallest arteries, or arterioles, and the smallest veins, or venules (see circulatory system). Capillaries form a fine network throughout the body’s organs and tissues. Their thin walls are permeable; as a result, they allow blood and cells to exchange constituents such as oxygen, glucose, carbon dioxide, and water (see respiration).

Capillaries open and close to blood flow according to the requirements of different organs for oxygen and nutrients. For example, when a person is running, most of the capillaries in the leg muscles are open, but at rest many are closed. The opening and closing of skin capillaries helps to regulate temperature. The blood flow through each capillary is controlled by a tiny circle of muscle at its entrance.

DISORDERS
A direct blow to an area of the body may rupture the capillary walls, causing bleeding under the skin, which in turn results in swelling and bruising.

Capillaries become more fragile in elderly people, in people taking high doses of corticosteroid drugs, and in those suffering from scurvy (vitamin C deficiency). All such people have a tendency to develop purpura (small areas of bleeding under the skin which often appear as reddish-purple patches).

capillary haemangioma
See haemangioma.

Caplan’s syndrome
A combination of rheumatoid arthritis and pneumoconiosis (a lung disorder that is caused by inhalation of certain mineral dusts). In Caplan’s syndrome, large areas of fibrous (scar) tissue form in the lungs, often causing severe shortness of breath.

capping, dental
See crown, dental.

capsule
An anatomical structure enclosing an organ or body part. For example, the liver, kidneys, joints, and eye lenses are all enclosed in capsules.

The term “capsule” is also used to describe a soluble, elongated shell, usually made of gelatine, which contains a drug to be taken by mouth. The coating of some capsules prevents potentially irritant drugs from being released into the stomach, or allows drugs to be released slowly to enable them to be taken less frequently.

capsulitis
Inflammation of a capsule, a structure that encloses an organ or joint. One example of capsulitis is frozen shoulder.

STRUCTURE OF CAPILLARIES
These minute blood vessels have thin, permeable walls, which allow the transfer of oxygen, glucose, and water from blood to tissues.

White blood cell protruding through cell wall

Oxygen, glucose, and water
Carbon dioxide, waste products, and excess water
Red blood cell

Captopril
An ACE inhibitor drug. These drugs are used in the treatment of hypertension (high blood pressure), heart failure, and diabetic nephropathy (kidney damage).

caput
The Latin word for head. The term is commonly used of the caput succedaneum: a soft, temporary swelling in the scalp of newborn babies, which is caused by pressure during labour. The word “caput” was once also used to refer to the face, skull, and associated organs; to the origin of a muscle; or to any enlarged extremity, such as the caput femoris, the head of the femur (thigh bone).

carbamazepine
An anticonvulsant drug that is chemically related to the tricyclic antidepressants. Taken orally or as suppositories, carbamazepine reduces the frequency of seizures that are caused by abnormal nerve signals in the brain and is used mainly in the long-term treatment of epilepsy. The drug is also prescribed to relieve neuralgia (intermittent severe pain caused by nerve damage or irritation) and as a mood-stabilizing drug in the treatment of psychiatric disorders such as mania.

carbaryl
An insecticide used to treat head lice and crab lice. Carbaryl is applied topically as a liquid; however, it must not come into contact with the eyes or with areas of broken skin.

carbonxolone
An ulcer-healing drug that is used to treat inflammation and ulceration of the oesophagus, but which has now largely been superseded by antibiotics and by proton pump inhibitors. A gel containing carbonxolone is commonly used to relieve mouth ulcers.

carbimazole
A drug that is used to treat hyperthyroidism (overactivity of the thyroid gland). Carbimazole is slow to take effect, so beta-blockers may be given to relieve symptoms in the interim.

Long-term treatment with carbimazole may reduce the production of blood cells by the bone marrow, so regular blood counts are required. Side effects may include headaches, dizziness, joint pain, and nausea.
**Carbohydrates**

A group of compounds, including starches (complex carbohydrates) and sugars (simple carbohydrates), that are composed of carbon, hydrogen, and oxygen and supply the body with its main source of energy.

**Types and Sources**

Carbohydrates are found in fruits, cereals, and root vegetables. They fall into two main groups: available carbohydrates and unavailable carbohydrates.

The main available carbohydrates are starches and sugars, which are metabolized into glucose for the body’s use. Unavailable carbohydrates include cellulose, which cannot be broken down by digestive enzymes and makes up the bulk of dietary fibre (see fibre, dietary).

**Carbohydrate Metabolism**

The different types of carbohydrates are processed by the body in different ways. Monosaccharides (also known as simple sugars), which include glucose (grape sugar), galactose (a milk sugar), and fructose (fruit sugar), can all be absorbed, unchanged, into the bloodstream, whereas disaccharides (also known as “double” sugars), including sucrose, maltose, and lactose (a milk sugar), need to be broken down into simple sugars before they are absorbed. Starches also have to be broken down into simple sugars before they can be absorbed by the body. This process is carried out by enzymes (chemical catalysts) in the digestive tract.

The simple sugars (mainly glucose) are then absorbed through the intestinal wall and into the bloodstream for distribution throughout the body. Some glucose is burned up immediately (see metabolism) in order to generate energy for cells that need a constant supply, such as brain cells and red blood cells. Galactose and fructose are converted to glucose in the liver to be used by body cells. Surplus glucose is transported to the liver, muscles, and fat cells where it is converted into glycogen and fat for storage.

When blood glucose levels are high, glycogen storage is stimulated by insulin, a hormone that is secreted by the pancreas. When blood glucose levels become low, insulin secretion diminishes and glucagon, another hormone produced by the pancreas, stimulates the conversion of stored glycogen to glucose for release into the bloodstream. Fat cannot be converted to glucose, although it can be used as a fuel to conserve glucose.

In the disorder diabetes mellitus, carbohydrate metabolism is disturbed by a deficiency of insulin.

**Carbolic Acid**

See phenol.

**Carbon**

A nonmetallic element that is present in all the fundamental molecules of living organisms, such as proteins, fats, and carbohydrates, and as well as in some inorganic molecules, such as carbon dioxide, carbon monoxide, and sodium bicarbonate. Pure carbon is the major constituent of diamond, coal, charcoal, and graphite.

**Carbon Dioxide (CO₂)**

A colourless, odourless gas. Carbon dioxide consists of one carbon atom linked to two oxygen atoms and has the chemical formula CO₂. The gas is present in small amounts in the air and is an important by-product of metabolism in cells. It is produced by the breakdown of substances such as carbohydrates and fats to produce energy. It is then carried in the bloodstream to the lungs, where it is exhaled.

Carbon dioxide helps to control the rate of respiration: when a person exercises, CO₂ levels in the blood rise, causing the person to breathe more rapidly in order to expel carbon dioxide and to take in more oxygen.

Carbon dioxide that is compressed and cooled to -78°C becomes liquid dry ice, which is used in cryosurgery (destruction of diseased tissues by freezing).

**Carbon Monoxide (CO)**

A colourless, odourless, poisonous gas. Carbon monoxide consists of one carbon atom linked to one oxygen atom and has the chemical formula CO. It
toxin is present in vehicle exhaust fumes and is produced by inefficient burning of coal, gas, or oil.

**POISONING**

Carbon monoxide is toxic because it binds with *haemoglobin* (the oxygen-carrying molecule in red blood cells), which prevents the blood from carrying oxygen to the body tissues. As a result, the tissues are deprived of oxygen, and asphyxiation occurs. The initial symptoms of acute high-level carbon monoxide poisoning include dizziness, headache, nausea, and faintness. Continued inhalation of the gas may lead to loss of consciousness, permanent brain damage, and even death. Low-level exposure to carbon monoxide over a period of time may cause fatigue, nausea, diarrhoea, abdominal pain, and general malaise.

**carbon tetrachloride (CCl₄)**

A colourless, poisonous, volatile chemical with a characteristic odour. Carbon tetrachloride consists of one carbon atom linked to four chlorine atoms and has the chemical formula CCl₄. Formerly used in domestic dry-cleaning fluids, its use is now restricted to industry.

Carbon tetrachloride is an extremely dangerous chemical, and it can cause dizziness, confusion, and liver and kidney damage if a significant amount of the chemical is inhaled or swallowed. (See also *household poisons*.)

**carbuncle**

A cluster of interconnected **boils** (painful, pus-filled, inflamed hair roots). Carbuncles are usually caused by infection with the bacterium *Staphylococcus aureus*. The back of the neck and the buttocks are the most common sites. The swellings mainly affect people with reduced immunity, particularly those with *diabetes mellitus*.

Treatment is usually with an **antibiotic drug**. In addition, the application of hot **compresses** may encourage the pus-filled heads of the boils to burst, which relieves pain. Occasionally, incision and drainage (together with removal of the core of the carbuncle) may be necessary if a carbuncle is persistent, and drainage and healing have not occurred spontaneously.

**carcinogen**

Any agent that is capable of causing **cancer**, such as tobacco smoke, high-energy radiation, or asbestos fibres.

**CHEMICAL CARCINOGENS**

Chemicals form the largest group of carcinogens. Major types include polycyclic aromatic hydrocarbons (PAHs), which occur in tobacco smoke, pitch, tar fumes, and soot. Exposure to PAHs may lead to cancer of the respiratory system or skin. In addition, certain aromatic amines used in the chemical and rubber industries may cause bladder cancer after prolonged exposure.

**PHYSICAL CARCINOGENS**

The best-known physical carcinogen is high-energy radiation, such as nuclear radiation and *X-rays*. Radiation may also come from **ultraviolet light**, for example in sunlight. Another known physical carcinogen is asbestos (see *asbestos-related diseases*).

Exposure to radiation may cause cancerous changes in cells, especially in cells that divide quickly; for example changes in the precursors of white blood cells in the bone marrow causes *leukaemia*. The level of risk depends on the dosage and duration of exposure to the carcinogen. Over many years, exposure to ultraviolet radiation in sunlight can cause skin cancer.

**BIOLOGICAL CARCINOGENS**

Only a few biological agents are known to cause cancer in humans. *Schistosoma haematobium*, one of the blood flukes responsible for the tropical disease *schistosomiasis*, can cause cancer of the bladder; and *Aspergillus flavus*, a fungus that produces the poison aflatoxin in stored peanuts and grain, is believed to cause liver cancer.

Viruses that are associated with cancer include some strains of the human papilloma virus, which are linked to cancer of the cervix; the hepatitis B and C viruses, which are linked to liver cancer; and some types of herpes virus, which are associated with *Kaposi’s sarcoma* and *Burkitt’s lymphoma*.

**AVOIDANCE OF CARCINOGENS**

In industry, known carcinogens may be banned. Alternatively, as in the nuclear industry and in hospital X-ray departments, they may be allowed only if their use is considered essential, if exposure to them is strictly limited, and if regular medical screening is provided for workers using them.

Outside industry, people are exposed to very few known, unavoidable, high-risk carcinogens. Any substance that could possibly be carcinogenic, such as a food additive, a cosmetic, or a chemical for use in drugs, must be carefully screened by an official body (such as the Medicines Control Agency, which assesses drugs in the UK) before it is allowed to be manufactured.

**carcinogenesis**

The development of a cancer caused by the action of *carcinogens* (factors that cause cancer) on normal cells.

Carcinogens are believed to alter the DNA in cells, particularly in *oncogenes* (genes that control the growth and division of cells). An altered cell divides abnormally fast, passing on the genetic changes to all of its offspring cells. Thus, a group of cells is established that is not affected by the body’s normal restraints on growth.

**carcinoid syndrome**

A rare condition caused by an intestinal or lung tumour, called a carcinoid, which secretes excessive amounts of the hormone serotonin and often also other chemicals, such as *bradykinin*. Carcinoid syndrome is characterized by bouts of facial flushing, diarrhoea, and wheezing, but symptoms usually occur only if the tumour has spread to the liver or has arisen in a lung.

Carcinoid tumours in the intestine, lung, and, more rarely, the liver are sometimes removed surgically, but, in most cases, surgery is unlikely to be of benefit. In these circumstances, symptoms may be relieved by drugs such as octreotide, which often inhibits the growth of the tumour.

**carcinoid tumour**

A type of hormone-secreting cancerous tumour. Carcinoids most often occur in the small intestine or rectum but occasionally also develop in the lungs. (See also *carcinoid syndrome*.)

**carcinoma**

Any cancerous tumour (see cancer) that arises from cells in the covering surface layer or lining membrane of an organ. A carcinoma is distinguished from a *sarcoma*, which is a cancer arising in bone, muscle, or connective tissue. The most common cancers of the lungs, breast, stomach, skin, cervix, colon, and rectum are carcinomas.

**carcinoma in situ**

The earliest, usually curable, stage of a cancer. In this stage, the disease has not yet spread from the surface layer of cells in an organ or other tissue.
Carcinomatosis

The presence of cancerous tissue in different sites of the body due to the spread of cancer cells from a primary (original) cancerous tumour.

Symptoms

The symptoms of carcinomatosis may include weight loss, lack of energy, and various other problems depending on the sites of the metastases (secondary tumours). For example, metastases in the lungs may cause coughing and breathlessness; those that develop in the liver may cause jaundice.

Diagnosis and treatment

A diagnosis of carcinomatosis may be confirmed by X-rays or by radionuclide scanning of the bones and lungs, by biochemical tests, or in the course of an operation. Anticancer drugs or radiotherapy may be given to destroy the metastases. The condition will not be improved by removing the primary tumour unless the tumour is producing a hormone that directly stimulates the growth of metastases.

Cardiovascular aneurysm

Ballooning of an area of a ventricle (lower chamber) of the heart, usually as a result of damage following a myocardial infarction (heart attack). (See also ventricular aneurysm.)

Cardiac arrest

A halt in the pumping action of the heart. Cardiac arrest occurs when the heart's rhythmic muscular contractions stop, and usually results from abnormal electrical activity. It causes sudden collapse, loss of consciousness, and the absence of pulse and breathing.

Causes

The most common cause of cardiac arrest is a myocardial infarction (heart attack). Other possible causes include respiratory arrest, electrical injury, loss of blood, hypothermia, drug overdose, and anaphylactic shock (an extremely severe type of allergic reaction).

Diagnosis and treatment

The survival of the patient depends on prompt restoration of the heartbeat and the oxygen supply to the brain. Cardiopulmonary resuscitation may be used to maintain the circulation until the heartbeat resumes.

A diagnosis of cardiac arrest can only be confirmed by monitoring the electrical activity of the heart using ECG. This helps medical personnel distinguish between ventricular fibrillation (the rapid, uncoordinated contraction of individual heart muscle fibres) and asystole (the complete absence of heart muscle activity), which are the two abnormalities of heart rhythm that can lead to cardiac arrest.

Ventricular fibrillation may be corrected by defibrillation (the application of an electric shock to the heart). Asystole is more difficult to reverse but may respond to injection of adrenaline or to an electrical pacemaker.

Outlook

In general, recovery after ventricular fibrillation is more likely than after a cardiac arrest triggered by asystole.

Cardiac arrhythmia

See arrhythmia, cardiac.

Cardiac asthma

Difficulty in breathing that is similar to asthma but is the result of pulmonary oedema (fluid on the lungs); the oedema, in turn, is due to heart failure (the inability of the heart to cope with its workload). Attacks of cardiac asthma usually occur at night. The disorder is not related to bronchial asthma and requires different treatment.

Cardiac catheter

See catheterization, cardiac.

Cardiac cycle

The sequence of events, lasting for less than a second, that make up each beat of the heart. A heartbeat has three phases: diastole, atrial systole, and ventricular systole. In diastole, the heart relaxes. During atrial systole, the atria (upper chambers of the heart) contract, and in ventricular systole, the ventricles (the heart's lower chambers) contract. The sinoatrial node (the heart's natural pacemaker) regulates the timing of the phases by sending electrical impulses to the atria and the ventricles.

Cardiac dysrhythmia

See dysrhythmia, cardiac.

Cardiac massage

Rhythmic compression of the heart. Cardiac massage is performed when the heart has stopped beating, in order to maintain blood circulation, especially to vital organs such as the brain. It involves repeatedly squeezing the heart to force blood out of it and into the circulatory system, then releasing the pressure on the heart so that it fills with blood again. Cardiac massage is continued until the heart resumes beating or the person is declared dead.

There are two main types: external cardiac massage, which involves pressing on the chest to squeeze the heart, and internal cardiac massage, when the exposed heart is massaged by hand. (See also cardiopulmonary resuscitation.)

Cardiac muscle

See muscle.

Cardiac neurosis

Excessive anxiety about the condition of the heart. Cardiac neurosis usually follows a myocardial infarction (heart attack) or heart surgery, but sometimes occurs when the person has had no previous heart trouble.

A person who has cardiac neurosis experiences symptoms that are typical of heart disease, such as breathlessness and chest pain, and may be reluctant to exercise or work for fear of having a heart attack. Medical investigation reveals no physical problem, however. Psychotherapy may help an affected person to overcome the anxiety and resume a normal, active life.

Cardiac oedema

An abnormal build-up of fluid in body tissues that is caused by heart failure (inability of the heart to cope with its workload). (See also oedema.)

Cardiac output

The volume of blood pumped by the heart each minute. Cardiac output is a measure that is used to assess how efficiently the heart is working. At rest, a healthy adult's heart pumps between 2.5 and 4.5 litres of blood per minute. During exercise, however, this figure may rise to as much as 30 litres per minute. A low output during exercise may indicate damage to the heart muscle or major blood loss.

Cardiac stress test

One of a group of tests used to assess the function of the heart in people who experience chest pain, breathlessness, or palpitations during exercise. A cardiac stress test establishes whether the patient has coronary artery disease (in which the blood supply to the heart muscle is impaired).

An ECG machine records the patterns of the heart's electrical activity while the heart is stressed. This is usually
achieved by the patient exercising on a treadmill or stationary bicycle. Specific changes in the electrical pattern as exercise levels increase indicate angina pectoris (chest pain due to impaired blood supply to the heart muscle).

Cardiac stress testing may also be used in conjunction with radionuclide scanning in order to identify damaged areas of heart muscle.

cardiology
The study of the function of the heart and the investigation, diagnosis, and medical treatment of disorders of the heart and blood vessels, such as atherosclerosis (fat deposits on the artery walls) and hypertension (high blood pressure).

Some disorders reduce the pumping efficiency of the heart. They include arrhythmias (abnormalities in the rate or rhythm of the heartbeat; see arrhythmia, cardiac), coronary artery disease (in which the blood supply to the heart muscle is impaired), cardiomyopathy (in which the heart muscle itself is abnormal), and heart valve disorders.

Some babies are born with structural defects of the heart and/or the major blood vessels that emerge from it (see heart disease, congenital). Diseases of the lungs and blood vessels can also have adverse effects on heart function.

Many people with heart problems are treated by their general practitioners, but some may be referred to a cardiologist (a heart specialist). Investigations may include tests such as echocardiography (viewing the structure and movement of the heart using ultrasound) and detailed interpretation of ECGs (electrocardiograms, which measure the electrical activity of the heart). If coronary artery disease is suspected, the cardiologist may perform coronary angiography (taking X-ray images of blood vessels) and possibly widen any blocked blood vessels (see angioplasty, balloon). A cardiologist may, in turn, refer a patient to a cardiovascular surgeon if surgical treatment is required.

cardiomegaly
Enlargement of the heart. This condition may take the form of hypertrophy (thickening) of the heart muscle or of dilatation (increase in volume) of one or more of the heart chambers.

CAUSES
Hypertrophy of the heart muscle occurs in conditions in which the heart has to work harder than normal to pump blood. These disorders include hypertension (high blood pressure), which causes the wall of the left ventricle to thicken; pulmonary hypertension (raised blood pressure in the lungs), in which the wall of the right ventricle thickens; and one type of cardiomyopathy (disease of the heart muscle), in which the walls of one or both ventricles may thicken.

Dilation of a heart chamber may be due to heart valve incompetence (failure of a valve to close properly after a contraction). In aortic insufficiency, failure of the aortic valve to close completely allows blood to flow back from the aorta into the left ventricle after each contraction, eventually enlarging the chamber.

SYMPTOMS
Symptoms of cardiomegaly may not occur until the heart has enlarged to the point where it cannot cope with additional stress (for example, as a result of exercise or infection). The heart’s reduced pumping efficiency leads to heart failure, with symptoms of breathlessness and ankle swelling.

DIAGNOSIS AND TREATMENT
Cardiomegaly is diagnosed by a physical examination, chest X-ray, and ECG (measurement of the electrical activity of the heart). Treatment is directed at the underlying cause.

cardiomyopathy
Any disease of the heart muscle that weakens the force of cardiac contractions, thereby reducing the efficiency of blood circulation. Cardiomyopathies may be the result of infectious, metabolic, nutritional, toxic, autoimmune, or degenerative disorders. However, in many cases, the cause is unknown.

TYPES
There are three principal forms of the condition: hypertrophic, dilated, and restrictive cardiomyopathy.

In hypertrophic cardiomyopathy, the heart muscle is abnormally thickened. This condition is usually inherited.

In dilated cardiomyopathy, which is often of unknown cause, metabolism (chemical activity) of the heart muscle cells is abnormal and the heart’s walls tend to balloon out under pressure.

Restrictive cardiomyopathy is a condition in which the heart walls are unusually inflexible, so that the heart cannot fill sufficiently with blood. It is often caused by scarring of the endocardium (the inner lining of the heart) or by amyloidosis (infiltration of the muscle with a starchlike substance).

SYMPTOMS AND SIGNS
Symptoms of cardiomyopathy include fatigue, palpitations, and chest pain. Palpitations may be due to an abnormal heart rhythm such as atrial fibrillation (rapid, uncoordinated contractions of the upper chambers of the heart).

The condition may lead to heart failure, in which the pumping action of the heart becomes less efficient. Symptoms of heart failure include breathing difficulty and oedema (abnormal fluid accumulation in body tissues).

DIAGNOSIS
A chest X-ray may show enlargement of the heart, and echocardiography (an ultrasound technique for imaging the structure and movement of the heart) may show thickened heart muscle. A biopsy (small tissue sample removed for microscopic analysis) of heart muscle may reveal muscle cell abnormalities.

TREATMENT
Symptoms of cardiomyopathy may be treated with diuretic drugs to control heart failure and antiarrhythmic drugs to correct the abnormal heart rhythm. In many cases, heart muscle function deteriorates, and the only remaining option is a heart transplant.

cardiopulmonary bypass
The procedure by which the circulation of blood around the body is maintained while the heart is stopped during heart surgery. A heart–lung machine is used to maintain the supply of oxygenated blood to the body tissues.

cardiopulmonary resuscitation
The administration of life-saving measures to a person who has suffered a cardiac arrest (in which the heart stops pumping blood). A person in cardiac arrest shows no sign of breathing and has no detectable pulse or heartbeat.
Brain damage is likely if the brain is starved of blood, and therefore oxygen, for more than three to four minutes.

First, mouth-to-mouth resuscitation (see rescue breathing) is given in order to restart the casualty’s breathing. If this step fails, repeated chest compressions, using the heel of the hand, are applied to the lower part of the breastbone (see external cardiac massage) until emergency medical help arrives. These measures are used alternately to restore blood circulation to the brain.

cardiocography
See fetal heart monitoring.

cardiovascular
A term that means “pertaining to the heart and blood vessels”.

cardiovascular disorders
Disorders of the heart (see heart disorders box), blood vessels, and blood circulation (see arteries, disorders of; veins, disorders of).

cardiovascular surgery
The branch of surgery that is concerned with the heart and blood vessels. Cardiovascular surgery can be divided into two main areas.

One area, sometimes called cardiothoracic surgery, includes operations to prevent or repair damage to the heart itself and to the major blood vessels within the chest cavity. Cardiothoracic surgery is used, for example, to help treat damage due to congenital heart disease (see heart disease, congenital) or a myocardial infarction (heart attack).

The second area, which is known as vascular surgery, is concerned with the treatment of blood vessels elsewhere in the body, such as in the legs. (See also heart valve surgery, coronary artery bypass, and heart transplant.)

cardioversion
An alternative name for defibrillation.

carditis
A general term for inflammation of any part of the heart or its linings. There are three types. Myocarditis (inflammation of the heart muscle) is usually caused by a viral infection. Endocarditis (inflammation of the internal lining of the heart) is usually due to a bacterial infection. Pericarditis (inflammation of the outer covering of the heart) is usually the result of a viral or bacterial infection but may be associated with a myocardial infarction (heart attack) or an autoimmune disorder, such as systemic lupus erythematosus.

caries, dental
The gradual erosion of enamel (the hard covering of a tooth) and dentine (the softer substance that lies beneath the enamel). This condition is more commonly known as tooth decay.

CAUSES
The main cause of dental caries is plaque, a sticky substance consisting of food deposits, saliva by-products, and bacteria that collects on the surface of teeth. The breakdown of food deposits by bacteria creates acid that eats into the enamel to form cavities. Left unchecked, decay spreads to the dentine, and as the cavity enlarges, bacteria may invade and destroy the pulp tissue at the core of the tooth.

SYMPTOMS
Initial decay usually occurs on the grinding surfaces of the back teeth and on areas around the gum line. In the early stages, dental caries does not usually cause any symptoms. Advanced decay causes toothache (see pulpitis), however, which may be aggravated by eating very sweet, hot, or cold food. Sometimes advanced decay can also cause halitosis (bad breath).

TREATMENT
Treatment consists of drilling away the area of decay and filling the cavity (see filling, dental). In advanced decay, it may be necessary to remove the infected pulp and replace it with a filling (see root-canal treatment) or to extract the tooth (see extraction, dental).

PREVENTION
The risk of dental caries occurring is reduced by cutting down on sugar consumption, practising good oral hygiene, and visiting the dentist regularly. Water fluoridation and the use of fluoride toothpaste also helps to prevent caries.

carminative
A medicine that relieves abdominal wind (flatulence). Carminatives are used in the treatment of colic.
carotenaemia
A harmless condition in which blood levels of carotene, an orange pigment in certain vegetables, are very high as a result of excessive intake of these foods. Carotenaemia may cause temporary yellowing of the skin, especially on the palms and soles. Unlike jaundice, carotenaemia does not cause yellowing of the whites of the eyes.

carotene
A yellow or orange pigment found in carrots, tomatoes, and leafy green vegetables. The most important form of carotene is beta-carotene, an antioxidant. Beta-carotene is converted in the intestines into retinol (see vitamin A), which is essential for vision and healthy skin. Excessive intake of foods containing carotene may cause carotenaemia (temporary yellowing of the skin).

carotid artery
Any of the main arteries of the neck and head. There are two common carotid arteries (left and right), each of which divides into two main branches (internal and external).

The left carotid artery arises from the aorta and runs up the neck on the left side of the trachea (windpipe). The right carotid artery arises from the subclavian artery (which branches off the aorta) and follows a similar route on the right side of the neck. Just above the level of the larynx (voicebox), each carotid artery divides to form an external carotid artery and an internal carotid artery.

The external arteries have multiple branches that supply most of the tissues in the face, scalp, mouth, and jaws. The internal arteries enter the skull to supply the brain and eyes. At the base of the brain, branches of the two internal carotids and the basilar artery join to form a ring of blood vessels called the circle of Willis. Narrowing of these vessels may be associated with transient ischaemic attack (TIA); obstruction of them causes a stroke.

The carotid arteries have two specialized sensory regions in the neck: the carotid sinus, which monitors blood pressure, and the carotid body, which monitors the oxygen content of the blood and helps to regulate breathing. The carotid artery is one of the points at which the pulse can be measured. (See also carotid bruit; carotid doppler scanning; carotid sinus syndrome.)

carotid sinun syndrome
A condition mainly affecting elderly people, in which the carotid sinus, a structure within the common carotid artery of the neck that regulates blood pressure, is overly sensitive.

The carotid sinus is a pocket in the artery at the point where the vessel divides to form two branches. It contains sensors that continually monitor blood pressure. When the blood pressure is raised, the sinus sends messages to the brain, which signals blood vessels to widen and the heart rate to slow, thus lowering the pressure.

In carotid sinus syndrome, the sinus reacts too readily: simply turning the neck suddenly or coughing can trigger the sensors. As a result, the brain slows the heart rate and lowers blood pressure excessively, causing the affected person to faint. This problem may be avoided by the insertion of a pacemaker, which will help to maintain a normal heart rate, overriding any inappropriate messages from the carotid sinus.

carpal tunnel syndrome
Numbness, tingling, and pain in the thumb, index finger, and middle fingers. Carpal tunnel syndrome is caused by compression of the median nerve at the wrist. The carpal tunnel, through which the nerve passes, is a narrow gap formed by the carpal bones of the wrist and a ligament that lies over them. The condition may affect one or both of the hands and is sometimes accompanied by weakness in the thumb. Symptoms may be worse at night.

CAUSES
Carpal tunnel syndrome is common among people who use computer keyboards, who make constant, repetitive hand movements. The condition also occurs without obvious cause in middle-aged women. In addition, it is quite common in pregnancy; in women who have begun using oral contraceptives; in those who suffer from premenstrual syndrome; and in men and women who suffer from rheumatoid arthritis, myxedema (thickening and coarsening of the skin and other body tissues), and acromegaly (a condition in which there is abnormal enlargement of the skull, jaw, hands, feet, and internal organs).

TREATMENT
The condition often disappears without any treatment. Persistent symptoms may be treated by the injection of a corticosteroid drug under the ligament.
CARPOPEDAL SPASM

Alternatively, the ligament may be cut surgically in order to relieve pressure on the nerve.

carpopedal spasm
Involuntary contraction of muscles in the hands and feet. Carpopedal spasm is due to low levels of calcium in the blood. This problem, in turn, may be caused by hyperventilation (abnormally rapid breathing) or by disorders such as hypoparathyroidism.

carpus
The eight bones of the wrist.

carrier
A person who is able to pass on an infectious or inherited disease without actually suffering from it themselves.

car sickness
See motion sickness.

cartilage
A type of connective tissue (a material that holds body structures together) made up of varying amounts of the gel-like substance collagen. Cartilage is not as hard as bone, but it nevertheless forms an important structural component of various parts of the skeletal system, including the joints. Much of the fetal skeleton is formed entirely of cartilage. During childhood, the cartilage is gradually converted to bone by a process known as ossification.

**TYPES**
There are three main types of cartilage: hyaline cartilage, fibrocartilage, and elastic cartilage. Each type is composed of a different proportion of collagen and has a particular function.

- **Hyaline cartilage** is a tough, smooth tissue that lines the surfaces of joints, such as the knee, providing an almost frictionless layer over the bony parts of the joint. If the lining becomes worn (as occurs in osteoarthritis) or damaged, the movement of that joint may be painful or severely restricted.

- **Fibrocartilage** contains a large proportion of collagen and is solid and strong. This type of cartilage makes up the discs that are situated between the bones of the spine (see disc, intervertebral). It also forms the shock-absorbing pads of tissue within joints.

- **Elastic cartilage** is soft and rubbery. It is found in structures such as the outer ear and the epiglottis.

**caruncle**
A general term for a small, fleshy swelling. Caruncles can be normal, such as on the inner corner of the eye. Some are abnormal, appearing as polyp-like growths; this type may be found, for example, at the opening of the urethra (the tube by which urine leaves the bladder).

**Casal’s necklace**
A red rash forming a clearly defined ring around the neck. It is a symptom of pellagra, a disorder caused by lack of the B vitamin niacin in the diet.

cascar
A type of stimulant laxative drug, which can be used when rapid onset of action is needed. Cascara is now rarely used.

caseous abscess
An abscess (collection of pus) containing matter that resembles curds or cottage cheese. Caseous abscesses are most commonly due to tuberculosis.

cast
A rigid casing applied to a limb or other part of the body to hold a broken bone or dislocated joint in position as it heals. Most casts are made of bandages impregnated with resin or plaster of Paris, which are applied while wet and harden as they dry. Casts are removed using an electric saw that cuts through the cast but does not damage the skin.

castor oil
A colourless or yellow-tinged oil that is obtained from the leaves of the castor oil plant, Ricinus communis. If taken orally, castor oil irritates the lining of the small intestine and has a powerful laxative action that completely empties the bowel. Zinc and castor oil are combined in a soothing ointment to treat conditions such as nappy rash.

castration
The surgical removal of the testes (see orchidectomy). The term “castration” is sometimes also used to refer to removal of the ovaries (see oophorectomy).

Castration is performed when the testes or ovaries are diseased. It may also be carried out in order to reduce the level of testosterone (a male sex hormone produced in the testes) or of oestrogen (a female sex hormone produced in the ovaries) in people who have certain types of cancer that are stimulated by these hormones.

Orchidectomy and oophorectomy are performed less frequently since the introduction of gonadorelin analogues, which are drugs that also act to reduce the amount of testosterone and oestrogen produced by the body.

catabolism
A chemical process by which constituents of food stored in the body (for example, fats) are broken down, releasing energy into the body cells (see biochemistry; metabolism).

catalepsy
A physical state in which the muscles of the face, body, and limbs stay in a semi-rigid, statuelike position for minutes, hours, or even days. Catalepsy sometimes occurs in people who have schizophrenia or epilepsy but may also be due to brain disease or certain drugs.

catalyst
A substance, such as an enzyme, that increases the rate of a chemical reaction without being permanently changed itself by that reaction.

catataplexy
A sudden loss of muscle tone, causing an involuntary collapse without loss of consciousness. Triggered by intense
emotion, particularly laughter, it occurs almost exclusively in sufferers of sleep disorders such as narcolepsy.

**cataract**
Loss of transparency of the lens of the eye, as a result of changes in its protein fibres. At an advanced stage, the front part of the lens becomes densely opaque, but the cataract never causes total blindness. A densely opalescent lens will still transmit light, but the clarity and detail of the image will be lost. Cataract usually occurs in both eyes, but in most cases one eye is more seriously affected than the other.

**CAUSES**
Almost everyone over 65 has some degree of cataract; the condition might be considered part of the normal aging process. Regular exposure to ultraviolet light increases the risk.

Other causes of cataract include an injury to the eye, particularly if a foreign body enters the lens. Cataract is also common in people with diabetes mellitus and may develop at an earlier age if blood sugar levels are not well controlled. Long-term use of corticosteroid drugs may contribute to cataract.

**Congenital** cataract may be due to an infection of the mother in early pregnancy, especially with rubella (German measles), or to the toxic effects of certain drugs in pregnancy. It may also be associated with Down’s syndrome or the rare genetic disorder galactosaemia.

**SYMPTOMS**
Cataract is entirely painless and causes only visual symptoms. The onset of symptoms is almost imperceptible, although night driving may be affected in the early stages. There is slow, progressive loss of visual acuity (increasing blurring of vision). The person may become shortsighted and notice disturbances in colour perception.

**TREATMENT**
When vision has become significantly impaired, **cataract surgery** is performed to remove the lens and replace it with an implant. Provided the eye is otherwise healthy, cataract surgery generally gives excellent results.

**cataract surgery**
Removal of the lens from the eye. Cataract surgery is done to restore sight in people whose vision is impaired by a cataract. The lens is usually replaced with a plastic implant during the operation. Alternatively, for young people and those with other eye disorders, a contact lens or spectacle lens fitted after the operation may be preferable.

**catarrh**
Oversecretion of mucus by inflamed mucous membranes (see rhinitis), sinuses (see sinusitis) or air passages.

**catatonia**
A state in which a person becomes mute or adopts a bizarre, rigid pose. The eyes usually remain open and the person may seem awake, but they make no voluntary movements. The state is seen in a rare form of schizophrenia and some types of brain disease.

---

**PROCEDURE FOR CATARACT SURGERY**

In a normal, healthy lens there is no interference with the passage of light rays. Even when peripheral opacities develop, vision is not limited until the central zone is affected. Dense nuclear opacities, however, such as that shown on the right, cause deteriorating vision. The affected lens cannot be restored to its former transparency, hence the need for surgical replacement.

**Appearance of cataract**
In preparation for surgery, measurements are taken of the cornea and the eye’s length to calculate the power of the lens implant that will be needed to restore vision fully. The operation may be performed using general or local anaesthesia; there is no pain in either case. Instruments of remarkable delicacy and precision are used for the procedure, usually with the help of microscope magnification.

1. An ultrasound probe is inserted into the lens capsule through a small incision in the cornea. The incision is made using a diamond tipped instrument.
2. The ultrasound probe softens the lens by emitting sound waves. It then sucks out the softened lens tissue. Only the front part of the lens capsule is removed.
3. An artificial lens is placed inside the lens capsule. The incision in the cornea is left to heal naturally, or it may be closed with a few surgical stitches.
cathartic
A term that means “having the power to purify or cleanse”. A cathartic drug stimulates movement of the bowels (see laxative drugs).

catheter
A flexible tube that is inserted into the body to drain or introduce fluids or to carry out other functions. Catheters are commonly used to drain urine from the bladder (see catheterization, urinary). Other procedures using catheters may be performed in order to investigate the condition of the heart (see catheterization, cardiac), to widen obstructed blood vessels, or to control bleeding. (See also balloon catheter.)

catheterization, cardiac
A diagnostic procedure in which a fine, sterile catheter (flexible tube) is introduced into the heart through a vein or artery in the arm or leg. Cardiac catheterization is used to diagnose and assess the extent of congenital heart disease (see heart disease, congenital) and coronary artery disease, and to diagnose and treat some disorders of the heart valves (see valvuloplasty).

During the procedure, the pressure within the chambers of the heart may be measured, samples of blood and tissue may be taken for laboratory analysis, or a radiopaque dye (a substance that is opaque to X-rays) may be injected into the arteries in order for the cavities of the heart to be visible on an X-ray (see angiography).

The procedure causes little discomfort and is performed under local anaesthesia (see anaesthesia, local). A small incision is made in an artery or vein near the skin surface, and the catheter is introduced into the vessel. The tube is passed along the blood vessels and into the heart.

catheterization, urinary
The insertion of a sterile catheter (a flexible tube) into the bladder in order to drain urine from the body.

WHY IT IS DONE
Urinary catheterization is carried out when a person is unable to empty the bladder normally or is incontinent (see incontinence, urinary). The procedure is also performed during certain operations in which a full bladder might block the surgeon’s view of surrounding organs; in bladder function tests such as cystometry and cystourethrography; and to monitor urine production in critically ill patients.

HOW IT IS DONE
There are two principal techniques: urethral catheterization (described in the illustrated box below), and suprapubic catheterization.

Suprapubic catheterization is used if it is not possible to pass a catheter up the urethra (for example, if the urethra is abnormally narrow). This form of catheterization involves the insertion of a catheter into the bladder directly through the abdominal wall, and this is carried out under local anaesthesia (see anaesthesia, local).

cation
An ion of positive charge. An example of a cation is the sodium ion in saline solution. (See also electrolyte.)

cation exchange resin
A type of drug used to remove excess potassium that has accumulated in the body because of renal failure.

CAT scanning
An abbreviation for computerized axial tomographic scanning, which is commonly known as CT scanning.

cat-scratch fever
An uncommon disease that develops in people (mostly children) who have suffered a scratch or bite from a cat. The fever is due to infection with a bacterium called Bartonella henselae.

urethral catheterization of the bladder

A urinary catheter is usually passed into the bladder through the urethra. First, the doctor or nurse cleans the opening of the urethra with antiseptic solution to avoid introducing infection into the urinary tract. He or she then applies a local anaesthetic gel to the urethra. The procedure usually takes about 10 minutes.

Inserting a catheter
The catheter is passed up the urethra until urine flows down the tube, indicating the tip is in the bladder.

Self-retaining catheter
If the catheter is to remain in the bladder, a self-retaining type is used. This catheter has a balloon at its tip that can be inflated and filled with sterile water.
SYMPTOMS
The main symptom, appearing three to ten days after the bite or scratch, is a swollen lymph node near the affected area. The node may become painful and tender, and an infected blister may develop at the site of the injury. A fever, rash, and headache may occur.

DIAGNOSIS AND TREATMENT
Diagnosis of cat-scratch fever is confirmed by biopsy (removal of a small sample of tissue for microscopic analysis) of the swollen lymph node and by a skin test. Analgesic drugs (painkillers) may be used to relieve the fever and headache. In most cases, the illness clears up completely within two months.

cats, diseases from
Cats carry various parasites and infectious organisms that can be spread to humans. Some of these are specific to cats; others may also affect dogs.

SPECIFIC DISEASES
The most serious disease that can be contracted from an infected cat is rabies. Anyone who is bitten by a cat (or any other animal) in a country where rabies is present should seek medical advice without delay.

Cat-scratch fever is an uncommon illness that is caused by infection with the bacterium Bartonella henselae following a scratch or bite from a cat.

Cats commonly carry the protozoan (single-celled parasite) Toxoplasma gondii, which causes the disease toxoplasmosis. Infection with the parasite, which is usually from contact with a cat’s faeces, is not generally serious, but it can have severe effects in pregnant women. Infections in early pregnancy can lead to miscarriage or severe malformation of the fetus. Later in pregnancy, infections can result in nervous system disorders in the fetus and may even lead to blindness in early childhood.

Cat faeces may also carry eggs of the cat roundworm, a possible cause of toxocariasis. Rarely, a larva from an ingested roundworm egg migrates to and lodges in an eye, causing deterioration of vision or blindness. Children who have been playing in sand or soil that has been contaminated by cat faeces are at risk of coming into contact with the worm eggs.

Other cat-related disorders in humans include tinea (fungal infections of the skin, hair, or nails), particularly ringworm (ringlike fungal patches, often on the scalp), bites from cat fleas, and allergic reactions to dander (scales from animal skin, hair, or feathers) that may cause asthma or articaria (nettle rash).

PREVENTION
Diseases from cats can be avoided by good hygiene, such as hand-washing, particularly after touching a cat. All pets should have regular worming and flea treatment and veterinary care if ill.

cauda equina
A “spray” of nerve roots resembling a horse’s tail that descends from the lower spinal cord and occupies the lower third of the spinal canal.

caudal
This word is used to refer to the lower end of the spine. The word “caudal” means “of the tail”.

caudal block
A type of nerve block in which a local anaesthetic is injected into the lower part of the spinal canal (the central space within the spine). Caudal block may be used to anaesthetize the buttocks and genitals as part of obstetric and gynaecological procedures.

cauliflower ear
Painful, swollen distortion of the pinna (ear flap) resulting from blows or friction that have caused bleeding in the soft cartilage of the ear.

Immediate treatment following an injury involves the use of ice-packs to reduce the swelling. In severe cases, a doctor may drain blood from the ear and apply a pressure bandage.

causalgia
A persistent, burning pain, usually in an arm or leg. Causalgia most often occurs as a result of injury to a nerve by a deep cut, limb fracture, or gunshot wound. The skin overlying the painful area may be red and tender, or blue, cold, and clammy. The condition may be aggravated by light sensations, such as touch, or by emotional factors.

In some cases, treatment with antidepressant drugs or anticonvulsant drugs is effective. A few people benefit from sympathectomy, in which nerves supplying the affected area are severed.

cautic
Describes substances that have a burning or corrosive action on body tissues or a burning taste. An example is caustic soda, the common name for sodium hydroxide. Caustic agents such as silver nitrate are used to destroy warts.

cauterization
The application of a heated instrument to destroy tissues, stop bleeding, or promote healing. Cauterization may be used to treat conditions such as haemorrhoids (piles) and cervical erosion. It has been largely replaced by electrocoagulation (use of high-frequency electric current and, increasingly, laser to seal blood vessels).

Caverject preparations
A brand name for preparations of alprostadil, a prostaglandin drug used to treat impotence, normally by self-injection.

cavernous sinus thrombosis
Blockage of a venous sinus (a channel for venous blood located deep inside the skull behind an eye socket) by a thrombus (an abnormal blood clot). Cavernous sinus thrombosis is usually a complication of a bacterial infection in an area drained by the veins entering the sinus. At first, only the veins behind one eye are affected, but within a few days the thrombosis may spread to the sinus behind the other eye.

CAUSES
Among the infections that can lead to cavernous sinus thrombosis are cellulitis (a severe skin infection) of the face, infections of the mouth, eye, or middle ear, sinusitis (infection of the air spaces of the facial skull), and septicaemia (infection in the bloodstream).

SYMPTOMS
Symptoms of cavernous sinus thrombosis include severe headache, high fever, pain and loss of sensation in and above the affected eye due to the pressure on the fifth cranial nerve, and proptosis (protrusion of the eyeball) due to swelling around and behind the eye. In some cases, vision may become blurred...
and eye movements may be paralysed due to pressure on the optic nerve and other cranial nerves.

**TREATMENT**

Treatment with **antibiotic drugs** and **anti-coagulant drugs** can save vision. Left untreated, blindness will result, and the infection may eventually prove fatal.

**cavity, abdominal**

See abdomen.

**cavity, dental**

A hole in a tooth, commonly caused by dental caries (see caries, dental).

**cavity, oral**

See mouth.

**cavity, pelvic**

The area of the body that lies below the abdomen, framed by the pelvic bones and lower spine. The pelvic cavity contains the lower digestive and urinary organs, nearly all of the reproductive organs in females, and part of the reproductive system in males.

**cavity, pleural**

The space between the two layers of the pleura (membrane) that lines the chest wall and the outside of the lungs.

**CD4 count**

A blood test used to monitor HIV infection and AIDS. The procedure involves counting the number of CD4 lymphocytes (white blood cells responsible for fighting infection) in a blood sample. CD4 lymphocytes are destroyed by HIV, and reduced levels of these cells indicate the progression of HIV and the eventual development of AIDS.

**cefadroxil**

A cephalosporin drug, which is used to treat bacterial infections.

**cefalexin**

A cephalosporin drug, which is used to treat bacterial infections.

**cefotaxime**

A cephalosporin drug, which is used to treat bacterial infections.

**cefuroxime**

A cephalosporin drug, which is used to treat bacterial infections.

**celecoxib**

A COX-2 inhibitor drug (a type of non-steroidal anti-inflammatory drug) used to relieve the pain and inflammation of rheumatoid arthritis and osteoarthritis. Side effects of celecoxib include nausea and diarrhoea. Abdominal discomfort may also occur, but can be minimized by taking the drug with food.

**cell death**

See apoptosis.

**cell division**

The processes by which cells multiply. **Mitosis** is the most common form of cell division, giving rise to daughter cells identical to the parent cells. **Meiosis** produces egg (see ovum) and sperm cells that differ from their parent cells in that they have only half the normal number of chromosomes.

**cellular immunity**

The part of the body’s defence mechanisms (see immune system) that attacks and destroys harmful cells directly rather than by using antibodies (proteins created to combat infection).

Lymphocytes (a type of white blood cell) mount a response against infectious organisms and other abnormal cells, such as cancer cells. There are two main types: T-lymphocytes, which provide cellular immunity, and B-lymphocytes,
Despite their fundamental similarities in structure, the cells of the body are differentiated so that they can perform a variety of specific tasks, such as caring oxygen (red blood cells), destroying invading microorganisms (white blood cells), and making hormones (secretory cells in glands). Some cells (nerve cells, for instance) cannot be replaced once they have been destroyed, while other cells (those that form toe- and fingernails, for instance) regrow and continue to function even after a person’s death. There are four main types of cells, which are grouped according to their primary functions.

**Epithelial cells**
These make up the tissues that cover the outside of the body and line the digestive, respiratory, and urinary tracts. The epithelium includes glandular tissue, which is specialized for secretion.

**Muscular tissue**
Muscle is formed from different types of muscle cells that are specialized to contract.

**Blood cells**
Red and white blood cells, and platelets, circulate individually in the blood to carry nutrients and combat infection and injury.

**Cellulitis**
A bacterial infection of the skin and the tissues beneath it, which usually affects the lower legs but can occur anywhere on the body. Cellulitis is most commonly caused by streptococci bacteria, which enter the skin via a wound.

**Symptoms**
There may be fever and chills; and the affected area is hot, red and swollen. Cellulitis is more severe in people with reduced immunity, such as those who have an immunodeficiency disorder.

Untreated cellulitis at the site of a wound may progress to *bacteraemia* (bacterial infection of the blood) and *septicaemia* (blood poisoning). Facial infections may spread to the eye socket.

**Treatment**
Treatment of cellulitis is with an *antibiotic* drug such as a *penicillin* drug or *erythromycin*. (See also *erysipelas*.)

**Cellulose**
A carbohydrate consisting of chains of glucose (a simple sugar). Cellulose is the main constituent of plant-cell walls. Because it cannot be digested, cellulose is an important source of dietary fibre (see *fibre, dietary*).
Celsius scale
A temperature scale in which the melting point of ice is defined as zero degrees (0°C) and the boiling point of water is 100 degrees (100°C). On this scale, the normal body temperature in humans is 37°C. The scale is named after the Swedish astronomer Anders Celsius (1701–1744). “Centigrade” is an obsolete name for the same scale.

To convert a Celsius temperature to Fahrenheit, multiply the figure by 1.8, then add 32. To convert Fahrenheit to Celsius, subtract 32, then multiply by 0.56. (See also Fahrenheit scale.)

cementum
Bonalike tissue surrounding the root of a tooth (see teeth).

centigrade scale
The obsolete name for the Celsius scale.

centrally acting antihypertensive drugs
A type of antihypertensive drug used in the treatment of hypertension (high blood pressure). Centrally acting antihypertensives, such as clonidine and methyldopa, act on the mechanism in the brain that controls blood-vessel size.

central nervous system
The anatomical term for the brain and spinal cord, often abbreviated to CNS. The central nervous system is made up of neurons (nerve cells) and supporting tissue, and works in tandem with the peripheral nervous system (PNS), which carries signals between the CNS and the rest of the body.

The CNS receives sensory information from organs such as the eyes and ears, and from sensory receptors in the body. It analyses this information, then initiates an appropriate motor response in the body, such as contracting a muscle. (See also nervous system.)

central venous pressure
The pressure within the right atrium, the chamber of the heart that receives oxygen-depleted blood from the body. Central venous pressure is measured by means of a fine tube, attached to a monitor, that is passed through a vein close to the heart and into the right atrium. By monitoring the pressure, doctors can estimate the volume of blood circulating around the body. This action may be of value following severe haemorrhage and in cases where the blood pressure is too low to deliver an adequate blood supply to organs and tissues (see shock).

centrifuge
This is a machine that separates the different components of a body fluid for analysis. When a fluid such as blood is spun at high speed around a central axis, groups of particles of varying density, such as red and white blood cells, are separated by centrifugal force and can be analysed independently.

cephalaxin
An alternative spelling of cefalexin, a common cephalosporin drug.

cephalhaematoma
An extensive, soft swelling on the scalp of a newborn baby. Cephalhaematoma is caused by bleeding into the space between the skull and its fibrous covering (the periostrum or pericranium) due to pressure exerted on the baby’s head during delivery. The swelling is neither painful nor serious and it gradually subsides, although this process may take several weeks.

cephalopelvic disproportion
A complication of childbirth (see childbirth, complications of) in which the mother’s pelvis is too narrow in proportion to the size of the baby’s head.

Cephalosporin drugs
COMMON DRUGS
- Cefaclor
- Cefadroxil
- Cefalexin
- Cefotaxime
- Cefoxitin
- Ceferoxime

A large group of antibiotic drugs, derived from the fungus ACREMONIUM ACREMONIUM, which are effective against a wide range of infections. Cephalosporins are used to treat ear, throat, and respiratory tract infections and conditions, such as urinary tract infections and the sexually transmitted infection gonorrhoea, in which the causative bacteria are resistant to other types of antibiotic.

HOW THEY WORK
Cephalosporin drugs interfere with the development of bacterial cell walls and inhibit the production of protein in the bacterial cells. As a result, the bacteria die. Some types of bacteria, however, produce an enzyme (a protein that acts as a catalyst) called beta-lactamase that can inactivate some of the older cephalosporin drugs. Newer cephalosporins are not affected by this enzyme.

SIDE EFFECTS
Occasionally, cephalosporin drugs may cause allergic reactions, such as rash, itching, and fever. Rarely, anaphylactic shock (a very severe allergic reaction) occurs. Other side effects include diarrhoea and blood disorders.

cerebellar ataxia
Jerky, staggering gait and other uncoordinated movements caused by disease of, or damage to, the cerebellum. Other features may include dysarthria (slurred speech), hand tremor, and nystagmus (abnormal jerky eye movements). Causes include stroke, multiple sclerosis, brain tumour, damage as a result of alcohol dependence, and an inherited disorder of the cerebellum.

cerebellar syndrome
A collection of symptoms, due to certain types of brain disorder, that include tremor, speech disturbance, and abnormal eye movements (nystagmus) and gait.
cerebellum
A region of the brain at the back of the skull, behind the brainstem. The cerebellum is concerned primarily with the maintenance of posture and balance and the coordination of movement.

STRUCTURE
The cerebellum is linked to the brainstem by thick nerve tracts. It consists of two hemispheres. From the inner side of each hemisphere arise three nerve fibre stalks, which link with different parts of the brainstem and carry signals between the cerebellum and the rest of the brain. Nerve fibres from the stalks fan out towards the deep folds of the cortex (outer part) of each cerebellar hemisphere, which consists of layers of what is often referred to as grey matter (interconnected nerve cells).

FUNCTION
Information about the body's posture and the state of contraction or relaxation in its muscles is conveyed from muscle tendons and the labyrinth in the inner ear via the brainstem to the cerebellum. Working with the basal ganglia (nerve cell clusters deep within the brain), the cerebellum uses this data to fine tune messages sent to muscles from the motor cortex in the cerebrum (the main mass of the brain).

DISORDERS
Disease or damage to the cerebellum may result in cerebral ataxia, which is characterized by jerky, staggering gait, slurred speech, and other uncoordinated movements of the body. Alcohol intoxication impairs cerebellar function and may produce similar symptoms.

cerebral haemorrhage
Bleeding that occurs within the brain due to a ruptured blood vessel (see intracerebral haemorrhage; stroke).

cerebral malaria
A potentially fatal complication of malaria (a disease transmitted by mosquitoes) that affects the brain and causes loss of consciousness.

cerebral oedema
An abnormal accumulation of fluid in the brain. The resulting compression of brain tissues may cause symptoms such as headache and visual disturbances. There are various causes for cerebral oedema, including injury, anoxia (lack of oxygen), and poisoning.

cerebral palsy
A disorder of posture and movement that results from damage to the developing brain before, during, or just after birth, or in early childhood. Cerebral palsy is nonprogressive. The disorder varies in severity from slight clumsiness of hand movement and gait to complete immobility.

CAUSES
In most cases, damage occurs before or at birth, sometimes as a result of cerebral hypoxia (an inadequate supply of oxygen to the brain). More rarely, the cause is a maternal infection that spreads to the baby in the uterus.

In rare cases, cerebral palsy is caused by kernicterus, which results from an excess of bile pigment in babies with haemolytic disease of the newborn. Possible causes after birth include encephalitis (inflammation of the brain tissue), meningitis (inflammation of the protective membranes covering the brain), head injury, or intracerebral haemorrhage (bleeding within the brain).

SYMPTOMS
Cerebral palsy may not be recognized until well into the baby's first year. Initially, the infant may have hypotonic (floppy) muscles, be difficult to feed, and show delay in sitting up without support. An affected child may go on to develop spastic paralysis (abnormal muscle stiffness), athetosis (involuntary writhing movements), or ataxia (loss of coordination and balance). Other nervous system disorders, such as hearing defects or epileptic seizures, may be present. About 70 per cent of children have mental impairment, but the rest are of normal or high intelligence.

DIAGNOSIS AND TREATMENT
If the condition is suspected from the symptoms and from neurological and developmental assessments, imaging tests such as CT scanning and MRI may be performed to identify brain damage.

Although there is no cure for cerebral palsy, much can be done to help affected children. A team of professionals working with the family can maximize the child's ability to function. Physiotherapy can help a child to develop muscular control and maintain balance. Speech therapy may improve speech and communication.

cerebral thrombosis
The formation of a thrombus (blood clot) in an artery within the brain. The clot may block the artery, cutting off the supply of blood, nutrients, and oxygen to the region of the brain tissue supplied by the artery. This problem may result in a stroke.

cerebrospinal fluid
A clear, watery fluid that circulates between the ventricles (cavities) within the brain, the central canal in the spinal cord, and the space between the brain and spinal cord and their protective coverings, the meninges. Cerebrospinal fluid functions as a shock-absorber, helping to prevent or reduce damage to the brain and spinal cord after a blow to the head or back. It contains glucose, proteins, salts, and white blood cells.

Examination of the fluid, samples of which are usually obtained by lumbar puncture, is used in the diagnosis of many conditions affecting the brain and spinal cord, including meningitis and subarachnoid haemorrhage.

Accumulation of cerebrospinal fluid within the skull during the development of the fetus, or in infancy, may cause the skull to become enlarged (a condition known as hydrocephalus).

cerebrovascular accident
Any sudden rupture or blockage of a blood vessel in the brain. The problem causes serious bleeding and/or local
obstruction to blood circulation, and leads to a stroke (damage to part of the brain due to interrupted blood supply).

Blockage may be due to thrombosis (clot formation) or to embolism (a clot fragment, or an air bubble carried in the circulation). Rupture of vessels may result in different patterns of bleeding: intracerebral haemorrhage (bleeding in the brain) or subarachnoid haemorrhage (bleeding around the brain).

cerebrovascular disease
Any disease affecting an artery supplying blood to areas inside the brain. Such diseases include atherosclerosis (narrowing of the arteries) and defects in arterial walls that cause aneurysm (a balloon-like swelling in an artery).

The disease may eventually cause a cerebrovascular accident, which commonly results in a stroke. Extensive narrowing of blood vessels throughout the brain can be a cause of dementia.

cerebrum
The largest and most developed part of the brain, and the site of most conscious and intelligent activities.

STRUCTURE
The main components of the cerebrum are two large hemispheres that grow out from the upper part of the brainstem (an extension of the spinal cord). The surface of the cerebrum is made up of a series of folds called gyri, which are separated by fissures called sulci, with a deep longitudinal fissure separating the two hemispheres.

The four main surface regions of each hemisphere – the frontal, parietal, temporal, and occipital lobes – are named after the bones that are overlying them. Each hemisphere has a central cavity, called a ventricle, that is filled with cerebrospinal fluid. This cavity is surrounded by an inner layer, consisting of clusters of nerve cells called the basal ganglia. There is a middle layer of white matter composed mainly of nerve fibres, which carry information between particular areas of the cortex and between the cortex, central brain, and brainstem. The outer surface layer of each hemisphere is the cerebral cortex, which is also known as the grey matter, where much of the sensory information from organs such as the eyes and the ears is processed. A thick band of fibres called the corpus callosum carries nerve signals between the two cerebral hemispheres.

FUNCTION
Specific sensory processing takes place in separate regions. For example, visual perception is located in a part of the occipital lobe called the visual cortex.

The cortex also contains “motor” areas concerned with initiating signals for movements of the skeletal muscles. Linked to the sensory and motor areas of the cortex are association areas. These regions integrate information from various senses and also perform functions such as comprehension and recognition, memory storage and recall, thought, and decision-making.

Some cortical functions are localized to one “dominant” hemisphere (the left in almost all right-handed and many left-handed people). Two clearly defined areas in the dominant hemisphere are Wernicke’s area, which is responsible for the comprehension of spoken and written language, and Broca’s area, which is concerned with language expression.

DISORDERS
Damage to particular areas of the cerebrum may cause specific syndromes. For example, damage to the frontal lobe may cause mental apathy, whereas a parietal lobe injury may result in geographical disorientation. Disease of the temporal lobe may cause amnesia (memory loss), and visual defects may result from occipital lobe damage.

Quite often, however, cerebral disease causes nonspecific symptoms such as convulsions and headaches.

certification
An outdated term for procedures to commit a person to be compulsorily detained for mental health treatment.

cerumen
The medical term for earwax.

Cerumol
A brand-named preparation used for the removal of earwax.
cervical
This term can mean either relating to the neck or relating to the cervix (the neck of the uterus).

cervical cancer
See cervix, cancer of.

cervical dysplasia
Changes in the surface cells of the cervix (the neck of the uterus) that may in time become cancers.

TYPES
There are three grades of cervical dysplasia: mild, moderate, and severe. They are based on the severity of the changes seen in cells obtained from a cervical smear test. Abnormalities can also be classified as grades of cervical intraepithelial neoplasia. In mild dysplasia, abnormal cells may return to a normal state without treatment. Severe dysplasia, left untreated, may progress to cervical cancer (see cervix, cancer of).

CAUSES
The cause is not known, but risk factors include smoking and unprotected sex at an early age or with many partners.

TREATMENT
Treatment depends on the severity of the condition. For mild or moderate dysplasia, the abnormal cells may be destroyed by laser treatment, or by freezing at colposcopy (inspection of the cervix with a viewing instrument). Alternatively, loop excision (surgical removal of an area of the cervix) may be carried out. If the dysplasia is severe, loop excision or cone biopsy are used.

cervical ectopy
A condition affecting the cervix (the neck of the uterus) in which a layer of mucus-forming cells that are more characteristic of the inner lining of the cervix appear on its outside surface. There is no loss of tissue or ulceration of the cervix. The tissue may, however, be more fragile, and tend to bleed and secrete more mucus, than normal.

CAUSES
Cervical ectopy may be present from birth. Other possible causes include injury to the cervix during labour and long-term use of oral contraceptives.

SYMPTOMS
Most women with cervical ectopy have few or no symptoms. Some, however, experience vaginal bleeding at unexpected times and may have a vaginal discharge. The cervix has a fragile, reddened area on the surface.

DIAGNOSIS AND TREATMENT
The condition is often detected during a routine cervical smear test. Only women with symptoms need treatment. Affected tissue may be destroyed using cautery (application of a heated instrument), cryosurgery (freezing), diathermy (heat), or laser treatment.

cervical incompetence
Abnormal weakness of the cervix (the neck of the uterus) that may result in recurrent miscarriages. Normally, the cervix remains closed until the onset of labour. An incompetent cervix may gradually widen under the weight of the fetus from about the 12th week of pregnancy onwards, or may suddenly open during the second trimester.

DIAGNOSIS AND TREATMENT
The condition is detected by a pelvic examination or by ultrasound scanning. Treatment is with a suture (stitch) applied like a purse string around the cervix at about the 12th week of pregnancy. The suture is left in position until the pregnancy is at or near full term and is then cut to allow the mother to deliver the baby normally.

cervical intraepithelial neoplasia
Also known as CIN, abnormalities in the cells of the cervix (the neck of the uterus) that may become cancerous. The CIN grading system is used to distinguish levels of change in the surface cells of the cervix. The term is applied to biopsy (tissue) samples taken during colposcopy, (inspection of the cervix with a viewing instrument) following an abnormal cervical smear test. Grades CIN 1–3 broadly correspond to mild to severe cervical dysplasia in the cells obtained from a smear test.

cervical mucus method
A form of contraception based on identifying days on which to abstain from sexual intercourse and thereby avoid pregnancy. This technique involves monitoring the changes in the mucus secreted by a woman’s cervix. (See contraception, natural methods of.)

cervical osteoarthritis
A degenerative disorder, also called cervical spondylosis, that affects the joints between the cervical vertebrae (the bones in the neck). Cervical osteoarthritis mainly occurs in middle-aged and elderly people, but occasionally the degeneration begins earlier due to an injury, such as a whiplash neck injury sustained in a road traffic accident.

SYMPTOMS
The main symptoms of cervical osteoarthritis are neck pain and stiffness. Pressure on the nerves between affected vertebrae may cause pain in the arms and shoulders, numbness tingling and weakness in the hands. Symptoms tend to flare up from time to time with periods of mild discomfort between.

Other symptoms, such as dizziness, unsteadiness, and double vision when turning the head, may also occur as a result of pressure on blood vessels running through the vertebrae to the brain. Rarely, pressure on the spinal cord can cause weakness or paralysis in the legs and loss of bladder control.

DIAGNOSIS AND TREATMENT
X-rays and other imaging procedures such as MRI (a technique that produces cross-sectional or three-dimensional pictures of body structures) are used to diagnose cervical osteoarthritis.

Treatment of severe neck pain and stiffness may include heat treatment, supporting the neck in a collar, and the analgesic drugs (painkillers). Physiotherapy may improve neck posture and movement and is useful when the pain has eased. Pressure on the spinal cord may be relieved by surgery (see decompression, spinal canal).

cervical rib
A congenital abnormality, which is of unknown cause, in which the lowest of the seven cervical vertebrae (neck bones) forms a rib parallel to a normal one.

LOCATION OF CERVICAL RIB
The overdeveloped seventh cervical vertebra forms a rib parallel to a normal one.
has overdeveloped to form an extra rib that lies parallel to and above the first normal rib. The abnormality can vary from a small, bony swelling to a fully developed rib and it may occur on only one or on both sides.

**SYMPTOMS**
In many cases, there are no symptoms. If the rib presses on the lower brachial plexus (the group of nerves passing from the spinal cord into the arm), however, there may be pain, numbness, and pins-and-needles affecting both the forearm and hand.

**DIAGNOSIS AND TREATMENT**
An X-ray will show the presence of a cervical rib, but other possible causes of pain and tingling in the hand or arm (such as carpal tunnel syndrome or a disc prolapse) still need to be excluded.

Exercises designed to strengthen the shoulder muscles and improve posture may bring relief. Severe or persistent symptoms may, however, require surgery in order to remove the rib.

**cervical smear test**
A test that is used to detect cervical dysplasia (abnormal changes in the cells of the cervix, the neck of the uterus) that could develop into cancer (see cervix, cancer of). A cervical smear test can also detect viral infections of the cervix, such as herpes simplex, papilloma (see warts, genital), and Chlamydia trachomatis.

**WHEN IT IS DONE**
A cervical smear test should be carried out within six months after a woman first starts to have sexual intercourse. A repeat test may be carried out between six and twelve months later. If no abnormality is detected on these smears, tests should subsequently be performed at approximately three-yearly intervals until the age of 65.

**HOW IT IS DONE**
Cervical smear tests are usually performed by doctors or nurses in general practice clinics or at sexual health clinics. A small sample of cells is taken from the surface of the cervix using a spatula or special brush and is examined under a microscope. If all the cells appear normal, nothing further needs to be done. If any cells show dysplasia, this will be graded according to severity, and repeat smear tests and further investigations, such as colposcopy (inspection of the cervix with a viewing instrument), may be required.

**cervical spondylosis**
An alternative name for the neck disorder cervical osteoarthritis.

**cervicitis**
Inflammation of the cervix (the neck of the uterus). The condition is usually due to a sexually transmitted infection, such as gonorrhoea, chlamydial infections, or genital herpes (see herpes, genital). However, cervical infection may also result from injury to the cervix during childbirth or surgery.

**SYMPTOMS**
Cervicitis often does not produce symptoms, although there may be a vaginal discharge, irregular vaginal bleeding, and lower abdominal pain.

**COMPLICATIONS**
If it is left untreated, cervicitis can spread to cause endometritis (inflammation of the lining of the uterus), salpingitis (inflammation of the fallopian tubes), or pelvic inflammatory disease.

If a pregnant woman has cervicitis, her baby may be infected during delivery, resulting in neonatal ophthalmia (eye infection) or, less commonly, pneumonia due to chlamydial infection.

**DIAGNOSIS AND TREATMENT**
The condition is diagnosed by means of internal examination and by taking swabs of the vaginal discharge, which...
are then analysed in order to verify the identity of the organism that is responsible for the condition.

Treatment is with antibiotic drugs or antiviral drugs. If symptoms persist, the area may be cauterized by electrocoagulation (an electric current is applied), cryotherapy, (freezing), or laser treatment.

**BIOPSY OF THE CERVIX**

If a woman has recurrent abnormal smears, colposcopy and punch biopsy or loop excision of the abnormal areas will be carried out. If the areas cannot be seen completely by colposcopy, a larger sample of tissue is removed by cone biopsy. This procedure is used for treatment as well as diagnosis.

**Cervix**

A small, cylindrical organ, several centimetres in length and less than 2.5 cm in diameter, comprising the lower part and neck of the uterus (womb). The cervix separates the body and cavity of the uterus from the vagina. The fibrous, smooth muscle tissue of the cervix creates a form of sphincter (circular muscle), which can stretch open in pregnancy and childbirth.

**FUNCTION**

The cervical canal runs through the cervix. It allows the passage of blood during menstruation and of sperm from the vagina into the uterus following sexual intercourse, and forms part of the birth canal during childbirth. After puberty, mucus is secreted by the glandular cells in the canal to assist the entry of sperm into the upper cervix. In addition, the mucus protects the sperm and provides them with energy.

During pregnancy, the internal muscular fibres increase in size, thereby lengthening the cervix and acting as a barrier for the retention of the fetus. Towards the end of pregnancy, the cervix begins to shorten in readiness for labour and delivery. During labour the cervical canal widens up to 10 cm in diameter to allow the baby to pass from the uterus. Soon after childbirth, the muscles in the cervix contract and the canal returns to its original size.

**DISORDERS**

The cervix may be injured, or may develop infections or other disorders (see cervix disorders box, below). Such conditions are usually investigated by means of a pelvic examination, a cervical smear test, or swabs taken from the cervix. In cases of suspected cancer or a precancerous condition, a colposcopy (inspection of the cervix with a viewing instrument) may be performed.

**Cervix, cancer of**

One of the most common forms of cancer affecting women worldwide. Cancer of the cervix (the neck of the uterus) has well-defined precancerous stages in which abnormal changes occur in cells on the surface of the cervix (see cervical dysplasia). These types of change can be detected by a cervical smear test. In many cases, this detection allows early treatment leading to a complete cure. If left untreated, however, cancer of the cervix may spread to the organs in the pelvis.

**TYPES**

There are two main types of cervical cancer: the squamous type and a much rarer form called adenocarcinoma.

The squamous type of cervical cancer is thought to be associated with some types of human papillomavirus (HPV), which may be contracted during sexual intercourse. The other factors that predispose a woman to developing this type of cancer are smoking, starting to have sex at an early age, having many sexual partners, and having a depressed immune system.

The second type of cervical cancer, adenocarcinoma, sometimes occurs in women who have never had sexual intercourse. Its causes are unknown.

**SYMPTOMS**

In many cases, cancer of the cervix is detected before symptoms develop. If
the condition is advanced, there may be vaginal bleeding or a bloodstained discharge at unexpected times, such as between periods, after sexual intercourse, or after the menopause. There may be pain if the cancer has spread into the deeper parts of the cervix and then out into the pelvic tissues.

**DIAGNOSIS AND TREATMENT**

If a smear test has an abnormal result, *colposcopy* (inspection of the cervix with a viewing instrument) or a *cone biopsy* may be carried out.

A localized cancer in its early stages may be destroyed by *electrocoagulation* (application of an electric current), *diathermy* (heat treatment), *laser treatment*, or *cryosurgery* (freezing).

If the cancer has spread into the cervical canal, a cone biopsy may be sufficient to remove all of the diseased tissue. In more advanced cases affecting the pelvic organs, *radiotherapy* may be given. In certain severe cases, radical surgery, in which the bladder, vagina, cervix, uterus, and rectum are removed, may be recommended possibly along with chemotherapy.

**cestodes**

The scientific name for tapeworms, a group of long, flat, multisegmented parasites (see *tapeworm infestation*).

**cetirizine**

An *antihistamine drug* that is used to relieve the symptoms of certain conditions such as allergic *rhinitis* (hay fever) and *articularia* (nettle rash).

**cetrimide**

An *antiseptic* that is used in many preparations for cleansing the skin.

**CFC-free inhalers**

Pressurized aerosol *inhalers* (devices for delivering drugs to treat asthma and other lung disorders) in which chlorofluorocarbons, or CFCs (used to propel drugs out of the inhalers), have been replaced by alternative propellants. This change has been made in response to evidence that CFCs are harmful to the ozone layer in the earth’s atmosphere.

**CFC propellants**

See chlorofluorocarbon propellants.

**Chagas’ disease**

An infectious parasitic disease found only in parts of South and Central America. Chagas’ disease is spread by insects commonly called cone-nosed or assassin bugs. The *parasites* live in the bloodstream and can affect the heart, intestines, and nervous system.

Symptoms include swelling of the *lymph nodes* and fever. Long-term complications include damage to the heart. The drug nifurtimox kills the parasites but has unpleasant side effects.

**chalazion**

A round, painless swelling in the upper or lower eyelid caused by obstruction of one of the *meibomian glands*, which lubricate the edges of the eyelids. Chalazions are sometimes called meibomian cysts. They can occur at any age and may be more common in people suffering from the skin conditions *acne*, *rosacea*, or *seborrheic dermatitis*.

If the cyst becomes infected, the eyelid becomes more swollen, red, and painful. A large swelling putting pressure on the *cornea* at the front of the eye can cause blurring of vision. About one-third of chalazions disappear without treatment, but large cysts may need to be removed surgically.

**change of life**

A phrase that is popularly used to describe the *menopause*, in which a drop in hormone levels has a variety of physical and mental repercussions.

**chaperone**

An individual who accompanies a doctor during the physical examination of a patient. Chaperones provide protection for both doctor and patient against accusations of improper conduct.

The term “chaperone” is also used to refer to a *protein* that helps other proteins to fold up into their correct three-dimensional shapes.

**chapped skin**

Sore, cracked, rough skin, usually on the hands and face (particularly the lips), caused by dryness. Chapping is caused by the lack, or removal, of the natural oils that keep skin supple. It tends to occur in cold weather, when oil-secreting glands produce less oil, or after repeated washing or wetting.

Chapping can be prevented by wearing protective gloves or applying barrier *creams* before immersing the hands in water, then drying the skin well. Areas of chapped skin can be treated with hand or face cream.

**charcoal**

A form of carbon that is used in medicine mainly as an adsorbent agent (a substance that binds to toxins) in the emergency treatment of some types of poisoning and drug overdose.

**Charcot–Marie–Tooth disease**

An inherited muscle-wasting disease of the legs (see *peroneal muscular atrophy*).

**Charcot’s joint**

A joint damaged by repeated injuries that go unnoticed due to loss of sensation in the area (see *neuropathic joint*).

**check-up**

See examination, *physical*.

**cheilitis**

Inflammation, cracking, and dryness of the lips. There are several possible causes of cheilitis, including ill-fitting dentures, a local infection, an allergy to cosmetics, excessive sunbathing, or deficiency of riboflavin (vitamin B2). Treatment is given for the underlying cause; in the meantime, a soothing skin cream can help to relieve the soreness.
**CHEST PAIN**

---

**CHEMICAL PATHOLOGY**

See pathology, chemical.

**CHEMISTRY**

A pharmacist – a health-care professional who prepares drugs, makes up and supplies prescriptions, and may also give advice on the treatment of common or minor illnesses.

**CHERUBISM**

An inherited disease, also known as familial fibrous dysplasia of the jaw. Cherubism is so called because it produces swelling at either side of the jaw, giving the face a cherubic appearance.

**CHEST**

The upper part of the trunk. The chest, also known as the thorax, extends from the base of the neck down to the diaphragm muscle.

**CHEST COMPRESSION**

Another name for external cardiac massage. Chest compressions are carried out as part of the life-saving technique cardiopulmonary resuscitation.

**CHEST PAIN**

Pain in the chest often has no serious cause, but in some cases it may be a symptom of an underlying disorder requiring urgent treatment. The pain may be in the chest wall (in the skin, the underlying muscles, or the ribs) or in an organ within the chest.

Causes

Common causes of pain in the chest wall are a strained muscle or an injury, such as a broken rib. A sharp pain that travels from the back of the chest around to the front may be due to pressure on a nerve root where it leaves the spine; nerve compression may result from disorders such as osteoarthritis of the vertebrae. Pain in the side of the chest may be caused by pleurisy (inflammation of the muscles between the ribs and of the diaphragm muscle, associated with a viral infection). The viral infection herpes zoster (shingles) may cause severe pain along the course of a nerve in the chest wall. In Tietze’s syndrome, inflammation at the junctions of the rib cartilages causes pain on the front of the chest wall.

A common cause of pain within the chest is acid reflux (regurgitation of acid from the stomach into the oesophagus); this problem may cause heartburn, a pain behind the sternum (breastbone). More serious causes include disorders involving the lungs, such as pneumonia (inflammation of the lungs due to infection) or, rarely, pulmonary embolism (a blood clot that has lodged in an artery in the lung). Cancerous lung tumours (see lung cancer).

To make an accurate diagnosis of the underlying cause, it is important for the patient to describe the location, quality (e.g. burning, pressing, or sharp), severity, and duration of the pain, any factors that relieve it or make it worse, and any other symptoms, such as breathing difficulty. In addition, the doctor will perform a physical examination, including listening to chest sounds with a stethoscope and feeling for areas of tenderness in the chest wall. He or she may also arrange for other diagnostic procedures to be carried out.

---

**CHEMICAL FORMULA**

See formula, chemical.

**CHEMOTHERAPY**

The term usually used to refer to treatment with anticancer drugs. The word “chemotherapy” may also describe the use of antibiotic drugs to treat infectious diseases, particularly tuberculosis.

Chemotherapy for cancer works by destroying cancer cells or preventing them from multiplying. The drugs also affect healthy tissues, however, so the treatment is often given in short courses, with drug-free periods in between to allow normal cells to recover. Normal tissues often affected include bone marrow (causing anaemia), the mouth, the intestinal lining, the hair follicles, and the ovaries and testes; sometimes causing severe side effects.

**CHENOODEOXYCHOLIC ACID**

A constituent of bile that is necessary for the absorption of fat from the diet and also for the excretion of cholesterol.

**CHERRY ANGIOMA**

An alternative name for a Campbell de Morgan’s spot (a small, bright red, non-cancerous spot on the trunk or limbs).

**CHERRY-RED SPOT**

A red spot that can be seen on the retina of infants who have the inherited metabolic disorder Tay–Sachs disease.

---

**CHOLESTATIN**

A constituent of bile that is necessary for the absorption of fat from the diet and also for the excretion of cholesterol.

**CHOLESTEROL**

A constituent of bile that is necessary for the absorption of fat from the diet and also for the excretion of cholesterol.

---

**CHEMICAL PATHOLOGY**

See pathology, chemical.

**CHEMISTRY**

A pharmacist – a health-care professional who prepares drugs, makes up and supplies prescriptions, and may also give advice on the treatment of common or minor illnesses.

**CHENOODEOXYCHOLIC ACID**

A constituent of bile that is necessary for the absorption of fat from the diet and also for the excretion of cholesterol.

**CHERRY ANGIOMA**

An alternative name for a Campbell de Morgan’s spot (a small, bright red, non-cancerous spot on the trunk or limbs).

**CHERRY-RED SPOT**

A red spot that can be seen on the retina of infants who have the inherited metabolic disorder Tay–Sachs disease.
cancer; mesothelioma) may also cause pain as they enlarge in size and press on the pleura and the ribs.

Pain in the centre of the chest may be due to a heart disorder. The common disorder angina pectoris produces pain that may spread from the chest to the throat, jaw, or arms. It is caused by an inadequate blood supply to the heart, commonly due to coronary artery disease. Myocardial infarction (heart attack) causes a similar pain to angina but is usually more severe and is not relieved by rest. Acute pericarditis (inflammation of the membrane covering the heart) produces severe pain that may be relieved slightly when the person leans forwards. Mitral valve prolapse may cause sharp pain, usually on the left side of the chest.

Chest pain may also be a result of anxiety and emotional stress (see hyperventilation; panic attack).

TREATMENT
The treatment of chest pain depends on the underlying cause. For example, antibiotic drugs may be given for chest pain due to pneumonia, and surgery is needed to treat some lung tumours or some cases of coronary artery disease.

chest thrust
A first-aid technique that is used to unblock the airway of a person who is choking. Chest thrusts involve standing behind the casualty, reaching around his or her chest, and placing one fist, thumb inwards, against the lower breastbone. The fist is then grasped with the other hand, and the casualty’s chest wall is thrust sharply inwards and upwards up to five times. The pressure simulates the coughing reflex and may expel the obstruction.

For an infant, the technique involves the first- aider laying the baby face-upwards and head downwards along his or her forearm, placing two fingertips of the other hand on the baby’s lower breastbone, and giving up to five sharp thrusts into the chest.

chest X-ray
One of the most frequently performed medical tests, usually carried out to examine the heart or lungs. Chest X-rays are used to confirm diagnoses of heart disorders, such as enlargement of a heart chamber, or lung diseases, such as tuberculosis or lung cancer. They may also be used to examine the ribs after an injury. The procedure is simple, quick, and painless. (See also X-rays.)

Cheyne–Stokes respiration
An abnormal pattern of breathing in which the rate and depth of respiration vary rhythmically. Cheyne–Stokes respiration is characterized by repeated cycles, each lasting a few minutes, of deep, rapid breathing that becomes slower and shallower and then stops for between 10 and 20 seconds.

The pattern of Cheyne–Stokes respiration may be due to a malfunction in the part of the brain that controls breathing (as occurs in some cases of stroke and head injury). It may be due to heart failure or occur in healthy people at high altitude, especially during sleep.

chickenpox
A common, mild infectious disease, also called varicella, most often occurring in children. Symptoms are a rash and slight fever. In adults, chickenpox is uncommon but usually more severe. An attack gives lifelong immunity, but the causative virus remains dormant in nerves and may reappear later in life to cause herpes zoster (shingles).

CAUSE AND SYMPTOMS
Chickenpox is caused by the varicella zoster virus, which is spread in airborne droplets. A widespread rash develops two to three weeks after infection and consists of clusters of small, red, itchy spots that become fluid-filled blisters within a few hours. After several days, the blisters dry out to form scabs.

Scratching the blisters can lead to secondary infection and scarring. In adults, or in anyone whose immune system is suppressed by drug treatment or illness, serious complications involving the lungs can occur.

People with chickenpox are highly infectious from about two days before the rash appears to about a week afterwards. Nonimmune pregnant women should be particularly careful to avoid children with chickenpox or anyone with shingles, because the disease may be serious in pregnancy and newborn babies could suffer a severe attack.

TREATMENT
In most cases, no specific treatment is needed. Paracetamol helps to reduce fever, and calamine lotion may be used to relieve itching. Anyone at high risk who has been exposed to the virus may be given treatment with immunoglobulin, which may prevent the condition from developing. In severe cases of chickenpox, in both children and adults, aciclovir (an antiviral drug) is given.

chingoe
A painful, itchy swelling, about the size of a pea, caused by a sand flea that lives in sandy soil in Africa and tropical America. When stepped on, the flea penetrates the skin of the feet and lays eggs. Chigoe fleas should be removed with a sterile needle, and the wounds treated with an antiseptic.

chilblain
An itchy, purple-red swelling, usually on a toe or a finger. Chilblains are caused by excessive constriction (narrowing) of small blood vessels below the surface of the skin in cold weather. They are most common in young children and elderly people, and women are more susceptible to them. They generally heal without treatment.

child abuse
Maltreatment of children. Child abuse includes physical injury, sexual abuse, emotional mistreatment, and/or neglect; it occurs at all levels of society.

Child abuse can cause severe physical and psychological damage in the victims. In addition, being deprived or ill-treated in childhood may predispose some affected people to repeat the pattern of abuse with their own children.

childbed fever
See puerperal fever.

childbirth
The event during which a baby leaves the mother’s uterus (womb) and enters the outside world. The process of childbirth, known as labour, normally takes place between 38 and 42 weeks of pregnancy, as timed from the mother’s last menstrual period.

For most women who receive a high standard of medical care during pregnancy (see antenatal care) and delivery, childbirth presents no serious problems. The development of specialized equipment and the availability of blood transfusions and antibiotic drugs have made childbirth much safer for both mother and baby. In developing countries, however, the number of women who die from childbirth remains high (see maternal mortality).

ONSET OF LABOUR
It is often difficult to determine precisely when labour has started. During the last three months of pregnancy, the uterus begins to contract in preparation for the birth. Such contractions, called
CHILDBIRTH

STAGES OF CHILDBIRTH

At the onset of labour, painful and regular uterine contractions begin and the cervix (the neck of the womb) starts to dilate (widen). The mother is usually examined vaginally every two to four hours to assess the extent of dilation. The duration of the first stage of labour depends on several factors, but primarily on whether the baby is the mother’s first or a subsequent child. Fetal heart monitoring is often carried out, and the frequency, strength, and duration of the mother’s contractions are recorded. During the second stage of labour, the contractions become stronger and the woman feels the urge to push; however, she is advised to push only during a contraction. Once the baby is delivered, he or she is usually laid on the mother’s abdomen, but may first be warmed, dried, and checked by a midwife or doctor.

THE FIRST STAGE

With the first contractions, the normally thick, tough cervix becomes thinned and softened and is gradually pulled up until it becomes effaced (merged with the walls of the uterus). The cervix then begins to dilate (stretch open) with each contraction. It is fully dilated when the opening is about 10 cm in diameter. This stage of labour can take 12 hours or more for first babies, but only a few hours for subsequent babies.

THE SECOND STAGE

As the baby’s head descends, it reaches the pelvic floor muscles, which cause the head to rotate until eventually the baby’s chin is pointing down towards the mother’s rectum. As the baby is pushed further down the birth canal, the mother’s anus and perineum (the area between the vulva and anus) begin to bulge out, and soon the baby’s head can be seen at the opening of the vagina. As the head emerges, the perineal tissues are stretched very thin; sometimes it is necessary to perform an episiotomy (cutting of the tissues under local anaesthetic) to prevent them from tearing. As soon as the baby’s head emerges, it turns, usually aided by the midwife, so it is once more in line with the body. With the next few contractions, one shoulder is delivered at a time; then the rest of the baby slides out. After delivery, the cord is clamped and cut.

THE THIRD STAGE

Three to 10 minutes after the birth, the placenta (afterbirth) separates from the uterine wall and is removed by gentle traction on the cord. Drugs such as ergometrine or oxytocin may be used to aid its expulsion and to reduce bleeding. Rarely, the placenta may have to be manually removed, under general or epidural anaesthetic, by an obstetrician. Any tears or incisions are cleaned and stitched. This may be done while the mother holds her baby.

ELECTRONIC FETAL MONITORING

This may be performed if the fetus is at risk, or as a routine check. The fetal heart rate and the mother’s uterine contractions are recorded.

Fetal monitoring devices

In the procedure shown above, the baby’s heartbeat is detected by a metal plate strapped to the lower belt. A plate beneath the upper belt detects the contractions. An alternative method is to attach an electrode to the baby’s head; the electrode is linked to the monitor by a wire passed through the mother’s vagina.

Before birth, the cervix is closed.

After delivery, the cervix is effaced and fully dilated.

Once both of the shoulders are out, the rest of the baby’s body emerges easily.

The head emerges.

The head is supported.

Delivery of the baby

Umbilical cord

Placenta being delivered

The placenta is usually expelled within a few minutes of the baby’s birth.

Widened vagina

Placenta

**Braxton Hicks' contractions** may be mistaken for the onset of labour. However, when the contractions become progressively more painful and occur more regularly and with shorter intervals between, labour has probably started.

At the onset of labour, the cervix (the neck of the uterus) becomes thinned and softened and then begins to dilate with each contraction. During this time, there may be a “show”, which is when the mucous plug that blocks the cervical canal during pregnancy is expelled as a bloody discharge. “Breaking of the waters”, which is the rupture of the amniotic sac (the fluid-filled membranous bag that protects the fetus in the uterus), may occur either as a slow trickle of fluid from the vagina or as a sudden gush.

**STAGES OF LABOUR**

Childbirth occurs in three stages (see illustrated box on p.163 for details).

The first stage of childbirth covers the period lasting from the onset of labour to the point when the woman’s cervix is fully dilated, which is when the opening has widened to about 10 cm in diameter. The duration of this stage varies from woman to woman and from birth to birth.

The second stage of labour lasts from full dilation of the cervix until the delivery of the baby. In this stage, the mother feels the urge to push with each strong contraction. As the baby’s head descends into the mother’s vagina, the baby rotates to face the mother’s back. Once the baby’s head is delivered, the rest of the body follows with the next contractions. After delivery, the umbilical cord, which connects the baby to the placenta, is clamped and cut.

In the third stage of labour, the delivery of the placenta (the afterbirth) takes place. This event happens within about ten minutes of the baby’s birth.

**PAIN RELIEF**

Pain relief is available during normal labour and delivery. There are various forms, including opioid analgesic drugs, epidural anaesthesia, and pudendal block. (See also childbirth, complications of; childbirth, natural.)

**childbirth, complications of**

Problems that occur during labour and delivery. Complications may affect the mother, the baby, or both. Some are potentially life-threatening, especially to the baby if they impair the baby’s oxygen supply (see fetal distress).

**MATERNAL PROBLEMS**

If contractions begin, or if the membranes rupture, before the 37th week of pregnancy, premature labour may occur, with the delivery of a small, immature baby (see prematurity).

Premature rupture of the amniotic sac (the fluid-filled, membranous bag that protects the fetus in the uterus) can lead to infection in the uterus, requiring prompt delivery of the baby and treatment with antibiotic drugs.

Slow progress in the first stage of a normal labour may be due to inadequate contractions of the uterus. It is usually treated with intravenous infusions of synthetic oxytocin. If the mother cannot push strongly enough, or if the contractions are ineffective in the second stage of labour, the baby may be delivered by forceps delivery, vacuum extraction, or caesarean section.

Rarely, eclampsia (convulsions associated with raised blood pressure) may develop during labour. This disorder requires treatment with anticonvulsant drugs and oxygen, and a caesarean section will be necessary.

Bleeding before labour (ante partum haemorrhage) or during labour may be caused by premature, partial separation of the placenta from the wall of the uterus. Less commonly, it may result from a condition called placenta praevia, in which the placenta lies over the opening of the cervix. Blood loss after the delivery (postpartum haemorrhage) is usually due to failure of the uterus to contract after delivery, or to retention of part of the placenta.

**FETAL PROBLEMS**

If the baby lies in the breech position (see breech delivery), or in any other malpresentation (not lying in the normal head-down position in the uterus), caesarean section may be necessary.

Multiple pregnancies (see pregnancy, multiple) carry an increased risk of problems during delivery due to the difficulty of predicting the position of the second or subsequent babies. It is also more likely that babies in multiple pregnancies will be born prematurely.

**FETAL–MATERNAL PROBLEMS**

If the mother’s pelvis is too small in proportion to the head of her baby (a condition known as cephalopelvic disproportion), the baby may have to be delivered by caesarean section.

**childbirth, natural**

The use of relaxation and other techniques to help cope with pain and minimize the use of drugs and medical intervention during childbirth.

**child development**

The acquisition of physical, mental, and social skills in children. Although there is wide variation in individual rates of progress, most children develop certain skills within predictable age ranges (see the illustrated boxes opposite and overleaf).
FACTORS AFFECTING DEVELOPMENT
The capability for acquiring new skills is dependent upon the maturity of the child’s nervous system. Individual rates of maturity are determined genetically and modified by environmental factors in the uterus and after birth. For example, premature children miss out on a portion of the growing time in the uterus; therefore, the time that they take to progress should be calculated from the full-term pregnancy date, not the actual date of birth.

Sight and hearing are both crucial to a child’s general developmental progress; any defect in these areas will affect the child’s ability to watch, listen, learn, and imitate. Intelligence also affects the speed of development. Speaking to and playing with children is essential for their language development and to help them practise new physical skills. Introducing children to other children also provides them with a great deal of stimulation.

DEVELOPMENTAL MILESTONES
Development is assessed in early childhood by looking at the child’s abilities in four major areas: physical skills; hearing and language; vision and fine movement; and social behaviour and play. Children acquire particular skills at widely recognized stages known as developmental milestones.

All children acquire skills in much the same order (for example, a child will not learn to stand before learning to sit); however, the rate at which these skills are acquired varies enormously from child to child. A child may develop more rapidly in one area than in another. A more detailed assessment is required only if a child’s progress is significantly slower than average or if a parent is concerned for other reasons (see developmental delay).

CHILD GUIDANCE
A form of care provided by a multidisciplinary diagnosis and advice team, which helps children suffering from emotional or behavioural difficulties (see behavioural problems in children). Indications of such problems include poor performance at school, disruptive or withdrawn behaviour, breaking the law, and drug abuse.

<tr>
<td>Babies can lift up their heads and chests and roll from front to back and back to front. They can sit up with support, bounce up and down, and bear weight on their legs if supported.</td>
</tr>
<tr>
<td><strong>9 months</strong></td>
</tr>
<tr>
<td>Babies try to crawl, sit without support, and pull themselves up to standing or sitting positions. They can step purposefully on alternate feet if they are supported.</td>
</tr>
<tr>
<td><strong>1 year</strong></td>
</tr>
<tr>
<td>Children can crawl on hands and knees and walk around furniture (holding on). They may be able to walk alone or with one hand held.</td>
</tr>
<tr>
<td><strong>18 months</strong></td>
</tr>
<tr>
<td>Children can walk well with feet closer together. They can stoop to pick up objects, run with care, walk upstairs with one hand held, and crawl backwards downstairs.</td>
</tr>
<tr>
<td><strong>Vision and fine movement</strong></td>
</tr>
<tr>
<td><strong>By 6 months</strong></td>
</tr>
<tr>
<td>Babies look intently at everything and everybody. They follow moving objects with their eyes and reach for objects with one or both hands. Objects are transferred from hand to hand and brought to the mouth.</td>
</tr>
<tr>
<td><strong>9 months</strong></td>
</tr>
<tr>
<td>Babies are visually very alert. Their grasp involves mostly the index and middle fingers. They can manipulate objects with both hands, but have difficulty voluntarily releasing grasped objects.</td>
</tr>
<tr>
<td><strong>1 year</strong></td>
</tr>
<tr>
<td>Children can grasp small objects well and release grasped objects easily. Both hands are used equally. They can hold a block in each hand and bang the blocks together.</td>
</tr>
<tr>
<td><strong>18 months</strong></td>
</tr>
<tr>
<td>Children can build a tower of three blocks (when shown), enjoy turning pages of a book, can grip a crayon, scribble, and make dots. They may use one hand more than the other.</td>
</tr>
<tr>
<td><strong>Hearing, understanding, and speech</strong></td>
</tr>
<tr>
<td><strong>By 6 months</strong></td>
</tr>
<tr>
<td>Babies turn their heads to locate sources of sound and have begun to understand the tone of their mother’s voice. They enjoy making vowel sounds and tuneful noises. They laugh and squeal.</td>
</tr>
<tr>
<td><strong>9 months</strong></td>
</tr>
<tr>
<td>Babies listen to sounds and understand “no” and other words. They babble in long strings (making sounds such as ba-ba, da-da, ma-ma) and start using sound to attract attention. (Deaf babies’ utterances are monotonous and do not develop in complexity.)</td>
</tr>
<tr>
<td><strong>1 year</strong></td>
</tr>
<tr>
<td>Children turn when they hear their own name spoken. They have some understanding of how other people feel; they know what most household objects are used for; they may babble meaningfully to themselves; and they may say two or three words.</td>
</tr>
<tr>
<td><strong>18 months</strong></td>
</tr>
<tr>
<td>Children comprehend short communications spoken directly to them but do not understand the difference between statements, commands, and questions. Vocabulary may contain six to 20 words.</td>
</tr>
<tr>
<td><strong>Social behaviour and play</strong></td>
</tr>
<tr>
<td><strong>By 6 months</strong></td>
</tr>
<tr>
<td>Babies enjoy looking at their images in mirrors and playing peekaboo games. They can grasp objects and can also shake, bang, and otherwise manipulate them. They will not, however, look for objects that are shown and then hidden. They are shy with strangers.</td>
</tr>
<tr>
<td><strong>9 months</strong></td>
</tr>
<tr>
<td>Babies look for objects that are shown and then hidden, thus showing the beginnings of memory. They imitate hand clapping, wave bye-bye, and show great determination in getting objects. They continue to be shy with strangers.</td>
</tr>
<tr>
<td><strong>1 year</strong></td>
</tr>
<tr>
<td>Children spend less time putting objects in their mouths and more time releasing objects by throwing them, dropping them, putting them in boxes. They play pat-a-cake and like to be around a familiar adult to whom they demonstrate affection.</td>
</tr>
<tr>
<td><strong>18 months</strong></td>
</tr>
<tr>
<td>Children actively explore their homes. They enjoy moving things into and out of boxes and looking at picture books. They use spoons and cups and can take off their shoes and socks. They are also determined, impetuous, selfish, and cannot be reasoned with. They alternate between clinging to a familiar adult and struggling to break free.</td>
</tr>
</tbody>
</table>
Child guidance professionals include the specialists such as psychiatric social workers, psychiatrists, and psychologists. These people often work closely together in hospital paediatric departments, in schools, or in child-guidance clinics.

Various methods of assessment and therapy may be employed, depending on the age of the child and the problem involved. For young children, play therapy may be used to help with diagnosis. Older children may be offered counselling, psychotherapy, or group therapy. Family therapy may be of benefit in cases where there are relationship difficulties between child and one or both parents.

chill

A shivering attack accompanied by chattering teeth, pale skin, goose pimples, and feeling cold. Chill frequently precedes a fever. Repeated or severe shivering suggests serious illness.

Chinese medicine

Traditional Chinese medicine is based on the theory that a universal life-force, called chi, manifests itself in the body as two complementary qualities called yin and yang. According to this belief, vigorous yang and restraining yin must be in balance, and the chi must flow evenly for good health.

Treatments for illness aim to restore the balance between yin and yang and normalize the flow of chi in the body. They include Chinese herbal medicine, physical techniques such as acupressure and acupuncture, and t’ai chi.

chiropractic

A system of treatment for a range of disorders, that is based on manipulation of the spine. The main principle of chiropractic is the theory that disease stems from the misalignment of bones, which causes various problems with the nerves and muscles.

chlamydial infections

A group of infectious diseases caused by chlamydiae, a group of bacteria that can multiply only by invading the cells of another life-form.

### CHILD DEVELOPMENT: 2–5 YEARS

| Locomotion | 2 years | Children can climb furniture and walk up and down stairs (using two feet to each step). |
| 3 years | Children can climb with agility, throw and kick balls, ride tricycles, and run around corners. |
| 4 years | Children walk up and down stairs with one foot on each step, and can stand, walk, and run on tiptoe. |
| 5 years | Children can stand and hop on one foot, and are skilful in rolling, sliding, and swinging. |

| Vision and fine movement | 2 years | Children can build towers of six or seven blocks, can unscrew a lid, and show a definite right- or left-handedness. |
| 3 years | Children hold crayons with an adult grasp and can undo buttons, but may need help buttoning them up. Their handedness is clearly established. |
| 4 years | Children hold a pencil with a mature grasp, can copy simple letters (i.e. O, T, H or V), and can build a tower of more than 10 blocks. |
| 5 years | Children can match 10 or 12 colours, can copy many more letters, and can draw the full body of a person with a recognizable head and facial features. |

| Hearing, understanding, and speech | 2 years | Children begin to listen to general conversation. They obey simple instructions and can use 50 or more words meaningfully. They constantly talk to themselves and can put two or more words together to communicate. |
| 3 years | Children listen to conversation and enjoy nursery stories. They understand the difference between statements, commands, and questions. They have large vocabularies and speak clearly in sentences; there may be some errors. |
| 4 years | Children can repeat softly spoken words at a distance of 1 m. They speak fluently and with correct grammar, and can provide their full names, ages, and addresses. They tell long stories, confusing fact and fantasy. |
| 5 years | Children enjoy reciting rhymes, telling stories, and having books read to them. |

| Social behaviour and play | 2 years | Children ask the names of everything and enjoy participating in nursery rhymes and songs. They ask for food and drink and indicate toilet needs. They begin to play with toys more imaginatively, though they may not like to share them. They are constantly demanding and will throw tantrums if their desires are thwarted. |
| 3 years | Children constantly ask questions. They can dress and undress and eat with a fork and spoon. They are dry and clean during the day and sometimes at night. Three year olds can play with toys imaginatively and will share with others. They can be reasoned with and have fewer tantrums. They are also more affectionate to younger siblings. |
| 4 years | Children continue asking questions constantly. They are more independent and skilful in dressing, undressing, eating, and washing. They need to play with other children and can share with others. They can understand past, present, and future. |
| 5 years | Children ask the meaning of abstract words. They like to build complex structures out of bricks or other objects. They continue in imaginative and dramatic play. They enjoy companionship and understand the need for rules and fair play. They have an understanding of time and are generally sensible, restrained, and independent. |
TYPES
Two main species of chlamydiae cause disease in humans. They can be treated with antibiotic drugs.

The first species, *Chlamydia trachomatis*, is responsible for some sexually transmitted infections, including about half of all cases of *nongonococcal urethritis* in men and *pelvic inflammatory disease* in women. It can also cause the tropical eye disease *trachoma*.

A second species, *Chlamydia psittaci*, is responsible for *psittacosis*. This is a rare form of pneumonia that is transmitted to humans from birds.

*Chlamydia* is also responsible for a type of pneumonia (see *Chlamydia pneumoniae*).

*Chlamydia pneumoniae*

An infectious organism that can cause a mild form of *pneumonia*, which occurs particularly in young adults.

*Chlamydia psittaci*

An organism that mainly affects birds but can occasionally spread to people who are in contact with pigeons, parrots, parakeets, or poultry. It causes a type of pneumonia called *psittacosis*.

*Chlamydia trachomatis*

An organism that belongs to the *Chlamydia* group and has several strains. In men, it is a major cause of the sexually transmitted infection *nongonococcal urethritis*, which may cause a discharge from the penis. In women, the infection usually causes no symptoms, but can lead to *pelvic inflammatory disease* and possibly *salpingitis* (inflammation of the fallopian tubes). A baby born to a woman with chlamydial infection may acquire an acute eye disorder called neonatal *ophthalmia*.

In some parts of Africa and Asia, certain strains of *Chlamydia trachomatis* cause *trachoma*, a serious eye disease that is the most common cause of blindness worldwide.

chloasma
A skin condition, also called melasma, in which blotches of pale brown pigmentation appear on the face, notably on the forehead, nose, and cheeks. The condition is aggravated by sunlight. Chloasma sometimes develops during pregnancy. More rarely, it is associated with the menopause or the use of *oral contraceptives*. The areas of abnormal pigmentation usually fade in time, but the condition may recur.

**chlordiazepoxide**
A *benzodiazepine drug* mainly used in the treatment of *anxiety*. **Chlorambucil**
An *anti-cancer drug* that is used in the treatment of some types of cancer, such as *Hodgkin’s disease*. **Chloramphenicol**
An *antibiotic drug* commonly used as drops to treat superficial eye infections. Chloramphenicol is also used to treat life-threatening infections of unknown cause. Rarely, tablets or injections are associated with aplastic *anaemia*.

**Chloroform**
A brown swelling in an *ovary*. Chocolate cysts may develop in *endometriosis*, a condition in which endometrial tissue (which forms the lining of the uterus) is found in sites outside the uterus. The colour is the result of clotted blood within the cysts.
**CHOKING**

**choke**

Partial or complete inability to breathe due to an obstruction of the airways. Choking is often caused by food or drink entering the trachea (the windpipe) or the bronchi (the main airways to the lungs) instead of passing from the pharynx (throat) into the oesophagus (gullet). Normally, coughing dislodges the food or drink. An obstruction that partially blocks the airway, and which cannot be dislodged by coughing, is more serious. If the airway is completely blocked, total suffocation will occur if the obstruction is not removed.

If an obstruction cannot be cleared by the use of first-aid techniques, such as the Heimlich manoeuvre, or removed by hand, it may be necessary to perform an emergency tracheostomy (the making of an incision into the trachea and insertion of a tube through it into the lungs) to restore the airway. The object may then be removed by laryngoscopy or bronchoscopy (procedures that involve a viewing tube through which instruments are passed).

**cholangiocarcinoma**

A cancerous growth in one of the bile ducts. Cholangiocarcinoma causes jaundice and weight loss.

**cholangiography**

An imaging procedure involving the use of a contrast medium (a substance that is opaque to X-rays) to make the bile ducts visible on X-rays. It is used to diagnose biliary stones (which are similar to gallstones, but they develop in the bile ducts instead of the gallbladder) and narrowing or tumours of the bile ducts. The procedure is being superseded by ultrasound scanning and MRI, both of which can be used to locate stones.

**cholangitis**

Inflammation of any of the bile ducts, such as the common bile duct, which leads from the liver and gallbladder to the small intestine (see biliary system). There are two forms of the condition: acute ascending cholangitis and sclerosing cholangitis.

**ACUTE ASCENDING CHOLANGITIS**

This form of cholangitis is usually due to bacterial infection of the duct and its bile. The infection, in turn, generally results from blockage of the duct — for example, by a gallstone (see bile duct obstruction). The infection spreads up the duct and may affect the liver. The main symptoms of acute ascending cholangitis are recurrent bouts of jaundice, abdominal pain, chillis, and fever.

Mild attacks are treated with antibiotic drugs and fluids. Severe attacks may be accompanied by life-threatening septicaemia (blood poisoning) and kidney failure. In these cases, the infected material may be drained from the bile duct during surgery or endoscopy (a procedure in which instruments are passed through a viewing tube).

**SCLEROSING CHOLANGITIS**

In this rare condition, all the bile ducts within and outside the liver become narrowed. This causes cholestasis (stagnation of the bile in the liver), chronic jaundice, and itchiness of the skin, and the liver is progressively damaged.

The drug colestyramine may relieve itching. The only other treatment available is a liver transplant.

**chole-**

A prefix that means “relating to the bile or the biliary system”, as in cholecytitis (inflammation of the gallbladder).

**cholcalciferol**

An alternative name for colecalciferol, also called vitamin D₃ (see vitamin D).

**cholecystectomy**

Surgical removal of the gallbladder. Cholecystectomy is usually performed to deal with the presence of troublesome gallstones. It is also used in cases of acute cholecystitis (inflammation of the gallbladder) and as an emergency treatment for rupture of the gallbladder or empyema (accumulation of pus).

Cholecystectomy may be carried out using conventional surgery or, more commonly, by minimally invasive surgery using a laparoscope (a type of viewing tube through which instruments can be passed), as shown in the illustrated box opposite.

**cholecystitis**

Acute or chronic painful inflammation of the gallbladder.

**CAUSES AND SYMPTOMS**

Acute cholecystitis is usually caused by a gallstone obstructing the outlet from the gallbladder. The trapped bile inside becomes more concentrated, because water is absorbed from it, and irritates the gallbladder walls. Bacterial infection of the bile may result. The main symptom of acute cholecystitis is severe, constant pain in the right side of the abdomen under the ribs, accompanied by fever and, occasionally, jaundice.

Repeated mild attacks of acute cholecystitis can lead to a chronic form of the condition, in which the gallbladder shrinks, its walls thicken, and it ceases to store bile. Symptoms include indigestion, pains in the upper abdomen, nausea, and belching; they may be aggravated by eating fatty foods.

**TREATMENT AND COMPLICATIONS**

Treatment of cholecystitis usually involves the use of analgesic drugs, antibiotic drugs, and an intravenous infusion of nutrients and fluids. In some affected people, complications develop. These may include peritonitis (inflammation of the lining of the abdominal cavity), if the gallbladder bursts, and empyema (an accumulation of pus). Both of these complications require urgent surgical treatment. Cholecystectomy (removal of the gallbladder) is the usual treatment for chronic cholecystitis.

**cholecystography**

An X-ray procedure in which a contrast medium (a substance that is opaque to X-rays) is used for viewing of the gallbladder and common bile duct. The technique of cholecystography is usually used for the detection of gallstones but has largely been replaced by ultrasound scanning of the gallbladder.

**cholecystokinin**

A hormone that is produced in the duodenum (the first section of the small intestine) in response to the ingestion of fats and certain other food substances. Cholecystokinin stimulates the gallbladder to release bile into the duodenum, and triggers the secretion of digestive enzymes from the pancreas, thus aiding the breakdown of foods to release nutrients. Cholecystokinin is also found in the brain, where it has a function as a neurotransmitter.

**choledochal cyst**

A widening of the common bile duct, which carries the digestive juice bile from the liver and gallbladder to the duodenum. The disorder is congenital (present at birth), but symptoms may not develop until early adulthood; they consist of abdominal pain and jaundice (yellow coloration of the skin and eyes due to the accumulation of bilirubin, a bile pigment). Surgery is needed to correct the abnormality.
cholelithiasis
See gallstones.

cholera
An infection of the small intestine by the bacterium Vibrio cholerae. The disease causes profuse watery diarrhoea, which can lead to dehydration and death in severe untreated cases.

CAUSE AND INCIDENCE
Infection is acquired by ingesting contaminated food or water. Outbreaks of the disease occur regularly in northeast India, but worldwide cholera is controlled by sanitation.

SYMPTOMS
Cholera starts suddenly, between one and five days after infection, with diarrhoea that is often accompanied by vomiting. More than 500 ml of fluid may be lost each hour and, if this fluid is not replaced, severe dehydration and then death may occur within hours. The fluid loss is caused by the action of a toxin produced by the cholera bacterium that greatly increases the passage of fluid from the bloodstream into the large and small intestines.

TREATMENT
Treatment is with water containing salts and sugar (see oral rehydration therapy) and, in severe cases, by intravenous infusion. Antibiotic drugs can shorten the period of diarrhoea and infectiousness. After adequate rehydration, affected people usually make a full recovery from the infection.

PREVENTION
Cholera is controlled worldwide by the improvement of sanitation, and in particular by ensuring that sewage is not permitted to contaminate water supplies used for drinking. Vaccination against cholera is not recommended. Travellers planning to visit cholera-infected areas are advised to consume only water that has been boiled, or bottled drinks from reliable sources.

cholestasis
Stagnation of bile in the small bile ducts within the liver, leading to jaundice and liver disease. The obstruction to the flow of bile may be intrahepatic (within the liver) or extrahepatic (in the bile ducts outside the liver).

CAUSES
Intrahepatic cholestasis may develop as a result of viral hepatitis (see hepatitis, viral) or as an adverse effect of various drugs. The flow of bile will improve gradually as the inflammation from hepatitis subsides or when a causative drug is discontinued.

The bile ducts outside the liver can become blocked by abnormalities such as gallstones or tumours (see bile duct obstruction). Rarely, the ducts are absent from birth (see biliary atresia).

TREATMENT
Bile duct obstruction and biliary atresia are often treated surgically to ensure or restore the free passage of bile from the liver to the duodenum.
cholestatic jaundice
Jaundice (yellow discolouration of the skin) that occurs as a result of cholestasis (obstruction in the flow of bile to the intestine).

cholesteatoma
A rare but serious condition in which skin cells proliferate and grow inwards from the ear canal into the middle ear. Cholesteatoma usually occurs as a result of long-standing otitis media (a middle-ear infection) together with a defect in the eardrum (see eardrum, perforated). If left untreated, it may grow and damage the small bones in the middle ear and surrounding structures.

Cholesteatoma needs to be removed surgically through the eardrum or by mastoidectomy (removal of the mastoid bone, which is located behind the ear, together with the cholesteatoma).

cholesterol
A fat-like substance that is an important constituent of body cells and also is involved in the formation of hormones and bile salts. Cholesterol is made by the liver from various foods, especially those containing saturated fats (see fats and oils), although a small amount is absorbed directly from cholesterol-rich foods such as eggs and shellfish.

Both cholesterol and fats (triglycerides) are transported in the blood as lipoproteins. These are particles with a core, which is made of varying proportions of cholesterol and triglycerides, and an outer layer made of proteins.

CHOLESTEROL-RELATED DISEASES
High blood cholesterol levels increase the risk of atherosclerosis (accumulation of fatty deposits on the lining of the arteries) and with it the risk of coronary artery disease or of stroke (damage to part of the brain due to interruption of its blood supply). In general, cholesterol transported in the bloodstream as low-density lipoproteins (LDLs) or as very low-density lipoproteins (VLDLs) is a risk factor for these conditions, while cholesterol in the form of high-density lipoproteins (HDLs) seems to protect against arterial disease.

Levels of cholesterol in the blood are influenced by diet, genetic factors, and metabolic diseases such as diabetes mellitus. Cholesterol levels can be measured by blood tests. They are measured in millimoles per litre (mmol/L). The optimum level is less than 5.0. Higher levels may require dietary modification.

Sometimes, however, medication (such as simvastatin) may be required to reduce the risk of arterial diseases.

cholesterolosis
Abnormal deposits of cholesterol in the lining of the gallbladder that may be associated with the development of gallstones. Cholesterolosis is sometimes known as strawberry gallbladder because of the appearance of an affected gallbladder.

cholesteramine
An alternative spelling for the lipiodowering drug colestyramine.

cholic acid
One of the acids contained in bile.

cholinergic crisis
A condition that affects people with myasthenia gravis who are undergoing treatment with cholinesterase inhibitors. The problem is caused by an overdose of cholinesterase inhibitors. During a cholinergic crisis, the muscle weakness that is associated with myasthenia gravis worsens dramatically, and needs emergency medical treatment.

cholinesterase inhibitors
COMMON DRUGS
- Neostigmine
- Pyridostigmine

A group of drugs, also known as anticholinesterases, that are used to relieve muscle weakness resulting from myasthenia gravis. In this disease, abnormal activity of the immune system causes the destruction of receptors on muscle cells that bind with acetylcholine, a neurotransmitter that makes the muscles contract. Cholinesterase inhibitors block the action of acetylcholinesterase, the enzyme that normally breaks down acetylcholine, allowing the neurotransmitter more time to act. The drugs are also used to reverse the effects of muscle-relaxant drugs given with general anaesthesia.

chondro-
A prefix denoting a relationship to cartilage, as in chondrocyte, a cell that produces cartilage.

chondrocalcinosis
The presence of calcium pyrophosphate in joint cartilage. The condition, which occurs in pseudogout (a form of arthritis), causes pain and swelling.

chondroma
A noncancerous tumour composed of cartilage, affecting the bones. Chondromas most often occur in the hands and feet (see chondromatosis).

chondromalacia patellae
A painful knee disorder, one cause of anterior knee pain, in which the cartilage lining the hip and knee joints; this inflammation may eventually lead to osteoarthritis.

chondrosarcoma
A cancerous growth of cartilage (connective tissue composed of the gel-like substance collagen). Chondrosarcoma
occurs within or on the surface of large bones, such as the femur (thigh bone), causing pain and swelling.

The condition usually appears in middle age. The tumour may develop slowly from a noncancerous tumour (see chondroma; dyschondroplasia) or may grow rapidly from an area of previously normal bone. If a limb is affected, amputation of the bone above the tumour usually results in a permanent cure. Treatment of sites such as the pelvis or ribs is more difficult.

**chordae tendineae**

Stringlike strands of fibre that attach the flaps of the mitral and tricuspid heart valves to the walls of the ventricles (lower heart chambers). The chordae tendineae, which are popularly known as the heartstrings, prevent the valves from turning inside out.

**chordee**

Abnormal curvature of the penis, usually downwards. Chordee most often occurs in males with hypospadia, a birth defect in which the opening of the urethra lies on the underside of the penis instead of at the tip. It is usually corrected by surgery, between the ages of one and three years.

**chorea**

A condition that is characterized by irregular, rapid, jerky movements, usually affecting the face, limbs, and trunk. The movements are involuntary and, unlike tics, they are not predictable but occur at random. Chorea disappears during sleep. The disorder is sometimes combined with athetosis (continued writhing movements); this combined condition is known as choreoathetosis.

**TYPES AND CAUSES**

Chorea arises from disease or disturbance of structures lying deep within the brain (in particular, the paired nerve cell groups called the basal ganglia). The condition is a feature of Huntington’s disease and Sydenham’s chorea. It may also occur in pregnancy, when it is called chorea gravidarum. In addition, chorea may be a side effect of certain drugs, including oral contraceptives; certain drugs for psychiatric disorders; and drugs for treating Parkinson’s disease.

**TREATMENT**

If the cause of chorea is an underlying disease, the condition may be treated with drugs that inhibit the nerve pathways concerned with movement. If chorea has occurred as a side effect of a drug, the drug may be withdrawn and a substitute provided.

**choreoathetosis**

A condition characterized by uncontrollable movements of the limbs, face, and trunk. In this disorder, the jerky, rapid movements typical of chorea are combined with the slower, continuous writhing movements of athetosis.

Choreoathetosis may occur in children with cerebral palsy. It may also be a side effect of certain drugs.

**choriocarcinoma**

A rare, cancerous tumour that develops from placental tissue (see placenta) in the uterus. Choriocarcinoma usually occurs as a complication of a hydatidiform mole (a noncancerous tumour that arises in placental tissue); however, it sometimes develops after a normal pregnancy, a miscarriage, or an abortion. Occasionally, the tumour may not appear until months or even years after the pregnancy that gave rise to it.

**SYMPTOMS**

There may be no early symptoms. The tumour may become apparent because of persistent bleeding from the vagina after a miscarriage or abortion, or for more than eight weeks following childbirth. If it is left untreated, the tumour destroys the walls of the uterus; and the cancer may also spread in the bloodstream to the vagina and vulva and then to the liver, lungs, brain, and bones.

**DIAGNOSIS AND TREATMENT**

Any woman who has been treated for a hydatidiform mole is screened regularly by ultrasound scanning. Blood and urine levels of human choriocarcinon gonadotrophin (HCG), a hormone that is normally produced by the placenta, are also measured because high levels of this hormone in the body are associated with choriocarcinoma.

Treatment with anticancer drugs is usually very successful. Hysterectomy (surgical removal of the uterus) may also be necessary.

**chorion**

One of the two membranes that surround the embryo. The chorion lies outside the amnion, has small fingerlike projections called the choriocytic villi, and develops into the placenta.

**chorionic gonadotrophin**

See gonadotrophin, human choriocarcinoma.

**chorionic villi**

The short, fingerlike projections that extend from the surface of the chorion (the membrane that surrounds a fetus). (See also choriocarcinoma sampling; villus.)

**chorionic villus sampling (CVS)**

A method of diagnosing genetic abnormalities in a fetus. The test involves taking a small sample of tissue from the chorionic villi at the edge of the placenta for laboratory analysis. The cells have the same chromosome makeup as those that form the fetus, so they can be used to detect genetic abnormalities. After removal, the villi cells are transported to a laboratory for chromosome analysis.

CVS is offered to women at a higher-than-normal risk of having a child with a genetic disease, such as thalassaemia, or a chromosomal abnormality, such as Down’s syndrome. It is normally performed at around the 10th week of pregnancy and can be carried out via the abdomen (below) or vaginally, depending on the location of the placenta. CVS slightly increases the risk of miscarriage.

**choroid**

A layer of tissue at the back of the eye, beneath the retina. The choroid contains a network of blood vessels that supply nutrients and oxygen to the retina and to the surrounding tissues in the eye.

**choroiditis**

Inflammation of the choroid (the blood-rich layer of tissue at the back of the eye). Choroiditis may occur on its own
or as part of a generalized inflammation affecting the whole eye (see uveitis). The condition is often the result of infections such as toxocariasis or toxoplasmosis, and, more rarely, of sarcoidosis, syphilis, and histoplasmosis, although it sometimes has no obvious cause. Chorioiditis is painless but causes blurring of vision.

Treatment of chorioiditis includes corticosteroid drugs to reduce the inflammation and antibiotic drugs for any causative infection.

**STRUCTURE OF CHOROID**

The choroid lines the inside of the eyeball. It thickens around the lens to form the ciliary body. Muscles stretching between the choroid and the lens contract to adjust the shape of the lens in focusing.

**choroid plexus**

A network of thin-walled blood vessels in the eye or brain. The choroid plexus of the eye supplies blood to the retina. In the brain, the choroid plexus lines the ventricles (cavities) and produces cerebrospinal fluid.

**Christmas disease**

A rare genetic bleeding disorder in which there is deficient production of one of the proteins in blood that is needed for blood coagulation (see blood clotting).

Christmas disease has similar features to haemophilia. However, the deficient proteins are different. In Christmas disease the deficiency is of a protein called factor IX, while in haemophilia the deficiency is of the protein factor VIII.

**chromium**

A metallic element that plays a vital role in the activities of several enzymes (substances that control the rate of chemical reactions) in the body.

Chromium is needed in only minute amounts (see trace elements). In excess, it is toxic. It causes inflammation of the skin, and, if inhaled, damages the nose. Chromium fumes may increase the risk of lung cancer.

**chromosomal abnormalities**

Variations from normal in the number or structure of chromosomes contained in a person’s cells. In most cases, the chromosomal abnormality is present in all of the body’s cells. The possible effects range from virtually none to a lethal condition, depending on the particular type of abnormality.

**CAUSES**

The cause of a chromosomal abnormality is generally a fault in the process of chromosome division, either during the formation of an egg or sperm, or during the first few divisions of a fertilized egg. Occasionally, a parent passes on an abnormal arrangement of his or her own chromosomes.

**TYPES**

Chromosomal abnormalities are classified according to whether they involve the 44 autosomes (pairs of very similar chromosomes) or the two sex chromosomes (X and Y). A whole extra set of chromosomes per cell is called polyploidy; this is lethal in early pregnancy.

**AUTOSOMAL ABNORMALITIES**

These abnormalities cause physical and mental defects of varying severity. Some types of autosomal abnormality, known as trisomy, involve the presence of an extra chromosome on one of the 22 pairs of autosomes. The most common trisomy is Down’s syndrome, which is caused by the presence of three number 21 chromosomes.

Sometimes, part of a chromosome is missing, as in cri du chat syndrome. In translocation, a part of a chromosome is joined to another, causing no ill effects in the person but a risk of abnormality in his or her children.

**SEX CHROMOSOME ABNORMALITIES**

Normally, a female has two X chromosomes and a male has an X and a Y. Abnormalities may occur if there are missing or extra sex chromosomes.

In Turner’s syndrome, a girl is born with only a single X chromosome in her cells instead of the normal complement of two. The condition causes physical abnormalities, defective sexual development, and infertility.

In boys, one or more extra X chromosomes causes Klinefelter’s syndrome. This condition results in defective sexual development and infertility.

The presence of an extra X chromosome in women or of an extra Y chromosome in men normally has no physical effect but increases the risk of mild learning difficulties.

**DIAGNOSIS**

If suspected, chromosomal abnormalities can be diagnosed by chromosome analysis in early pregnancy, using amniocentesis or chorionic villus sampling.

Because chromosomal abnormalities affect every one of a person’s cells, no cure is possible. Many disorders caused by autosomal chromosome defects result in early death. Others, such as Down’s syndrome, are compatible with survival but cause physical and mental disability. Hormonal or surgical treatment, or a combination, can help to correct some of the developmental defects caused by Klinefelter’s and Turner’s syndromes.

Anyone who has a child or other family member affected by a chromosomal abnormality may wish to consider genetic counselling to establish the risk of his or her future children being affected by the condition.

**chromosome analysis**

Study of the chromosomes in cells to find out if a chromosomal abnormality is present or to establish its nature.

**WHY IT IS DONE**

Some pregnancies are associated with a higher-than-average risk of the baby having a chromosomal abnormality. Risk factors include an older mother, the birth of a previous child with a chromosomal defect, or a defect or translocation (rearrangement) in the mother’s or the father’s chromosomes. In many cases, there are no identifiable risk factors, and so all pregnant women are offered a preliminary blood test (see antenatal screening) to identify those at high risk of a fetal abnormality. If the fetus is at high risk, a sample of cells is taken for chromosome analysis. If a serious abnormality, such as Down’s syndrome, is identified, the parents will be offered termination of the pregnancy (see abortion, induced) and genetic counselling to assess the risk of a subsequent pregnancy being affected.
Chromosome analysis is also carried out when a baby is stillborn without an obvious cause, or when a baby is born with abnormal physical characteristics that suggest a chromosomal defect, such as Turner’s syndrome.

The analysis of the sex chromosomes may be carried out in order to establish the chromosomal sex of a child whose genitals have an ambiguous appearance (see genitalia, ambiguous); to confirm or to exclude the diagnosis of chromosomal abnormalities; or to investigate infertility.

HOW IT IS DONE
Fetal cells for analysis can be obtained by amniocentesis or chorionic villus sampling. Chromosome analysis in children and adults uses white blood cells taken from a blood sample.

chromosomes
Threadlike structures that exist inside the nuclei (see nucleus) of cells and carry inherited information governing all cellular activities and functions. Each chromosome contains around 30,000 genes (units of inheritance), which are arranged in single file along a long double filament of DNA. The sequence of chemical units, or bases, in the DNA provides the coded instructions for cellular activities. Each cell contains the chemical machinery for decoding these instructions (see genetic code; nucleic acids).

All of an individual’s body cells (with the exception of egg or sperm cells) carry the same chromosomal material, which has been copied by a process of cell division from the original material in the fertilized egg. Each human cell normally contains 46 chromosomes made up of 23 pairs. Half of each pair of chromosomes comes from the mother and half from the father.

TYPES OF CHROMOSOMES
In each set of chromosomes, 22 pairs are autosomal, which are the same in both sexes, and the remaining pair are the sex chromosomes.

There are two types of sex chromosome, called X and Y. In females, the sex chromosomes are a matched pair of X chromosomes. In males, one is an X and the other is a Y. The mother’s egg contributes an X chromosome to every offspring. The father’s sperm contributes the other chromosome in the pair: an X in girls or a Y in boys.

The Y chromosome is thought to provide all of the information required for the development of male sexual characteristics. In the absence of the Y chromosome, the female pattern of development takes place.

CHROMOSOME DIVISION
When a cell divides, all of its components, including the chromosomes, are duplicated into the two offspring cells.

The process by which most body cells divide is called mitosis. Shortly before cell division, the DNA in each chromosome is copied; if viewed under a microscope, chromosomes at this stage appear as double rods joined at an area called the centromere. As cell division proceeds, the duplicated chromosomes are pulled apart, divided at the centromeres, so that each daughter cell will receive a single copy of each of the usual 46 chromosomes.

### PROCEDURE FOR CHROMOSOME ANALYSIS

1. **In antenatal testing**, a collection of fetal cells is obtained by amniocentesis or by chorionic villus sampling. In a test on a baby, child, or adult, white blood cells are obtained from a sample of blood.

2. The cells are suspended in a medium containing substances that encourage them to divide. Chemicals are then added that stop the cells from dividing at a stage where their chromosome content is most easily visible.

3. The cells are spread on a microscope slide and stained. A selected few (in which the chromosomes are clearly visible and well separated) have their nuclei photographed or are closely examined through a high-powered microscope.

4. The chromosomes are matched up and arranged into the 22 pairs of autosomes and the sex chromosomes. A study of the complete set will reveal any abnormalities.

---

**Appearance of a dividing chromosome**

Just after a chromosome has copied itself, the copies are joined at a constriction (centromere) that divides them into long and short “arms”.

**Types of chromosomes**

- **Autosomal chromosomes**: Identical in both males and females.
- **Sex chromosomes**: Distinct in males and females. Males have an X and a Y chromosome, while females have two X chromosomes.

**Appearance of sex chromosomes**

In females, both sex chromosomes are X chromosomes (XX). In males, one sex chromosome is X and the other is Y (XY).
When egg or sperm cells are formed, by a process called meiosis, there are two important departures from the normal process of chromosome division. First, after the DNA has been copied (before division takes place), some sections of chromosomal material are exchanged between the two members of each chromosome pair. This helps to ensure that each of a person’s eggs or sperm contains a different combination of chromosomal material, and this is the reason why siblings (with the exception of identical twins) have a unique appearance. In other cases, there is no such preceding illness or event.

**DIAGNOSIS**
There is no diagnostic test for chronic fatigue syndrome, and investigations of the condition are usually aimed at excluding other possible causes of the symptoms, such as anaemia. A physical examination, blood tests, and a psychological assessment may be carried out. If no cause can be found, a diagnosis of chronic fatigue syndrome can be made from the symptoms.

**TREATMENT**
Analgesic drugs (painkillers) or antidepressant drugs may help to relieve the symptoms. Physiotherapy or psychotherapy may also be helpful. Chronic fatigue syndrome is a long-term disorder, but the symptoms clear up after several years in some people.

**chronic glaucoma**
See glaucoma.

**chronic heart failure**
See heart failure.

**chronic obstructive lung disease**
See pulmonary disease, chronic obstructive.

**chronic obstructive pulmonary disease**
See pulmonary disease, chronic obstructive.
chronological age
The most common measurement of an individual’s age.

Churg–Strauss syndrome
A condition characterized by vasculitis (inflammation in the walls of small blood vessels), which mainly affects adults in their thirties who have asthma. It is thought to be due to an allergy of unknown cause.

The vasculitis can cause a variety of symptoms, depending on the parts of the body that are affected. Common problems include abdominal pain, if the bowel is involved, and skin rashes. The disease may be severe or even life-threatening, although in most cases it responds well to treatment with oral corticosteroid drugs. The drug treatment may need to be continued, at a low dose, for some time to prevent a recurrence of the condition.

chylomicron
A globule of fat (see fats and oils) that is carried into the bloodstream from the intestine following the digestion of a meal containing fat.

Cicatrin
The brand name for an antibacterial skin preparation.

ciclosporin
An immnosuppressant drug that is used following transplant surgery. The drug reduces the risk of tissue rejection and the need for large doses of corticosteroid drugs. Ciclosporin may need to be taken indefinitely after a transplant. It is also used to treat rheumatoid arthritis and other autoimmune disorders.

Because ciclosporin suppresses the immune system, it increases the susceptibility of the body to various infections. Swelling of the gums and increased hair growth are fairly common side effects. The drug may also cause kidney damage, so it is necessary for anyone who is taking it to undergo regular monitoring of kidney function.

Cilest
The brand name for a combined oral contraceptive.

cilia
Hairlike, mobile filaments that exist on the surface of some epithelial cells (see epithelium). Cilia are found in particularly abundant amounts in the linings of the respiratory tract, where they move rhythmically to propel dust and mucus out of the airways.

ciliary body
A structure in the eye containing muscles that alter the shape of the lens to adjust focus. (See also accommodation.)

cimetidine
An H2-receptor antagonist, which is a type of ulcer-healing drug. Cimetidine can be taken in tablet or liquid form, or it may be injected. The drug promotes healing of gastric and duodenal ulcers (see peptic ulcer) and reduces the symptoms of oesophagitis (inflammation of the gullet).
Side effects include fatigue, dizziness, and skin rashes. Rarely, the drug may cause impotence and gynaecomastia (breast enlargement in men).

CIN
The abbreviation for cervical intraepithelial neoplasia.

cinnarizine
An antihistamine drug used to control nausea and vomiting due to travel sickness, or to reduce nausea and vertigo in disorders of the inner ear such as labyrinthitis and Ménière’s disease. High doses of the drug are sometimes used to improve circulation in people with peripheral vascular disease and Raynaud’s disease. Side effects of cinnarizine may include drowsiness, lethargy, a dry mouth, and blurred vision.

Cipramil
A brand name for citalopram, an antidepressant drug.

ciprofloxacin
An antibiotic drug that is used to treat infections of the respiratory, gastrointestinal, and urinary tracts. Ciprofloxacin may also be used as an initial treatment for anthrax.

Ciproxin
A brand name for ciprofloxacin, an antibiotic drug.

circadian rhythms
Any pattern of physiological functions that is based on a cycle approximately 24 hours long (also called a diurnal rhythm). One example of this pattern is the daily cycle of sleeping and wakefulness. (See also biorhythms.)

circulation, disorders of
Conditions affecting the flow of blood around the body. (See arteries, disorders of; veins, disorders of.)

circulatory collapse
A life-threatening condition in which the circulatory system is unable to maintain an adequate blood flow to the organs and tissues of the body (see shock). Circulatory collapse can occur when the heart stops beating (see cardiac arrest), or be due to loss of blood or problems with the blood vessels.

circulatory system
The heart and blood vessels, which together are responsible for the maintenance of a continuous flow of blood through the body. Also known as the cardiovascular system, the circulatory system provides the body tissues with a supply of oxygen and nutrients, and carries away carbon dioxide and other waste products.

STRUCTURE AND FUNCTION
The circulatory system has two main parts: the systemic circulation, which supplies blood to the whole body apart from the lungs; and the pulmonary circulation to the lungs, which supplies the blood with fresh oxygen (see circulatory system box, overleaf).

Oxygen-rich blood from the pulmonary circulation enters the systemic circulation via the left ventricle of the heart. The ventricle pumps it under high pressure into the aorta (the body’s main artery), from where it travels through arteries and smaller arterioles to all parts of the body. Within the body tissues, the arterioles branch into networks of fine blood vessels known as capillaries. Oxygen and other nutrients pass from the blood through the thin capillary walls and into the tissues; carbon dioxide and other waste products pass in the opposite direction. Deoxygenated blood is returned to the heart via venules (small veins), veins, and the venae cavae (the two principal veins in the body).

Within the systemic circulation, there is also a bypass (the portal circulation) that carries nutrient-rich blood from the stomach, intestine, and other digestive organs via the portal vein to the liver. Nutrients and other substances pass into the liver cells for processing, storage, breakdown, or re-entry into the general circulation. Blood passes out of the liver through
The heart and blood vessels create a continuous flow of blood around the body to provide tissues with oxygen and nutrients. The circulatory system also removes waste products. The systemic circulation deals with the supply of blood to all parts except the lungs; the pulmonary (lung) circulation reoxygenates the blood.

**SYSTEMIC CIRCULATION**

- Internal carotid artery
- External carotid artery
- Subclavian artery
- Aorta
- Pulmonary vein
- Heart
- Brachial artery
- Superior mesenteric artery
- Inferior vena cava
- Radial artery
- Iliac artery
- Iliac vein
- Femoral artery
- Femoral vein

**PULMONARY CIRCULATION**

- Trachea (windpipe)
- Superior vena cava
- Right atrium
- Right ventricle
- Inferior vena cava
- Aorta
- Left atrium

** Blood circulation**
The right side of the heart receives deoxygenated blood from the systemic ("body") circulation via the vena cavae. The heart pumps this blood to the lungs, where it is oxygenated and returns to the left side of the heart (pulmonary circulation). It is then pumped via arteries to the tissues, where the blood releases oxygen. Deoxygenated blood then returns to the heart.

**CAPILLARY NETWORK**

All tissues contain a network of tiny capillaries. Blood enters these vessels from the arterioles and is drained by venules.
the hepatic vein and rejoins the main systemic circulation via the inferior (lower) vena cava.

Venous blood returns to the right atrium of the heart to enter the pulmonary circulation. It is pumped from the right ventricle through the pulmonary artery to the lungs, where carbon dioxide is exchanged for oxygen. The reoxygenated blood then returns via the pulmonary veins to the heart and re-enters the systemic circulation.

On its journey from the heart to the body tissues, blood is forced along the arteries at high pressure. In contrast, blood flowing through the veins and back to the heart is at low pressure. It is kept moving by muscles in the limbs, which compress the veins and thus squeeze blood through them, and by valves in the veins that prevent the blood from flowing backwards. (See also **lymphatic system; respiration**).

**circumcision**

Surgical removal of the foreskin of the **penis**. Circumcision is usually performed on newborn babies for religious or hygienic reasons. In some cases, it may be medically required to treat **phimosis** (a tight foreskin that causes ballooning on urination), recurrent attacks of **balanitis** (infection under the foreskin due to retained secretions), or **paraphimosis** (painful compression of the shaft of the penis by a retracted foreskin).

**circumcision, female**

Removal of all or some parts of the female external genitalia: the **clitoris**, labia majora, and labia minora (see **labia**). Female circumcision is sometimes combined with narrowing of the entrance to the **vagina**.

Female circumcision is common in certain parts of Africa but has no valid medical purpose. It can cause retention of urine and injuries during sexual intercourse and childbirth.

**cirrhosis**

A condition of the **liver** that results from long-term damage to liver cells. In cirrhosis, bands of fibrosis (internal scarring) develop, leaving **nodules** of regenerating cells that are inadequately supplied with blood. Liver function is gradually impaired; the liver no longer effectively removes toxic substances from the blood (see **liver failure**). The distortion and fibrosis also lead to **portal hypertension** (abnormally high blood pressure in the veins leading from the intestines and spleen to the liver).

**CAUSES**

The most common cause of cirrhosis is excessive **alcohol** consumption. Another possible cause is one of the forms of chronic **hepatitis** (inflammation of the liver). Other causes, which are rare, include disorders of the bile ducts; **haemochromatosis**, in which increased iron absorption occurs; **Wilson's disease** (an increase in copper absorption); **cystic fibrosis**, which causes obstruction of the bile ducts with mucus; and **heart failure**.

**SYMPTOMS AND COMPLICATIONS**

Cirrhosis may go unrecognized until symptoms such as mild **jaundice**, **oedema** (an accumulation of fluid in body tissues) and vomiting of blood develop. There may be enlargement of the liver and spleen. Men may experience loss of body hair and enlargement of the breasts due to an imbalance in sex hormones caused by liver failure.

Complications of cirrhosis include **ascites** (an accumulation of fluid in the abdominal cavity), **oesophageal varices** (enlarged veins within the oesophagus wall), and **hepatoma** (liver cancer). Cirrhosis may also cause toxins to build up in the brain, producing symptoms such as confusion and coma (see **hepatic encephalopathy**).

**TREATMENT**

Treatment is focused on slowing the rate at which liver cells are being damaged, if possible by treating the cause. Any complications will also be treated. In some cases, however, the cirrhosis progresses and a **liver transplant** may need to be considered.

**cisplatin**

An **anticancer drug** used to treat some cancers of the **testis** and the **ovary**.

**citalopram**

An **antidepressant drug** belonging to a group called selective serotonin reuptake inhibitors (SSRIs). Citalopram takes up to four weeks to reach its full effect; it gradually improves the user's mood, energy levels, and level of interest in everyday activities.

The drug may cause gastrointestinal problems such as nausea, vomiting, or diarrhoea, but these usually diminish with continued use. Citalopram may also cause drowsiness and, for this reason, people taking the drug should avoid alcohol, and should not carry out activities such as driving vehicles until they have learned how strongly citalopram affects them.

**CJD**

The abbreviation for **Creutzfeldt–Jakob disease**.

**CK**

The abbreviation for **creatine kinase**.

**clamp**

An instrument that is used during surgical procedures to compress the cut end of an organ or blood vessel temporarily, in order to prevent leakage of blood or other fluids.

**clap**

A slang term for **gonorrhoea**.

**clarithromycin**

An **antibiotic drug** that belongs to the macrolide group. Clarithromycin is used to treat infections of the skin and the respiratory tract.

**classic migraine**

A type of **migraine** attack accompanied by an aura (neurological disturbances), nausea, and vomiting.

**claudication**

A cramplike pain in a muscle, most often in the legs, due to inadequate blood supply. Claudication in the legs is usually caused by blockage or narrowing of arteries due to **atherosclerosis** (see **peripheral vascular disease**). In intermittent claudication, pain is felt in the calves after walking a certain distance and is relieved by rest.

A rarer cause is spinal **stenosis** (narrowing of the canal carrying the spinal cord), causing pressure on the nerve roots that pass into either leg.

**claustrophobia**

An intense fear of being in enclosed spaces, such as lifts or tunnels, or of being in crowded areas. The usual treatment is **behaviour therapy** involving techniques that gradually lessen the patient’s anxiety. (See also **phobia**.)

**clavicle**

The collarbone. The two clavicles, one on each side, form joints with the top of the sternum (breastbone) and the scapula (shoulderblade). The clavicles support the arms and transmit forces from the arms to the central skeleton.
Most fractures of the clavicle occur as a result of a fall on to the shoulder or on to an outstretched arm. When the clavicle is broken, the arm must be supported in a sling and a figure-of-eight bandage must be used to keep the fractured bone ends together. Healing takes about three weeks.

**CLAVULARY ACID**

A substance that is combined with the penicillin drug amoxicillin to produce the antibiotic drug co-amoxiclav.

**claw-foot**

A deformity of the foot in which the arch of the foot is exaggerated and the tips of the toes turn under. Claw-foot may be present from birth, or it may result from damage or disruption to the nerve or blood supply to the muscles of the foot. Surgery may improve the condition.

**claw-hand**

A deformity in which the fingers are permanently curled. It is caused by injury to the ulnar nerve, which controls the muscles of the thumb and fingers. Treatment includes repairing the nerve by using splints to hold the fingers straight, or cutting a tendon in the wrist to allow the fingers to straighten.

**claw-toe**

A deformity of unknown cause in which the end of one or more affected toes bends downwards so that the toe curls under. A painful corn may form on the tip of the toe or on the top of the bent joint. Protective pads can relieve pressure from footwear. In severe cases, surgery may be required.

**clear liquid diet**

A diet consisting solely of clear or strained fluids, such as broth, ginger ale, or fruit juices. A clear liquid diet provides little nourishment. It is mainly used for very short periods, such as during the first 24 hours following surgery or in the initial stages of an episode of diarrhoea and vomiting.

**cleft lip and palate**

A split in the upper lip and/or palate that is present at birth. Cleft lip is a vertical, usually off-centre split in the upper lip; it may be a small notch, or may extend to the nose. The gum may also be cleft, and the nose may be crooked. The term "harelip" refers only to a midline cleft lip, which is rare. Cleft palate is a gap that may extend from the back of the palate to behind the teeth and be open to the nasal cavity. The condition is often accompanied by other problems such as partial deafness and possibly other birth defects.

**TREATMENT**

Surgery to repair a cleft lip may be undertaken in the first few days after birth or when the baby is about three months of age. Surgery improves the child’s appearance; after repair, speech defects are rare. A cleft palate is usually repaired at about 12 months, but further surgery, orthodontic treatment, and speech therapy may be required.

**cleidocranial dysplasia**

Also called cleidocranial dysostosis, a rare, autosomal dominant genetic disorder causing malformation of the bones, particularly those in the skull and shoulders. An affected person typically has absent or underdeveloped clavicles (collarbones), and can move the shoulders forwards so that they almost touch. The sutures (fixed joints) of the skull bones take longer than normal to fuse together. There may also be abnormalities in the structure of the pelvis, fingers, teeth, and vertebrae (bones of the spinal column).

**clemastine**

An antihistamine drug that is used to relieve the symptoms of allergic conditions such as urticaria (nettle rash) and allergic rhinitis (hay fever). Clemastine can cause drowsiness so driving and hazardous work should be avoided.

**clergyman’s knee**

Inflammation of the bursa (the fluid-filled sac) that cushions the pressure point above the tibial tubercle (the bony prominence just below the knee). The condition is caused by prolonged kneeling. (See also bursitis.)

**climacteric**

See menopause.

**clindamycin**

An antibiotic drug that may be prescribed as a skin preparation to treat severe acne or in creams to treat bacterial vaginal infections. Sometimes, it is also given as tablets or by injection.

Clindamycin can have serious side effects. In particular, it may cause a potentially life-threatening form of bowel inflammation called antibiotic-associated colitis. For this reason, the drug is prescribed only when other types of antibiotic cannot be used.

**clinic**

A hospital department or health-care institution for the treatment of particular diseases (such as conditions that are specific to women or to men, or sexually transmitted infections).

**clinical diagnosis**

A procedure in which a doctor determines the nature of a disorder on the basis of an individual’s description of his or her symptoms and a physical examination. Unlike pathological diagnosis, a clinical diagnosis does not depend on the analysis of tissue specimens taken from the body.

**clinical pharmacology**

The branch of pharmacology (the science concerned with the nature and action of drugs) that deals with the use of drugs in patients, in hospitals and in the community. Clinical pharmacologists are concerned with drug doses; when and when not to give specific drugs (indications and contraindications); administration; and side effects.

**clinical psychology**

The branch of psychology (the scientific study of mental processes) concerned with the diagnosis and treatment of emotional and behavioural problems.
clinical trial
See trial, clinical.

Clinistix
A brand-name product that detects glucose (sugar) in urine and which can be used by people with diabetes mellitus to monitor their condition. Clinistix consists of test strips impregnated with a chemical that reacts with glucose.

Clinitest
The brand name of a product that detects glucose (sugar) in urine, which some people with diabetes mellitus use to monitor their condition. Clinitest consists of tablets containing a chemical that reacts with glucose.

Cloquinal
An antibiotic drug and antifungal drug used as ear drops to treat infections of the outer ear. Cloquinal is also included in some skin preparations.

clip
A small metal device used by surgeons to hold a wound closed or to prevent leakage from a blood vessel. Specialized plastic clips are used in female sterilization operations (see sterilization, female) to seal the fallopian tubes.

clitoridectomy
An operation to remove the clitoris (see circumcision, female).

clitoris
A small, sensitive, erectile organ that is part of the female genitalia. It is partly enclosed in the labia and covered by a fold of skin called the prepuce, or hood. The clitoris swells and becomes more sensitive during sexual stimulation.

clobazam
A type of benzodiazepine drug used in the treatment of anxiety and epilepsy.

clobetasone
A corticosteroid drug, used as a cream or an ointment to treat inflammatory skin conditions, such as eczema.

clofibrate
A lipid-lowering drug that helps to reduce levels of cholesterol and triglycerides in the blood. Clofibrate is prescribed as a treatment for some types of hyperlipidaemia.

Clomid
A brand name for clomifene, a drug that is used to treat female infertility.

clomipramine
A tricyclic antidepressant drug, which is used as a treatment for depression. Side effects include dry mouth, blurred vision, and constipation.

clomifene
A drug used to treat female infertility caused by failure to ovulate. Minor side effects may include hot flushes, headache, nausea, breast tenderness, and blurred vision. More seriously, ovarian cysts occasionally develop, but they shrink when the dose is reduced. The drug may also cause multiple births.

clomipramine
A tricyclic antidepressant drug, which is used as a treatment for depression. Side effects include dry mouth, blurred vision, and constipation.

Clonazepam
A benzodiazepine drug used mainly as an anticonvulsant drug to prevent and treat epileptic fits (see epilepsy). It also prevents petit mal attacks in children. Side effects include drowsiness, dizziness, fatigue, and irritability.

clonazepam
A benzodiazepine drug used mainly as an anticonvulsant drug to prevent and treat epileptic fits (see epilepsy). It also prevents petit mal attacks in children. Side effects include drowsiness, dizziness, fatigue, and irritability.

clonidina
An antihypertensive drug that controls hypertension (high blood pressure) by acting on the part of the brain that regulates the size of blood vessels. Clonidine is also used to control hot flushes in menopausal women and to treat some cases of migraine. Possible side effects of the drug include constipation, drowsiness, dry mouth, and dizziness. Caution should be taken if high doses of the drug are suddenly stopped because this can cause a dangerous rise in blood pressure.

clonus
A series of rapid, abnormal muscle contractions. Clonus is a sign of damage to nerve fibres that carry impulses from the motor cortex in the cerebrum of the brain to a particular muscle. It may occur in the wrist, knee, ankle, or toe in response to stretching of the muscles in that area. It may also be a feature of seizures (see clonic convulsion).

clopodogrel
An antiplatelet drug that is used to prevent the formation of unwanted blood clots in individuals who are suffering from atherosclerosis.

Clopixol
The brand name of zuclopenthixol, an antipsychotic drug.

closed-angle glaucoma
An alternative term for acute glaucoma.

closed fracture
A type of fracture, also known as a simple fracture, in which the broken bone ends do not penetrate the overlying skin.
**Clostridium**

Any of a group of rod-shaped bacteria. Clostridia are found in soil and in the gastrointestinal tracts of humans and animals. They produce powerful toxins and are responsible for potentially life-threatening diseases such as botulism, tetanus, and gangrene.

**clot**
See blood clotting.

**clotrimazole**
An antifungal drug that is used to treat yeast and fungal infections, especially candidiasis.

**clotting factor**
A circulating protein that is activated during the blood clotting process. There are a number of clotting factors, which are involved in a complex series of chemical reactions leading to the formation of a blood clot.

**clotting time**
The time taken for blood to coagulate, which is measured in tests by the observation of a blood sample under laboratory conditions. (See also blood clotting tests.)

**cloudy urine**
An abnormality in the appearance of urine, which may be caused by a urinary tract infection or the presence of salts. (See also urine, abnormal.)

**clove oil**
An oil distilled from the dried flower-buds of Eugenia Caryophyllata that is used mainly as a flavouring in pharmaceuticals. Clove oil is sometimes used to relieve abdominal pain due to flatulence and as a remedy for toothache.

**cloxacillin**
A penicillin-type antibiotic drug used to treat infections with staphylococcal bacteria (see penicillin drugs).

**clozapine**
A type of antipsychotic drug. Clozapine is used to treat schizophrenia in patients who have not responded well to other forms of treatment, or in those who have experienced severe side effects from more conventional drugs. A person taking clozapine needs to have regular blood tests because the drug may cause a serious decrease in the number of white blood cells.

**Clozaril**
A brand name for clozapine.

**clubbing**
Thickening and broadening of the fingertips and ends of the toes, which is usually accompanied by increased curving of the nails. Clubbing is associated with certain chronic lung diseases, such as lung cancer, bronchiectasis, and fibrosing alveolitis; with some heart abnormalities; and, rarely, with the inflammatory bowel diseases Crohn’s disease and ulcerative colitis.

**club-foot**
A deformity of the foot that is present from birth (see talipes).

**clumping**
The common name for agglutination, a process in which tiny particles that the body identifies as foreign (see antigen), such as the proteins on the surfaces of bacteria or foreign red blood cells, stick together to form visible masses. This process is an immune system reaction caused by antibodies (proteins manufactured by the immune system; see antibody) called agglutinins. Particles of a particular antigen will only clump together in the presence of the specific agglutinin to that antigen.

Looking for clumping can be used as a means of determining people’s blood groups. In blood typing, samples of a person’s blood are mixed with antibodies against the blood types A and B to see if clumping occurs with either of these antibodies, neither, or both (see blood groups). In cross-matching, a sample of a person’s blood is mixed with a sample of blood from a possible donor; if the red blood cells clump together, it shows that the two samples of blood are of incompatible types. In addition, bacteria can be identified using samples that contain agglutinins to specific bacteria (as, for example, in the latex agglutination test).

**cluster headaches**
Brief but severe headaches that recur up to several times a day over a period of a few days or weeks. Cluster headaches tend to affect one side of the head or face, often in a characteristic pattern, and may also cause pain and watering of the eye. The cause is uncertain, but they may be due to dilation of blood vessels in the brain, as in migraine. Beta-blocker drugs may be given in order to lessen the dilation of the blood vessels and reduce the severity and frequency of cluster headaches.

**CMV**
The abbreviation for cytomegalovirus, which is a type of herpes virus.

**CNS**
The abbreviation for central nervous system (the brain and spinal cord).

**CNS stimulants**
Drugs that increase mental alertness (see stimulant drugs).

**coagulation, blood**
The main mechanism by which blood clots are formed. Coagulation involves a complex series of reactions in the blood plasma (see blood clotting).

**coal tar**
A thick, black, sticky substance that is distilled from coal. Coal tar is a common ingredient in many ointments and medicinal shampoos that are prescribed for certain skin and scalp disorders, such as psoriasis and some types of dermatitis and eczema.

**co-amilofruse**
A combined preparation that contains the diuretic drugs amiloride and furosemide (frusemide).

**co-amoxiclav**
A penicillin drug containing a mixture of amoxicillin and clavulanic acid. It is a more powerful antibiotic than amoxicillin alone, so it is used to treat infections caused by strains of bacteria that are resistant to amoxicillin.

**coarctation of the aorta**
A congenital heart defect of unknown cause, in which there is narrowing in a section of the aorta that supplies blood to the lower body and legs. To compensate for this problem the heart has to work harder than normal, thereby causing hypertension (high blood pressure) in the upper part of the body.

**SYMPTOMS**
Symptoms of coarctation of the aorta usually appear in early childhood. They include headache, weakness after exercise, cold legs, and, rarely, breathing difficulty and swelling of the legs due to heart failure. Associated abnormalities include a heart murmur, weak or absent pulse in the groin, lack of synchroniza-
tion between the groin and wrist pulses, and blood pressure that is higher in the arms than in the legs.

**DIAGNOSIS AND TREATMENT**

X-rays confirm the diagnosis. Surgery to correct the defect is usually performed before four years of age.

- **Coat’s disease**

A disease that causes a progressive deterioration in vision. It is congenital (present at birth) but usually begins in childhood, and affects boys more than girls. The cause is unknown.

In Coat’s disease, the capillaries (tiny blood vessels) supplying the retina become damaged and leak fluid (a process called exudation). As a result, the retina does not function properly. Usually, only one eye is affected. Vision may be impaired in the centre of the visual field or around the edges. In some cases, a squint develops. There is also a risk of retinal detachment.

Diagnosis involves viewing the retina through an ophthalmoscope, and by imaging the blood vessels using fluorescein dye. Treatment may involve sealing the capillaries by photocoagulation (treatment with light rays) or cryotherapy (treatment with cold). If given early enough, it may stabilize the disease and may even improve vision. In some cases, the disease stabilizes by itself.

- **cobalamin**

A complex molecule that contains cobalt and is part of vitamin B12.

- **cobalt**

A metallic element. Cobalt is found in foods as a constituent of vitamin B12. A radioactive form is used in radiotherapy.

- **Cobb syndrome**

A very rare disorder in which spinal cord angiomomas (noncancerous tumours of the blood or lymph vessels) occur together with arteriovenous malformations (abnormal connections between arteries and veins) in the overlying skin. It is congenital (present from birth) but is almost never inherited.

The symptoms usually appear in childhood or adolescence; they include weakness, paralysis, loss of sensation, and loss of bowel and bladder control. Treatment includes surgery to block the blood flow to the abnormal vessels (see embolization) and to relieve pressure on the spinal cord (see decompression, spinal canal).

- **coccydynia**

A pain in the region of the coccyx. Coccydynia may result from a blow to the base of the spine in a fall, prolonged pressure due to poor posture when sitting, or the use of the lithotomy position (lying on the back with hips and knees bent) during childbirth. The pain usually eases in time. Treatment may include heat, injections of a local anaesthetic, and manipulation.

- **coccyx**

A small, triangular bone, commonly called the tailbone, made up of four tiny bones fused together at the base of the spine. Together with a larger bone called the sacrum, situated just above it, the coccyx forms the back section of the pelvis. There is very little movement between the coccyx and sacrum, and later in life the two structures commonly become fused together.

- **coclumeral implant**

A device that is used to treat profoundly deaf people who are not helped by hearing aids. Unlike a hearing aid, which amplifies sounds, a cochlear implant converts sounds into electrical signals that are relayed to the cochlear nerve deep in the inner ear (see cochlear implant box, overleaf).

The implant consists of tiny electrodes that are surgically implanted in the cochlea, and a receiver that is embedded in the skull just behind and above the ear. A microphone, sound processor, and transmitter are worn externally. A cochlear implant does not restore normal hearing, but it enables patterns of sound to be detected. Combined with lip-reading, it may enable speech to be understood.

- **coccus**

The singular of cocci.

- **cocci**

Spherical bacteria, some of which cause infections in humans (see staphylococcal infections; streptococcal infections).
Cockayne’s syndrome
An autosomal recessive genetic disorder that causes premature aging and deterioration of the nervous system. The syndrome causes dwarfism (see short stature) and abnormally rapid aging (see progeria). Affected people also have very thin skin that is extremely sensitive to the effects of sunlight. In addition, there may be visual problems due to degeneration of the retina (see retinitis pigmentosa) or atrophy (wasting away) of the optic nerve; deafness; and learning difficulties. The age at which symptoms appear and the course of the disease vary from one individual to another.

There is no cure for the aging or the neurological symptoms, but an affected person can protect his or her skin from sun damage by avoiding exposure to ultraviolet light, or by applying a sunblock to protect areas of exposed skin when outdoors in sunlight.

cod-liver oil
A pale yellow oil obtained from the liver of fresh cod, which is a valuable source of vitamin A and vitamin D.

cod-dyramol
A compound analgesic drug (painkiller) that contains paracetamol and dihydro-codeine.

coeziac disease
A condition, sometimes called gluten-sensitive enteropathy, that results from hypersensitivity to gluten, a protein found in wheat, rye, and some other cereals. Exposure to foods containing gluten causes an abnormal immune response in which the lining of the small intestine is damaged. The condition leads to malabsorption and results in vitamin and mineral deficiencies.

CAUSES AND SYMPTOMS
Coeliac disease tends to run in families, and varies in severity. The disorder may first appear during infancy, or may not develop until adulthood.

In babies, symptoms usually develop within six months of the introduction of gluten into the diet. The baby may become listless and irritable, develop vomiting and diarrhea, and become dehydrated and seriously ill. Babies and children may also fail to grow or to gain weight, and may suffer from muscle wasting, especially around the buttocks. In adults, symptoms that include tiredness, breathlessness, abdominal pain, diarrhoea, vomiting, and swelling of the legs may develop over several months. In addition, a chronic, distinctive rash called dermatitis herpetiformis may occur.

Damage to the intestinal lining and malabsorption cause weight loss and result in faeces that are bulky and foul-smelling. The resulting vitamin and mineral deficiencies can result in anaemia as well as skin problems. Some affected people suffer damage to the intestinal lining but never develop symptoms of the disease.

DIAGNOSIS AND TREATMENT
Diagnosis may be made by blood tests but in most cases jejunal biopsies, in which tissue samples from the lining of the jejunum (the central part of the small intestine) are taken for examination, are also performed.

Coeliac disease is treated by a lifelong gluten-free diet, which can relieve symptoms within weeks of its introduction. Specially manufactured foods, such as gluten-free flour and pasta, are available. Without such treatment, there may be a long-term risk of cancers developing in the small intestine.

coenzyme
A nonprotein chemical, occurring naturally in the body, that plays a role in assisting the proper functioning of some types of enzyme (proteins that regulate chemical reactions in the body). (See also NAD.)

Coffin–Siris syndrome
An autosomal genetic disorder characterized by absence or underdevelopment of the tips of the little finger and little toe. Other features include hirsutism (excessive hair), hypotonia (lack of muscle tone) and weak joints, and learning difficulties.

cognition
Mental processes by which knowledge is acquired. Such cognitive processes include perception, problem-solving, and reasoning.

cognitive–behavioural therapy
A method of treating psychological disorders such as anxiety and depression, based on the idea that problems arise
from a person’s faulty cognitions (erroneous ways of perceiving the world and oneself). In cognitive–behavioural therapy, the patient is helped to identify negative or false cognitions and then encouraged to try out new thought strategies. For example, a patient may be asked to keep a diary of his or her thoughts and feelings, in order to identify triggers for distress, and may be taught techniques for responding differently to upsetting thoughts.

cognitive dissonance
A state of mental or emotional tension caused by inconsistency and disagreement among different aspects of a person’s thoughts, beliefs, values, and behaviour. (For example, a person may buy a well-made pair of shoes but find that they are actually very uncomfortable.) People may try to reduce such tension by reinterpreting or rationalizing the situation. (For example, the person with the uncomfortable shoes may persuade himself or herself that the comfort of the shoes will improve with continued wear.)

cogwheel rigidity
A term that is sometimes used for a characteristic muscle stiffness seen in people with Parkinson’s disease. When the limbs of an affected person are passively moved, the muscles stretch in a series of small jerks.

coil
The common name for any of the various types of intrauterine contraceptive device (see IUD; Mirena).

coitus
Another term for sexual intercourse.

coitus interruptus
A method of contraception (see contraception, withdrawal method of) in which the man withdraws his penis from the woman’s vagina before ejaculation (the discharge of semen) occurs. Coitus interruptus is unreliable because sperm can be released before orgasm occurs, and it may cause psychosexual dysfunction in men and women.

colchicine
A drug derived from the autumn crocus (Colchicum autumnale). Colchicine is used to treat acute attacks of gout and to reduce their frequency. Side effects include vomiting and diarrhoea.

cold abscess
An abscess caused by infection with the tuberculosis bacterium. A cold abscess does not usually produce redness and heat, hence its name.

cold, common
A common viral infection that causes inflammation of the mucous membranes lining the nose and throat.

CAUSES
There are at least 200 highly contagious viruses that are known to cause the common cold. These organisms are easily transmitted in minute airborne droplets sprayed from the coughs or sneezes of infected people. In many cases, cold viruses are also spread to the nose and throat by hand-to-hand contact with an infected person, or by handling objects that have become contaminated with the virus.

SYMPTOMS AND TREATMENT
The symptoms of a cold typically include a stuffy or runny nose, sore throat, headache, and cough. They usually intensify over 24–48 hours (unlike the symptoms of influenza, which tend to worsen rapidly over a few hours).

Most colds clear up by themselves within a week. Affected people can take simple measures to cope with symptoms; for example, mild analgesic drugs or cold remedies may help to relieve aches and pains, and cough remedies can soothe a cough. Sometimes, however, infection spreads and may cause laryngitis, tracheitis, acute bronchitis, sinusitis, or otitis media. In these cases, a bacterial infection may develop on top of the viral infection, and antibiotic drugs may be needed to treat it. (Antibiotics are ineffective against viruses, so they will not cure colds.)

cold injury
Localized tissue damage caused by chilling of part of the body. Cold injury is distinct from hypothermia, which refers to chilling of the whole body.

The most serious form of cold injury is frostbite. In this condition, an area of skin and flesh becomes frozen, hard, and white as a result of exposure to very cold, dry air. Sometimes there is restriction of the blood supply to the affected area. Another type of injury, immersion foot, occurs when the legs and feet are kept cold and damp for hours or days. The main risk of both conditions is that the blood flow will be slowed so much that the tissues die and, as a result, develop gangrene. Less serious forms of cold injury include chilblains and chapped skin.

cold remedies
Preparations used to relieve symptoms of colds (see cold, common). The main ingredient of cold remedies is usually a mild analgesic drug, such as paracetamol or aspirin, which helps to relieve aches and pains. Other common ingredients include antihistamine drugs and decongestant drugs, designed to reduce nasal congestion; caffeine, which acts as a mild stimulant; and vitamin C.

cold sore
A small skin blister, usually around the mouth, commonly caused by a strain of the herpes simplex virus called HSV1 (herpes simplex virus type 1).

CAUSES AND SYMPTOMS
The first attack of the virus may be symptomless; alternatively, it may cause a flu-like illness with painful mouth and lip ulcers, called gingivostomatitis. The virus then lies dormant within nerve cells, but may occasionally be reactivated and cause cold sores.

Reactivation of the virus may occur after exposure to hot sunshine or a cold wind, during a common cold or other infection, or in women around the time of their menstrual periods. Prolonged attacks may occur in people whose immunity to infection has been reduced due to illness or treatment with immunosuppressant drugs.

In many cases, an outbreak of cold sores is preceded by tingling in the lips, followed by the formation of small blisters that enlarge, causing itching and soreness. Within a few days the blisters burst and become encrusted. Most disappear within a week.

TREATMENT
The antiviral drug aciclovir, applied as a cream, may prevent cold sores if used at the first sign of tingling.

colecalciferol
An alternative name for vitamin D₃ (see vitamin D).

colecystectomy
The surgical removal of part or all of the colon (the major part of the large intestine, which produces faeces).

WHY IT IS DONE
Partial colectomy is usually carried out to remove damaged or distorted sections of colon. It may be performed to
treat severe cases of diverticular disease (in which abnormal pouches form in the colon wall); to cut out a cancerous tumour (see colon, cancer of); or to remove a narrowed part of the intestine that is causing a blockage to the passage of faeces.

Total colectomy is performed to treat severe cases of ulcerative colitis, when the condition cannot be controlled by drugs. It may also be performed on individuals with familial polyposis (see polyposis, familial), an inherited condition in which large numbers of growths develop in the colon.

HOW IT IS DONE
In a partial colectomy, the diseased section of the colon is removed, and the ends of the severed colon are joined. A temporary colostomy (which allows the discharge of faeces from the large intestine through an artificial opening in the abdominal wall) may be needed until the rejoined colon has healed.

In a total colectomy, the whole of the large intestine is removed, either with or without the rectum. If the rectum is removed, an ileostomy (similar to a colostomy, but using the small intestine) may be performed.

RECOVERY
The colon usually functions normally after a partial colectomy. But in a total colectomy, the large intestine’s ability to absorb water from faeces is reduced; this can result in diarrhoea. Antidiarrhoeal drugs may therefore be required.

colestyramine
A lipid-lowering drug used to treat some types of hyperlipidaemia (very high levels of fats in the blood). It is also used to treat diarrhoea in disorders such as Crohn’s disease.

colic
A term that means “pertaining to the colon”. The term “colic” also refers to a severe, spasmodic form of abdominal pain that occurs in waves of increasing intensity. (See also biliary colic; colic, infantile; renal colic; colic, uterine.)

colic, biliary
See biliary colic.

colic, gallstone
Another term for biliary colic.

colic, infantile
Episodes of irritability and excessive crying in otherwise healthy infants. The condition is thought to be due to muscle spasms in the intestines.

A baby that suffers an attack of colic cries or screams incessantly, draws up his or her legs towards the stomach, and may become red in the face and possibly also pass wind. The baby will not respond to normal methods of comforting, such as feeding or cuddling. Colic often tends to be worse in the evenings; the symptoms may also be made worse by tiredness or stress.

Colic can be very distressing, but it is harmless. Usually, the condition first appears at the age of three to four weeks, and it clears up without treatment by the age of 12 weeks. Carers should seek medical help, however, if additional symptoms, such as fever, develop, or if they are finding it difficult to cope with the baby.

colic, renal
See renal colic.

colic, uterine
Cramping abdominal pains that are usually associated with menstruation. (See also dysmenorrhoea.)

coliform bacteria
A group of rod-shaped bacteria that inhabit the intestine. Coliform bacteria include Escherichia and other genera that are sometimes associated with gastrointestinal illnesses.

colistin
One of the polymyxin group of antibiotic drugs. Colistin is used in topical preparations for eye and skin conditions. It may also be given orally to destroy bacteria in the large intestine, in people who are particularly susceptible to infection. In addition, colistin may be used in a nebulizer in order to treat lung infections. The drug is used only to treat infections that are resistant to other antibiotic drugs because it is toxic and may cause damage to kidney and nerve tissue.

colitis
Inflammation of the colon. Colitis causes diarrhoea, usually containing blood and mucus. Other symptoms may include abdominal pain and fever.

CAUSES
Colitis is a feature of the inflammatory bowel disorders ulcerative colitis and Crohn’s disease. It may also be associated with other conditions that cause inflammation in the colon or rectum, such as diverticular disease or proctitis, or with cancer (see colon, cancer of). In addition, it may result from infection with various types of microorganism, such as campylobacter and shigella bacteria, viruses, or amoebae. One form of colitis may be provoked by antibiotic drugs; the drugs destroy bacteria that normally live in the intestine and allow Clostridium difficile, a bacterium that causes irritation, to proliferate.

DIAGNOSIS
Investigations into colitis may include examination of a sample of faeces for micro-organisms or for obvious or hidden blood (see faecal occult blood test); sigmoidoscopy or colonoscopy (viewing of the inside of the colon); biopsy (tissue sampling) of the inflamed areas or ulcers; and a barium enema (see barium X-ray examinations).

TREATMENT
If the cause is an infection, antibiotics may be needed. Crohn’s disease and ulcerative colitis are treated with corticosteroid and immunosuppressant drugs, together with a special diet.

collagen
A tough, fibrous protein. Collagen is the body’s major structural protein, forming an important part of tendons, bones, and connective tissue.

collagen diseases
See connective tissue diseases.

collapse
A nonmedical term for a state of prostration or extreme exhaustion. The word “collapse” may also be used to describe a fainting fit or loss of consciousness. The medical term circulatory collapse refers to a life-threatening condition in which the blood no longer circulates effectively.

collarbone
The common name for the clavicle.

collar, orthopaedic
A soft foam or stiffened device that is worn around the neck to relieve pain or give additional support.

Colles’ fracture
A break in the radius (one of the bones of the forearm) just above the wrist, in which the wrist and hand are displaced backwards, restricting movement and causing swelling and severe pain. The
fracture is usually the result of putting out a hand to lessen the impact of a fall. It is more common in elderly people, due to weakening of the bones by aging or osteoporosis.

The broken bones are manipulated back into place and set in a cast. Healing of the bones takes up to six weeks. Hand and wrist movements usually return to normal, but there may be minor wrist deformity.

Collet–Sicard syndrome
A condition resulting from damage to the cranial nerves that control muscles in the tongue and throat. It is usually due to a head injury or to compression of the nerves by a tumour. The syndrome causes paralysis of muscles in the tongue, palate, throat, larynx (voicebox), and neck on one side. There is no cure, but the cause is treated if possible.

collodion
A syrupy mixture of ether, alcohol, and pyroxylin used in skin preparations for minor cuts and abrasions. Collodion acts by evaporating rapidly to leave a protective film over the area.

colloid
A form of fluid that is similar to a suspension (a fluid consisting of insoluble particles of a substance suspended in a liquid). Particles in a suspension are large and heavy enough to be separated from the liquid in a centrifuge. A colloid has smaller, lighter particles that can only be separated out of the liquid by spinning at a very high speed. In medicine, plasma proteins are separated from blood and sometimes used in colloid preparations to treat shock.

The term “colloid” also refers to a material that contains protein and is found in the thyroid gland.

coloboma
A rare birth defect in which a gap exists in the tissues of the eye. The gap may be in the eyelid or in part of the eyeball, such as the iris, retina, or choroid. A coloboma in the iris will be visible as a black notch, or as a gap stretching from the pupil to the edge of the iris.

The condition results from incomplete development of the eyes while the baby is still an embryo; this problem may, in turn, be linked to certain chromosomal abnormalities. Coloboma may range from minor to severe. In some cases, it may cause blurred vision or decreased visual acuity.

colon
The major part of the large intestine.

STRUCTURE
The colon is a segmented tube, about 1.3 m long and 6.5 cm wide, that forms a large loop in the abdomen. It consists of four sections: the ascending, transverse, and descending colons, and the S-shaped sigmoid colon, which connects with the rectum.

The colon consists of four layers. It has a tough outer membrane that protects it from damage. The next layer comprises muscles that contract and relax rhythmically to move the intestinal contents along (see peristalsis). Inside the muscular layer is a submucous coat containing blood vessels and lymph vessels (see lymphatic system). The innermost layer produces mucus, which helps to lubricate the passage of waste material.

FUNCTIONS
The main functions of the colon are to absorb water and mineral salts from food residue and to concentrate the remaining waste products. The material that remains after digestion enters the colon from the small intestine. As this substance passes through the colon, the water and salts that it contains are absorbed into the blood vessels in the submucous coat. The waste material becomes increasingly concentrated and is finally expelled from the rectum in the form of faeces. (See also digestive system; intestine, disorders of.)

colon, cancer of
A malignant tumour of the colon (the major part of the large intestine). Cancers of the colon or of the rectum (the lower part of the colon), which are generally referred to as colorectal cancer, are among the most common forms of cancer. They most often occur in people over the age of 60.

CAUSES
A genetic basis has been found for some types of colon cancer. Up to one in three cases are associated with a family history of colon disease. In particular, an inherited disorder called familial adenomatous polyposis (in which large numbers of polyps develop in the colon) greatly increases the risk. In the majority of cases, however, the precise cause is not known. Contributory factors include diet: eating a lot of meat and fatty foods and not enough fibre may increase the risk. The disease also sometimes occurs in association with ulcerative colitis.

SYMPTOMS
The first symptoms of colon cancer include an inexplicable change in
bowel movements (either constipation or diarrhoea), blood mixed in with the faeces, and pain in the lower abdomen. Sometimes, however, there are no symptoms until the tumour has grown large enough to cause an obstruction in the intestine (see intestine, obstruction of) or perforate it (see perforation).

**DIAGNOSIS AND TREATMENT**

Successful treatment of cancer of the colon depends, crucially, on an early diagnosis. Screening may be carried out to detect early signs. This procedure includes a test to detect blood hidden in the faeces (see faecal occult blood test). If the test is positive, doctors may perform sigmoidoscopy and colonoscopy to view the inside of the colon. A biopsy may be performed at the same time.

In most cases, a partial colectomy is carried out. In this procedure, the diseased part of the colon is removed, together with a surrounding area of healthy tissue, then the cut ends of the colon are rejoined. Surgery may be combined with radiotherapy or possibly with chemotherapy. The chance of survival depends on how far the tumour has spread, but colon cancer in its early stages can be cured.

### PROCEDURE FOR COLOSTOMY

An incision is made in the abdominal wall and part of the colon is pulled through. In a temporary colostomy, a small loop is exposed, and an opening is made in it large enough for faeces to pass through. If the rectum and anus have been removed, the cut end of the colon is brought to the skin surface. The edges of the opening or severed end are stitched to the skin at the edges of the abdominal incision to create a stoma (artificial opening) through which faeces will be expelled.

### colon, disorders of

**See intestine, disorders of.**

### colon, irritable

**See irritable bowel syndrome.**

### colon, malignant

**See cancer.**

### colon, perforation

**See intestine, perforation of.**

### colon, spastic

**See irritable bowel syndrome.**

### Colorado tick fever

A viral illness transmitted by the bites of infected ticks. It occurs in the mountain areas of the western United States, usually in early summer. Symptoms appear 3–6 days after a tick bite; they include flulike chills and fever, severe headache, nausea, and sometimes a red, raised rash. The illness usually lasts for a few days, subsides, then returns for a further few days. The virus can, how-ever, remain in the blood for several months.

Treatment involves removal of the tick as soon as possible and taking analgesic drugs (painkillers) if necessary. Tick bites can be prevented by wearing clothing that covers the arms and legs and tucking trouser legs into socks. (See also ticks and disease.)

### colorectal cancer

A general term referring to cancer of the colon (see colon, cancer of) and/or of the rectum (see rectum, cancer of).

### colostomy

An operation in which part of the colon is brought to the surface of the skin through an incision in the abdominal wall. The exposed part is formed into a stoma, an artificial opening through which faeces are discharged into a bag attached to the skin. A colostomy may be either temporary or permanent.

A temporary colostomy may be performed at the same time as a partial colectomy (removal of part of the colon) to allow the remainder of the colon to heal without faeces passing through and contaminating it. The colostomy is closed when the rejoined colon has healed. A permanent colostomy is needed if the rectum or anus has been removed (for example, to treat colon cancer) and normal defaecation is therefore impossible.

### colostrum

A thick, yellowish fluid that is produced by the breasts during the first few days after childbirth, before being replaced by breast milk. Colostrum contains less fat and sugar, but more minerals and protein, than breast milk. It also has a high content of lymphocytes (white blood cells) and immunoglobulins, which help to protect the baby against infections.
colour blindness
See colour vision deficiency.

colour vision
The ability to see and distinguish the different parts of the colour spectrum, which consists of electromagnetic radiation (energy waves) with a range of wavelengths between about 400 and 700 nanometres (millionths of a millimetre). Different wavelengths trigger nerve signals in the retina (the light-sensitive layer of cells at the back of the eye); these signals pass to the brain and are interpreted as violet, indigo, blue, green, yellow, orange, and red.

RETINAL FUNCTION
As light falls on the retina, it strikes light-sensitive cells called rods and cones. The rods can detect all visible light, but only the cones can distinguish colour. There are three types of cone: red-sensitive, blue-sensitive, and green-sensitive. Each of these types of cone responds more strongly to a particular part of the light spectrum. The cones are most concentrated in a central area of the retina called the fovea; for this reason, colour vision is most accurate for objects that are viewed

COLOUR VISION
Light, consisting of radiation of various wavelengths, is focused on the retina. At the back of the retina, light-sensitive rod and cone cells are stimulated to emit electrical impulses.

The impulses then travel through cells called bipolar cells to a layer called the ganglion cells, where some initial processing occurs, before passing to the brain via the optic nerve.

COLOUR VISION

Location of colour-sensitive cells
The rods and cones are located at the back of the retina. Behind them is a darkly pigmented layer of cells, which reduces light scattering. Colour vision depends on the cones, which are concentrated in an area called the fovea.

Colour response of cones (right)
There are three classes of cone. One of these (red-sensitive) responds best to light of long wavelengths; another (blue-sensitive) to light of short wavelengths; and the third (green-sensitive) to intermediate wavelengths.

Response to white light
White light consists of a mixture of all wavelengths (colours), and it therefore stimulates all three classes of cone to signal equally. This pattern of response is interpreted as whiteness by the brain.

Response to red light
Light with a long wavelength (red light) produces a strong response from red-sensitive cones, a weak response from blue-sensitive cones, and an intermediate response from green-sensitive cones. This pattern of signalling is interpreted as the colour red by the brain.
COLOUR VISION DEFICIENCY

directly. Colour vision is, therefore, poor at the periphery of vision.
When light hits a cone, it causes a structural change in the pigment within
the cone, which in turn causes the cone to emit an electrical signal. This
signal passes to the brain via the optic nerve. Colour perception requires a
minimum level of light; below this level, everything is perceived only by
the rods and is seen as various shades of grey. (See also colour vision deficiency;
eye; perception; vision.)

colour vision deficiency

Any abnormality in colour vision that
causes a person to have difficulty in
distinguishing between certain colours.

TYPES

The most common type of colour
vision deficiency is the reduced ability
to discriminate between red and green.
Most cases of red–green colour vision
deficiency are the result of defects in
the light-sensitive cells in the retina.
These defects are usually inherited, and
tend to be sex-linked (see genetic disorder);
the majority of sufferers are
male, while females are unaffected, but
they can pass on the disorder to their children.
Occasionally, defects may be acquired as a result of diseases of the
retina or the optic nerve, or they are
causd by injury. There are two forms of
red–green deficiency. A person with
a severe green deficiency has difficulty
in distinguishing between oranges,
greens, browns, and pale reds. A severe
red deficiency causes all shades of red
to appear dull.

A much rarer colour vision deficiency
exists in which blue cannot be distin-
guished. This condition may be inher-
ited, or it may be due to degeneration
of the retina or the optic nerve. Monochromatism (the total absence of
colour vision) also exists, but this defi-
cency is very rare.

Colpermin

A brand name for peppermint oil. This
preparation is used to relieve the pain
that results from muscle spasms in irritable bowel syndrome and diverticular disease.

colposcopy

Viewing of the cervix (the neck of the uterus) and vagina using a magnifying instrument called a colposcope. Col-
poscopy is carried out to detect areas of precancerous tissue (see dysplasia) or
of early cervical cancer (see cervix, can-
cer of). Removal of tissue samples (see biopsy) or treatment to remove any
abnormal areas can be performed dur-
ing colposcopy, and this is usually done
under local anaesthetic.

coma

A state of unconsciousness and unres-
ponsiveness to external stimuli (for
example, pinching) or internal stimuli
(such as a full bladder).

CAUSES

Coma results from disturbance or dam-
age to areas of the brain involved in
conscious activity or maintenance of
consciousness — in particular, parts of
the cerebrum, upper parts of the brain-
stem, and central regions of the brain,
especially the limbic system.

Conditions that can produce coma
include severe head injury; disorders
such as stroke or cardiac arrest, in which
part or all of the brain tissue is deprived
of blood; or infectious disorders that
affect the brain, such as meningitis and
encephalitis. In addition, excessively
high or low blood levels of certain sub-
stances may result in coma; for exam-
ple, a person with diabetes mellitus
may become comatose if his or her
blood level of glucose (sugar) rises or
falls to an abnormal degree.

SYMPTOMS

There are varying depths of coma. In
less severe forms, the affected person
may make small movements and res-
pond to certain stimuli. In a deep
coma, the person does not make any
movements or respond to any stimu-
lus. However, even people in deep
comas may show some automatic
responses, for example breathing
unaided and blinking. If the lower
brainstem is damaged, however, vital
functions are impaired, and artificial
ventilation and maintenance of the cir-
culation are required.

OUTLOOK

If brain damage is minor and revers-
sible, the person may make a full
recovery, but deep coma due to severe
trauma may result in long-term neuro-
logical problems such as muscle
weakness or changes in behaviour. A
person in a deep coma (a persistent vegetative state) may be kept alive for years
provided the brainstem is still func-
tioning. Complete and irreversible loss
of brainstem function leads to brain
death (the permanent cessation of all
brain functions).

combination drug

A preparation containing more than
one active substance.

comedo

Another name for a blackhead.

commensal

A bacterium or other organism that nor-
mally lives in or on the body without
either harming or benefiting its host.

comminuted fracture

A type of fracture in which the bone
shatters into more than two pieces. A
severe blow, such as an impact occur-
ing in a car accident, may result in a
comminuted fracture.

commode

A portable chair that contains a remov-
able toilet bowl in its seat.

common cold

See cold, common.

communicable disease

Any disease due to a microorganism or
parasite that can be transmitted from
one person to another. (See also conta-
gious; infectious disease.)

compartment syndrome

A painful cramp due to compression of
a group of muscles within a confined
space. It may occur when muscles are
enlarged due to intensive sports train-
ing or to an injury such as shin splints.
Cramps induced by exercise usually
disappear when the exercise is stopped.
Severe cases may require fasciotomy to
improve blood flow and prevent devel-
opment of a permanent contracture.

compensation

The adjustment made by an organ to
make up for changes in body function
or structure. An example of compensa-
tion is the increased size of one kidney
when the other has been removed.

complement

A collection of proteins in the plasma
(the fluid part of blood) that helps to
destroy foreign cells and is an impor-
tant part of the immune system.

complementary medicine

A group of therapies, often described as
“alternative”, that are now increasingly
used to complement or to act as an
alternative to conventional medicine.
Such treatments fall into three broad categories: touch and movement (as in acupuncture, massage, and reflexology); medicinal (as in naturopathy, Chinese medicine, and homeopathy); and psychological (as in biofeedback, hypnotherapy, and meditation).

**complete abortion**
The expulsion from the uterus of an embryo or a fetus together with its membranes and placenta (see abortion).

**complete heart block**
See heart block.

**complex**
A term used in medicine to mean a group or combination of related signs and symptoms that form a syndrome (as in Eisenmenger complex), or a collection of substances of similar structure or function (as in vitamin B complex). In psychology, a complex (for example, the Oedipus complex) denotes a group of unconscious ideas and memories that have emotional importance.

**compliance**
The degree to which patients follow medical advice.

**complication**
A condition resulting from a preceding disorder or from its treatment.

**compos mentis**
Latin for “of sound mind”.

**compound**
A term used in chemistry to describe a substance that contains two or more chemically combined elements. In pharmacy, a compound is a preparation that contains a number of ingredients.

**compound fracture**
A type of fracture, also known as an open fracture, in which a broken bone breaks through the overlying skin. In this type of fracture, there is a high risk of infection.

**compress**
A pad of lint or linen applied, under pressure, to an area of skin. Cold compresses soaked in ice-cold water or wrapped around ice help to reduce pain, swelling, and bleeding under the skin after an injury (see ice pack). Hot compresses increase the circulation and help to bring boils to a head. A dry compress may be used to stop bleeding from a wound or may be coated with medication to help treat infection.

**compression syndrome**
A collection of localized neurological symptoms, such as numbness, tingling, discomfort, and muscle weakness, that is caused by pressure on a nerve.

**compulsive behaviour**
See obsessive-compulsive disorder.

**computed tomography**
Another name for CT scanning.

**computer-aided diagnosis**
The use of computer technology in certain diagnostic tests and procedures. It involves the use of probability-based computer systems that store information on thousands of cases of different disorders, detailing the type, location, duration, symptoms, medical history, and diagnosis. A patient’s symptoms and medical history can be entered into a computer, which then compares the details with existing data and produces a list of the most likely diagnoses.

**conditioning**
The formation of a specific physical or behavioural response to a particular stimulus in the environment.

**classical conditioning**
In classical conditioning, a stimulus that consistently evokes a particular response is paired repeatedly with a second stimulus that would not normally produce the response. Eventually, the second stimulus begins to produce the response whether or not the first stimulus is present. This phenomenon was shown by the physiologist Ivan Pavlov. He observed that dogs salivated in anticipation of food (an unconditioned response to a stimulus). He then devised a procedure in which a bell was rung every time a dog was given food; once the procedure had been repeated several times, the dog began to salivate every time it heard the bell (a conditioned response to a stimulus) even if no food was presented.

**operant conditioning**
In operant conditioning, attempts are made to modify behaviour by rewarding or punishing a subject (animal or human) every time the subject shows a particular response to a specific stimulus. A response that is rewarded will be reinforced and become more frequent, while one that is punished will be inhibited and become less frequent.

**USE IN MEDICINE**
Behavioural psychology (see behaviour therapy) is based on the idea that inappropriate behaviour patterns in some psychological disorders are learned through conditioning. It is thought that these patterns can be modified by the same process of conditioning.

**condom**
A barrier method of contraception in the form of a thin latex rubber or plastic sheath, which is placed over a man’s penis before sexual intercourse. Condoms also provide some protection against sexually transmitted infections.
CONDOM, FEMALE

condom, female
A barrier method of contraception in the form of a sheath that is inserted into a woman’s vagina before sexual intercourse. Female condoms also offer some protection against sexually transmitted infections.

conduct disorders
Repetitive and persistent patterns of aggressive and/or antisocial behaviour, such as vandalism, substance abuse, and persistent lying, in children or adolescents. (See also behavioural problems in children; adolescence.)

conduction
The movement of particular forms of energy, such as nerve impulses and sound waves, through a system.

conductive deafness
Deafness caused by faulty conduction of sound from the outer to the inner ear. Causes include excess earwax or fluid in the middle ear (see glue ear).

conduit
A channel or tube that conveys fluid. Conduits may be created surgically to redirect the flow of body fluids. The most common form of artificially constructed conduit is an ileal conduit, which is created from part of the small intestine to divert urine out of the body.

condyle
A round projection on the end of a bone that fits into a hollow on another bone to form a joint; an example of a condyle is the elbow.

condyloma
A warty skin growth that usually occurring in moist areas of the body, for example the genitals. The most common type of condyloma is caused by the human papillomavirus (see genital warts). Condylomata are highly infectious flattened growths that may develop around the genitals in the second stage of syphilis.

condyloma acuminatum
See warts, genital.

cone
A type of light-sensitive cell located in the retina of the eye. Cones play a major role in colour vision.

cone biopsy
A surgical procedure in which a conical or cylindrical section of tissue from the lower part of the cervix (neck of the uterus) is removed (see biopsy of the cervix box on p.159). A cone biopsy is performed following an abnormal result of a cervical smear test if the extent of the precancerous or cancerous area cannot be seen by colposcopy (inspection of the cervix with a viewing instrument). (See also cervix, cancer of.

confabulation
The use of a fictional story to make up for gaps in memory. The phenomenon occurs most commonly in chronic alcoholics who suffer from Wernicke–Korsakoff syndrome. It may also occur in people with head injuries.

confidentiality
The ethical principle that a doctor does not disclose any information given in confidence by a patient.

The patient’s consent is necessary before a doctor supplies confidential information to an insurance company, an employer, or a lawyer. Doctors must, however, disclose information about patients when required to do so by law, or when they are faced with injuries or disorders that indicate a serious crime. Doctors are also required to notify health authorities about patients with specified infectious diseases.

Treatment of young children is usually discussed with the parents, but an older child’s request for confidentiality is generally respected if the doctor feels that he or she is competent enough to understand the issues involved.

confluent
A term meaning “merging or running together”. It is used, for example, in relation to individual skin blemishes that merge to form one abnormal area.

congenital
A term meaning “present at birth”. Congenital abnormalities (sometimes called birth defects) may be inherited. Alternatively, they may result from damage or infection occurring either in the uterus or at the time of birth.

congenital adrenal hyperplasia
See adrenal hyperplasia, congenital.

congenital amputation
See amputation, congenital.

congenital heart failure
See heart failure.

conjoined twins
See twins, conjoined.

conjunctiva
The transparent membrane covering the sclera (white of the eye) and lining the inside of the eyelids. Cells in the conjunctiva produce a fluid that lubricates the lids and the cornea.

conjunctival haemorrhage
An alternative term for subconjunctival haemorrhage (bleeding in the white of the eye).

conjunctivitis
Inflammation of the conjunctiva, causing redness, discomfort, and discharge from the affected eye.
connective tissue diseases
Certain autoimmune disorders (disorders in which the immune system attacks the body’s own tissues) that often affect blood vessels and produce secondary damage to connective tissue. Connective tissue diseases include rheumatoid arthritis, polyarteritis nodosa, systemic lupus erythematosus, systemic sclerosis, and dermatomyositis.

Conn’s syndrome
A disorder caused by the secretion of excessive amounts of the hormone aldosterone. The overproduction of this hormone is caused by a noncancerous tumour of one of the adrenal glands. (See also aldosteronism.)

consciousness
A state of alertness in which a person is fully aware of his or her thoughts, surroundings, and intentions.

consent
Also sometimes referred to as informed consent, the legal term describing a patient’s agreement to a doctor performing an operation, arranging drug treatment, or carrying out a diagnostic test. The patient’s consent is also needed before a doctor supplies confidential information to an insurance company, an employer, or a lawyer.

Consent is valid only if the patient has been fully informed about the purpose of that particular procedure, the likely outcome, and any complications and side effects. Consent cannot be given by young children or by people who are not considered to be competent, but a relative may give or withhold consent on their behalf.

constipation
The infrequent or difficult passing of hard, dry faeces. Constipation may be uncomfortable but in the short term is usually harmless.

causes
The most common cause of constipation is insufficient fibre in the diet (see fibre, dietary), because fibre assists the propulsion of waste matter through the colon. Other common causes include lack of regular bowel movements due to poor toilet-training in childhood or repeatedly ignoring the urge to move the bowels. Constipation in elderly people may be due to immobility or to weakness of the muscles of the abdomen and the pelvic floor.

Occasionally, constipation is a symptom of an underlying disorder. This is especially likely if it is part of a persistent change in bowel habits in someone over the age of 40, or if it is accompanied by other symptoms such as blood in the faeces, pain on moving the bowels, or weight loss. Conditions that may cause constipation include haemorrhoids, anal fissure, irritable bowel syndrome, and narrowing of the colon due to disorders such as diverticular disease or cancer (see colon, cancer of).

TREATMENT
Self-help measures such as establishing a regular bowel routine, increasing the amount of fibre in the diet, and drinking more fluids are usually beneficial. Prolonged use of laxative drugs should be avoided, because this can impair the normal functioning of the colon.

Constriction
A narrowed area in the body, or the process of narrowing.

Consultant
In the UK, a doctor, usually attached to a certain hospital, who is a specialist in a particular branch of medicine and who takes full responsibility for the patients in his or her care.

Contact dermatitis, allergic
A type of dermatitis caused by an allergic skin reaction to a substance that is harmless for most people. Common causes include nickel and rubber. (See also irritant dermatitis.)

Contact lenses
Thin, shell-like, transparent discs fitted over the cornea of the eye that are used to correct defective vision. Contact lenses are most commonly used for the correction of myopia (shortsightedness) and hypermetropia (longsightedness). In addition, noncorrective lenses are available for cosmetic use, for example to change eye colour.

Types
There are several types. Hard plastic lenses give good vision; they are also long-lasting and durable, inexpensive, and easy to maintain. Sometimes, however, these lenses are difficult for the wearers to tolerate and may fall out. Hard gas-permeable lenses are more comfortable because they allow oxygen to pass through to the eye, but are less durable. Soft lenses are the most comfortable because of their high water...
content. Disposable soft lenses are for single use only; extended-wear lenses are worn for up to a month.

Other types of contact lenses include rigid scleral lenses, which cover the whole of the front of the eye and are used to disguise disfigurement; bifocal contact lenses; and toric contact lenses, which have an uneven surface curvature and can correct astigmatism. **PROBLEMS**

Hard plastic lenses may cause abrasion of the cornea if worn for too long. Soft lens wearers sometimes develop sensitivity of the eyes and lids. Any type of contact lens may cause redness of the eye. The most serious complication of using lenses is infection, which can occasionally cause permanent damage to the cornea and affect vision; meticulous hygiene lowers the risk.

**contact tracing**

A service provided by clinics treating sexually transmitted infections, in which all contacts of a person diagnosed as having a sexually transmitted infection are traced and then encouraged to be examined and treated. Contact tracing is also used in cases of other infections, especially tuberculosis, meningitis, and imported tropical diseases.

**contagious**

A term used to describe a disease that can be transferred from person to person by ordinary social contact. All contagious diseases, such as the common cold or chickenpox, are infectious. The term “contagious” does not apply to the many infectious diseases, such as typhoid, syphilis, or AIDS, which are spread by other means.

**continuous positive airway pressure (CPAP)**

A method of ventilation (mechanically assisted breathing) in which the air pressure inside a patient’s airways is kept above atmospheric pressure.

**continuous positive pressure ventilation (CPPV)**

A rarely used method of ventilation (mechanically assisted breathing) in which positive pressure is applied to the airways to produce each inhalation.

**contraception**

The control of fertility to prevent pregnancy. Contraception can be achieved by a variety of methods. Some forms
METHODS OF CONTRACEPTION

Forms of contraception include natural, barrier, hormonal, and postcoital methods. Most are for use by women. Another option is sterilization, surgery that disrupts part of the male or female reproductive system to render a person permanently infertile.

Female condom
The female condom is placed in the vagina with the open end extending just beyond the vaginal opening.

Male condom
Condoms should be checked for holes and air squeezed from the tip to prevent bursting. They may be used with a spermicide. On withdrawal, the rim should be held to stop the condom slipping off.

Hormone injection
A progestogen is injected by a doctor or nurse into a muscle in the woman’s arm or buttock. The hormone is released into her body over a period of 8 to 12 weeks, after which time the procedure is repeated.

Female condom
The female condom is placed in the vagina with the open end extending just beyond the vaginal opening.

Diaphragm in position
An IUD is a small piece of moulded plastic with strings attached. Some contain copper or a progestogen. The IUD is fitted in the uterus to stop fertilized eggs implanting.

IUD in position
An IUD is a small piece of moulded plastic with strings attached. Some contain copper or a progestogen. The IUD is fitted in the uterus to stop fertilized eggs implanting.

Diaphragm in position
A diaphragm is a rubber dome held in place over the cervix by means of a coiled metal spring in its rim. It physically prevents sperm from reaching the cervix.

Temperature method
This natural form of contraception involves charting a woman’s temperature to see whether ovulation has taken place. The temperature should be taken at the same time each day, on waking. Ovulation precedes a temperature rise. A rise in temperature for three days means the end of the fertile time.

Temperature method
This natural form of contraception involves charting a woman’s temperature to see whether ovulation has taken place. The temperature should be taken at the same time each day, on waking. Ovulation precedes a temperature rise. A rise in temperature for three days means the end of the fertile time.

Hormonal implant
A flexible rod containing a progestogen hormone is inserted into the woman’s arm, under the skin, where it releases progestogen into the blood.

The pill
Contraceptive pills contain oestrogen to prevent ovulation, and/or a progestogen, which changes the cervical mucus to prevent sperm penetration, or alters the uterine lining to prevent implantation.

STERILIZATION

This procedure offers an almost completely safe and reliable form of birth control; it is usually irreversible. It does not affect sex hormones, so a man produces sperm-free semen and a woman produces normal eggs that do not reach the uterus.

Male sterilization (vasectomy)
The vas deferens (tube from a testis to the urethra) on each side is cut so sperm cannot enter the urethra.

Female sterilization
A laparoscope (viewing tube) is inserted, under anaesthetic, through the abdominal wall. An instrument is passed through it to cut or seal the fallopian tubes.
CONTRACEPTION, BARRIER METHODS OF

prevent ovulation in the woman; others stop sperm from meeting an ovum in the fallopian tube (preventing fertilization), or prevent a fertilized ovum from implanting in the uterus.

Some contraceptive methods involve changes in sexual activity; such methods include total or periodic abstinence from intercourse (see contraception, natural methods of) and coitus interruptus, in which sexual intercourse is stopped before ejaculation occurs. Other methods, known as barrier methods (see contraception, barrier methods of), involve the use of condoms to prevent sperm from coming into contact with eggs. Hormonal methods, including the use of oral contraceptives, implants, and injections (see contraceptives, injectable), prevent conception by altering the hormone balance in a woman's body. Further forms of contraception include the use of intrauterine devices (see IUDs); postcoital methods (see contraception, emergency); or sterilization of the male (see vasectomy) or female (see sterilization, female).

contraception, barrier methods of

The use of a device and/or a chemical that will physically stop sperm from reaching an ovum, thus preventing fertilization and pregnancy. Barrier methods and spermicides (preparations that kill sperm), when used together correctly, can be highly effective in preventing conception. Barrier methods of contraception also help to prevent the sexual transmission of diseases such as HIV, genital herpes (see herpes, genital), and viral hepatitis (see hepatitis, viral).

The male condom, a latex sheath that covers the penis, is one of the most widely used barrier contraceptives. The female condom (see condom, female), which lines the vagina, is similar to the male condom but is larger.

Other barrier methods that are used by women include the diaphragm and the cap. The diaphragm (see diaphragm, contraceptive) is a hemispherical dome of thin rubber with a metal spring in the rim to hold it in place against the vaginal wall, blocking the entrance to the cervix. It is used with a spermicide. A cervical cap (see cap, cervical) is an alternative to the diaphragm.

Spermicides, in the form of aerosol foams, creams, gels, and pessaries, are placed in the vagina as close as possible to the cervix shortly before sexual intercourse. Although some condoms are precoated with spermicide, not all types of spermicide should be used with rubber barrier devices. (See also the illustrated box on previous page.)

contraception, emergency

Measures to avoid pregnancy following unprotected sexual intercourse. There are two main methods: hormonal and physical. In the first, oral contraceptives (the “morning after” pill) should be taken in a high dose as soon as possible after unprotected sexual intercourse: preferably within 12 hours, but no later than 72 hours afterwards. The pills contain a high dose of the hormone progesterone. In the physical method, an IUD is inserted by a doctor within five days of unprotected sex. Both methods are thought to work by preventing a fertilized egg from implanting in the uterus. (See also the illustrated box on previous page.)

contraception, hormonal methods of

The use by women of synthetic progestogen drugs, often combined with synthetic oestrogens, to prevent conception. The combined pill (see oral contraceptives), the best-known form of hormonal contraception, contains both an oestrogen and a progestogen; it acts by suppressing ovulation (the release of an egg from an ovary). Progestogen drugs make cervical mucus thick and impenetrable to sperm. They also cause thinning of the endometrium (lining of the uterus), which reduces the chance of a fertilized egg implanting successfully. Progestogens can be given as pills, as contraceptive implants under the skin, or by injection (see contraceptives, injectable), or they can be released into the uterus by some IUDs. (See also the illustrated box on previous page.)

contraception, natural methods of

Methods of avoiding conception that do not involve the use of any contraceptive hormones or devices. These methods are based on attempts to pinpoint a woman's fertile period around the time of ovulation, so that sexual intercourse can be avoided at this time.

The calendar method is based on the assumption that ovulation takes place around 14 days before menstruation. Due to its high failure rate, it has been largely superseded by other methods.

The temperature method is based on the normal rise of a woman's body temperature in the second half of the menstrual cycle, after ovulation has occurred. The woman takes her temperature each day using an ovulation thermometer. Sex is considered to be safe only after there has been a rise in temperature lasting at least three days.

The cervical mucus method involves attempting to pinpoint the fertile period by charting the appearance and amount of cervical mucus during the menstrual cycle. Certain changes in the mucus occur before and often at ovulation. The symptothermal method is a combination of the temperature and mucus methods. (See also the illustrated box on previous page.)

contraception, postcoital

See contraception, emergency.

contraception, withdrawal method of

See coitus interruptus.

contraceptive

Any agent that reduces the likelihood of conception. (See also contraception.)

contraceptive implant

A hormonal method of contraception in which a long-acting progestogen drug is inserted under the skin inside the upper arm. An implant consists of a small, flexible rod that steadily releases the drug into the bloodstream. It functions continually for several years.

contraceptives, injectable

A hormonal method of contraception in which long-acting progestogen drugs are injected every two to three months. Injectable contraceptives are very effective, but they may cause menstrual disturbances, weight gain, headaches, and nausea, especially in the first few months.

contractions, uterine

Rhythmic, squeezing muscular spasms that occur in the walls of the uterus before and during childbirth in order to expel the baby from the uterus. Regular contractions indicate the start of labour and increase in strength and frequency throughout the first stage. (See also Braxton Hicks' contractions.)

contracture

A deformity that is caused by shrinkage of tissue in an area of skin, muscle, or a tendon and that may restrict the movement of a joint. Skin contractures commonly occur as a result of scarring following extensive burns or other
injuries. Other types of contracture are caused by inflammation and shrinkage of connective tissues; examples of these include Dupuytren’s contracture and Volkman’s contracture.

**contraindication**
Factors in a patient’s condition that would make it unwise to pursue a certain line of treatment.

**contrast enema**
A contrast medium (opaque substance), which is introduced through the anus, that enables the colon and rectum to be seen in outline on an X-ray. (See also barium X-ray examinations.)

**contrast medium**
A substance that is opaque to X-rays and is introduced into hollow or fluid-filled parts of the body to render them visible on X-ray film. Barium is one of the most commonly used contrast media (see barium X-ray examinations).

**controlled drug**
One of a number of drugs that are subject to restricted use because of their potential for abuse. Controlled drugs include opiates such as cocaine and morphine, amphetamine drugs, and barbiturate drugs.

**controlled trial**
A scientific method of testing the effectiveness of new treatments or of comparing different treatments.

In a typical controlled drug trial, two comparable groups of patients with the same illness are given courses of apparently identical treatment. Only one group, however, actually receives the new treatment; the second group (known as the control group) is given a placebo (a harmless substance containing no active ingredients). Alternatively, the control group may be given an established drug that is already known to be effective. After a predetermined period, the two groups are assessed medically. If the patients on the new treatment show a greater improvement than those on the placebo (or those on an existing treatment), this result proves that the drug has a beneficial effect.

Controlled trials must be conducted “blind” (meaning that the patients do not know which treatment they are receiving). In a “double-blind” trial, neither the patients nor the doctors who assess them know who is receiving which treatment.

**contusion**
Bruising to the skin and underlying tissues from a “blunt” injury such as an abrasion (graze) or an impact.

**convalescence**
The period of recovery following an illness or a surgical operation during which the patient gradually regains strength before returning to their normal activities.

**convergent squint**
A type of squint in which the abnormal eye is directed too far inwards towards the other eye.

**conversion disorder**
A psychological disorder, formerly called hysteria, in which repressed emotions appear to be unconsciously converted into physical symptoms such as blindness, loss of speech, or paralysis. Conversion disorder is generally treated by psychotherapy.

**convulsion**
See seizure.

**convulsion, febrile**
Twitching or jerking of the limbs with loss of consciousness that occurs in a child after a rapid rise in body temperature. Febrile convulsions are common and usually affect children between the ages of six months and five years.

**CAUSES**
The convulsions are due to immaturity of the temperature-lowering mechanism in the brain; the mechanism allows the child’s body temperature to rise too rapidly in response to infections such as measles or influenza.

**TREATMENT AND PREVENTION**
Treatment involves lowering the temperature by sponging the child’s face and body with tepid water and using a fan. Seizures can often be prevented in susceptible children by giving paracetamol at the first signs of fever.

**OUTLOOK**
Most children who have one or more febrile convulsions suffer no long-term effects. However, there is a very small risk of developing epilepsy, which is increased in children with a pre-existing abnormality of the brain or nervous system, or children with a family history of epilepsy.

**Cooley's anaemia**
See thalassaemia.

**COPD**
The abbreviation for chronic obstructive pulmonary disease (see pulmonary disease, chronic obstructive).

**copper**
A metallic element that is an essential part of several enzymes (substances that regulate chemical reactions in the body). Copper is required by the body in only minute amounts (see trace elements). An excess in the body may occur as a result of the rare inherited disorder Wilson’s disease.

**co-proxamol**
An analgesic drug (painkiller) containing paracetamol and the weak opioid analgesic drug dextropropoxyphene. Co-proxamol is used to relieve mild to moderate pain that has not responded to paracetamol or other nonopiod analgesics alone. Side effects include dizziness, drowsiness, constipation, and nausea. The drug may be habit-forming if taken over a long period.

**cordotomy**
A surgical procedure in which certain bundles of nerve fibres within the spinal cord are severed. Cordotomy is carried out to relieve persistent, severe pain that has not responded to other treatment. It is most frequently performed to treat pain occurring in the lower trunk and legs, especially in people who have cancer.

**cord, spermatic**
See spermatic cord.

**cord, testicular**
See spermatic cord.

**cord, umbilical**
See umbilical cord.

**cord, vocal**
See vocal cords.

**corn**
A small area of thickened skin on a toe or other part of the foot. A corn is caused by the pressure of a tight-fitting shoe. The dead skin cells form a hard plug that extends down into the skin tissues. Pressure on this plug can cause pain. If a corn is painful, a spongy ring or corn pad can be placed over it to relieve the pressure. If the corn persists, the area of thickened skin can be removed by a chiropodist.
**Corneal Abrasion**

A scratch or defect in the epithelium (outer layer) of the cornea caused by a small, sharp particle in the eye (see eye, foreign body in) or by an injury. Corneal abrasions usually heal quickly but may cause severe pain and photophobia.

Treatment of a corneal abrasion includes covering the eye with a patch and analgesics to relieve pain. If the ciliary muscles go into spasm, eyedrops containing cycloplegic drugs may be used to paralyse the ciliary muscle. Antibiotic eyedrops are usually given to prevent bacterial infection (which can lead to a corneal ulcer).

**DISORDERS OF THE CORnea**

Various injuries or conditions can affect the sensitive cornea.

**Injury**

A corneal abrasion (scratch) can become infected and progress to a corneal ulcer. Penetrating corneal injuries can cause scarring, which may lead to impairment of vision. Chemical injuries can result from contact with a corrosive substance such as an acid or alkali.

In actinic keratopathy, the outer layer of the cornea is damaged by ultraviolet light. In exposure keratopathy, damage occurs as a result of reduced protection from the tear film and blink reflex.

**Infection**

The cornea can be infected by viruses, bacteria, or fungi. Some infections can cause ulceration, the herpes simplex virus being especially dangerous.

**Inflammation**

True inflammation of the cornea (called keratitis) is uncommon because the cornea contains no blood vessels.

**Corneal Graft**

The surgical transplantation of donor corneal tissue to replace a damaged cornea. In most grafts, tissue is taken from a human donor after death. The success rate of corneal grafts is generally high, because the cornea has no blood vessels; this reduces access for white blood cells, which could otherwise cause rejection of the donor tissue.

**Corneal Transplant**

See corneal graft.

**Corneal Ulcer**

A break, erosion, or open sore in the cornea. It usually affects the outer layer of the cornea, but in some cases may penetrate down to the middle layer.

Corneal ulcers are commonly caused by a corneal abrasion. They may also be due to chemical damage, or infection with bacteria, fungi, or viruses (particularly herpes virus). Eye conditions such as keratoconjunctivitis sicca and eyelid deformities such as entropion or ectropion increase the risk of an ulcer.

Ulcers are revealed by introducing fluorescein dye into the eye. Infections and predisposing eye conditions are
treated according to their cause. A superficial, noninfectious ulcer usually heals quickly; if it fails to do so, it may be treated with a “bandage” contact lens or with tarsorrhaphy (temporary sealing of the eyelids).

coronary
Any structure that encircles another like a crown. The term is usually used to refer to the coronary arteries, which surround the heart and supply it with blood. It is also sometimes used as a nonmedical term for a heart attack (see myocardial infarction).

coronary artery
Either of the two main arteries that supply the heart with oxygen-rich blood. These vessels, known as the left and right main coronary arteries, arise directly from the aorta (the main artery in the body). The term “coronary artery” is also applied to any of the arteries that branch off from the main coronary arteries, such as the left circumflex artery and the left anterior descending artery. Blockage of a coronary artery as a result of atherosclerosis (an accumulation of fatty deposits in the artery) can lead to myocardial infarction. (See also coronary artery disease.)

coronary artery bypass
A major heart operation that is carried out in order to bypass coronary arteries that have become narrowed or blocked (usually as a result of atherosclerosis). The procedure involves using additional blood vessels (such as a mammary artery or a vein from the leg) to improve blood flow to the heart muscle. A coronary artery bypass is performed if symptoms of coronary artery disease have not been relieved by drugs, or if balloon angioplasty (a surgical procedure used to widen blocked arteries) is inappropriate or has failed.

Before surgery, sites of blockage are identified using an imaging procedure called angiography. Usually, a heart–lung machine is needed to maintain the circulation during the operation, although sometimes minimally invasive surgery may be used to bypass the artery, thereby avoiding the need to stop the heart.

The long-term outlook is good following a coronary artery bypass. However, the grafted vessels may also eventually become blocked by atherosclerosis. (See also Coronary artery bypass box, overleaf.)

coronary artery disease
Narrowing of the coronary arteries, which supply blood to the heart, leading to damage or malfunction of the heart. The most common heart disorders due to coronary artery disease are angina pectoris (chest pain due to insufficient oxygen reaching the heart) and myocardial infarction (heart attack).

CAUSES
The usual cause is atherosclerosis, in which fatty plaques develop on artery linings. An affected vessel can become totally blocked if a blood clot forms or lodges in the narrowed area.

Atherosclerosis has many interrelated causes, including smoking, a high-fat diet, lack of exercise, being overweight, and raised blood cholesterol levels. Other risk factors include a genetic predisposition and diseases such as diabetes mellitus and hypertension.

SYMPTOMS
In its early stages, coronary artery disease often produces no symptoms. The first sign is frequently the chest pain of angina, or an actual heart attack.

The disease may also cause arrhythmias (abnormalities in the heartbeat); in severe cases, arrhythmia can cause cardiac arrest (in which the heart stops beating). In elderly people, it may lead to heart failure, in which the heart gradually becomes less and less efficient.

TREATMENT
Drugs are given to help the heart to function more efficiently and to relieve symptoms. These include glyceryl trinitrate and other nitrate drugs; calcium channel blockers; beta-blockers; potassium channel activators; and vasodilator drugs.

If drug treatment fails to relieve the symptoms of coronary artery disease, or if there is extensive narrowing of the coronary arteries, blood flow may be improved by balloon angioplasty or coronary artery bypass surgery.

coronary care unit
A specialist ward for the care of acutely ill patients who may have suffered a myocardial infarction (heart attack) or another serious cardiovascular disorder.

coronary heart disease
An alternative name for coronary artery disease.

coronary thrombosis
A condition in which a thrombus (blood clot) narrows or blocks one of the coronary arteries, thereby preventing sufficient oxygen from reaching a section of the heart muscle. In most cases, the thrombus forms in a blood vessel that has already been narrowed by atherosclerosis. Sudden blockage of a coronary artery will cause a myocardial infarction (heart attack).

coroner
A public officer appointed to inquire into a cause of death when it is unknown or when unnatural causes are suspected.

cor pulmonale
Enlargement of, and strain upon, the right side of the heart, that is caused by one of several chronic lung diseases. Damage to the lungs leads to pulmonary hypertension (abnormally high blood pressure in the arteries that supply the lungs). The resulting “back pressure” of blood puts strain on the heart, and may eventually cause right-sided heart failure with oedema.

corpus callosum
The band of nerve fibres that forms a connection between the two hemispheres of the brain.

corpus cavernosum
One of two cylindrical bodies of erectile tissue that is found in both the clitoris and the penis. The spongy structure of the corpus cavernosum allows the tissue to become rigid when it becomes filled with blood.

corpuscle
Any minute body or cell, particularly red and white blood cells or certain types of nerve ending.

corpus luteum
A small tissue mass in the ovary that develops from a ruptured egg follicle after ovulation (the release of an egg). The corpus luteum secretes the female sex hormone progesterone, which causes the lining of the uterus to thicken in preparation for implantation of a fertilized egg. If fertilization does not occur, the corpus luteum shrinks and dies.

corrosive oesophagitis
A type of oesophagitis that is caused by swallowing caustic chemicals.

corset
A device that is worn around the trunk to relieve back pain and treat spinal injuries or deformities.
CORONARY ARTERY BYPASS

This procedure is now the most common and successful major heart operation in the Western world. Each year some 10,000 people in the UK undergo the operation, which can relieve them from dependence on drug treatment for heart disease and restore them to active life.

**HOW IT IS DONE**

Coronary artery bypass is a major procedure, requiring two surgeons and lasting up to five hours.

1. The first surgeon makes an incision down the centre of the patient’s chest. The heart is then exposed by opening the pericardium.

2. Simultaneously, several incisions are made in the leg, and a length of vein removed.

3. Before any incisions are made in the coronary arteries, the patient is connected to a heart-lung machine. This takes over the function of the heart and lungs while the surgeon repairs the heart.

4. The section of the vein taken from the leg is then sewn to the aorta and to a point below the blockage. If several arteries are blocked, they can be bypassed by using other sections from the same leg vein, or an arterial graft may be taken from the chest.

5. The heart-lung machine is disconnected, allowing the blood to flow back into the coronary arteries.

**WHY IT IS DONE**

Narrowed coronary arteries are unable to supply the heart muscle with a sufficient amount of blood, and, as a result, the heart muscle becomes starved of oxygen. This may cause angina (chest pain) or damage to the heart tissue. By joining lengths of a vein (taken from the leg during the operation) to the aorta and to a point below the blockages, the narrowed or blocked sections of coronary artery can be bypassed.

**Before the operation**

- Diseased coronary artery
- Affected area
- Coronary arteries

**After the operation**

- Bypass
- Second surgeon removes vein from leg

**Site of incision**

![Diagram of chest incision](image)

**Anaesthetist**

- First surgeon prepares heart for bypass

**Heart-lung machine**

- Oxygenated blood from heart-lung machine
- Superior vena cava (tied off)
- Deoxygenated blood to heart-lung machine
- Inferior vena cava (tied off)

**Wire suture**

- Aorta
- Bypass
- Coronary arteries

6. Finally, the breastbone is wired together, and the pericardium and chest are sewn up.

![Diagram of bypass operation](image)
cortex
The outer layer of certain organs, such as the brain or kidneys.

corticosteroid drugs

**COMMON DRUGS**
- Beclometasone + CORTisone
- Dexamethasone + Fludrocortisone
- Hydrocortisone + Prednisolone
- Prednisone + Triamcinolone

A group of drugs that are chemically similar to corticosteroid hormones, which are produced by the adrenal glands.

**WHY THEY ARE USED**
Corticosteroid drugs are used as hormone replacement therapy in Addison’s disease and when the adrenal glands or pituitary gland have been destroyed by disease or have been removed. They are also used to treat inflammatory intestinal disorders, such as ulcerative colitis and Crohn’s disease, and as an urgent treatment for the inflammation in the artery supplying the retina that occurs in temporal arteritis. Other uses of corticosteroid drugs include the treatment of autoimmune diseases such as systemic lupus erythematosus and rheumatoid arthritis, and the treatment of asthma, eczema, and allergic rhinitis.

Corticosteroid drugs are also used to prevent organ rejection following transplant surgery and in the treatment of some types of cancer, such as lymphoma or leukaemia. In addition, injections of corticosteroids may be administered to relieve pain in disorders such as tennis elbow and arthritis.

**POSSIBLE ADVERSE EFFECTS**
Side effects are uncommon when corticosteroid drugs are used in the form of cream or taken by inhaler. However, tablets taken in high doses for long periods may cause diabetes mellitus, hypertension, osteoporosis, oedema, peptic ulcer, Cushing’s syndrome, inhibited growth in children, and, in rare cases, cataract or psychosis. High doses of the drugs also impair the immune system, increasing the risk of serious infections such as septicaemia and tuberculosis; and chickenpox can be life-threatening in people taking corticosteroids.

Long-term treatment suppresses production of corticosteroid hormones by the adrenal glands, and sudden withdrawal may lead to adrenal failure, which can be life-threatening. For this reason, anyone who is taking corticosteroids, or who has recently taken them, should always carry a steroid treatment card and inform a doctor of the fact before undergoing any other form of medical treatment.

**corticosteroid hormone**
Any of a variety of hormones that is produced by the cortex of the adrenal glands. There are two main groups of corticosteroid hormone: glucocorticoids (such as hydrocortisone, cortisone, and corticosterone) and mineralocorticoids (such as aldosterone). (See also corticosteroid drugs; steroid hormones.)

**corticotropin**
An alternative name for ACTH (adrenocorticotrophic hormone).

**Corti, organ of**
See organ of Corti.

cortisol
An alternative name for hydrocortisone, a corticosteroid hormone that is produced by the adrenal glands.

cortisone
A corticosteroid hormone that is produced synthetically. Cortisone is used as a replacement hormone in the treatment of Addison’s disease. Side effects of the hormone include peptic ulcer and bleeding in the stomach.

---

**Corynebacterium**
A genus of gram-positive (see Gram’s stain), rod-shaped bacteria. Corynebacteria cause disease, including diphtheria in humans and various types of infection in domestic animals and birds.

coryza
A term for the nasal symptoms of the common cold (see cold, common).

**COSHH Regulations**
The abbreviation for the Control of Substances Hazardous to Health Regulations, which is one of the major legal provisions in the UK regarding the use of dangerous chemicals in the workplace.

**cosmesis**
A term used for any procedures that are carried out to improve a person’s appearance or to correct a disfiguring physical defect, such as cosmetic surgery, cosmetic dentistry, or the use of make-up to cover physical flaws.

**cosmetic dentistry**
Procedures to improve the appearance of the teeth or prevent further damage to the teeth and/or gums. Cosmetic dentistry procedures include: fitting an orthodontic appliance to correct teeth

---

**HOW CORTICOSTEROIDS WORK**

When given as hormone replacement therapy (such as in Addison’s disease), corticosteroids supplement or replace natural hormones. Large doses have an anti-inflammatory effect (right) because they reduce the body’s production of prostaglandin (natural chemicals that cause inflammation in damaged tissues such as an arthritic joint). They also suppress the immune system by reducing release and activity of white cells.

- Inflamed skin
- Dilated blood vessels
- Increase in white blood cells

![Corticosteroids](image)

- Reduced inflammation
- Blood vessels return to normal
- Fewer white blood cells

---

**COSMETIC DENTISTRY**
COSMETIC SURGERY

that are out of alignment or an incorrect bite (see malocclusion); fitting a crown; bonding to treat chipped or stained teeth; and bleaching of discoloured teeth.

cosmetic surgery
Any operation performed to improve appearance rather than to cure or treat disease. Cosmetic surgery techniques include the removal of skin blemishes or dermabrasion; rhinoplasty to alter the shape or size of the nose; face-lifts; mammoplasty to reduce or enlarge the breasts; body contour surgery to remove excess body fat and tissue; hair transplants; blepharoplasty to remove excess skin on the eyelids; and mentoplasty to alter the size or shape of the chin.

As with any surgical procedure, all forms of cosmetic surgery carry the risk of side effects from the anaesthetic, and of complications arising from the operation itself.

costal
A term meaning “relating to the ribs”.

costalgia
Pain that occurs around the chest as a result of damage to a rib or to one of the intercostal nerves beneath the ribs. Damage to an intercostal nerve most commonly results from an attack of the viral infection herpes zoster (shingles). The pain is difficult to treat and has a tendency to persist.

Costen’s syndrome
A term that is sometimes used to describe facial pain due to temporo-mandibular joint disorders.

costosternal
A combined term sometimes used to describe the junction of the ribs and the sternum (breastbone).

cot death
See sudden infant death syndrome.

cO-trimoxazole
An antibacterial drug that is a combination of trimethoprim and sulfamethoxazole. Because of rare but potentially serious side effects, co-trimoxazole is now used to treat certain infections only in circumstances in which they cannot be treated with other drugs. Its main use is for the prevention and treatment of pneumocystis pneumonia in people with AIDS.

cough
A reflex action that helps to clear the airways of sputum, a foreign body, or any other irritant or blockage. A cough is described as “productive” when it brings up mucus or sputum and “unproductive” or “dry” when it does not.

CAUSES
Many coughs are due to irritation of the airways by dust, smoke (see cough, smoker’s), or a viral infection of the upper respiratory tract (see cold, common laryngitis; pharyngitis; tracheitis). Coughing is also a feature of bronchitis, asthma, pneumonia, and lung cancer.

TREATMENT
Over-the-counter cough remedies are available, but, in general, they just ease symptoms. More specific treatment is directed at the underlying disorder.

coughing up blood
A symptom, also called haemoptysis, caused by the rupture of a blood vessel in the airway, lung, nose, or throat.

The coughed-up blood may appear as bright-red or rusty-brown streaks, clots in the sputum, a pinkish froth, or, more rarely, blood alone. In all cases, medical assessment is needed.

CAUSES
Many disorders can cause haemoptysis. The most common are infections, such as pneumonia or bronchitis; and congestion and rupture of blood vessels in the lungs due to heart failure, mitral stenosis, or pulmonary embolism. A cancerous tumour can also produce haemoptysis by eroding the wall of a blood vessel.

DIAGNOSIS AND TREATMENT
Investigations into coughing up blood include chest X-ray, and, in some cases, bronchoscopy. In about a third of cases, no underlying cause is found. Treatment depends on the cause.

cough remedies
Over-the-counter medications used for treating a cough. There are various preparations, but the effectiveness of most is unproven. Expectorant cough remedies are purported to encourage expulsion of sputum by making it less viscous (sticky). Cough suppressants, which control the coughing reflex, include some antihistamine drugs and codeine. They may be helpful in controlling coughing at night that prevents sleep; however, they cause drowsiness and often cause constipation as well.

TYPES OF COSMETIC SURGERY

There is a range of cosmetic surgery procedures for various parts of the body. The sites of some of the more commonly performed operations are shown below. The procedures vary in the permanency of their results and in the likelihood of achieving a satisfactory appearance.
cough, smoker’s
A recurrent cough that is due to smoking. The cough is usually triggered by the accumulation of thick sputum in the airways as a result of inflammation caused by tobacco smoke. Giving up smoking will usually stop the cough, but it may take time. In general, the longer a person has been smoking, the longer it takes for the cough to clear. Smokers who have a persistent cough should seek medical advice, particularly if the cough changes, because smoking is associated with lung cancer.

counselling
Advice and psychological support from health professionals to help people to deal with personal difficulties. Counselling is used to address problems at school, work, or in the family; provide advice on medical problems and sexual and marital problems; help people to deal with addictions; and give support during life crises. Types of counselling include genetic counselling, trauma counselling, and sex therapy.

In most cases counselling is a one-to-one activity, but it may also be carried out in small groups. (See also child guidance; family therapy; marriage guidance; psychotherapy.)

Cowden’s disease
An autosomal dominant genetic disorder, also called multiple hamartoma syndrome, in which non-cancerous growths develop in tissues, including the skin, mouth, and intestines. Skin growths may include flat-topped, flesh-coloured lesions on the face. Multiple polyps may grow in the intestines.

People with Cowden’s disease are also at increased risk of developing certain cancers, particularly thyroid cancer, colorectal cancer, and, in women, breast and ovarian cancer. There is no specific treatment for the condition, but affected individuals are carefully monitored in order that early signs of these cancers can be detected.

cowpox
An infection caused by the vaccinia virus, which usually affects cows. This virus was used in the past to confer immunity against smallpox.

coxa vara
A deformity of the hip in which the angle between the neck and head of the femur (thigh-bone) and the shaft of the femur is reduced, resulting in shortening of the leg, pain and stiffness in the hip, and a limp. The most common cause is a fracture to the neck of the femur or, during adolescence, injury to the developing part of the head of the femur. Coxa vara can also occur if the bone tissue in the neck of the femur is soft, a condition that may be congenital or the result of a bone disorder such as rickets or Paget’s disease. Treatment may include surgery (see osteotomy).

COX-2 inhibitor drugs
A group of nonsteroidal anti-inflammatory drugs (NSAIDs) that are less likely to cause stomach irritation than the other NSAIDs. One example of a COX-2 inhibitor drug is celecoxib.

coxsackievirus
One of a group of viruses responsible for a broad range of diseases. There are two main types of coxsackievirus: A and B. The best known of the type A infections is hand, foot, and mouth disease, which is a common childhood disorder characterized by blistering of skin around the mouth, hands, and feet. Type B viruses can cause serious illnesses such as meningitis, pericarditis, and pneumonia.

CPAP
The abbreviation for continuous positive airway pressure.

CPPV
The abbreviation for continuous positive pressure ventilation.

crab lice
See pubic lice.

cramp
A popular term for a highly potent, fast-acting form of cocaine.

cracked heel
See heel, cracked.

cradle cap
A skin condition, common in babies, and most prevalent between the age of 3 and 9 months, in which thick, yellow scales occur in patches over the scalp. Cradle cap is harmless as long as the skin does not become infected. It can be treated by daily use of a simple shampoo. Alternatively, warm olive oil may be rubbed into the baby’s scalp and left on overnight to loosen and soften the scales, which can be washed off the following day. A mild ointment that contains an antifungal drug and a corticosteroid drug may be prescribed if the skin becomes inflamed.

Appearance of cradle cap
Thick, yellow, scaly patches occur on the scalp of babies, most commonly between the age of 3 and 9 months. It is not clear why cradle cap occurs.

crandall’s syndrome
A rare congenital disorder that runs in families and is characterized by twisted, brittle hairs, sensorineural deafness, and hypogonadism (underdevelopment
of the ovaries or testes). The condition is associated with deficiencies of luteinizing hormone and growth hormone.

**cranial nerves**

Twelve pairs of nerves that emerge from the underside of the brain. Each of the cranial nerves has a number as well as a name; the numbers are used to indicate the sequence in which the nerves emerge from the brain.

Certain cranial nerves primarily send sensory information from the ears, nose, and eyes to the brain. These nerves are the vestibulocochlear nerve (hearing and balance), olfactory nerve (smell), and optic nerve (vision). Other cranial nerves carry impulses that move the muscles in the head and neck. They are the oculomotor nerve, the trochlear nerve, and the abducent nerve (producing eye movements), the spinal accessory nerve (producing head and shoulder movements), and the hypoglossal nerve (producing tongue movements).

Some cranial nerves have both sensory and motor functions. They are the facial nerve (facial expressions, taste, and the secretion of saliva and tears), the trigeminal nerve (facial sensation and jaw movements), and the glossopharyngeal nerve (taste and swallowing). The vagus nerve has branches to all the main digestive organs, as well as to the heart and the lungs. It is a major component of the parasympathetic nervous system, which is concerned with maintaining automatic body functions such as breathing, the heartbeat, and digestion.

**craniopharyngioma**

A rare, non-hormone-secreting tumour of the pituitary gland. Symptoms of a craniopharyngioma may include headaches, vomiting, and defective vision. If the tumour develops in childhood, the child’s growth may be stunted and sexual development may not occur.

Craniopharyngiomas are usually surgically removed. If left untreated, they may cause permanent brain damage.

**craniosynostosis**

The premature closure of one or more of the joints (sutures) between the skull bones in infants. If all of the joints are involved, the growing brain may be compressed and there is a risk of brain damage due to the increased pressure inside the skull. If the abnormality is localized, the head may be deformed.

Craniosynostosis may occur before birth and may be associated with other birth defects. It may also occur in an otherwise healthy baby, or in a baby with a disorder such as rickets.

---

**CRANIAL NERVES**

All but two of the cranial nerve pairs connect with nuclei in the brainstem. The olfactory and optic nerves, in contrast, link directly with parts of the cerebrum. The nerves emerge through openings in the cranium (skull); many then divide into branches.

Certain cranial nerves are principally concerned with transmitting sensory information from organs such as the ears, nose, and eyes to the brain. Others carry impulses that move the tongue, eyes, and facial (and other) muscles, or stimulate glands such as the salivary glands. A few nerves have both sensory and motor functions. The 10th, or vagus nerve, is one of the most important parts of the parasympathetic nervous system, and has branches to the main digestive organs, the heart, and the lungs.
If the brain has been compressed, an operation may be performed to separate the fused skull bones.

**craniotomy**
The temporary removal of a section of the skull to enable doctors to perform an operation on the brain. A craniotomy may be carried out to take a sample of tissue for analysis, remove a tumour, or drain an abscess or blood clot.

**cranium**
The part of the skull around the brain.

**C-reactive protein**
A protein produced by the body in response to inflammation. The blood level of this protein is measured to evaluate treatment of inflammatory conditions.

**cream**
A thick, semi-solid preparation with moisturizing properties, used to apply medications to the skin.

**creatine kinase**
An enzyme (a protein that alters the rate of a chemical reaction in the body) found in muscle. After damage to muscle cells, including those of the heart muscle, creatine kinase leaks into the blood. Increased levels of the enzyme can be detected by diagnostic tests (see muscle enzymes). Different types of creatine kinase exist in different types of muscle. If blood tests show a raised level of the form found in heart muscle, this may indicate that a myocardial infarction (heart attack) has occurred. Raised levels of the form found in skeletal muscles may indicate a range of disorders, from muscular injury to diseases such as muscular dystrophy.

**creatinine**
A waste product from chemical processes in the muscles. The kidneys filter it from the blood for excretion in urine.

**creatinine clearance**
A type of kidney function test in which the level of creatinine in the blood and the urine is measured. The blood level is measured, then the urine is collected and tested over 24 hours to measure the level of creatinine being excreted. The two levels are compared; if there is a high level of creatinine in the blood but a low level in the urine, it shows that the kidneys are not effectively clearing creatinine from the body.

**crepitation**
A cracking sound in the lungs (heard through a stethoscope) due to a build-up of fluid. (See also auscultation.)

**crepitus**
A grating sound or sensation caused by rough surfaces inside the body rubbing together. Crepitus may be felt or heard when the ends of a broken bone rub against each other, or when cartilage on the surfaces of a joint has worn away due to osteoarthritis. Faint crepitis may be heard in the lung due to abnormalities such as inflation in pneumonia.

The term also describes the cracking sound made when an air pocket under the skin (see emphysema, surgical), or an area of gas gangrene, is pressed.

**cretinism**
A congenital condition in infants that is characterized by stunted growth, failure of normal development, learning difficulties, and coarse facial features. Cretinism occurs when the thyroid gland produces insufficient amounts of, or fails to produce any, of the thyroid hormone thyroxine at birth. However, provided that the condition is recognized early, replacement therapy with thyroxine can effect a cure. (See also hypothyroidism.)

**Creutzfeldt–Jakob disease**
A rare, progressive degenerative disease of the brain. Creutzfeldt–Jakob disease (CJD) is thought to be caused by infection with a prion (a type of infectious protein). A similar agent causes scrapie in sheep and bovine spongiform encephalopathy (BSE) in cattle.

**TYPES**
One form of CJD largely affects middle-aged or elderly people, and appears to have no obvious cause. A second form occurs in younger people. and this is associated with contamination during

---

**PROCEDURE FOR CRANIOTOMY**
Before the operation, all or part of the patient’s scalp is shaved. After a general anaesthetic has been given, layers of skin, muscle, and membrane are cut away from the skull at the planned operation site and the bone is cut with a saw (see below). The “lid” of bone is then either folded back on a “hinge” of muscle or removed completely. The dura (the outermost of the three membranes that surround the brain) is then opened to reveal the inner membranes and the brain.

Gigli’s saw
The bone between the burr holes is cut using Gigli’s saw, which is passed between the burr holes using a malleable saw guide.

**Diagram:**
- Burr holes
- A series of burr holes is made. The holes must be very close together if the bone is thick.

---
brain surgery or transplants from infected people, or with treatment using infected human growth hormone or gonadotrophins.

A third form, new variant (nv) CJD, was first identified in 1995 and affects people in their teens and 20s. It is thought to be acquired by eating beef infected with BSE. This form causes pathological changes in the brain that are similar to the changes found in cattle suffering from BSE.

SYMPTOMS
Symptoms are broadly similar for all forms of the disease. Slowly progressive dementia (deterioration in brain function) and myoclonus (sudden muscular contractions) occur; coordination diminishes; the intellect and personality deteriorate; and blindness may develop. As the disease progresses, speech is lost and the body becomes rigid.

OUTLOOK
There is no treatment, and death usually occurs within two to three years.

cri du chat syndrome
A rare congenital condition that causes severe learning difficulties, abnormal facial appearance, low birth weight, and short stature. It is characterized by a cat-like cry in infancy. Cri du chat syndrome is caused by a chromosomal abnormality. There is no treatment. (See also genetic counselling.)

Crigler–Najjar syndrome
A rare genetic disorder in which there is an absence or lack of the liver enzyme that breaks down bilirubin (the yellowish pigment in the digestive juice bile) for excretion. The condition appears in early childhood.

Children with Crigler–Najjar syndrome have jaundice (yellowing of the skin and whites of the eyes, due to a buildup of bilirubin in the blood). In some children, the liver enzyme is completely absent, and the condition is fatal by about two years of age. Some other children may just have insufficient amounts of the enzyme, and may live into adulthood. A liver transplant may be the only effective treatment for the syndrome.

crisis
A term for a turning point in the course of a disease (either the onset of recovery or deterioration). The word is also used to describe a distressing and difficult episode in life.
OUTLOOK
Some people in whom the disease is localized remain in normal health indefinitely and seem to be cured.

cromoglicate
See sodium cromoglicate.

crossbite
A type of malocclusion (an abnormal relationship between the upper and lower teeth) in which some or all of the lower front teeth overlap the upper front teeth. A molar crossbite, in which the upper and lower back teeth overlap, can also occur.

cross-eye
A type of strabismus (squint) in which one of the eyes turns inwards relative to the other, or in which both eyes turn inwards towards each other.

cross-matching
A procedure to determine compatibility between the blood of a person who requires a blood transfusion and that of a donor. Red blood cells from one person are combined with serum (the clear fluid that separates from blood when it clots) from the other. Clumping of red blood cells indicates the presence of antibodies, showing that the blood is not compatible.

croup
A common disorder in infants and young children, in which narrowing and inflammation of the airways causes hoarseness, stridor (a grunting noise during breathing), and a barking cough.

Croup may be caused by a viral or bacterial infection affecting the larynx, epiglottis, or trachea. Most cases are due to a viral infection and are generally mild. Other causes include diphtheria, allergy, spasms due to insufficient calcium levels in the blood, and inhalation of a foreign body.

Humidifying the air can help to ease breathing. In some cases, corticosteroid drugs administered through a nebulizer, and oxygen, may be prescribed. If the infection is bacterial, it is treated with antibiotic drugs.

Crouzon’s syndrome
An autosomal dominant genetic disorder that causes facial deformities. Affected people have these features: eyes that protrude (see exophthalmos) and are spaced widely apart; a squint; an abnormally tall skull; a large, beaked nose; and an underdeveloped upper jaw, which makes the lower jaw look as if it is protruding.

crowding, dental
See overcrowding, dental.

crowning
The popular name given to the phase in the second stage of labour (see childbirth) when the baby’s head first appears at the mother’s vaginal opening.

HOW CROWNS ARE FITTED
The tooth is filed down to form a peg over which the replacement is fitted. An impression of the peg and the natural tooth is taken and a replica is made. Using this replica as a model, the artificial crown is constructed.

POST CROWNS
If the natural tooth is badly decayed or has been weakened, its crown is removed and a post crown is fitted.

1 This tooth is so decayed that a retaining peg cannot be fashioned.

2 The tooth’s natural crown is completely removed.

3 A gold post is cemented into the root canal and the crown is then cemented over the post.
cruciate ligament
One of the two ligaments in the knee that pass over each other to form a cross. The ligaments form connections between the femur and tibia inside the knee joint and prevent overbending and overstraightening at the knee.

crush syndrome
Damage to a large amount of muscle (usually as a result of a serious accident), which causes kidney failure. The damaged muscles release proteins into the bloodstream, temporarily impairing kidney function. As a result, some substances normally excreted in the urine build up to toxic levels in the blood. If left untreated, crush syndrome may be fatal, but dialysis allows the kidneys time to recover.

crutch palsy
Weakness or paralysis of muscles in the wrist, fingers, and thumb in people who walk with a crutch under the armpit. Crutch palsy is due to pressure on the nerves supplying these muscles. It does not occur if elbow crutches are used.

crying in infants
A normal response in babies to needs or discomforts, such as hunger or thirst. Most healthy babies stop crying when their needs are attended to. In a few cases, persistent crying may be due to a physical cause such as intolerance of cow's milk or an illness (such as an ear or throat infection, or a viral fever).

cryo-
A prefix meaning "ice cold". It is used of medical procedures that involve the use of freezing or low temperatures.

cryopreservation
The preservation of living cells or tissue samples by freezing. The technique is used to store human eggs for in vitro fertilization, sperm for artificial insemination, or plasma and blood obtained from people with rare blood groups.

cryosurgery
The use of temperatures below freezing to destroy tissue, or the use of cold during surgical procedures to produce adhesion between an instrument and an area of body tissue.

Cryosurgery causes only minimal scarring. It is used to treat cancerous tumours in sites where heavy scarring can block vital openings, such as in the cervix, the liver, and the intestines. It may be used in eye operations, for example in cataract surgery and treatment for retinal detachment. It is also commonly used for removing warts, skin tags, some birthmarks, and some skin cancers, and to treat haemorrhoids.

cryotherapy
The use of cold or freezing temperatures or substances in treatment. (See also cryosurgery.)

cryptococcosis
A rare infectious disorder caused by inhaling the fungus Cryptococcus neoformans, which is found especially in soil contaminated with pigeon faeces. The most serious form of the infection can take is meningitis. Another form of infection causes growths in the lungs, resulting in chest pain and a cough, or on the skin, causing a rash of ulcers. Most cases of cryptococcosis occur in people with reduced immunity, such as those with AIDS.

Cryptococcal meningitis is diagnosed from a sample of spinal fluid. A combination of the antifungal drugs amphoterin B and flucytosine is usually prescribed to treat the infection. Most cases in which only the lungs are infected need no treatment.

cryptophthalmus
A birth defect in which the opening between the upper and lower eyelids is absent. (See also Fraser's syndrome.)

cryptorchidism
A developmental disorder of male infants in which the testes fail to descend normally into the scrotum (see testis, undescended).

cryptosporidiosis
A type of diarrhoeal infection caused by protozoa, which may be spread from person to person or be transmitted from domestic animals to people. The disease causes watery diarrhoea and sometimes fever and abdominal pain. It is most common in children but also occurs in people with AIDS.

In most cases, rehydration therapy is the only treatment needed. In people whose immune system is suppressed, however, the infection may be much more severe. Such people may need to be admitted to hospital for treatment with intravenous fluids and antidiarrhoeal drugs.

CSF
The abbreviation for cerebrospinal fluid.

CS spray
A noxious powder, also known as CS gas or tear gas, that is used in aerosol form as a means of riot control. CS spray causes severe irritation of the eyes, airways, and skin, and sometimes nausea and vomiting. Its effects are short-lived, usually lasting for only a few minutes.

CT scanning
A diagnostic technique in which the combined use of a computer and a machine emitting X-rays produces cross-sectional images of the body tissues.

A CT (computed tomography) scanner is a machine that is shaped like a doughnut that rotates around the patient’s body. The machine contains one or more X-ray sources and, on the opposite side, some X-ray detectors. Unlike a conventional X-ray image, which shows only a few levels of tissue density, the X-ray detector can register hundreds of levels of density. It sends this information to a computer, which processes the data and shows the results as an image on a monitor. CT images usually show the body as "slices", in which the different tissues can be seen in detail. In some machines, this information can be used to produce a three-dimensional reconstruction of the area scanned.

CT scanning has revolutionized the diagnosis and treatment of tumours, abscesses, and haemorrhages in the brain, as well as head injuries and strokes. The procedure is also used to locate and show tumours, to investigate a wide range of diseases, and to aid needle biopsy in organs of the trunk.

Newer types of CT scanners use a spiral technique: the scanner rotates around the body as the patient is moved slowly forwards on a bed, causing the X-ray beams to follow a spiral course. Images can be made of hollow organs such as the colon (a procedure known as “virtual colonoscopy”). For some procedures, injected or swallowed contrast media (chemicals that are opaque to X-rays) may be used to make certain tissues more easily visible.

The images produced during CT scanning can be stored digitally or on conventional X-ray film. (For details of the procedure, see Performing a CT scan box, opposite.)
cuff
A body structure that consists of muscle and tendon fibres and encircles a joint. (See also rotator cuff.)
culture
A growth of bacteria or other microorganisms, cells, or tissues cultivated artificially in the laboratory. Microorganisms are collected from the site of an infection and cultured in order to produce adequate amounts so that tests to identify them can be performed. Cells from a fetus may be cultured to diagnose disorders prenatally. Healthy cells may be cultured for the study of chromosomes (see chromosome analysis). Some types of tissue, such as skin, may be cultured to produce larger amounts that can then be used for grafting. Other tissues are cultivated to provide a medium in which viruses can be grown and identified in the laboratory; viruses will only multiply within living cells.
cupping
An ancient procedure in which the practitioner draws blood to the skin surface by applying a heated vessel to the skin. It produces an inflammatory response thought to relieve bronchitis, asthma, and musculoskeletal pains.
curare
An extract from the bark and juices of various trees that has been used for centuries by South American Indians as an arrow poison. Curare kills by producing muscle paralysis. Synthetic compounds that are related to curare are sometimes used to produce paralysis during surgery.
cure
The process of restoration to normal health after an illness. The word “cure” usually means the disappearance of a disease rather than simply a halt in its progress. A treatment that ends an illness may also be called a cure.
curettage
The use of a surgical instrument called a curette to scrape abnormal tissue, or samples for analysis, from the lining of a body cavity or from the skin.
curettage, dental
The scraping of a cavity or other dental surface with a curette (a narrow, spoon-shaped instrument). Dental curettage is one method used to remove the lining of periodontal pockets and diseased tissue from root surfaces in periodontitis. This enables the healthy underlying tissue to reattach itself to the root surface.
curette
A spoon-shaped surgical instrument used for scraping away material or tissue from an organ, cavity, or surface.
Curling’s ulcer
A type of stress ulcer that occurs specifically in people who have suffered extensive skin burns.
Cushing’s syndrome
A hormonal disorder caused by an abnormally high level of corticosteroid hormones in the blood. Cushing’s syndrome is characterized by a reddened, moon-shaped face, wasting of the limbs, thickening of the trunk, and a humped upper back. Other symptoms include acne; stretch marks on the skin; bruising; osteoporosis (loss of bone density); susceptibility to infection and peptic ulcers; and, in women, increased hairiness. Mental changes frequently also occur, causing depression, insomnia, paranoia, or, euphoria. Oedema, hypertension, and diabetes mellitus may develop. In children, growth may be suppressed.

The excess of hormones is most commonly due to prolonged treatment with corticosteroid drugs. Such cases of Cushing’s syndrome are usually mild. In other cases, high hormone levels are due to overactivity of the adrenal glands because of an adrenal tumour, or due to a pituitary tumour affecting production of ACTH (adrenocorticotrophic hormone), which in turn stimulates the adrenal glands.

Cushing’s syndrome due to corticosteroid drugs usually disappears when the dose of the drug is gradually reduced. In cases of Cushing’s syndrome that are caused by an adrenal gland tumour, the tumour will be removed surgically. If the cause of the disease is a pituitary tumour, it may be removed surgically or shrunken by irradiation and drug treatment. In both of these cases, surgery is followed by hormone replacement therapy.

cushion
Any soft body structure resembling a pad or cushion, such as a bursa.

cusp
A tapering point, such as on a tooth. The term also refers to the flaps of the heart valves.

cusp, dental
One of the protrusions found on the grinding surface of a tooth.

cutaneous
Relating to the skin.

cutaneous anthrax
See anthrax.

cutaneous horn
See horn, cutaneous.

cutdown
Creation of a small skin incision in order to gain access to a vein, to take blood or to give intravenous fluid. This procedure is sometimes needed when a vein cannot be identified through the skin, in conditions such as shock.

cuticle
The outermost layer of skin. The term commonly refers to the thin flap of skin at the base of a nail, and also to the outer layer of a hair shaft.

CVA
The abbreviation for cerebrovascular accident.

CVP
The abbreviation for central venous pressure (the pressure within the right atrium of the heart).

CVS
The abbreviation for chorionic villus sampling, and for cardiovascular system.

cyanide
Any of a group of salts of hydrocyanic acid. Most of these substances are extremely poisonous, and their inhalation or ingestion can rapidly lead to breathlessness and paralysis, followed by unconsciousness and death. Certain cyanides are eye irritants and are used in tear gases.

cyanocobalamin
An alternative name for vitamin B12.

cyanosis
A bluish coloration of the skin or mucous membranes caused by an abnormally high level of deoxygenated haemoglobin in the blood. Cyanosis confined to the hands and feet is not serious; it is usually due to slow blood flow, often as a result of exposure to cold. A blue tinge to the lips and tongue, however, could be caused by a serious heart or lung disorder such as chronic obstructive pulmonary disease or heart failure.

cyclopentiazide
A thiazide diuretic drug used to reduce oedema associated with heart failure, kidney disorders, cirrhosis of the liver, and to treat hypertension. Side effects of this drug include lethargy, loss of appetite, leg cramps, dizziness, rash, and impotence.

cyclophosphamide
An anticancer drug used in the treatment of Hodgkin’s disease and leukaemia. It is also used as an immunosuppressant and to treat connective tissue diseases.

cycloplegia
Paralysis of the ciliary muscle of the eye, which makes accommodation difficult. In some circumstances, cycloplegia may be induced by cycloplegic drugs to facilitate eye examinations.

cyclosporin
An alternative spelling for ciclosporin.

cyclothymia
A personality characteristic typified by marked changes of mood from cheerful, energetic, and sociable to gloomy, listless, and withdrawn. Mood swings may last for days or months and may follow a regular pattern.

Cymalon
A brand name for an over-the-counter preparation containing sodium bicarbonate, sodium carbonate, citric acid, and sodium citrate. This preparation is commonly used to relieve the symptoms of cystitis.

cyproterone acetate
A drug that blocks the action of androgen hormones. It is used to treat prostate cancer (see prostate, cancer of) and occasionally to reduce male sex drive. Side effects include weight gain and an increased risk of blood clots.

cyst
An abnormal but usually harmless lump or swelling filled with fluid or semi-solid material. Cysts occur in body organs or tissues. There are various types, including sebaceous cysts, dermoid cysts, ovarian cysts, breast cysts, Baker’s cysts, and cysts that form around parasites in diseases such as hydatid disease or amoebiasis. Cysts may need to be removed surgically if they disrupt the function of body tissues.

cyst-/cysto-
Relating to the bladder, as in cystitis (inflammation of the bladder).

cystectomy
The surgical removal of part or all of the bladder. The procedure is used for treating bladder cancer (see bladder tumours). Radical cystectomy (in which
all of the bladder is removed) is followed by the construction of an alternative channel for urine, usually ending in a stoma in the lower abdomen (see urinary diversion). In men, the prostate gland and seminal vesicles are also removed, usually resulting in impotence. In women, the uterus, ovaries, and fallopian tubes are removed. After radical cystectomy, the patient has to wear an external pouch to collect urine.

**Cystic fibrosis**

A serious and potentially fatal genetic disorder, characterized by a tendency to develop chronic lung infections combined with an inability to absorb fats and other nutrients from food. The main characteristic feature of cystic fibrosis (CF) is the secretion of sticky, viscous mucus in the nose, throat, airways, and intestines.

**CAUSES**

CF is caused by an inherited defect in a gene. The defect is recessive, which means that one faulty gene must be inherited from each parent before any abnormality appears. People with only one defective gene have no symptoms but are “carriers” and can pass the gene on to their children.

**HOW CYSTECTOMY IS DONE**

Radical cystectomy is a major procedure performed under general anaesthesia. An incision is made in abdomen, and the ureters are cut and tied. The bladder and other lower abdominal organs are removed. The stoma is then formed from part of the small intestine. After the operation, the patient is given intravenous infusions of fluids, salt, and glucose until the intestines are functioning normally again.

- **Men**
  - In men, the prostate gland and the bladder are removed

- **Women**
  - In women, the uterus, fallopian tubes, ovaries, and part of the vagina (as well as the bladder) are removed

**Formation of the stoma**

A short section of small intestine, with its blood vessels, is detached from the remainder of the intestines. The two ureters are joined to this loop of intestine. One end of the loop is then sealed, and the other inserted through the abdominal wall to form the stoma.

**Urine expulsion**

Urine produced by the kidneys is channelled via the ureters and intestinal loop to the stoma, where it leaves the body.

The defective gene causes a biochemical abnormality in which the faulty movement of ions across cell membranes affects mucus formation. As a result, the mucus-forming glands in several organs do not function properly. Most seriously, the glands in the lining of the bronchial tubes produce thick mucus, which predisposes the person to chronic lung infections. Another serious malfunction is poor or absent secretion of pancreatic enzymes, which are involved in the breakdown and absorption of fats in the intestine. The sweat glands are also affected and excrete excessive amounts of salt.

**SYMPTOMS AND COMPLICATIONS**

The course and severity of CF vary. Typically, a child passes unformed, pale, oily, foul-smelling faeces and may fail to thrive. Often, growth is stunted and the child has recurrent respiratory infections. Without prompt treatment, pneumonia, bronchitis, and bronchiectasis may develop, causing lung damage. Most males and some females are infertile. Excessive salt loss from sweating may lead to heatstroke and collapse.

**DIAGNOSIS AND TREATMENT**

Early diagnosis, confirmed by simple sweat and blood tests, improves the outlook for children with CF. Prompt treatment with intensive physiotherapy and antibiotics helps to reduce the severity and frequency of lung infections. In addition, lung function may be improved by treatment with dornase alfa, a genetically engineered version of a human enzyme, which is administered by nebulizer. Pancreatin and a diet rich in proteins and calories are given to bring about weight gain and encourage more normal faeces. Supervision of the treatment is best carried out from a special centre that is staffed by paediatricians, nurses, and physiotherapists who have particular knowledge of the disease.

**OUTLOOK**

The highly specialized treatment now available for people with CF maximizes their chances of a reasonable quality of life. About 9 in 10 children survive into their teens; many live well into their 40s. Progressive respiratory failure is the usual cause of death, but in some cases a heart-lung transplant may be considered.

**Cystinosis**

A rare genetic disorder in which the amino acid cystine accumulates in cells throughout the body.
The juvenile form of cystinosis becomes apparent in the first year of life, at which time cystine deposits damage the eyes, resulting in impaired vision. The deposits also lead to potentially fatal kidney failure.

In the adult form, which is less severe, the main symptoms are eye problems, including extreme sensitivity to light (see photophobia). The kidneys are much less likely to be affected in adults than in children.

cystinuria

An inherited disorder (see metabolism, inborn errors of) in which the kidneys are unable effectively to process certain amino acids (the chemical compounds that make up proteins). Cystinuria is inherited in an autosomal recessive manner (see genetic disorders) and occurs in around one in 1,000 births.

Under normal circumstances, blood is filtered as it passes through the kidneys; a wide range of substances is removed, then useful compounds, such as amino acids, are reabsorbed. In cystinuria, this process does not work effectively. As a result, high levels of four amino acids, particularly cystine, occur in the urine. This excess cystine can result in the development of a rare form of kidney stones (see renal calculi) in both adults and children.

Cystinuria is usually detected in people who have symptoms of kidney stones, or in those who have passed stones that, on analysis, are found to contain cystine. The diagnosis can be confirmed by urine tests that measure the levels of amino acids. Treatment involves drinking large amounts of fluids regularly in order to dilute the urine and reduce the concentration of cystine. If the levels of cysteine remain high, the drug penicillamine may be required to help prevent the formation of new stones.

cystitis

Inflammation of the lining of the bladder that is usually the result of a bacterial infection.

CAUSES

Cystitis is more common in women than men because the urethra is short, so it is relatively easier for the bacteria that cause the disorder to pass into the bladder. A bladder calculus (stone), a bladder tumour, or a urethral stricture can obstruct urine flow and increase the risk of infection. In men, cystitis is rare; it usually occurs when an obstruction, such as an enlarged prostate gland (see prostate, enlarged), compresses the urethra. Cystitis in children is often associated with a structural abnormality of the ureters, which allows reflux (backward flow) of urine towards the kidneys.

The use of catheters (see catheterization, urinary) also carries the risk of infection. People with diabetes mellitus are especially susceptible to urinary tract infections because they have higher-than-normal levels of glucose in their urine which encourages the growth of bacteria.

SYMPTOMS

The main symptoms are a frequent urge to pass urine and a burning pain on urinating. The urine may be foul-smelling or may contain blood. There may also be fever and chills, and lower abdominal discomfort. However, in children there are frequently no symptoms relating to the urinary tract, and they may have only generalized symptoms, such as fever and vomiting.

TREATMENT

Symptoms of mild cystitis may be relieved by drinking 0.5 litre of fluid every four hours, which helps to flush out the bladder. Any bacterial infection is treated with antibiotic drugs to prevent bacteria from spreading upwards to the kidneys and causing pyelonephritis (infection of the kidneys).

cystostomy

A procedure that is used to assess the function of the bladder and also to investigate urinary incontinence or poor bladder emptying; it is also used to detect abnormalities of the nerves supplying the bladder. In this procedure, a catheter is inserted into the bladder, then the internal pressure is measured as the bladder is filled and then emptied. (See urodynamics.)

cystoscopy

The examination of the urethra and bladder using a cystoscope inserted up the urethra. A cystoscope is a viewing instrument, which can be rigid or flexible, sometimes with a camera at the tip (see endoscopy).
Cystoscopy is used to inspect the bladder for calculi (stones), bladder tumours, sites of bleeding and infection, and, in children, to investigate vesicoureteric reflux. Cystoscopy is also used to take urine samples from the ureters so that doctors can look for infection or tumour cells. Radiopaque dye may be injected into the ureters by means of the cystoscope during the X-ray procedure of retrograde pyelography (see urography).

Certain treatments can also be performed through the cystoscope. These include the removal of bladder tumours or calculi and the insertion of stents (narrow tubes) into a ureter to relieve an obstruction.

**cystostomy**
The surgical creation of a hole in the bladder. Cystostomy is usually carried out to drain urine in cases where the introduction of a catheter (flexible tube) would be either inadvisable or simply impossible.

**cystourethrography, micturating**
An X-ray procedure that is used for studying the bladder during the passing of urine. Micturating cystourethrography is most commonly used in young children to detect abnormal reflux of urine (backflow of urine up the ureters) as the bladder empties. (See urodynamics.)

**cytology**
The study of cells. The main use of cytology is to detect abnormal cells; it is widely used to screen for cancer (as in the cervical smear test) or to confirm a diagnosis of cancer, and is increasingly used in antenatal screening to detect certain fetal abnormalities. Examination of cells from body fluids helps doctors to determine the cause of conditions such as pleural effusion (fluid in the pleural cavity around the lungs) and ascites (abnormal accumulation of fluid in the abdominal cavity); for example the tests can identify whether cancer or infection is present.

Cells are collected by procedures such as scraping or fine-needle aspiration biopsy. For antenatal tests, cells from the fluid that surrounds and cushions the fetus in the uterus are obtained by means of amniocentesis or chorionic villus sampling.

**cytomegalovirus**
One of the most common herpes viruses. Cytomegalovirus (CMV) infection causes infected cells to appear enlarged. The virus may produce an illness that is similar to glandular fever (see mononucleosis, infectious), but usually there are no symptoms. Individuals with impaired immunity are more seriously infected. CMV in a pregnant woman can cause birth defects and brain damage in the baby.

**cytopathology**
The microscopic study of cells in health and disease. (See also cytology.)

**cytoplasm**
The jellylike substance that contains the internal structures of a cell. Cytoplasm is 90 per cent water, but it also contains enzymes, amino acids, and other chemicals that are required for cell function.

**cytotoxic drugs**
A group of anticancer drugs that kill or damage abnormal cells. Cytotoxic drugs may also damage or kill healthy cells, especially those that multiply rapidly, such as the cells in hair follicles or those in the intestinal lining.
dacycystitis
Inflammation of the tear sac, usually resulting from the blockage of the tear duct. The condition sometimes occurs in infants if the tear duct has not developed normally. In adults, it may follow inflammation in the nose or an injury. The cause is often unknown.

Symptoms include pain, redness, and swelling between the inner corner of the eyelids and the nose. Infection may occur and cause a discharge.

The obstruction may be cleared by flushing the tear duct with saline. Anti-biotic eye-drops or ointment are given for infection. In infants, massaging the tear sac may clear a blockage. Surgery to drain the tear sac (dacryocystorhinostomy) is occasionally necessary.

Dacylitis
Inflammation of the fingers or toes. Dactylitis sometimes occurs in people who have the inherited blood disorder sickle cell anaemia. Less commonly, the condition can be associated with tuberculosis or syphilis infection.

Daktacort
A brand name for a cream containing a combination of synthetic hydrocortisone (a corticosteroid drug) and miconazole (an antifungal drug). Daktacort is used to treat inflamed skin conditions, such as eczema and dermatitis, where a fungal infection is also suspected.

Daktarin
A brand name for miconazole, an antifungal drug used in the treatment of athlete’s foot and other common fungal skin infections. Daktarin gel is used to treat oral thrush (see candidiasis).

Dalacin
A brand name for clindamycin, an antibiotic that may be applied to the skin to treat severe acne or as a vaginal cream in the treatment of bacterial vaginal infections. Due to its toxic side effects, Dalacin is given as tablets or by injection only for serious infections, when other antibiotics cannot be used.

danazol
A drug used for treating endometriosis (a condition in which fragments of the uterine lining occur elsewhere in the pelvic cavity), noncancerous breast disease, and menorrhagia (heavy periods).

Danazol suppresses the release of gonadotrophin hormones (pituitary hormones that stimulate activity in the ovaries), which in turn reduces the production of the hormone oestrogen. This action usually prevents ovulation and causes irregularity or absence of menstrual periods.

Possible adverse effects include nausea, rash, and weight gain. Pregnancy should be avoided while taking danazol.

D and C
An abbreviation for dilatation and curettage, a gynaecological procedure in which the cervix (neck of the uterus) is dilated, then the endometrium (lining of the uterus) is scraped away and a sample is removed for analysis. D and C was once used to diagnose disorders of the uterus, but has largely been replaced by hysteroscopy, an endoscopic technique for viewing the uterus lining or taking a biopsy (tissue sample) from the lining. Endometrial biopsies can also be taken using a small vacuum suction device.

dander
Minute scales that are shed from an animal’s skin, hair, or feathers. Dander from humans and pets floats in the air or settles on surfaces, making up a large proportion of household dust. Some people are allergic to animal dander and develop the symptoms of allergic rhinitis (hay fever) or of asthma if they inhale the scales.

dandruff
A harmless condition in which dead skin is shed from the scalp, often producing white flakes. The usual cause is a rash called seborrhoeic dermatitis. Frequent use of an antidandruff shampoo usually controls dandruff.

danthron
See dantron.

dantrolene
A muscle-relaxant drug used to relieve muscle spasm caused by spinal injury, stroke, or neurological disorders such as cerebral palsy. The drug does not cure the underlying disorder, but it often improves mobility.

dantron
A stimulant laxative drug used to treat constipation in the terminally ill. Constipation is common in these patients as a side effect of treatment with opioid analgesic drugs (painkillers). Dantron may colour the urine red.

dapsone
An antibacterial drug used to treat Hansen’s disease (leprosy) and dermatitis herpetiformis. Combined with pyrimethamine, dapsone is also used to prevent malaria. The drug may cause nausea, vomiting, and, rarely, damage to the liver, red blood cells, and nerves.

Darier’s disease
A rare, progressive skin disorder, also known as keratosi follicularis, that is inherited as an autosomal dominant genetic trait (see genetic disorders). The disease is characterized by the development of a number of greasy, pigmented papules (raised spots) on the scalp, the face and neck, behind the ears, and along the middle of the back.

daydreaming
The conjuring up of pleasant or exciting images or situations in one’s mind during waking hours.
day surgery
Surgical treatment carried out in a hospital or clinic without an overnight stay. The proportion of all operations performed on a day-surgery basis has risen substantially in recent years. Modern anaesthesics and surgical techniques, in particular minimally invasive surgery, allow a swifter recovery than in the past, so that patients can often return home within a few hours of surgery.

DDAVP
A brand name for desmopressin, which is a synthetic form of ADH (antidiuretic hormone).

DDT
The abbreviation for the insecticide dichlorodiphenyltrichloroethane. DDT was once widely used in the fight against diseases transmitted by insects, particularly in hot climates. However, some insects have developed resistance to the toxic effects of DDT, and this resistance can be passed on to their offspring. (See also pesticides.)

deafness
Complete or partial loss of hearing in one or both ears. There are two types of deafness: conductive deafness, which is caused by faulty propagation of sound from the outer to the inner ear; and sensorineural deafness, in which there is a failure in the transmission of sounds to the brain.

CAUSES
The most common cause of conductive deafness in adults is earwax. Otosclerosis, a condition in which the stapes (a small bone in the middle ear) loses its normal mobility, is a less common cause. In children, conductive deafness is usually due to otitis media (middle-ear infection) or glue ear (accumulation of sticky fluid in the middle ear). In rare cases, deafness results from a ruptured eardrum (see eardrum, perforated).

Sensorineural deafness may be present from birth. This type of deafness may result from a birth injury or damage resulting from maternal infection with rubella in early pregnancy. Damage to the inner ear may also occur soon after birth as the result of severe neonatal jaundice.

In later life, sensorineural deafness can be due to damage to the cochlea and/or labyrinth of the inner ear. It may result from prolonged exposure to loud noise, or be caused by Ménière’s disease, certain drugs, or some viral infections. The cochlea and labyrinth also degenerate naturally with old age, resulting in presbyacusis. Sensorineural deafness due to damage to the acoustic nerve may be the result of an acoustic neuroma (a noncancerous tumour that develops on the nerve).

SYMPTOMS AND SIGNS
A baby who is congenitally deaf fails to respond to sounds, and, although crying is often normal, he or she does not babble or make the usual baby noises that lead to speech. In an adult who has started to become deaf, sounds heard are not only quieter than before, but may be distorted and less clear.

Deafness may be accompanied by tinnitus (noises in the ear) and vertigo (dizziness and loss of balance). Sometimes deafness can lead to confusion and sometimes to depression.

DIAGNOSIS
Examination of the ear with an otoscope (a viewing instrument with a light attached) can show if the outer-ear canal is blocked by wax, or if the eardrum is inflamed, perforated, or has fluid behind it.

After a physical examination, hearing tests may be performed; these tests can determine whether deafness is conductive or sensorineural.

TREATMENT
The treatment depends on the exact cause of the deafness. Removal of excess earwax remedies conductive deafness in many cases. Otosclerosis is generally treated by an operation known as stapedectomy, in which the stapes is replaced with an artificial substitute. Glue ear may also be treated by surgery (see myringotomy) and by the insertion of a grommet (a small tube that allows fluid to drain away from the middle ear).

Many children who are born deaf can learn to communicate effectively, often by using sign language. Cochlear implants (electrodes implanted in the inner ear that can receive sound signals) may help profoundly deaf adults and children, but they are not suitable for everyone. People who have sensorineural deafness usually need hearing-aids to increase the volume of sound reaching the inner ear. Lip-reading is invaluable for people who have difficulty hearing, whatever the type and severity of their deafness. Other aids, such as an amplifier for the earpiece of a telephone, are available to help deaf people perform everyday tasks. (See also ear, hearing.)
death
Permanent cessation of all vital functions. The classic indicators of death are the permanent cessation of heart and lung function, and, in almost all cases, these remain the criteria by which death is certified. Brain death is the irreversible cessation of all functions of the entire brain, including the brainstem (the part of the brain that controls involuntary actions such as breathing).

The diagnosis of death under normal circumstances, when the individual is not on a ventilator, is based on the absence of breathing, absence of heartbeat, and on the pupils being fixed wide open and unresponsive to light.

When an individual has been placed on a ventilator machine, the criteria for diagnosing brain death are based on clear evidence of irreversible damage to the brain; persistent deep coma; no attempts at breathing when the patient is taken off the ventilator; and complete lack of brainstem function. (See also death, sudden; mortality.)

deadly 

decalcification, dental
The dissolving of minerals in a tooth. Dental decalcification is the first stage of tooth decay. It is caused by bacteria in plaque acting on the refined carbohydrates (mainly sugars) in food to produce acid, which, after prolonged or repeated exposure, causes changes to occur on the surface of the tooth. If the decalcification penetrates the enamel layer, it spreads into the dentine and permits bacteria to enter the inner pulp. (See also caries, dental.)

decay, dental
See caries, dental.

decerebrate
The state of being without a functioning cerebrum, the main controlling part of the brain. This situation occurs if the brainstem is severed, which effectively isolates the cerebrum.

decidua
The lining of the uterus (womb) during the course of pregnancy. The surface layers of the decidua are shed from the body during childbirth.

deciduous teeth
See primary teeth.

decomposition
The gradual breakdown of organic matter (such as food or dead tissue) into other chemical compounds by way of bacterial and/or fungal action, heat, or other processes.

decompression sickness
A hazard of divers and of others who work in or breathe compressed air or other mixtures of gases. Decompression sickness is also called “the bends”. It results from gas bubbles forming in the tissues and impeding the flow of blood.

CAUSE
At depth, divers accumulate inert gas in their tissues from the high-pressure gas mixture they breathe (see scuba-diving medicine). Problems can usually be avoided by allowing the excess gas in their tissues to escape slowly into the lungs during controlled slow ascent or release of pressure. If the ascent is too rapid and the pressure falls too quickly, gas can no longer be held within the tissues and is released as bubbles.

SYMPTOMS
Bubbles of gas may block blood vessels, causing symptoms such as skin itching.

How decompression sickness occurs
On ascent, pressure is reduced rapidly and the gas may form bubbles that may, in turn, cause symptoms. Divers avoid this by ascending slowly.
and mottling and severe pain in and around the larger joints. Symptoms of nervous system impairment (such as leg weakness or visual disturbances) are particularly serious, as is a painful, tight feeling across the chest.

**TREATMENT**

Divers with decompression sickness are immediately placed inside a recompression chamber. Pressure within the chamber is raised, causing the bubbles within the tissues to redissolve. Subsequently, the pressure in the chamber is slowly reduced, allowing the excess gas to escape safely via the lungs.

**OUTLOOK**

If treated promptly by recompression, most divers with the “bends” make a full recovery. In serious, untreated cases, however, there may be long-term complications such as partial paralysis. Repeated episodes may lead to degenerative disorders of the bones or joints.

**decompression, spinal canal**

Surgery to relieve pressure on the spinal cord or a nerve root emerging from it (see microdiscectomy). Pressure may have various causes, including a disc prolapse (“slipped” disc); a tumour or abscess of the spinal cord; or a tumour, abscess, or fracture of the vertebrae. Any of these conditions can cause weakness or paralysis of the limbs and loss of bladder control.

To treat major disc prolapses and tumours, a laminectomy (removal of the bony arches of one or more vertebrae) to expose the affected part of the cord or nerve roots may be performed.

Recovery after treatment depends on the severity and duration of the pressure, the success of the surgery in relieving the pressure, and whether any damage is sustained by the nerves during the operation.

**decongestant drugs**

Drugs used to relieve nasal congestion, commonly in people who have upper respiratory tract infections. The drugs are thought to work by narrowing the blood vessels in the membranes lining the nose. This action reduces swelling, inflammation, and the amount of mucus that is produced by the nasal lining. Common decongestants include ephedrine, oxymetazoline, and phenylephrine. Small amounts of these drugs are found in many over-the-counter cold remedies.

There is little objective evidence that decongestants effectively relieve respiratory disorders. Taken by mouth, they may cause tremor and palpitations, and, taken for longer than five days, they become ineffective; if they are stopped at this stage, symptoms may be worse than at the start of treatment. Therefore, they should not be used continuously for more than five days without medical advice. Decongestants may be unsuitable for people with certain medical conditions and must be avoided in people taking MAOIs.

**decubitus**

The position of reclining or lying down, as in a decubitus ulcer (see bedsore).

**decubitus ulcer**

See bedsore.

**decussation**

A point at which two or more structures in the body cross over each other to the opposite side. An example is the point at which nerve fibres intercross in the central nervous system.

**deep vein thrombosis**

See thrombosis, deep vein.

**defaecation**

The expulsion of waste material as faeces from the body through the anus.

**defence mechanisms**

Techniques used by the mind to lessen unpleasant or unwelcome emotions, impulses, experiences, or events, and to avoid external or internal conflict.

**TYPES**

The principal defence mechanism is repression, which is the suppression of unacceptable thoughts. Other types of defence mechanism include displacement, rationalization, projection, reaction formation, and isolation.

In displacement, dangerous thoughts or feelings are redirected at a harmless object; for example, someone who is angry at another person may kick the furniture instead of hitting that person. Rationalization involves reinterpreting thoughts or actions in a more acceptable way; for example, a person may criticize someone else but claim “It’s for your own good”. In projection, a person attributes his or her own faults to someone else, for example by thinking “that person hates me” when in fact he or she hates that person. In reaction formation, an unacceptable feeling is hidden by actions that suggest the opposite; for example, someone may disguise hatred for another person by showing great concern for that person.
DEFIBRILLATION

In the mechanism of isolation, unpleasant memories (for example, of being assaulted) are retained but the feelings that go with them are hidden, so that a person may recall such an event apparently without emotion.

defibrillation
Administration of one or more brief electric shocks to the heart, usually via two metal plates, or paddles, placed on the chest over the heart. It is performed to return the heart’s rhythm to normal in some types of arrhythmia (irregular or rapid heartbeat), such as atrial fibrillation or ventricular fibrillation.

Defibrillation can be carried out as an emergency procedure to treat ventricular fibrillation, which is a cause of cardiac arrest and most commonly occurs after a heart attack (see myocardial infarction). It can also be used as a planned treatment, in which case it is performed under a brief general anaesthesia. Breathing may be maintained by artificial means for the duration of the procedure.

deficiency anaemia
A type of anaemia. See anaemia, iron deficiency; pernicious anaemia.

defluoridation
The removal of excess fluoride from drinking water, often using domestic water filters, to prevent fluorosis (mottling of tooth enamel) in consumers. (See also fluoridation; fluoride.)

defoliant poisoning
The toxic effects of plant poisons that cause leaves to drop off. Defoliants are poisonous if they are swallowed. Widely used defoliant poisons include sodium chlorate, potassium chlorate, phenoxy herbicides, and paraquat.

deformity
Any malformation or distortion of part of the body. Deformities may be congenital (present from birth), or they may be acquired as a result of injury, disorder, or disease.

Most congenital deformities are relatively rare. Among the most common are club-foot (talipes) and cleft lip and palate. Injuries that can cause deformity include burns, torn muscles, and broken bones. Disorders that may cause deformity include certain nerve problems, some deficiencies, such as rickets, and Paget’s disease of the bone. Disuse of a part of the body can lead to deformity through stiffening and contracture of unused muscles or tendons.

Many deformities can be corrected by means of orthopaedic techniques, plastic surgery, or specific exercises.

degeneration
Physical and/or chemical changes in cells, tissues, or organs that reduce their efficiency. Degeneration is a feature of aging and may also be due to disease processes. Other known causes include injury, reduced blood supply, poisoning (by alcohol, for example), or a diet deficient in a specific vitamin. (See also degenerative disorders.)

degenerative disorders
A term covering a wide range of conditions in which there is progressive impairment in the structure and function of a body system, organ, or tissue. The number of specialized cells or structures in the organ affected is usually reduced, and cells are replaced by connective tissue or scar tissue. In many cases, the cause of the disease is poorly understood, but degenerative disorders are the subjects of intensive research.

Degenerative nervous system disorders include Alzheimer’s disease, motor neuron disease, Huntington’s disease, and Parkinson’s disease. Degenerative disorders of the eye include Leber’s optic atrophy and senile macular degeneration. Degenerative disorders of the joints include osteoarthritis. Muscle degeneration occurs in muscular dystrophies.

Some degree of hardening of the arteries seems to be a feature of normal aging, but in certain people degenerative changes in the muscle coat of the arteries are unusually severe, and calcium deposits may be seen on X-rays (as in Monckeberg’s sclerosis, a type of arteriosclerosis).

In most cases, there is little that can be done to slow the progress of the disease, but it is often possible to relieve symptoms with drug treatment (for example, in Parkinson’s disease).

Degos syndrome
A rare disorder that affects the linings of small and medium-sized arteries throughout the body, particularly in the skin, intestine, and nervous system, causing the vessels to become blocked. The cause is unknown.

The disease typically produces multiple small skin lesions that initially appear as red, raised spots and then form depressed, white scars. Lesions may then form in arteries supplying other parts of the body, such as the intestine and the nervous system. This development may cause severe or even life-threatening problems, such as stroke from lesions that have formed in the brain and perforation of the intestine by lesions that penetrate through the intestine wall (see peritonitis).

dehiscence
The splitting open of a partly healed wound. The term is most commonly used to refer to the splitting open of a surgical incision that has been closed with sutures or clips.

dehydration
A condition in which a person’s water content is at a dangerously low level. Water accounts for about 60 per cent of a man’s body weight and about 50 per cent of a woman’s. The total content of water (and mineral salts and other substances that are dissolved in the body’s fluids) must be kept within fairly narrow limits to enable the healthy functioning of cells and tissues.

CAUSES
Dehydration occurs due to inadequate intake of fluids or excessive fluid loss. The latter may occur as a result of severe or prolonged vomiting or diarrhoea, or in people who have poorly controlled diabetes mellitus, diabetes insipidus, and certain types of kidney failure. Children are particularly susceptible to dehydration due to diarrhoea.

SYMPTOMS
The symptoms of severe dehydration are extreme thirst; dry lips and tongue; an increase in heart rate and breathing rate; dizziness; confusion; lethargy; and eventual coma. The skin looks dry and loses its elasticity. Any urine passed is small in quantity and dark-coloured. If there is also salt depletion (for example, due to heavy sweating), there may be headaches, cramps, and pallor.

TREATMENT
Drinking bottled mineral water helps to maintain the intake of salts. In cases of persistent vomiting and diarrhoea, rehydration therapy is required; salt and glucose rehydration mixtures are available from chemists.

In severe cases of dehydration, fluids may be given intravenously, and the water/salt balance is carefully monitored by means of blood tests and is adjusted as necessary.
déjà vu
French for “already seen”. A sense of having already experienced an event that is happening at the moment. Frequent occurrence may sometimes be a symptom of temporal lobe epilepsy.

Dejerine–Roussy syndrome
A rare neurological disorder, also called thalamic syndrome or central pain syndrome, that results from damage to the thalamus, the part of the brain that processes sensory information.

The main symptom is severe pain, possibly accompanied by other abnormalities such as loss of sensation or a “crawling” feeling in the skin.

delayed allergy
A type of hypersensitivity reaction that, unlike most forms of allergy, does not develop immediately on exposure to a particular allergen (a normally harmless substance that causes a reaction in people who have become sensitized to it).

Delayed allergies, also called type IV hypersensitivity reactions, may result from bacterial, viral, fungal, or protozoal infections or from vaccination with a live virus vaccine. Examples of such delayed allergic reactions include contact dermatitis and the body’s response to infection in tuberculosis.

delayed dentition
The late eruption of teeth. The term “delayed dentition” may refer to the eruption of the first deciduous teeth (see primary teeth) after the end of the 13th month of life or to the eruption of the first permanent teeth after the seventh year of life. Delayed dentition is a feature of various conditions that result in generally restricted growth (see short stature), such as hypothyroidism.

delayed puberty
Onset of puberty (sexual maturation) after the age of 14. In most cases, the child is simply developing at a slower rate than normal, a tendency that often runs in families, but in some cases there may be an underlying disorder.

One possible underlying cause of delayed puberty is underproduction of sex hormones. Rarely, the condition results from a problem with the hypothalamus or the pituitary gland, which are responsible for secreting sex hormones; a genetic abnormality affecting sexual development, such as Klinefelter’s syndrome in boys or Turner’s syndrome in girls; or a long-term illness, such as Crohn’s disease. Certain lifestyle factors, such as excessive exercise or an inadequate diet, may also delay puberty.

Treatment depends on the underlying cause. If delayed puberty runs in the child’s family, no action may be needed. In some cases, however, conditions causing delayed puberty may also lead to infertility, so the child may need further investigations in the future if he or she wishes to have children.

delayed shock
A common term for severe mental or physical reactions that may occur some time after a traumatic event (see post-traumatic stress disorder; shock; stress.)

Delhi belly
A popular name for gastroenteritis and infectious diarrhoea caused by ingesting contaminated food or water.

delinquency
Criminal behaviour in a young person who is below the official age at which he or she can be prosecuted. The term is often extended to include behaviour such as drug abuse, playing truant, or running away from home. Delinquency that occurs in juveniles is probably a result of a combination of social, psychological, and biological factors. Child guidance or family therapy may be recommended. Persistent offenders may be sent to special schools, taken into care, or made wards of court.

delirium
A state of acute mental confusion, commonly brought on by physical illness. Symptoms vary according to personality, environment, and the severity of illness. They may include failure to understand events or remember what has been happening, physical restlessness, mood swings, hallucinations, and panic. Fever and disturbances of body chemistry are often contributory factors.

Children and older people are most susceptible to delirium, particularly as a result of infection, following surgery, or when there is a pre-existing brain disturbance (such as dementia in an elderly person). Drugs, poisons, and alcohol are common precipitants.

delirium tremens
A state of confusion accompanied by trembling and vivid hallucinations. It usually arises in chronic alcoholics after withdrawal or abstinence from alcohol. Early symptoms include restlessness, agitation, trembling, and sleeplessness. The person may then develop a rapid heartbeat, fever, and dilation of the pupils. Sweating, confusion, hallucinations, and convulsions may also occur.

Treatment consists of rest, rehydration, and sedation. Vitamin injections, particularly of thiamine (see vitamin B complex), may be given, as some symptoms are linked to thiamine deficiency.

delivery
The expulsion or extraction of a baby from the mother’s uterus. In most cases, the baby lies lengthwise in the uterus with its head facing downwards; it is delivered head first through the vaginal opening by a combination of uterine contractions and the mother’s pushing (see childbirth). If the baby is lying in an abnormal position (see breech delivery; malpresentation), if uterine contractions are weak, or if the baby’s head is large in relation to the size of the mother’s pelvis, a forceps delivery or vacuum extraction may be required. If a vaginal delivery is impossible or dangerous to the mother or the baby, a caesarean section is necessary.

deltoid
The triangular muscle of the shoulder region that forms the rounded flesh of the outer part of the upper arm, and

**LOCATION OF THE DELTOID**

The deltoid muscle of the shoulder region forms the rounded, outer part of the upper arm and is attached to the scapula and clavicle.
passes up and over the shoulder joint. The wide end of the muscle is attached to the scapula (shoulderblade) and the clavicle (collarbone). The muscle fibres meet to form the apex of the triangle, which is attached to the humerus (the upper-arm bone) at a position about halfway down its length.

The central, strongest part of the deltoid muscle raises the arm sideways. The front and back parts of the muscle are used to twist the arm.

delusion
A fixed, irrational idea not shared by others and not responding to reasoned argument. The central idea in a paranoid delusion involves persecution or jealousy; for instance, a person may falsely believe that he or she is being poisoned or that a partner is persistently unfaithful (see paranoia).

Persistent delusions are an indication of serious mental illness, particularly schizophrenia and manic–depressive illness. (See also hallucination; illusion.)

demand pacemaker
A permanent artificial cardiac pacemaker (a device that sends electrical impulses to the heart to maintain a regular heart-beat) that discharges impulses only when the heart rate is abnormal. Such a pacemaker may be set to function only if the heart rate slows, or alternatively to override an abnormally rapid rate. (See also fixed-rate pacemaker.)

demasculinization
The loss, in a male, of normal male secondary sexual characteristics (see sexual characteristics, secondary). This includes reduced facial hair growth, along with testicular atrophy (wasting away of the testes) and shrinkage of the prostate gland. Demasculinization may occur in a range of conditions in which the testes are damaged or diseased. It may also result from disorders such as cirrhosis and kidney failure, which interfere with the processing in the body of the female sex hormone oestrogen. (See also feminization; intersex; masculinization; sex determination.)

dementia
A condition characterized by a generalized deterioration in brain function. Dementia most commonly affects the elderly; about 1 in 20 people over the age of 65, and up to 1 in 5 people over the age of 80, have the disorder.

CAUSES AND TYPES
Dementia is caused by damage to brain tissue. It is most commonly due to Alzheimer’s disease, which causes changes in the structure and chemistry of the brain. The second most common form is multi-infarct dementia. In this condition, narrowed or blocked arteries in the brain deprive the tissue of blood and oxygen; repeated small strokes (episodes of tissue damage due to a lack of blood) occur, causing deterioration that develops gradually and in stages. Other, rare forms of dementia include Lewy body dementia (in which small, spherical structures called Lewy bodies appear in the brain tissue); AIDS-related dementia; and deterioration that occurs as a result of progressive brain disorders such as Parkinson’s disease.

SYMPTOMS
The main symptoms of dementia are progressive memory loss, disorientation, and confusion. The affected person may not remember recent events, he or she may become easily lost in a familiar neighbourhood, and may be confused over days and dates. These symptoms may come on gradually and they may be hardly noticeable at first; in addition, the person may cover up any problems by confabulation (making up explanations in order to fill the gaps in his or her memory).

Sudden outbursts or embarrassing behaviour may be the first obvious signs of dementia. Unpleasant personality traits may be magnified; families of those affected may have to endure accusations, unreasonable demands, or even assault. Paranoia, depression, and delusions may occur as the disease progresses. Irritability or anxiety gives way to indifference towards all feelings and events. Personal care and hygiene are neglected, and speech becomes incoherent. Affected people may eventually need total nursing care.

TREATMENT
The management of the most common Alzheimer-type illness is based on the treatment of symptoms. The affected person should be kept clean and well-nourished, in comfortable surroundings and with good nursing care. Sedative drugs may be given to reduce restlessness or paranoid beliefs. These measures can help to ease distress for both the patient and their family.

For some people with mild to moderate Alzheimer’s disease, drug treatment with acetylcholinesterase inhibitors such as donepezil may halt the deterioration in mental function, or may even restore function to the level the person experienced six months previously. Regardless of treatment, however, Alzheimer’s disease is progressive, and usually leads to death within 10 years of onset.

dementia praecox
An outdated term formerly used to describe severe schizophrenia, especially that affecting adolescents or young adults.

demineralization
Excessive loss of the minerals calcium and phosphate from bone. Generalized demineralization can occur as a result of immobility following an illness or injury, or may be due to a bone disease such as osteomalacia. Patchy demineralization can be due to bone metastases (cancerous tumours that have spread from elsewhere in the body); this condition causes bones of the bone to weaken, increasing the risk of fractures.

De Morgan’s spots
See Campbell de Morgan’s spots.

De Morsier’s syndrome
Also called septo-optic dysplasia, a rare disorder that results from the abnormal development of the optic disc in the eye, the pituitary gland, and parts of the brain. De Morsier’s syndrome causes eye problems, including blindness in one or both eyes, abnormal eye movements such as nystagmus, squint, and dilation of the pupils (rather than the normal contraction) in response to light. Other symptoms of the syndrome include seizures, hypotonia (poor muscle tone), and hormonal problems, commonly a deficiency in growth hormone leading to short stature.

Treatment aims to relieve symptoms such as hormonal deficiencies, and to provide rehabilitation for affected people who have impaired vision.

demyelination
Breakdown of the fatty sheaths that surround and electrically insulate nerve fibres. The sheaths provide nutrients to the nerve fibres and are vital to the passage of electrical impulses along them. Demyelination “short-circuits” the functioning of the nerve, which causes loss of sensation, coordination, and power in specific areas of the body. The affected nerves may be within the central nervous system (CNS), compris-
ing the brain and the spinal cord, or may be part of the peripheral nervous system, which links the CNS to sense receptors, muscles, glands, and other organs throughout the body.

Patches of demyelination are visible on MRI scans of the brain in people who have multiple sclerosis, a disease with symptoms that include blurred vision, muscle weakness, and loss of coordination. The cause of the demyelination in multiple sclerosis is not known. In many cases of the disease, episodes of demyelination alternate with periods of partial or complete recovery of nerve function.

In the rare disorder encephalomyelitis, there is inflammation of nerve cells in the CNS and sometimes also areas of demyelination along the nerves.

dendritic ulcer
A type of corneal ulcer (affecting the transparent dome that forms the front of the eyeball) with threadlike extensions that branch out from the centre. Dendritic ulcers are commonly due to infection with herpes simplex virus.

denervation
The loss of the nerve supply to an area of skin, a muscle, an organ, or another body part. Nerves may be damaged by injury or by disease, or as a result of surgery. A denervated area loses all sensation, and its functioning may be impaired; for example, muscles may become paralysed. In some cases, the affected nerves may regrow, but often the damage is permanent.

dengue
A tropical disease caused by a virus spread by the mosquito Aedes aegypti. The symptoms include fever, headache, rash, and joint and muscle pains, which often subside after about three days. There is no specific treatment for dengue. Prevention involves protection against mosquito bites (see insect bites).

densitometry
An imaging technique that uses low-dose X-rays to measure bone density, as determined by the concentration of calcified material within bone tissue. Densitometry is used to diagnose and assess the severity of osteoporosis (wasting away of bone tissue), especially in the spine and the femur (thigh bone), and to assess its response to treatment.

During the procedure, X-rays are passed through the body. A computer assesses the amount of X-rays absorbed by the body and uses this information to calculate the bone density.

density
The “compactness” of a substance, defined as its mass per unit volume. In radiology, the term relates to the amount of radiation absorbed by the structure being X-rayed. Bone absorbs radiation well and appears white on X-ray film. A lung, which contains mostly air, absorbs little radiation and is dark on the film. The same is true for CT scanning and MRI. (See also specific gravity.)

dental emergencies
Injuries or disorders of the teeth and gums that require immediate treatment because of severe pain and/or because delay could lead to poor healing or to complications. A tooth that has become dislodged by injury can be reimplanted (see reimplantation, dental) into the gum successfully if this is done without delay, usually within 30 minutes of the injury. A partly dislodged tooth should be manipulated back into the socket in the gum immediately.
**DENTAL EXAMINATION**

**TYPES OF DENTAL X-RAY**

There are three types of X-ray. Each of the different types is useful for revealing particular dental problems.

- **Periapical X-rays**
  These X-rays give detailed pictures of whole teeth and the surrounding gums and bone. They show unerupted or impacted teeth, root fractures, abscesses, cysts, tumours, and the characteristic bone patterns of some skeletal diseases. The film, in a protective casing, is placed in the patient’s mouth and is held in position behind the teeth to be X-rayed.

- **Bite-wing X-rays**
  These X-rays show the crowns of the teeth. They are useful for detecting areas of decay between teeth and changes in bone that are caused by periodontal (gum) disease. The film is in a holder with a central tab on to which the patient bites.

- **Panoramic X-rays**
  These X-rays show all the teeth and surrounding structures on one large film. They are invaluable for finding unerupted or impacted teeth, cysts, jaw fractures, or tumours. Pictures are recorded continuously on to film as the camera swings around from one side of the jaw to the other.

Other dental emergencies include a broken tooth (see fracture, dental); severe toothache, which may be due to an abscess (see abscess, dental); Vincent’s disease (see gingivitis, acute ulcerative), which causes ulceration, and bleeding of the gums; and eruption of wisdom teeth that cut into the tongue.

**dental examination**

An examination of the mouth, gums, and teeth by a dentist as a routine check or during the assessment of a suspected problem.

Routine examinations are recommended so that tooth decay (see caries, dental), gum disease (see gingivitis), or mouth cancer can be detected and treated at an early stage, before they cause serious damage. During the examination, the dentist uses a metal instrument to probe for dental cavities, chipped teeth, or fillings. (See the illustrated box on p. 219.) Dental X-rays are sometimes carried out to detect problems, for example with the jaw, that may not be visible. The dentist also checks the bite, that is how well the upper and the lower teeth come together. Regular examinations in children enable a dentist to monitor the replacement of primary teeth by permanent, or secondary, teeth. Referrer for orthodontic treatment may be made.

**dental extraction**

See extraction, dental.

**dental floss**

A fine thread or tape, usually made of nylon, that is used to remove plaque (see plaque, dental) and food particles from hard-to-reach areas between the teeth and around the line of the gums (see flossing). Floss may be waxed or unwaxed, and some types contain fluoride. Flossing should be carried out regularly, in addition to toothbrushing.

**dental impaction**

See impaction, dental.

**dental X-ray**

An image of the teeth and jaws that provides information for the detection, diagnosis, and treatment of conditions that can threaten oral and general health. The part to be imaged is placed between a tube emitting X-rays and a photographic film. Because X-rays are unable to pass easily through hard tissue, a shadow of the teeth and bone is seen on the film. There are three types of dental X-ray: periapical X-ray, bite-wing X-ray, and panoramic X-ray.

Periapical X-rays are taken using X-ray film held behind the teeth. They give detailed images of whole teeth and the surrounding tissues. They can show unerupted or impacted teeth, root fractures, abscesses, cysts, and tumours, and can help diagnose some skeletal diseases. Bite-wing X-rays show the crowns of the teeth and can detect areas of decay and changes in bone due to periodontal disease. Panoramic X-rays show all the teeth and the surrounding structures on one large film. They can show unerupted or impacted teeth, as well as cysts, jaw fractures, or tumours.

The amount of radiation received from dental X-rays is extremely small; however, routine dental X-rays should be avoided during pregnancy.

**dentifrice**

A paste, powder, or gel used with a toothbrush to clean the teeth. Dentifrice usually contains a mild abrasive, along with detergents, colourings and flavourings, binding and moistening agents, and thickening agents. It also usually has fluoride added, and, sometimes, desensitizing agents.

**dentigerous cyst**

A fluid-filled cyst (lump or swelling) surrounding the crown of an unerupted tooth (see eruption of teeth). This type of cyst may produce swelling or resorption (loss of substance) of the adjacent tooth roots. Treatment is by extraction of the affected tooth and by surgical removal of the cyst.

**dentine**

The hard tissue that surrounds the pulp of a tooth (see teeth).
dentistry
The science or profession concerned with the teeth and their supporting structures. Most dentists work in general dental practice; others practise a specialized branch of dentistry.

Dentists in general practice undertake all aspects of dental care. They may refer patients to a consultant in one of the specialized branches of dentistry, such as orthodontics (correction of the alignment of teeth), prosthetics (fitting of bridgework and dentures), endodontics (treatment of diseases of the tooth pulp), and periodontics (treatment of disorders affecting the tissues supporting the teeth).

Dental hygienists carry out scaling (removal of hard deposits on the teeth) and demonstrate methods to keep the teeth and gums healthy.

dentition
The arrangement, number, and type of teeth in the mouth. In young children, primary dentition comprises 20 teeth (incisors, canines, and molars). These teeth are replaced between the ages of 6 and 13 years by the secondary (permanent) dentition. Secondary dentition comprises 32 teeth (incisors, canines, premolars, and molars). Often, the third molars (wisdom teeth) do not erupt until the age of 18–25, or even older in some cases; sometimes, they fail to erupt at all. (See also eruption of teeth.)

denture
An appliance that replaces missing natural teeth. A denture consists of a metal and/or acrylic (hard plastic) base that is mounted with acrylic teeth. The artificial teeth are matched to the person’s original teeth. Denture baseplates, which are created from impressions taken from the upper and lower gums, fit the mouth accurately.

deodorant
A substance that removes unpleasant odours, especially body odours.

deossification
The loss or removal of bone tissue, as in osteoporosis. (See also ossification.)

deoxygenation
In respiration, the release of oxygen from red blood cells to supply other tissues.

deoxyribonucleic acid
See DNA; nucleic acids.

dependence
Psychological or physical reliance on persons or drugs. An infant is dependent on its parents, but, as he or she grows, this dependence normally wanes. Some adults never become fully independent (see dependent personality).

Alcohol and drugs may induce physical or emotional dependence in users; a person who has a dependency may develop physical symptoms, such as sweating or abdominal pains, or become distressed if deprived of the drug. (See also alcohol dependence; drug dependence.)

dependent oedema
A form of oedema (the accumulation of fluid in body tissues) that mainly affects the lower parts of the body. It may be a feature of congestive heart failure. Oedema affecting the ankles may have various possible causes, such as immobility, varicose veins, and pregnancy.

dependent personality
A personality disorder characterized by an inability to function without significant guidance from others, feelings of helplessness when alone or when close relationships end, and a fear of separation. Other features of a dependent personality include difficulty in making decisions, low self-esteem, and hypersensitivity to criticism.

Dependent personality disorder is of unknown cause and normally first manifests itself in early adulthood. There is no specific treatment for the condition, but psychotherapy may gradually help sufferers to make their own choices. Medication, for example with antianxiety drugs or antidepressant drugs, may sometimes be effective in relieving associated symptoms.

depersonalization
A state of feeling unreal, in which an individual has a sense of detachment from self and surroundings. Depersonalization is frequently accompanied by derealization, in which the world is experienced as unreal. It is rarely serious and usually comes on suddenly and may last for moments or for hours. Depersonalization most often occurs in people who have anxiety disorders. Other causes include certain drugs and temporal lobe epilepsy.

depilatory
A chemical hair remover, such as barium sulphide, supplied as a cream and applied for cosmetic reasons or to treat hirsutism (excessive hairiness in women).

Depiix
A brand name for flupentixol, an antipsychotic drug used in the treatment of schizophrenia and other related illnesses. The drug may be given either orally or by injection. Possible adverse effects include an increased risk of parkinsonism (a set of neuromuscular symptoms including tremor, muscle rigidity, and slow movements).

Depo-provera
A brand name for medroxyprogesterone, a long-acting progestogen drug that is given by depot injection as a contraceptive. It is similar to progesterone hormone, a natural female sex hormone.

<table>
<thead>
<tr>
<th>TYPES OF DENTURES</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Partial dentures</strong></td>
</tr>
<tr>
<td>Partial dentures are used when only some of the teeth are missing. They fill unsightly gaps, make chewing easier, maintain clear speech, and keep the remaining teeth in the correct position. Teeth on either side of a gap may tip (making cleaning more difficult) or drift (placing unnatural stress on the tissues of the mouth). Partial dentures are held in place by metal clasps that grip adjacent teeth or by clasps combined with metal rests (extensions of the denture plate that rest on the surface of the tooth).</td>
</tr>
</tbody>
</table>

| **Full dentures** |
| Full dentures are needed when there are no teeth left in the mouth. They stay in place by resting on the gum ridges and, in the case of upper dentures, by suction. Fitting is sometimes delayed after extraction of teeth to allow the gums to shrink and change shape as they heal. |

| **Immediate dentures** |
| Immediate dentures are fitted immediately after extraction of teeth. They protect the gum and control bleeding from extraction sites. Since a toothless period is avoided, they are particularly useful for replacing front teeth. However, they can be expensive and require follow-up visits so that they continue to fit comfortably. They may also need replacing within a short time. |
corticosteroid drugs may be very effective in injections into the area of the skull. Release of the drug is slowed by the inclusion of substances such as oil or wax, and can be made to last for hours, days, or weeks.

A depot injection can be useful for patients who may not take their medication correctly. It also prevents the necessity of giving a series of injections over a short period. Drugs that may be given by depot injection include hormonal contraceptives (see contraception, hormonal methods of), corticosteroid drugs, and antipsychotic drugs. Side effects may arise due to the uneven release of the drug into the bloodstream.

**Depressed skull fracture**

A fracture in which a part of a skull bone is pushed towards the brain (see skull, fracture of). A depressed skull fracture usually results from a high-energy blow to a small surface area of the skull.

**Depression**

Feelings of sadness, hopelessness, and a loss of interest in life, combined with a sense of reduced emotional well-being. Most people experience these feelings occasionally, usually as a normal response to an upsetting event; for example, it is natural to feel depressed when a close relative dies. When a person’s behaviour and physical state are also affected, however, this is an indication that the symptom is part of a depressive illness.

Depression that occurs without any apparent cause, deepens, and persists may occur as part of a variety of psychiatric illnesses. Some people who suffer from depression are eventually diagnosed as having manic–depressive illness (also known as bipolar affective disorder) a condition characterized by episodes of depression alternating with mania (periods of overly excitable mood and uncontrolled behaviour).

**Symptoms**

Symptoms vary with the severity of the condition. In a person suffering from mild depression, the main symptoms are anxiety and a variable mood; the person may also have fits of crying that occur for no apparent reason. More severe depression may cause loss of appetite, difficulty in sleeping, tiredness, loss of interest in social activities, and impaired concentration. Movement and thinking become slower; alternatively, the opposite occurs, and the person may become extremely anxious. Severely depressed people may have thoughts of committing suicide and feelings of worthlessness. Hallucinations or delusions may occur in extreme cases.

**Causes**

Often, there is no single obvious cause, and a combination of factors may be involved. Depression may be triggered by physical illnesses (such as a viral infection), by hormonal disorders (such as hypothyroidism), or by the hormonal changes that occur following childbirth (see postnatal depression). Certain drugs, such as oral contraceptives, may contribute to the condition. Inheritance may play a part in manic–depressive illness. Some people become depressed in the winter (see seasonal affective disorder syndrome), probably in response to the long hours of darkness.

Aside from these causes, there are social and psychological factors that may play a role. Depression may also be related to the number of disturbing changes or events in a person’s life.

**Incidence**

Depression is the most common serious psychiatric illness. The World Health Organization ranks it fourth in the ten leading causes of disease worldwide. One person in six is estimated to suffer some degree of depression in their lifetime, and one person in 20 develops clinical depressive illness.

Depression is particularly common in people over 50, and appears to be more common in women; twice as many women as men seek help for the condition. This difference may result from the fact that women are more prepared to seek help for their symptoms, while men may be more likely to express their discontent in the form of problems such as alcohol abuse and violence.

**Treatment**

There are three main forms of treatment for depression, depending on the type and severity of the illness.

Treatment usually includes a form of psychotherapy, given either individually or in a group. This form of treatment is most useful for people whose personality and life experiences are the main causes of their illness. Types of therapy range from counselling to help deal with practical problems to more structured approaches such as cognitive–behavioural therapy or psychoanalysis. Antidepressant drugs may be very effective, with up to seven in ten affected people responding well to the first drug that is offered. Antidepressants are not addictive. Many drugs, however, do not start to take effect until about two weeks into treatment, and all types need to be continued after the symptoms of depression have cleared.

**ECT** (electroconvulsive therapy) is infrequently used in the UK, but it is still considered to be an effective treatment for people suffering from life-threatening depression. ECT may be life-saving, but it can cause mild, temporary memory impairment.

**Outlook**

Depression is often a recurrent disorder; up to three-quarters of people who have needed hospital treatment for depression will have another episode within 10 years. However, long-term antidepressant medication and psychological therapies can greatly reduce the risk of recurrence.

Despite the effectiveness of drug treatment, suicide remains a serious risk; nearly half of all deaths in people with recurrent depression are due to suicide. This risk can, however, be substantially reduced by maintenance treatment with antidepressive drugs.

**De Quervain’s disease**

An inflammatory condition that affects one of the tendons of the muscles that are used to move the thumb. In de Quervain’s disease, the sheath (covering) of this tendon becomes so inflamed and thickened that the tendon can no longer move through the sheath smoothly, and thumb movements are painful. The inflammation is often caused by overuse of the thumb.

Treatment is with rest, nonsteroidal anti-inflammatory drugs (NSAIDs), and corticosteroid drug injections into the affected tendon sheath, which may be helpful in relieving the inflammation, but in severe cases surgery is needed to loosen the sheath.
is a temporary rise in thyroid hormone levels (hyperthyroidism) lasting for a few weeks, as damage to the thyroid gland causes it to release its hormone stores. This is followed by insufficient levels (hypothyroidism) when the stores then become depleted.

Aspirin is used to treat the inflammation, with a short course of the corticosteroid drug prednisolone given in more severe cases. Thyroid function usually returns to normal once the illness has been treated.

**Dercum’s disease**

Also called adiposis dolorosa, a disorder characterized by the accumulation of localized, symmetrical fat deposits under the skin, mainly on the forearms and thighs. The swellings are uncomfortable or painful. Other symptoms of the disease include muscle weakness and headaches. The disease may cause death from heart failure. Dercum’s disease mainly affects middle-aged women and is thought to be an autosomal dominant genetic disorder.

**Derealization**

Feeling that the world has become unreal. It usually occurs together with depersonalization and may be caused by fatigue, hallucinogenic drugs, or disordered brain function.

**Dermabrasion**

Removal of the surface layer of the skin by high-speed sanding to improve the appearance of scars, such as from acne, or to remove tattoos.

**Dermatitis**

Inflammation of the skin, sometimes due to an allergy. Dermatitis is the same as eczema, and the terms can be used interchangeably. The following are types of dermatitis.

**SEBORRHOEIC DERMATITIS**

This condition is a red, scaly, itchy rash that develops on the face (particularly the nose and eyebrows), scalp, chest, and back. It often develops during times of stress and is probably caused by an excessive growth of yeast on the skin. Corticosteroid drugs and drugs that kill microorganisms may help.

**CONTACT DERMATITIS**

Contact dermatitis results from a reaction to some substance that comes in contact with the skin. Common causes are detergents, nickel, certain plants, and cosmetics. It may be treated with topical corticosteroids. A patch test (see skin tests) may be performed in order to identify the cause.

**PHOTODERMATITIS**

This form of dermatitis occurs in people whose skin is abnormally sensitive to light. A cluster of spots or blisters occurs on any part of the body exposed to the sun (see photosensitivity).

**Dermatitis artefacta**

Any self-induced damage to the skin. It may range from scratches to extensive mutilation that produces severe ulcers or other lesions. When given a medical examination, the affected person may vigorously deny having any part in causing the problem. Psychiatric assessment and treatment is required to control the behaviour. (See also factitious disorder.)

**Dermatitis herpetiformis**

A chronic skin disease in which clusters of tiny, red, intensely itchy blisters occur in a symmetrical pattern, most commonly on the back, elbows, knees, buttocks, and scalp. It usually develops in adult life and is believed to be related to coeliac disease, a condition in which the lining of the small intestine reacts to gluten, a constituent of wheat, rye, and some other cereals.

**Dermatology**

The branch of medicine that is concerned with the skin, hair, and nails, and their disorders.

**Dermatome**

An area of skin that is supplied with nerve fibres by a single spinal nerve from the cervical, thoracic, lumbar, or sacral regions of the spinal cord. The entire body surface is an interlocking pattern of dermatomes, which is similar from one person to another.

Abnormal sensation in a dermatome signifies damage to a particular nerve root, commonly due to a disc prolapse (“slipped” disc).

**Dermatome, surgical**

A surgical instrument for cutting varying thicknesses of skin for use in skin grafting procedures.

**Dermatomyositis**

A rare autoimmune disorder in which the muscles and skin become inflamed. In most cases the cause is unknown, but in some instances the disease is linked to an underlying cancer.

Dermatomyositis causes a skin rash that may first appear on the bridge of the nose and cheeks, followed by a purple discolouration on the eyelids and sometimes a red rash over the knees, knuckles, and elbows. Muscles become weak, stiff, and painful, particularly those in the shoulders and pelvis; affected people may find that they cannot raise their hands above their head, or cannot raise themselves from a squatting position. Calcium may be deposited in the muscles, particularly in affected children.

The diagnosis is made by medical examinations, blood tests, and biopsy of muscle tissue. Treatment is with corticosteroids and/or immunosuppressant drugs and physiotherapy. In about half of all cases, full recovery occurs after a few years. The remainder have persistent muscle weakness. In some cases, the disease eventually affects the lungs and other organs and may be fatal.

**Dermatophyte infections**

A group of common fungal infections affecting the skin, hair, and nails, also called tinea or, popularly, ringworm.

**Dermis**

The inner layer of the skin.

**Dermographism**

Abnormal sensitivity of the skin to mechanical irritation, to the extent that firm stroking leads to the appearance of itchy weals. The condition is a form of urticaria (nettle rash). It is most common in fair-skinned people who have a tendency to allergic conditions.

**Dermoid cyst**

A noncancerous tumour with a cell structure similar to that of skin. The growth contains hairs, sweat glands,
and sebaceous glands. Dermoid cysts may also contain fragments of cartilage, bone, and even teeth. The cysts can occur in various parts of the body, but they are most commonly found in the ovaries and on the skin around the head or neck, causing small, painless swellings. Dermoid cysts only rarely become cancerous.

Surgical removal of the cysts is usually recommended. (See also teratoma.)

dermoid tumour
See dermoid cyst.

Dermovate
A brand name for clobetasol, a topical corticosteroid drug that is applied to the skin. Dermovate is only prescribed for severe skin disorders that have not responded to treatment with another, weaker topical corticosteroid.

De Sanctis–Cacchione syndrome
A hereditary condition that is transmitted as an autosomal recessive trait (see genetic disorders). De Sanctis–Cacchione syndrome is characterized by xeroderma pigmentosum (extreme sensitivity of the skin to sunlight), impaired intellectual development, growth retardation (see short stature), and underdevelopment of the gonads (the testes or ovaries).

desensitization
A technique that is used in behaviour therapy for the treatment of phobias. The patient is gradually exposed to the feared object or situation while using relaxation techniques to control his or her feelings. The exposure is carried out repeatedly over several weeks or months, until the person no longer feels afraid when confronted with the object or situation.

desmopressin
A synthetic form of ADH (antidiuretic hormone) that is used to treat diabetes insipidus and bed-wetting (see enuresis).

desogestrel
A progestogen drug that is used with ethinylestradiol as an ingredient of some combined oral contraceptives. Desogestrel is reported to have a slightly higher risk of venous thromboembolism than older drugs. Possible side effects of desogestrel include weight changes and fluid retention. There may, in addition, be nausea, vomiting, headache, depression, and breast tenderness.

desquamation
The process by which the surface of the epidermis (the outer layer of the skin) is shed in the form of scales or small sheets. This process is a feature of seborrhoeic dermatitis (see dermatitis) and ichthyosis (an inherited scaling condition of the skin). Desquamation of the skin may occur after illnesses involving fever, particularly scarlet fever.

detached retina
See retinal detachment.

detergent poisoning
The toxic effects that can result from swallowing cleaning agents that are present in shampoos, laundry powders, and household cleaning liquids. These effects include vomiting, diarrhoea, and swelling of the abdomen.

detoxify
To remove the toxicity (the poisonous property) from a substance or to neutralize the substance’s toxic effects. Detoxification is one of the functions carried out by the liver.

The term “detoxification” is used to describe treatment for alcohol dependence and also a short-term diet in which toxins such as caffeine and alcohol are excluded and foods high in fats and sugar are avoided. “Detox” diets are usually based on fruits, vegetables, starches such as brown rice, and drinking plenty of water. People who follow these diets often feel physically and mentally refreshed afterwards, although there is no scientific evidence that the diets eliminate toxins faster than normal. Detox diets should be used only for a few days, and preferably with guidance from a doctor or dietician. They are not recommended for children.
DEVELOPMENTAL HIP DYSPLASIA

or adolescents, people with diabetes mellitus or eating disorders, or those who have any other medical condition.

**Detrusor instability**

Inappropriate contraction of the detrusor muscle in the wall of the bladder that causes an uncontrollable release of urine even when the bladder is not sufficiently full to trigger urination. It may have various causes, including bladder inflammation, obstruction of the bladder outlet (for example, by a stone or, in men, by an enlarged prostate gland), or damage to the nerves supplying the bladder. (See also incontinence, urinary.)

**Deutschländer’s disease**

A tumour of one of the metatarsal bones in the foot.

**Development**

The process of growth and change by which an individual matures physically, mentally, emotionally, and socially. It takes place in major phases: during the first two months of pregnancy (see embryo), and, to a lesser extent, during the rest of pregnancy (see fetus); during the first five years of life (see child development); and then again during puberty and adolescence.

**Developmental delay**

A term used if a baby or young child has not acquired new skills within the expected time range. Normally, new abilities and new patterns of behaviour appear at given ages, and existing behaviour patterns change and sometimes disappear (see child development).

Delays vary in severity, and may affect the development of one or more of the following skills: hand–eye coordination, walking, listening, language, speech, or social interaction.

**Generalized delay**

A child who is late in most aspects of development usually has a generalized problem. This may be due to a severe visual or hearing impairment, limited intellectual abilities (see learning difficulties), or damage to the brain before, during, or after birth. For further information on possible causes of generalized delay, see the table above.

**Specific forms of delay**

Delay in movement and walking often has no serious cause. In some cases, however, there are specific causes; these can include muscular dystrophy and spina bifida. Delay in developing manipulative skills (the ability to pick up and use objects with the hands) is often due to lack of adequate stimulation.

Delayed speech development may have various causes. The most important is deafness, which may cause the child to be unresponsive to sound. Autism is a rare cause; in this condition, hearing is normal but the child may be unresponsive to the human voice. Another possible cause is generalized difficulty with muscle control, which may affect speech production; this may occur in children who have cerebral palsy. Damage to, or structural defects of, the speech muscles, the larynx (voicebox), or the mouth may also cause speech difficulties, as may any disorder that affects the speech area of the brain (see aphasia; dysarthria; dysphoniaspeech disorders).

Children vary enormously in the age at which they gain control of bladder and bowel function. Usually, bowel control is acquired first. Delay in bladder control is much more common than delay in bowel control. Such delays have many possible causes (see enuresis; encopresis; soiling).

**Assessment**

Delays may first be noticed by parents; if this is the case, a health visitor or doctor should be consulted promptly. Delays may also be detected during routine developmental checks with a health visitor, family doctor, or paediatrician. These checks are performed at various ages, but usually at birth, six weeks, six to eight months, 18 to 24 months, three years, and five years.

A child who shows signs of developmental delay should undergo a full assessment. This will usually include a physical examination, along with hearing tests, vision tests, and a thorough developmental assessment. The child may need to undergo further investigations, such as blood tests, to check for any genetic abnormality, or referral to a specialist such as a neurologist, speech therapist, or physiotherapist.

**Treatment**

The treatment depends on the severity and probable cause of the delay. It may include a course of speech therapy or family therapy, or provision of physical aids such as glasses or a hearing aid. Parents are often of prime importance in providing help for their child. In some cases, however, the child may also benefit from being admitted to a school or special unit that provides education for children with specific difficulties.

**Developmental hip dysplasia**

A disorder present at birth in which the head of the femur (thigh-bone) fails to fit properly into the cup-like socket in the pelvis to form a normal joint. One or both of the hips may be affected.

**Cause and incidence**

The cause of developmental hip dysplasia is not known. The condition is more common in girls, especially in babies born by breech delivery or following pregnancies in which there was an abnormally small amount of amniotic fluid surrounding the fetus.

**Treatment**

If the dislocation is detected in early infancy, splints are applied to the thigh to manoeuvre the ball of the joint into the socket and keep it in position. These splints are worn for about three months and usually correct the problem. Progress may be monitored by ultrasound scanning and X-rays. Corrective surgery may also be required.

**Outlook**

If treatment is delayed, there may be lifelong problems with walking. Without treatment, the dislocation often leads to shortening of the leg, limping, and early osteoarthritis in the joint.
deviated nasal septum
See nasal septum.

deviation, sexual
An abnormal form of sexual behaviour, most common in men, in which sexual intercourse between adults is not the final aim. Forms of sexual deviation include exhibitionism, fetishism, paedophilia, and transvestism.

Devic’s disease
A rare condition, sometimes called neuromyelitis optica, in which there is demyelination of the fibres in the optic nerves and the spinal cord. The condition begins with inflammation of the optic nerves (see optic neuritis), leading to loss of vision. There are also attacks of numbness, muscle weakness, and loss of coordination in the parts of the trunk and limbs below the diseased area of the spine. In addition, the spinal cord damage may lead to disruption of urinary and bowel control and impairment of sexual function.

dexamethasone
A corticosteroid drug prescribed as a nasal spray to relieve nasal congestion caused by allergic rhinitis (hay fever), as eye drops in the treatment of iritis (inflammation of the iris), and as eardrops in the treatment of otitis externa (outer-ear infection).

Dexamethasone is given in tablet form or by injection to treat severe asthma and other inflammatory disorders, and to reduce inflammation of the brain due to head injury, stroke, or a brain tumour. It may also be injected into an inflamed joint to relieve the symptoms of osteoarthritis.

Dexamethasone nasal spray may cause nosebleeds; eye drops may cause irritation of the eyes. Prolonged use or high doses of dexamethasone tablets may cause the adverse effects common to the corticosteroid group of drugs.

dexamfetamine
A central nervous system stimulant (see amphetamine drugs; stimulant drugs) sometimes used to treat narcolepsy (a sleep disorder). It is also used in children with attention deficit hyperactivity disorder who have not responded to treatment with methylphenidate.

Because of its stimulant properties, dexamfetamine has become a drug of abuse. Excessive use leads to anxiety and drug psychosis. With prolonged use, physical tolerance develops: the drug’s stimulant effects lessen and a higher dose must then be taken to produce the same effect. Drug dependence (a physical or mental need for the drug) also develops after repeated use.

DEXA scan
Dual-energy X-ray absorptiometry, a technique that measures bone density by passing beams of low-dose radiation through bone. DEXA scans are used to assess the severity of the bone disorder osteoporosis. (See also densitometry.)

dextran
A polysaccharide (a type of carbohydrate) consisting of branched chains of glucose units. Dextran that are formed by the action of bacteria on sucrose in the mouth produce plaque (a rough, sticky coating on the teeth), which is a major cause of tooth decay (see caries, dental).

Commercially manufactured preparations of synthetic dextran solution may be used in surgery or in emergency treatment for shock, to increase the volume of the plasma (the fluid part of the blood) in the circulation. Dextran used for this purpose are known as plasma expanders.

dextrocardia
A rare condition, which is present from birth, in which the heart is situated in, and points towards, the right-hand side of the chest instead of the left. The heart may also be malformed. Sometimes, the position of the abdominal organs is also reversed, so that the liver is on the left-hand side and the stomach is on the right. The cause of dextrocardia is not known.

No treatment is necessary unless the heart is malformed, in which case surgical correction may be performed.

dextromethorphan
A cough suppressant that is available over the counter as an ingredient in many cough remedies.

dextromoramide
An opioid analgesic drug related to opium that is used to relieve severe pain following injury or surgery and during long-term illnesses. It relieves pain quickly but has only a short duration of action. Regular use of dextromoramide can produce drug dependence.

dextropropoxyphene
A weak opioid analgesic drug that is included in some compound analgesic preparations. The drug works rapidly and relieves mild to moderate pain for about four hours. Adverse effects of this drug may include drowsiness, dizziness, nausea, and vomiting.

dextrose
Another name for glucose.

diabetes, bronze
Another name for haemochromatosis, a rare genetic disease in which excessive amounts of iron are deposited in tissues. Bronze diabetes causes a bronze skin coloration, and sufferers often develop diabetes mellitus.

diabetes insipidus
A rare condition that is characterized by excessive thirst and the passing of large quantities of dilute urine. A person with diabetes insipidus may pass between five and 20 litres of urine every 24 hours, provided that this output is matched by a sufficient intake of water. If the lost water is not replaced, dehydration may occur, leading to confusion, stupor, and coma.

Diabetes insipidus usually results from a failure of the pituitary gland to secrete ADH (antidiuretic hormone), which normally regulates the amount of water excreted in the urine. This failure may be due to a disease of the pituitary gland, or may temporarily follow brain surgery. A rare form of the disease, called nephrogenic diabetes insipidus, is due to failure of the kidneys to respond to ADH.

Diagnosis mainly involves blood and urine tests. A doctor may measure output of urine over 24 hours. He or she may also measure urine output when fluid has been withheld for several hours; an affected person will continue...
to pass a large volume of urine. The person’s response to synthetic ADH may also be tested; if the urine output remains high even after the person has taken ADH, this indicates the nephrogenic form of the disease.

Treatment of ADH-related diabetes insipidus is with desmopressin (synthetic ADH). Treatment of nephrogenic diabetes insipidus is by a low-sodium diet and thiazide diuretic drugs.

diabetes mellitus

A disorder that develops when the cells of the body do not receive enough insulin. This hormone is produced by the pancreas; it normally enables body cells to take in glucose from the blood to generate energy, and enables the liver and fat cells to take in glucose for storage. A lack of insulin in the cells may occur because the pancreas produces too little, or none at all; alternatively, it may occur because the tissues are resistant to the hormone’s effects.

TYPES, CAUSES, AND INCIDENCE

There are two main types of diabetes mellitus, both of which tend to run in families. Type 1 (insulin-dependent) diabetes usually develops suddenly in childhood or adolescence. This type of diabetes is an autoimmune disorder in which the immune system destroys insulin-secreting cells in the pancreas and insulin production ceases. Affected people may be genetically predisposed to developing the condition; the disease process may be triggered by viral infection. They must have insulin injections or they may fall into a coma and die.

Type 2 (non-insulin-dependent) diabetes tends to develop gradually, mainly in people over the age of 40. This type is becoming more common in younger people, however, and is probably linked to dieting. Although insulin is still produced, there is not enough to meet the body’s needs because the tissues become relatively resistant to its effects. Obesity and inheritance are possible contributory factors; many people who develop Type 2 diabetes are overweight, and affected people often have close relatives with the condition.
DIABETIC ARTHROPATHY

Diabetes mellitus affects more than 120 million people worldwide. Type 2 diabetes is by far the more common form of the disease. About 1 in 50 people in the UK has this type. It is three to four times more common in black people, and seven times more common in Asians. It also becomes more common with increasing age.

SYMPTOMS

Lack of insulin causes high levels of glucose to remain in the blood. This, in turn, results in a high level of glucose in the urine. This condition, termed glycosuria, causes the passage of large quantities of urine, excessive thirst, and urinary tract infections. Lack of glucose in the cells causes weight loss, hunger, and fatigue, and leads to chemical imbalances. For further information on the symptoms, see the illustrated box on the previous page.

In Type 1 diabetes, symptoms such as thirst, weight loss, and excessive urination usually develop rapidly over a few weeks. If it is not promptly diagnosed and treated at this stage, it may lead to diabetic ketoacidosis, which is a potentially fatal condition.

Type 2 diabetes may be present for months or years while causing few noticeable symptoms. It may only be diagnosed when a complication (see below), such as poor vision, is detected during a medical check-up.

COMPLICATIONS

Some complications of diabetes mellitus result from damage to capillaries (tiny blood vessels) throughout the body. These conditions include retinopathy (damage to the retina, which is the light-sensitive part of the eye) and diabetic nephropathy (kidney damage). Damage to the blood vessels supplying nerves causes diabetic neuropathy (damage to nerve fibres); this may first appear in the fingers and toes, then spread up the limbs. The loss of sensation, and poor circulation, may result in ulcers on the feet and legs. Other problems include dizziness on standing and, in men, impotence.

People with diabetes have a greater risk of developing atherosclerosis (accumulation of fatty deposits on the lining of the arteries), hypertension (high blood pressure), other cardiovascular disorders, and diabetic cataract (opacity in the lens of the eye).

DIAGNOSIS AND TREATMENT

If diabetes mellitus is suspected, a urine sample will be taken and tested for the presence of glucose. The diagnosis is confirmed by a blood test to detect abnormally high levels of glucose in the blood. If the results of this test are unclear, a glucose tolerance test may be done. The person is asked to fast for several hours, and then is given glucose; the blood and the urine are tested at 30-minute intervals to show how efficiently the body is utilizing the glucose. Tests may also be carried out to detect and assess damage to organs such as the eyes, kidneys, and heart.

Treatment aims to keep blood glucose levels as normal as possible. Dietary control is an essential element. The ideal diet for a person with diabetes resembles the sort of healthy eating plan recommended for everyone (see diabetic diet). If the person is overweight, and particularly if he or she has Type 2 diabetes, weight loss can be achieved by a reduced-calorie diet. Also, regular exercise and treatment with antidiabetic drugs may be required.

In addition to general treatment, all people with Type 1 diabetes need to have regular injections of insulin. The injections are usually self-administered two, three, or four times a day. The insulin doses need to be matched to activity levels and food intake. If the glucose/insulin balance is not maintained, hyperglycaemia (too much glucose in the blood) or hypoglycaemia (too little glucose in the blood) may develop. Careful monitoring of blood glucose levels is also an essential part of self-treatment. Pancreas transplants have been tried as a possible cure for the condition, but with little success. Research is being done on a possible treatment involving transplantation of clusters of insulin-producing cells.

Treatment of type 2 diabetes usually consists of dietary measures, weight reduction, exercise, and antidiabetic drugs, often hypoglycaemic drugs such as sulphonylureas. Some people eventually need insulin injections.

In general, careful control of blood glucose levels reduces the risk of complications or, if such problems have already developed, slows their progression. People with diabetes should have regular medical check-ups so that any complications can be detected as early as possible. Additional tests, such as measurement of glycosylated haemoglobin (which shows blood glucose levels over the previous three months) and urine tests to detect proteinuria, can improve medical control and aid early detection of problems.

OUTLOOK

With modern treatment and efficient self-monitoring, people with diabetes mellitus can usually live a normal life; however, the disease is irreversible and life expectancy is reduced.

diabetic arthropathy

Joint damage associated with diabetes mellitus. It results from the loss of protective pain sensation that can occur when peripheral nerves are damaged (see diabetic neuropathy). The condition often affects the joints in the legs; the ankle is particularly vulnerable.

Affected joints (called neuropathic joints or Charcot’s joints) tend to be swollen and deformed but painless. Treatment includes fitting a special cast to reduce swelling in the limb, and the use of supportive footwear.

diabetic cataract

An opacity in the lens of the eye (see cataract) due to diabetes mellitus. The slow-growing opacities that often appear in old age (senile cataracts) tend to develop 10–15 years earlier than usual in people who have diabetes. Occasionally, young people with poorly controlled diabetes develop juvenile cataracts, which are diffuse opacities that develop rapidly. Treatment for diabetic cataract is the same as for other forms of cataract.

diabetic coma

A life-threatening state of unconsciousness and unresponsiveness, due either to diabetic ketoacidosis or to hyperglycaemia. The latter condition may be induced either by excessive doses of oral hypoglycaemic drugs or by an inadequate intake of food.

diabetic diet

A nutritional regime designed to prevent complications of diabetes mellitus by controlling the timing and amount of energy intake, thereby minimizing the occurrence of hyperglycaemia (high blood glucose levels) or hypoglycaemia (low blood glucose levels).

People with diabetes should follow the same kind of healthy diet that is recommended for people in general (see nutrition). The diet should be rich in complex carbohydrates (such as bread and pasta) and contain less than 30 per cent fat. In addition, the energy intake (see calorie) needs to be controlled in order to maintain a healthy
body weight. People who take insulin need to coordinate their meals with the times for their insulin injections.

**diabetic ketoacidosis**
A severe, acute complication of Type 1 diabetes mellitus, a condition in which the pancreas produces too little insulin. If levels of insulin are too low, the liver generates more glucose, but the tissues are unable to take up the glucose properly and have to break down fats to obtain energy, causing the production of acidic chemicals called ketone bodies. Diabetic ketoacidosis may be the first sign that a person has insulin-dependent diabetes, or it may develop in a person known to have the condition who has taken insufficient insulin.

The features of diabetic ketoacidosis include nausea; vomiting; deep, rapid breathing; breath that smells of acetone (like nail polish remover); and confusion. The condition can progress to severe dehydration and coma.

Treatment of diabetic ketoacidosis involves giving insulin to correct the deficiency and fluids containing salts to relieve dehydration.

**diabetic maculopathy**
See maculopathy, diabetic.

**diabetic nephropathy**
Kidney damage resulting from longstanding or poorly controlled diabetes mellitus. The disorder includes damage to capillaries (tiny blood vessels) in the kidneys and hardening of the tissues. As a result, the kidneys become less able to filter the blood efficiently. Protein may escape into the urine, depleting the body's supplies (see nephrotic syndrome). In severe cases, chronic kidney failure may develop. Many affected people have hypertension (high blood pressure), which may also cause damage to the blood vessels.

People with diabetes should have regular check-ups so any kidney problems can be treated as soon as possible. Checks may include urine tests for protein, as well as kidney function tests.

**diabetic neuropathy**
Any of various types of neuropathy (disease of or damage to the nerves) that result from longstanding or poorly controlled diabetes mellitus.

The most common type of diabetic neuropathy is called peripheral sensory neuropathy. In the early stages of this disorder, intermittent pain and tingling are felt in the extremities, particularly in the feet. The pain gradually worsens until, finally, pain sensation is lost to an area. People with sensory neuropathy in the feet can develop cuts, scrapes, or blisters that they may not notice. If left untreated, serious complications may result from such injuries. Daily observation of the feet is critical.

Another form of diabetic neuropathy is damage to motor nerves (which initiate movements). This problem causes weakened muscles. The foot is particularly susceptible, and may undergo a change of appearance as a result. A further form, diabetic amyotrophy, causes painful wasting of the thigh muscles.

Autonomic neuropathies affect the nerves that regulate involuntary vital functions. Symptoms and signs include postural hypotension (low blood pressure on standing); diarrhoea at night; inability to empty the bladder completely, which may lead to urinary tract infection; and impotence. Cranial neuropathies affect nerves that supply the head and face; damage to nerves supplying the eye muscles causes impaired vision and eye pain.

**diabetic pregnancy**
Pregnancy associated with diabetes mellitus. The term "diabetic pregnancy" may refer to a pregnancy in a woman with pre-existing diabetes, or to diabetes that develops during pregnancy; in the latter case, the condition is known as gestational diabetes.

Women with established diabetes can have a normal pregnancy provided that the diabetes is well controlled. Careful control of blood glucose levels must begin well before conception. Poor control may affect the baby’s growth, and increase the risk of fetal malformations and complications during pregnancy.

In gestational diabetes, the mother does not produce enough insulin to keep blood glucose levels normal. The condition is usually detected in the second half of pregnancy, when urine tests reveal the presence of glucose. Treatment is the same as for women who are pregnant with pre-existing diabetes, or to diabetic pregnancy. The term "pregnancy with diabetes" is the traditional teaching.
There are two methods of removing wastes from the blood and excess fluid from the body when the kidneys have failed. The first, haemodialysis, may also be used as emergency treatment in some cases of poisoning or drug overdose. It makes use of an artificial kidney (or "kidney machine") and can be carried out at home. Peritoneal dialysis needs an abdominal incision, which is performed in hospital but may also be done at home.

**HOW HAEMODIALYSIS IS DONE**

1. Access to the bloodstream for dialysis is obtained by a shunt (in the short term or in an emergency) or an arteriovenous fistula, in which an artery is joined surgically to a vein.

2. A needle inserted into the shunt or fistula carries blood to the machine. The machine pumps the blood through a filter attached to its side. Once inside the filter, the blood flows on one side of a membrane, and dialysate fluid flows on the other. Waste products and water pass from the blood, across the membrane, and into the dialysate fluid. The filtered blood returns from the machine to the body via another needle inserted into the shunt or fistula.

**WHY IT IS DONE**

In people with damaged kidneys, the process of maintaining the balance of electrolytes and water, and of excreting waste products, may fail, causing harmful, even life-threatening, effects. Dialysis can take over the function of the kidneys until they start working normally again. Or dialysis can function for the kidneys for the rest of a seriously affected person’s life if a kidney transplant is not performed.

**Diseased kidney**

The kidney at left was removed from a person with adult polycystic kidney disease – one of many disorders that may damage kidney function to the extent that dialysis is needed.

**HOW PERITONEAL DIALYSIS IS DONE**

1. A small abdominal incision is made, and a catheter is inserted into the peritoneal cavity. A bag of dialysate is attached to the catheter; the fluid passes into the cavity, where it is left for several hours. Used fluid is then drained out of the abdomen.

2. Waste products, and excess water from the blood vessels lining the peritoneal cavity, seep through the peritoneal membrane into the cavity and mix with the dialysate. The fluid is allowed to drain out (by the release of a clamp) through the catheter and into the empty dialysate bag.

3. The bag is discarded and replaced with a bag containing fresh dialysate. The procedure, which takes about an hour, can be performed during the day or overnight.
have pre-existing diabetes mellitus. Gestational diabetes disappears after the birth, but it is associated with an increased risk of the woman developing Type 2 diabetes in later life.

**diabetic retinopathy**
See retinopathy.

**diagnosis**
The process of identifying or finding out the nature of a disorder. The doctor listens to a patient’s account of his or her illness, and may carry out a physical examination. If further information is needed, tests or imaging procedures may be ordered after a provisional diagnosis has been formed (see *Steps in diagnosing a condition* box, previous page).

**diagnostic ultrasound**
The use of high-frequency sound waves to form images of internal organs and so help doctors to make diagnoses (see ultrasound scanning). Certain forms of ultrasound scanning are used to form moving images, such as images of the flow of blood through the heart (see Doppler echocardiography).

**dialysis**
A filtering technique used to remove waste products from the blood and excess fluid from the body as a treatment for kidney failure.

**WHY IT IS DONE**
Each day, the kidneys normally filter about 1,500 litres of blood. They help to maintain the fluid and electrolyte balance of the body. Important minerals and nutrients, such as potassium, sodium, calcium, amino acids, glucose, and water are reabsorbed into the blood. Urea, excess minerals, toxins, and drugs are excreted in the urine.

Dialysis is used to perform this function in people whose kidneys have been damaged due to acute or chronic kidney failure. Without dialysis, wastes accumulate in the blood and the electrolyte levels become unbalanced; this may be life-threatening. In chronic kidney failure, patients may need to have dialysis several times a week for the rest of their lives or until they can be given a kidney transplant. In acute kidney failure, dialysis is carried out more intensively until the kidneys are working normally.

**HOW IT IS DONE**
There are two methods: haemodialysis and peritoneal dialysis. In both procedures, excess water and wastes in the blood pass across a membrane into a solution called a dialysate, which is then discarded.

Haemodialysis filters out wastes by passing blood through an artificial kidney machine. The process needs to be performed three or four times a week, and each session lasts two to six hours. In peritoneal dialysis, the abdominal cavity is filled with dialysate, which is changed regularly, and the peritoneum (the membrane lining the abdominal cavity) acts as a natural filter. The procedure is often carried out overnight or continuously during the day and night.

**RISKS**
Both types of dialysis carry the risk of upsetting body chemistry and fluid balance, which can cause complications. In addition, peritoneal dialysis carries a risk of infection in the peritoneum.

**diamorphine**
A synthetic, opioid analgesic similar to morphine; diamorphine is another name for heroin. It is used to relieve severe pain and to relieve distress in acute heart failure. Diamorphine carries the risk of dependence. It may cause nausea, vomiting, and constipation. (See also heroin abuse.)

**Dianette**
A brand name for a combination of cyproterone acetate with ethinylestradiol (synthetic sex hormones). Dianette may be used to treat severe acne or hirsutism (excessive hairiness) in women.

**diaphragmatic hernia**
The protrusion of an abdominal structure through the diaphragm muscle into the thorax (chest cavity). The most common form of this problem is a hiatus hernia, in which part of the stomach protrudes through the space in the diaphragm that is normally occupied by the oesophagus.

**diaphragm, contraceptive**
A female barrier method of contraception in the form of a hemispherical dome of thin rubber with a metal spring in the rim. The diaphragm is inserted into the vagina and positioned over the cervix. (See also contraception, barrier methods.)

**diaphragm muscle**
The dome-shaped sheet of muscle that separates the chest from the abdomen. The diaphragm is attached to the spine,
ribs, and sternum (breastbone). It has openings for the oesophagus and major nerves and blood vessels.

The diaphragm plays an important role in breathing. During inhalation, its muscle fibres contract, causing it to move downwards and drawing air into the lungs. During exhalation, the diaphragm muscle relaxes and it moves upwards, causing air to leave the lungs. (See also breathing.)

diaphysis
The shaft, or central portion, of a long bone, such as the femur (thigh-bone). During bone formation, the epiphysis (end of the long bone) develops independently from the diaphysis, as they are initially separated by a mass of cartilage known as the epiphyseal plate. The diaphysis and epiphysis eventually fuse to form a complete bone.

diarrhoea
An increase in the fluidity, frequency, or volume of bowel movements, as compared to the usual pattern for a particular individual. Diarrhoea may be acute or chronic. The condition can be very serious in infants and in elderly people because of the risk of severe, potentially fatal, dehydration.

CAUSES
Acute diarrhoea is usually a result of consuming food or water contaminated with certain bacteria or viruses (see food poisoning). Infective gastroenteritis also causes diarrhoea and may be acquired as a result of droplet infection. Other causes of acute diarrhoea include anxiety and, less commonly, amoebiasis, shigellosis, typhoid fever and paratyphoid fever, drug toxicity, food allergy, and food intolerance.

Chronic diarrhoea generally takes the form of repeated attacks of acute diarrhoea. Such a pattern may be the result of an intestinal disorder such as Crohn’s disease, ulcerative colitis, cancer of the colon (see colon, cancer of), or irritable bowel syndrome. Diarrhoea that recurs, persists for more than a week, or is accompanied by blood requires medical investigation.

TREATMENT
The water and electrolytes (salts) lost during a severe attack of diarrhoea need to be replaced to prevent dehydration. Ready-prepared powders of electrolyte mixtures can be bought from chemists (see rehydration therapy). Antidiarrhoeal drugs, such as diphenoxylate and loperamide may help if the diarrhoea is disabling. They should not, however, be used to treat attacks of diarrhoea in children.

diastole
The period in the heartbeat cycle when the heart muscle is at rest; it alternates with systole, the period of muscular contraction. (See also cardiac cycle.)

diastolic pressure
The lowest level of blood pressure measured in the main arteries. Diastolic pressure is the pressure between heartbeats, when the ventricles (the lower chambers of the heart) are relaxed and filling with blood. Systolic pressure, the highest level of blood pressure in the main arteries, occurs when the ventricles of the heart contract.

The normal range of blood pressure varies with age and between individuals, but a young adult usually has a diastolic pressure of about 80 mmHg (mm of mercury) and a systolic pressure of about 120 mmHg. A persistently high diastolic pressure occurs in most cases of hypertension.

diathermy
The production of heat in a part of the body using high-frequency electric currents or microwaves. Diathermy can be used to increase blood flow and to reduce some types of deep-seated pain, for example in rheumatic or arthritic conditions. Diathermy can also be used to destroy tumours and diseased areas of tissue without causing bleeding. A diathermy knife is used by surgeons to coagulate bleeding vessels or to separate tissues without causing them to bleed (see electrocoagulation).

diathermy, short-wave
See short-wave diathermy.

diathesis
A predisposition towards certain disorders. For example, a bleeding diathesis is present when a bleeding disorder (such as haemophilia) makes a person susceptible to prolonged bleeding after an injury. A diathesis may be inherited or it may be acquired as a result of an illness or an injury.

diazepam
One of the benzodiazepine drugs, used mainly for the short-term treatment of anxiety and insomnia. Diazepam is also prescribed as a muscle-relaxant drug, as an anticonvulsant drug in the emergency treatment of epilepsy, and to treat alcohol withdrawal symptoms in people who are dependent on alcohol. It may also be administered intravenously in order to produce sedation in people undergoing certain medical procedures, such as endoscopy.

Diazepam may cause drowsiness, dizziness, and confusion; therefore, driving and hazardous work should be avoided while taking the drug. Alcohol increases the sedative effects of the drug, and should not be consumed while diazepam is being used.

Like other benzodiazepines, diazepam can be habit-forming if it is taken regularly, and its effects diminish with prolonged use. Individuals who have been taking diazepam regularly for more than two weeks should never stop their treatment suddenly; instead, they should gradually decrease the dose of the drug, under medical supervision, in order to avoid withdrawal symptoms (such as anxiety, sweating, or, rarely, after large doses, seizures).

DIC
See disseminated intravascular coagulation.

diclofenac
A nonsteroidal anti-inflammatory drug (NSAID) that is used to relieve pain and stiffness in arthritis and to hasten recovery following injury to muscles or ligaments. Possible adverse effects of the drug include nausea, abdominal pain, and peptic ulcer.

Didronel
A brand name for disodium etidronate (see etidronate, disodium), which is a bisphosphonate drug. Didronel is used to treat bone disorders such as Paget’s disease and osteoporosis.

diet
See nutrition.

diet and disease
A variety of diseases are linked with diet. Diseases due to a deficiency of nutrients are a major problem in poor countries. In children, starvation or malnutrition may result in marasmus or kwashiorkor, while vitamin deficiencies may cause rickets or keratomalacia (a condition that causes blindness). Vitamin deficiencies may lead to beriberi, pellagra, or scurvy.
GOOD DIETARY HABITS

- Eat fresh rather than preserved, packaged, or convenience foods.
- Eat plenty of vegetables and at least five portions of fruit every day. When raw or lightly cooked, they retain a higher nutritional value.
- Eat whole-grain products, including wholemeal bread.
- Cut down on sugar and salt in all foods.
- When choosing filling foods, eat potatoes in their skins, pasta, or rice.
- Cut down consumption of red meat; instead, eat fish, poultry, and pulses.
- Keep the fat content of your diet low and use polyunsaturated fats and vegetable oils rather than saturated fats.
- Eat whole-grain products, including wholemeal bread.
- Eat plenty of vegetables and at least five portions of fruit every day. When raw or lightly cooked, they retain a higher nutritional value.
- Many people’s diets contain too few natural vitamins; to remedy this problem, it is better to eat vitamin-rich foods than to take vitamin supplements. Women who are planning a pregnancy need to increase their intake of folic acid in order to reduce the risk of neural tube defects in the baby.
- Many illnesses are commonly ascribed to food allergy, but it is only rarely that a definite link is proved. Nut allergies, which may cause the life-threatening reaction anaphylaxis, and coeliac disease (a reaction to the protein gluten, which is found in wheat and other cereals) are examples of genuine food allergies. (See also nutritional disorders.)
- A form of amenorrhoea (cessation of menstruation) caused by major weight loss, although not necessarily by a lack of food. In some cases, the weight loss is deliberate and severe (see anorexia nervosa). Absence of menstrual periods occurs because the loss of body fat disrupts the levels of the female sex hormone oestrogen.
- The application of nutritional science to maintain or restore health. Dietetics involves not only a knowledge of the composition of foods, the effects of cooking and processing various foods, and dietary requirements, but also of psychological aspects of diet, such as eating habits (see nutrition).
**DIGESTION**

**THE DIGESTIVE PROCESS**

Digestion starts when food enters the mouth. It continues as the food is propelled through the digestive tract by waves of muscular contractions (peristalsis). The digestive process also involves various organs (the salivary glands, liver, gallbladder, and pancreas), which produce enzymes and acids that help to break down the food.

**ACTION OF DIGESTIVE AGENTS**

<table>
<thead>
<tr>
<th>Agent or enzyme</th>
<th>Digestive action</th>

</tr>
<tr>
<td>Hydrochloric acid (stomach), Pepsin (stomach), Trypsin (pancreas), Peptidase (small intestine)</td>
<td>Assist in the breakdown of proteins into polypeptides, peptides, and amino acids</td>
</tr>
<tr>
<td>Lipase (pancreas) Bile salts and acids (liver – stored in the gallbladder)</td>
<td>Break down fats into glycerol and fatty acids</td>
</tr>
</tbody>
</table>

**TIME SCALE**

The approximate period food spends in each part of the digestive system is shown below.

- **Mouth**: 1 minute
- **Oesophagus**: 10 seconds
- **Stomach**: 2–4 hours
- **Small intestine**: 1–6 hours
- **Large intestine**: 10 hours–several days
- **Rectum**: Undigested matter enters this final part of the large intestine and is expelled.

**Swallowing**

In the mouth, food is cut and ground by the teeth and mixed with saliva, which softens it and breaks down certain carbohydrates. After swallowing, the food mass (bolus) enters the oesophagus.
and there may be evidence of failure to thrive (restricted growth). In addition, heart abnormalities and hypocalcaemia (abnormally low levels of calcium in the blood) may occur.

Transplants of thymus tissue, or bone marrow transplants, may be successful in treating the immunodeficiency.

digestion
The process by which food is broken down into smaller components that can be transported and used by the body. (See also digestive system).

digestive system
The group of organs responsible for digestion. The digestive system consists of the digestive tract (also known as the alimentary tract or canal) and various associated organs.

STRUCTURE
The mouth, pharynx (throat), oesophagus (gullet), stomach, intestines, and anus make up the digestive tract. The intestines consist of the small intestine (comprising the duodenum, jejunum, and ileum) and the large intestine (comprising the caecum, colon, and rectum). Associated organs, such as the salivary glands, the liver, and pancreas, secrete digestive juices that help break down food as it goes through the tract.

FUNCTION
Food and the products of digestion are moved from the throat to the rectum by peristalsis (waves of muscular contractions of the intestinal wall).

Food is broken down into simpler substances before being absorbed into the bloodstream. Physical breakdown is performed by the teeth, which cut and chew, and the stomach, which churns the food. Chemical breakdown of food is performed by the action of enzymes (biological catalysts), acids, and salts. Carbohydrates are broken down into simple sugars. Proteins are broken down into polypeptides, peptides, and amino acids. Fats are broken down into glycerol, glycerides, and fatty acids.

In the mouth, saliva lubricates food and contains enzymes that begin to break down carbohydrates. The tongue moulds food into balls (called bolus) for easy swallowing. The food then passes into the pharynx, from where it is pushed into the oesophagus and is then squeezed down into the stomach. Once in the stomach, the food is mixed with hydrochloric acid and pepsin. These substances, produced by the stomach lining, help to break down proteins. When the food has been converted to a semi-liquid consistency, it passes into the duodenum, where bile salts and acids (produced by the liver) help to break down the fats it contains. Digestive juices released by the pancreas into the duodenum contain enzymes that further break down food.

Breakdown concludes in the small intestine, carried out by enzymes that are produced by glands in the intestinal lining. Nutrients are absorbed in the small intestine through tiny projections from the intestinal wall, called villi. The food residue enters the large intestine, where much of the water it contains is absorbed by the lining of the colon. Undigested matter is expelled via the rectum and anus as faeces.

digit
A division, such as a finger or toe, that is located at the end of a limb.

digitalis drugs
A group of drugs that are extracted from plants belonging to the foxglove family. They are used to treat heart conditions, most commonly atrial fibrillation (irregular, rapid beating of the upper chambers of the heart). Those most frequently used are digoxin and digitoxin.

digital subtraction angiography
See angiography.

digitoxin
A long-acting digitalis drug that is used to treat heart failure and certain types of arrhythmia (irregular heartbeat).

digoxin
The most widely used of the digitalis drugs. Digoxin is used in the treatment of heart failure and certain types of arrhythmia (irregular heartbeat), such as atrial fibrillation.

Blood tests are sometimes needed to ensure the correct digoxin dose, especially in patients with kidney disease. An excessive dose may cause headache, loss of appetite, nausea and vomiting, and visual disturbances. Digoxin occasionally disrupts the normal heartbeat, causing heart block.

Di Guglielmo’s disease
A form of acute myeloblastic leukaemia (see leukaemia, acute) characterized by excessive numbers of red blood cells in the bone marrow and bloodstream.

dihydrocodeine
A type of opioid analgesic drug (pain-killer). Side effects of dihydrocodeine include nausea and vomiting.

dilatation
A condition in which a body cavity, passage, or opening is enlarged or stretched due to normal physiological processes (such as childbirth) or because of the effects of disease.

The term “dilatation” also refers to medical procedures for achieving such enlargement, as in dilatation and curettage (see D and C).

dilatation and curettage
See D and C.

dilation
A term that is sometimes used as an alternative to dilatation.

dilator
An instrument used for stretching and enlarging a narrowed body cavity, passage, or opening, for example to enable an investigative procedure or surgery.

diltiazem
A calcium channel blocker drug that is used in the treatment of hypertension (high blood pressure) and angina pectoris (chest pain due to impaired blood supply to the heart muscle). Side effects of diltiazem may include headaches, loss of appetite, nausea, constipation, and swollen ankles.

dimeticone
A silicone-based substance, also known as simeticone, that is used in barrier creams and as an antifoaming agent in antacid preparations.

dioptrre
A unit of the power of refraction (the “strength”) of a lens; the greater the power, the stronger the lens. Lenses that cause parallel light rays to converge have a positive dioptric number and are used to correct longsightedness (see hypermetropia). Those that cause light rays to diverge have a negative number and are used to correct shortsightedness (see myopia).

dioxin
The name of a highly toxic group of chemicals. Dioxins are contaminants of some defoliant weedkillers (see defoliator poisoning; Agent Orange).
**Diphenhydramine**

An antihistamine drug that is used to treat allergic disorders such as *urticaria* (nettle rash) and allergic *rhinitis* (hay fever). Diphenhydramine is also used for the relief of temporary sleep disturbance, and is an ingredient in some cough remedies. It can cause drowsiness, dry mouth, and blurred vision.

**diphenoxylate**

An antidiarrhoeal drug that is chemically related to the opioid analgesic drugs (painkillers). Diphenoxylate lessens the contractions of the muscles in the walls of the intestines, thereby reducing the frequency of bowel movements.

**Diphtheria**

A bacterial infection that causes a sore throat, fever, and sometimes serious or even fatal complications. Diphtheria is caused by the bacillus *Corynebacterium diphtheriae*. The disease is now rare in developed countries as a result of mass immunization. In the UK, the vaccine is given at 2, 3, and 4 months, 3–5 years, and 13–18 years of age.

**Symptoms**

The infection may begin in the throat or in the skin. In the throat, multiplication of bacteria causes the formation of a membrane that may cover the tonsils and spread up over the palate or down to the larynx (voicebox) and the trachea (windpipe), causing breathing difficulty and a husky voice. Other symptoms include enlarged lymph nodes in the neck, an increased heart rate, and mild fever. If infection is confined to the skin, the bacteria may produce a yellowish lesion covered by a hard membrane.

Life-threatening symptoms occur only in people who are not immune to the disease. They are caused by a toxin that is released by the bacteria and affects the heart and nervous system. Occasionally, a victim collapses and dies within a day of developing throat symptoms. More often, the victim is recovering from diphtheria when heart failure or paralysis of the throat or limbs develops. These complications can occur up to seven weeks after the onset of infection in the throat.

**Treatment**

Diphtheria is treated with antibiotics; in addition, an antitoxin is given to neutralize the bacterial toxin. If severe breathing difficulties develop, a tracheostomy (the surgical introduction of a breathing tube into the windpipe) may also be necessary.

**Diplegia**

Paralysis affecting both sides of the body (both legs and, to a lesser extent, both arms). (See also spastic diplegia.)

**Diplopia**

The medical term that is used to describe double vision.

**Dipsomania**

A form of alcohol dependence in which periods of excessive drinking and craving for drink alternate with periods of relative sobriety.

**Dipyridamole**

A drug that reduces the stickiness of platelets in the blood and thereby helps to prevent the formation of abnormal blood clots within arteries. Dipyridamole may be used with aspirin or warfarin to prevent the formation of blood clots following stroke or transient ischaemic attack or in people who have artificial heart valves.

Possible adverse effects may include headache, flushing, and dizziness.

**Disability**

A loss or impairment of normal functioning or activity as the result of a physical or mental impediment. (See also handicap; rehabilitation.)

**Disaccharide**

A carbohydrate comprising two linked monosaccharide units. Lactose, maltose, and sucrose are all disaccharides.

**Discectomy**

A procedure in which part or all of a damaged intervertebral disc (see disc, intervertebral) is surgically removed. Discectomy relieves the symptoms of disc prolapse (in which an intervertebral disc ruptures and part of its pulpy core protrudes) by relieving the pressure that the protruding tissue places on nerves or nerve roots.

**Discharge**

A visible emission of fluid from an orifice or a break in the skin (such as a wound or burst boil). A discharge may be a normal occurrence, as in some types of vaginal discharge, but it could also be due to an infection or to inflammation, as occurs, for example, in rhinitis (inflammation of the lining of the nasal passages), urethritis (infection of the urethra), or in proctitis (infection of the rectum).

**Disciformis, keratitis**

A form of keratitis (inflammation of the cornea at the front of the eye) in which a disc-like opacity forms in the corneal tissue, usually as an immune response to a viral infection.

**Disc, intervertebral**

One of the flat, circular, platelike structures containing cartilage that line the joints between adjacent vertebrae (bones) in the spine. Each intervertebral disc is composed of a fibrous outer layer and a soft, gelatinous core. The discs act as shock absorbers to cushion the vertebrae during movements of the spine. With increasing age, intervertebral discs become less supple and more susceptible to damage from injury; one of the most common problems is disc prolapse (“slipped” disc).

**Disclaiming agents**

Dyes that make the plaque deposits on teeth more visible so that they can be seen and removed.

**Discoid lupus erythematosus**

A form of the chronic autoimmune disorder lupus erythematosus that is confined to the skin. It causes a red, itchy, scaly rash to appear, particularly on the face and scalp, behind the ears, and on any parts of the body that are exposed to sunlight. The disorder most commonly occurs in women between the ages of 25 and 45, and tends to run in families. Over a period of several years, discoid lupus erythematosus may subside and recur repeatedly with different degrees of severity. Diagnosis is by a skin biopsy, and treatment is with topical corticosteroid drugs or drugs such as hydroxychloroquine.

**Discoloured teeth**

Teeth vary in colour from individual to individual and, in general, secondary teeth are darker in colour than primary teeth. In addition, teeth often get darker with age. The term discoloured teeth, however, refers to teeth that are abnormally coloured or stained.

**Extrinsic stains**

Extrinsic stains (those found on the tooth’s surface) are common. They are usually easily removed by polishing and can be prevented by regular tooth cleaning. Smoking tobacco produces a brownish-black deposit on the teeth. Pigment-producing bacteria can leave a visible, usually green, line along the teeth.
teeth, especially in children. Some dyes in foodstuffs can cause yellowing; dark brown spots may be due to areas of thinned enamel stained by foods. Some bacteria produce an orange-red stain. Stains may also follow the use of drugs containing metallic salts.

**INTRINSIC STAINS**

Intrinsic stains (within the tooth's substance) are permanent, but they can be reduced by bleaching. Causes include the death of the pulp inside the tooth or the removal of the pulp during root canal treatment. The antibiotic drug tetracycline can be absorbed by developing teeth, and may cause yellowing of the teeth if given to children.

Mottling of the tooth enamel occurs if excessive amounts of fluoride are consumed during development of the enamel (see fluorosis). Hepatitis (liver disease) during infancy may lead to discoloration of the primary teeth. The teeth of children with congenital malformation of the bile ducts may be similarly affected.

**TREATMENT**

Many stains can be covered or diminished with whitening toothpastes or with cosmetic dental procedures such as bonding and bleaching.

**disc, optic**

See optic disc.

**disc prolapse**

A common disorder of the spine, in which one of the pads between the vertebrae (see disc, intervertebral) ruptures and part of its pulpy core protrudes. Commonly known as a slipped disc, it causes painful and at times disabling pressure on a nerve root or, less commonly, on the spinal cord. The lower back is most commonly affected, but disc prolapse can affect any of the vertebrae, including those in the neck.

**CAUSES**

A prolapsed disc may sometimes be caused by a sudden strenuous action (such as lifting a heavy weight), but it usually develops gradually, due to degeneration of the discs with age.

**SYMPTOMS**

Symptoms depend on the location of the affected disc. If the sciatic nerve root is compressed, it causes sciatica, which may be accompanied by numbness and tingling, and, eventually, by weakness in the muscles of the leg. A prolapsed disc in the neck causes neck pain and stiffness and weakness in the arm and hand.

**TREATMENT**

The symptoms of disc prolapse often improve with time, as the swelling around the protruding disc tissue clears.

---

**PHYSICAL AIDS FOR THE DISABLED**

A variety of specially designed or adapted articles are available to help disabled people carry out everyday activities. Such aids include prostheses, supports, and mobility aids to improve disabled people's general functioning, as well as items designed to help them perform specific tasks more easily.

Devices that help vision, hearing, and movement improve the ability of disabled people to cope with all aspects of daily life. Such devices include walking frames, glasses, hearing-aids, artificial limbs, corsets, and wheelchairs. For people with very severe conditions, ventilators, home dialysis, and artificial feeding devices are used to sustain life.

There are various household aids available that can help people to cook, feed themselves, wash, dress, use the toilet, and get in and out of beds and chairs. Specially designed furniture and other devices can help disabled parents to care for their children. Sexual aids can facilitate an active sex life.

<table>

</tbody>
</table>
A prolapsed disc in the lower back causes low back pain and, if a sciatic nerve root is compressed, sciatica (pain running down the back of the leg from the buttock to the ankle), sometimes accompanied by numbness and tingling. Low back pain and sciatica are usually aggravated by coughing, sneezing, bending, and sitting for long periods. Prolonged pressure on the sciatic nerve can lead to weakness in the muscles of the leg.

A prolapsed disc in the neck causes neck pain and stiffness. If the disc compresses the root of a nerve that supplies the arm, there will be tingling and weakness in that arm and hand.

In rare cases, pressure is exerted on the spinal cord itself, sometimes leading to paralysis of the legs and loss of bladder or bowel control.

Possible side effects depend on the drug taken. They include diarrhoea, rash, anaemia (a reduced level of the oxygen-carrying pigment haemoglobin in the blood), leukopenia (a low white blood cell count), and increased susceptibility to infection. Regular blood
tests and urine tests (see urinalysis) are needed during treatment to monitor the effects of DMARDs on the bone marrow, kidneys, and liver.

disinfectants
Substances that kill microorganisms and thus prevent infection. The term is usually applied to strong chemicals that are used to decontaminate objects, such as items of medical equipment.

dislocation, joint
Complete displacement of the two bones in a joint so that they are no longer in contact, usually as a result of injury. (Displacement that leaves the bones in partial contact is called subluxation.) It is usually accompanied by tearing of the joint ligaments and damage to the membrane encasing the joint.

SYMPTOMS AND COMPLICATIONS
Dislocation restricts or prevents the movement of the joint; it is usually very painful. The affected joint looks misshapen and swells. Injuries that are severe enough to cause dislocation often also cause fractures. In some cases, dislocation is followed by complications such as paralysis.

TREATMENT
The joint may be X-rayed to confirm dislocation and check for fracture. The bones are then manipulated back into their proper position, or an operation is performed to reset them. The bones are then immobilized in a splint or cast to allow healing to take place.

disodium etidronate
See etidronate disodium.

disopyramide
An antiarrhythmic drug that is used to treat an abnormally rapid heartbeat, as may occur after a myocardial infarction (heart attack). It reduces the force of heart muscle contraction. As a result, it may aggravate pre-existing heart failure. Other possible side effects include dry mouth and constipation.

disorder
Any abnormality of physical or mental function.

disorientation
Confusion as to time, place, or personal identity. Speech and behaviour tend to be muddled, and the affected person often cannot answer questions about time, date, present location, name, or address. Disorientation is usually due to a head injury, intoxication, or a chronic brain disorder, such as dementia. It may occasionally be due to somatization disorder (a psychological illness). (See also confusion; delirium.)

dispense
To prepare and distribute medicines to a patient according to the details on a doctor’s prescription.

displacement
The transference of feelings from one object or person to another. Displacement is usually performed consciously to obtain emotional relief in a manner that will not cause harm to oneself or to another person. Some psychotherapists believe that displacement is an unconscious defence mechanism.

dissecting aneurysm
An aneurysm (ballooning of an artery) that usually affects the first part of the aorta. It is caused by a tear in the inner layer of the arterial wall, which results in the inner layer peeling away from the outer layer. This results in blood collecting in the space between the inner and outer layers.

A dissecting aneurysm may rupture or may compress the blood vessels leaving the aorta, producing infarction (localized tissue death due to lack of blood supply) in the organs supplied by them. The patient will suffer from severe chest pain that often spreads to the back or the abdomen. Surgical repair may help relieve the symptoms.

dissection
Cutting of body tissues during surgery or for the purpose of anatomical study.

dissection
Cutting of body tissues during surgery or for the purpose of anatomical study.

disseminated intravascular coagulation (DIC)
A type of bleeding disorder in which abnormal clotting of blood leads to a depletion of coagulation factors in the blood; the consequence may be severe and spontaneous bleeding.

disseminated lupus erythematosis
An alternative name for systemic lupus erythematosus.

disseminated tuberculosis
A state in which the infectious disease tuberculosis has spread from the site of the original infection to affect several other parts of the body, either via the lymphatic system or in the bloodstream (see miliary tuberculosis).

dissociative disorders
A group of psychological conditions in which a particular mental function becomes cut off from the rest of the mind. Examples of dissociative disorders include hysterical amnesia (see hysteria), fugue, multiple personality disorder, and depersonalization. (See also conversion disorder.)

dissociative reaction
A psychological defence mechanism in which a person views unpleasant ideas or events, such as being assaulted, in an unusually detached way in order to protect himself or herself from overwhelming feelings such as fear. In more severe cases, certain mental processes are split off from the rest of a person’s mental activity and may function independently (see dissociative disorders).

dissonance
A term that is used in social psychology to describe a state that arises when an individual has minimal awareness of any discord, disagreement, or conflict within himself or herself. (See also cognitive dissonance.)

distal
A term describing a part of the body that is further away from another part with respect to a central point of reference, such as the trunk. For example, the fingers are distal to the arm. The opposite of distal is proximal.

Distalgesic
A brand name for co-proxamol, an analgesic drug containing paracetamol and the weak opioid dextropropoxyphene.

disulfiram
A drug that acts as a deterrent to drinking alcohol. It is prescribed for people who request help in overcoming alcohol dependence. Treatment with the drug is usually combined with a counselling programme.

Disulfiram causes a buildup of acetaldehyde in the body, causing flushing, headache, nausea, dizziness, and palpitations. Symptoms may start within 10 minutes of drinking alcohol and can last for several hours. Occasionally, large amounts of alcohol taken during treatment can cause unconsciousness.
dithranol
A drug that is used in the treatment of the skin condition psoriasis. Dithranol is prescribed as an ointment, paste, or cream and works by slowing the rate at which skin cells multiply. This effect can be boosted by ultraviolet light treatment (see phototherapy). Dithranol can cause skin inflammation.

diuretic drugs
Drugs that help to remove excess water from the body by increasing the amount that is lost as urine. Diuretic drugs are used in the treatment of a variety of disorders, including hypertension (high blood pressure), heart failure, the eye condition glaucoma, nephrotic syndrome (a kidney disorder), and cirrhosis of the liver.

TYPES
There are various types of diuretic drug, which differ markedly in their speed and mode of action. Thiazide diuretics cause a moderate increase in urine production. Loop diuretics are fast-acting, powerful drugs that are often used as an emergency treatment for heart failure. Potassium-sparing diuretics are used along with thiazide and loop diuretics, both of which may cause the body to lose too much potassium. Carbonic anhydrase inhibitors block the action of the enzyme carbonic anhydrase, which affects the amount of bicarbonate ions in the blood; these drugs increase urine output moderately but are effective only for short periods of time. Osmotic diuretics are used to maintain urine output following serious injury or major surgery.

POSSIBLE ADVERSE EFFECTS
Diuretics may cause chemical imbalances in the blood. The most common is hypokalaemia (low blood levels of potassium). This is usually treated with potassium supplements or potassium-sparing diuretic drugs. A diet rich in potassium may also be helpful. Some diuretics raise the blood level of uric acid, which increases the risk of gout. Certain diuretic drugs increase the blood glucose level, which may worsen diabetes mellitus.

**HOW DIURETICS WORK**

The normal filtration process of the kidneys (which takes place in the tubules) removes water, salts (mainly potassium and sodium), and waste products from the bloodstream. Most of the salts and water are returned to the bloodstream, but certain amounts are expelled from the body together with the waste products in the urine.

Diuretics interfere with this normal kidney action. Osmotic, loop, and thiazide diuretics reduce the amount of sodium and water taken back into the blood, thus increasing the volume of urine. Modifying filtration in this way reduces the blood's water content. Less water in the blood causes excess water in the tissues to be expelled in urine.

**DITHRANOL**

**diurnal rhythms**
A biological pattern that is based on a daily cycle; also called circadian rhythms. (See also biorhythms.)

**diverticula**
Small sacs or pouches that protrude externally from the wall of a hollow organ (such as the colon). They are thought to be caused by pressure forcing the lining of the organ though areas of weakness in the wall. Their presence in the walls of the intestines is characteristic of diverticular disease.

**diverticular disease**
The presence of small protruding sacs or pouches called diverticula in the intestinal wall, and the symptoms or complications caused by them. The term diverticulosis signifies the presence of diverticula in the intestine. Diverticulitis is a complication produced by inflammation in one or more diverticula.

**diverticulitis**
Inflammation of diverticula (abnormal pouches) in the wall of the intestine, particularly in the colon. Diverticulitis is a form of diverticular disease and a complication of diverticulosis.

**SYMPTOMS AND COMPLICATIONS**
The symptoms include fever, abdominal pain, vomiting, and rigidity of the abdomen. Intestinal haemorrhage may cause bleeding from the rectum.

Diverticula may perforate, or abscesses may form in the tissue around the colon, leading to peritonitis (inflammation of the lining of the abdomen). Other complications include intestinal bleeding, narrowing in the intestine, or a fistula (an abnormal channel between one part of the intestine and another).

**TREATMENT**
Diverticulitis usually subsides with bed rest and antibiotics. In severe cases, a liquid diet or intravenous infusion may be required. Surgery may be needed, in which the diseased section of the intestine is removed and the remaining sections are then joined back together. Some patients are given a temporary colostomy (an operation in which part of the colon is attached to the abdominal wall to form an opening for the discharge of faeces).

**diverticulosis**
A form of diverticular disease in which diverticula (abnormal pouches) exist in the wall of the intestine, particularly in
the colon. Complications of diverticulosis may include intestinal bleeding and diverticulitis. The cause is believed to be a lack of fibre in the diet (see fibre, dietary). Diverticulosis is very rare in developing countries, where high-fibre foods make up much of the diet.

SYMPTOMS
Symptoms occur in only a minority of people who have diverticulosis. They usually result from spasm or cramp of the intestinal muscle near diverticula. Many patients have symptoms similar to those of irritable bowel syndrome, including abdominal pain, a bloated sensation, and changes in bowel habits. In severe cases of diverticulosis, intestinal haemorrhage can lead to bleeding from the rectum.

TREATMENT
In people with cramps, a high-fibre diet, fibre supplements, and antispasmodic drugs may relieve the symptoms. A high-fibre diet also reduces the incidence of complications. Bleeding from diverticula usually subsides without treatment, but surgery is an option.

diving medicine
See scuba-diving medicine; decompression sickness.

Dixarit
A brand name for clonidine, an antihypertensive drug that is also used in the treatment of migraine and, in menopausal women, hot flushes.

dizziness
A sensation of unsteadiness and light-headedness. Dizziness may be a mild, brief symptom that occurs by itself, or it may be part of a more severe, prolonged attack of vertigo (a condition typified by a spinning sensation) with nausea, vomiting, sweating, or fainting.

CAUSES
Most attacks are harmless and are due to a fall in the pressure of blood to the brain. This can occur when getting up quickly from a sitting or lying position (called postural hypotension). Similar symptoms may result from a transient ischaemic attack, in which there is a temporary, partial blockage in the arteries that supply the brain.

Other possible causes include tiredness, stress, fever, anaemia, heart block (impairment of electrical activity in the heart muscle), hypoglycaemia (low blood sugar levels), and subdural haemorrhage (bleeding between the outer two membranes that cover the brain).

Dizziness as part of vertigo is usually due to a disorder of the inner ear, the acoustic nerve, or the brainstem. The principal disorders of the inner ear that can cause dizziness and vertigo are labyrinthitis and Ménière’s disease. Disorders of the acoustic nerve, such as acoustic neuroma, are rare causes of dizziness and vertigo. Brainstem disorders that can cause dizziness and vertigo include a type of migraine, brain tumours, and vertebrobasilar insufficiency.

TREATMENT
Brief episodes of mild dizziness usually clear up after taking a few deep breaths or after resting for a short time.

Severe, prolonged, or recurrent dizziness should be investigated by a doctor. Treatment depends on the underlying cause. For example, certain cases of dizziness and vertigo due to a disorder of the inner ear are treated with antihypertensive drugs or antihistamine drugs.

dizygotic twins
Nonidentical twins, also called fraternal twins. Dizygotic twins are the result of the simultaneous fertilization of two egg cells (ovum). They each have a placenta of their own and may be of different sexes. (See also monozygotic twins.)

DNA
The abbreviation for deoxyribonucleic acid. DNA is the principal molecule carrying genetic information in almost all organisms; the exceptions are certain viruses that use RNA.

DNA is found in the chromosomes of cells; its double-helix structure allows the chromosomes to be copied exactly during the process of cell division. A special form of DNA exists in mitochondria, the tiny energy-producing structures within cells (see mitochondrial DNA). Sections of DNA can also be created artificially (see recombinant DNA) during genetic engineering. (See also meiosis; mitosis; nucleic acids.)

DNA fingerprinting
See genetic fingerprinting.

dobutamine
A drug that is used in the treatment of heart failure and shock, and sometimes after cardiac arrest (a halt in the pumping action of the heart). The drug may be given by intravenous drip.

Dobutamine stimulates nerve cells in the heart to increase the heart rate and raise the blood pressure. For this reason, the drug may be used in a cardiac stress test to investigate potential coronary artery disease in cases where the patient is unable to exercise on a treadmill (see exercise ECG).

doctor
A qualified medical practitioner who is licensed to practise by the appropriate medical authority in his or her country, such as the General Medical Council in the UK.

dogs, diseases from
Infectious or parasitic diseases that are acquired from contact with dogs. They may be caused by viruses, bacteria, fungi, protozoa, worms, insects, or mites living in or on a dog.

Many parasites that live on dogs can be transferred to humans, for example through stroking the dog’s fur.

The most serious disease from dogs is the viral infection rabies. The UK is free of rabies, but travellers to countries in which rabies exists should treat any dog bite with suspicion. Dog bites can cause serious bleeding and shock and may become infected.

Toxocariasis and hydatid disease are potentially serious diseases caused by the ingestion of worm eggs from dogs.
In the tropics, walking barefoot on soil that is contaminated with dog faeces can lead to dog hookworm infestation.

Bites from dog fleas are an occasional nuisance. Ticks and mites from dogs, including a canine version of the scabies mite, are other common problems. The fungi that cause tinea infections in dogs can be caught by humans.

Some people become allergic to animal dander (tiny scales from fur or skin). They may, for example, suffer from attacks of asthma or urticaria (nettle rash) when a dog is in the house. (See also zoonoses.)

dominant
A term used in genetics to describe the characteristics of a gene. Many characteristics are determined by a single pair of genes, one of each pair being inherited from each parent. The dominant gene of the pair overrides its equivalent recessive gene, allowing it to be expressed.

For example, the gene for brown eye colour is dominant, so that if a child inherits the gene for brown eyes from one parent and the gene for blue eyes from the other parent, he or she will have brown eyes.

Some genetic disorders are determined by a dominant abnormal gene that overrides the effect of an equivalent normal gene that is recessive. Examples of such disorders include Marfan syndrome and Huntington's disease. In this case, a child will have the disease if he or she inherits the gene from one or both parents.

dominant characteristic
An inherited characteristic (external or internal physical feature) that appears in offspring even if they have inherited the gene for it from only one of their parents. See dominant.

dominant gene
See dominant.

dominant trait
An inherited trait (a characteristic or condition) that appears when just a single copy of the gene for that trait is present, as opposed to a recessive trait, which only appears when two copies of the appropriate gene are present. Dominant genes always mask the presence of recessive genes, and dominant traits can be inherited from one parent alone.

domperidone
An antiemetic drug used to relieve nausea and vomiting associated with some gastrointestinal disorders or during treatment with certain drugs or radiotherapy. Adverse effects may include breast enlargement and secretion of milk from the breast.

donepezil
An acetylcholinesterase inhibitor that is used to treat mild to moderate dementia due to Alzheimer's disease.

donor
A person who provides blood for transfusion; body tissues or organs for transplantation; or eggs or semen for artificial insemination. The organs that are most frequently donated are kidneys, corneas, heart, lungs, liver, and pancreas. Certain organs can be donated during a person’s lifetime; some are only used following brain death.

All donors should be free of cancer, serious infection (such as hepatitis B), and should not carry HIV. Organs for transplantation must be removed within a few hours of brain death, and before or immediately after the heartbeat has stopped. In some kidney transplants, the kidney is provided by a living donor, usually a relative whose tissues match well on the basis of tissue-typing. Tests are performed to ensure that both kidneys are healthy before one is removed.

Suitable related donors may also provide bone marrow for transplantation and sometimes skin for grafting. (See also blood donation; bone marrow transplant; organ donation; transplant surgery.)

Doose syndrome
A rare, inherited form of epilepsy. The condition is typified by muscular jerking, especially symmetrical jerking of the arms and shoulders and, in severe cases, twitching of the facial muscles. In addition, the affected person may fall to the ground and briefly lose consciousness. Doose syndrome can be treated with anticonvulsant drugs.

dopa
An amino acid that the body uses to form dopamine, an important neurotransmitter. Dopa is also formed as an intermediate stage when the body makes epinephrine, norepinephrine, and melanin. Levodopa, a form of dopa, is used to correct dopamine deficiency in people who have Parkinson's disease.

dopa-decarboxylase inhibitors
Drugs used in the treatment of the movement disorder Parkinson's disease. The two principal dopa-decarboxylase inhibitors, co-beneldopa and co-careldopa, are a combination of levodopa and benserazide and levodopa and carbidopa, respectively. These drugs stop levodopa from being activated except within the brain, which reduces the incidence of common side effects such as nausea and vomiting.

dopamine
A neurotransmitter (chemical released from nerve endings) found in the brain and around some blood vessels. It helps to control body movements: a deficiency of dopamine in the basal ganglia (groups of nerve cells deep in the brain) causes Parkinson's disease.

Synthetic dopamine is injected as an emergency treatment for shock caused by a myocardial infarction (heart attack) or septicemia (blood infection) and as a treatment for severe heart failure.

Doppler echocardiography
An investigation in which blood flow through the heart is assessed by the use of ultrasound (high-frequency sound waves). An ultrasound transducer is moved over the chest in the area of the heart. The waves emitted by the transducer are reflected by blood, forming echoes that are recorded to give a picture of blood flow. This allows the direction and speed of the blood flow to be measured.

Doppler echocardiography can be used to investigate the presence of some conditions of the heart and circulation, including abnormalities of the heart valves (see valvular heart disease). The procedure is painless and takes between 15 and 30 minutes to perform.

Doppler effect
A change in the frequency with which sound waves from a given source reach an observer when the source is in rapid motion with respect to the observer. Approaching sounds seem higher in pitch (frequency) than sounds that are moving away. This is due to the fact that the wavelengths of sounds from an approaching source are progressively foreshortened, whereas those from a receding source are stretched.

The Doppler effect is used in various medical ultrasound scanning techniques (see Doppler ultrasonography).
Doppler ultrasonography
A type of ultrasound scanning in which shifts in the frequency of ultrasonic waves are used to measure the velocity of moving structures. An emitter sends out pulses of ultrasound (inaudible, high-frequency sound) of a specific frequency. When the pulses bounce off a moving object (for example, blood flowing through a blood vessel), the frequency of the echoes is changed from that of the emitted sound. A sensor is able to detect the frequency changes and converts the data into useful information (about how fast the blood flows, for example).

Doppler ultrasonography is widely used to detect narrowing of arteries in the neck due to atherosclerosis (accumulation of fatty deposits on the artery walls) and to detect blood clots in veins (as occurs in deep vein thrombosis). In addition, Doppler ultrasound techniques are used to monitor the fetal heartbeat, to detect air bubbles during dialysis and in heart-lung machines, and to measure blood pressure. (See also Doppler echocardiography.)

Dorffman–Chanarin syndrome
A very rare, autosomal recessive genetic disorder affecting fat metabolism (see lipidosis). The disease is congenital (present from birth). It is characterized by ichthyosis (thickened, scaly skin); myopathy (degeneration of muscle), and sometimes also defects in vision and in hearing. Blood tests show abnormal white blood cells containing vacuoles (tiny spaces) filled with fat.

dorsal
Relating to the back, located on or near the back, or describing the uppermost part of a body structure when a person is lying face-down. For example, dorsalgia describes pain in the back, and the dorsal part of the hand is the back of the hand. In human anatomy, the term dorsal means the same as posterior. The opposite of dorsal is ventral (meaning anterior or front).

dose
A term used to refer to the amount of a drug to be taken at a particular time, or to the amount of radiation to which an individual is exposed during a session of radiotherapy. Drug dose may be expressed in terms of the weight of the active substance, the volume of liquid to be taken, or its effects on body tissues. The amount of radiation that is absorbed by body tissues during a session of radiotherapy is expressed in units called millisieverts (see radiation units).

dosulepin
A tricyclic antidepressant drug used in the treatment of depression. The drug has a sedative action and is particularly useful in cases of depression accompanied by anxiety or insomnia. Possible adverse effects include blurred vision, dizziness, flushing, and rash.

dothiepin
The former name for dosulepin.

double-blind
A type of controlled trial that tests the effectiveness of a particular treatment or compares the benefits of different treatments. In double-blind trials, neither the patients undergoing the treatments nor the doctors who are assessing them know which of the patients are receiving which treatment. This eliminates any expectations about which treatment will be most effective.

double contrast enema
Radiologic investigation (see radiology) of the intestine (the main part of the digestive tract). A contrast medium (a substance opaque to X-rays) is introduced into the passage or cavity to be examined. The area is then distended (widened) by the introduction of air. A thin coating of the contrast medium is left on the walls of the intestine. As a result, the area to be examined is shown in outline on X-ray images. (See also barium X-ray examinations.)

double vision
Also known as diplopia, double vision is a condition in which a person sees two visual images of a single object instead of only one image. The two images are separate, but each of them is quite clearly focused.

CAUSES
It is usually a symptom of a squint, especially of paralytic squint, in which paralysis of one or more of the eye muscles impairs eye movement. Other causes include a tumour in the eyelid or a tumour or blood clot behind the eye. Double vision can also occur in exophthalmos, when the eyeballs protrude as the result of an underlying hormonal disorder.

DOWN’S SYNDROME

TREATMENT
Double vision needs immediate investigation. The treatment depends on the underlying cause.

douche
The introduction of water and/or a cleansing agent into the vagina using a bag and tubing with a nozzle. Douching is unnecessary for hygiene and is ineffective contraception. It may cause infection or spread existing infection into the uterus or fallopian tubes.

Down’s syndrome
A chromosomal abnormality that results in a variable degree of learning difficulty and a characteristic physical appearance in affected individuals.

CAUSES
People with Down’s syndrome have an extra chromosome (47 instead of the normal 46). Affected individuals have three copies of chromosome number 21 instead of two; for this reason, the disorder is also called trisomy 21. In most cases, it is the result of a sperm or egg being formed with an extra chromosome 21, due to the failure of the chromosome 21 pair to part and enter separate cells during meiosis. If one of these abnormal egg or sperm cells takes part in fertilization, the baby will also have the extra chromosome. This type of abnormality is more likely if the mother is aged over 35.

A less common cause is a chromosomal abnormality called a translocation, in which part of one parent’s own

Down’s syndrome child using sign language
There is a greater than normal risk of congenital deafness in Down’s babies. Typical features of the condition include upward sloping eyes that are covered at the corners, small facial features, and a large tongue that tends to stick out.
chromosome number 21 has joined with another chromosome. The parent is unaffected but has a high risk of having Down’s children.

**SYMPTOMS**

Typical physical features of a person with Down’s syndrome include small face and features; upward-sloping eyes with folds of skin that cover their inner corners; large tongue; flattened back to the head; short, broad hands, with a single horizontal crease on the palm (see simian crease); and short stature. Learning difficulties are very common, and range from mild to severe; however, affected people often have cheerful, friendly personalities.

People with Down’s syndrome have a greater than normal risk for certain disorders. One possible problem is a heart defect at birth (see heart disease, congenital), which affects up to two in five babies. Others include intestinal atresia (a narrowing in the intestines) and congenital deafness. Acute leukaemia is more common than in other children. Down’s syndrome children are also especially susceptible to ear infections. Affected adults over the age of 40 have a higher than normal risk of developing Alzheimer’s disease.

**DIAGNOSIS**

Screening tests during early pregnancy, including a nuchal thickness scan (a form of ultrasound scanning to measure the skin at the back of the neck) indicate those fetuses likely to have the syndrome. Amniocentesis is then offered; this test involves chromosome analysis of fetal cells. In some cases, Down’s syndrome is only recognized once the baby has been born. The diagnosis is confirmed by chromosome analysis of cells from the baby.

**OUTLOOK**

There is no cure for the condition, but many Down’s syndrome children can make the most of their capacities with appropriate environmental and educational stimulation and support. Some children learn skills such as reading and writing, and some adults may be able to work; however, most affected people cannot live independently and need long-term care from their families or in a residential home.

**doxazosin**

An antihypertensive drug taken to reduce high blood pressure (see hypertension). Possible side effects include dizziness, headache, and nausea.

**doxorubicin**

An anticancer drug given by injection, often with other anticancer drugs. It is used in the treatment of a variety of cancers, including lung cancer.

**doxycycline**

A tetracycline drug used in the treatment of chronic prostatitis, pelvic inflammatory disease, acne, and chest infection in chronic bronchitis. It is also used to prevent and treat malaria. Taking the drug with food reduces possible side effects.

**drainage angle**

The gap between the outer edge of the iris (the coloured ring of muscle in the eye) and the cornea (the transparent covering of the eyeball). This structure, and the network of tissue behind it (the trabecular network), allows excess aqueous humour to drain from the front chamber of the eye. Blockage of the drainage angle causes acute glaucoma.

**drain, surgical**

An appliance that is inserted into a body cavity or a wound in order to release air or permit drainage of fluid. Drains range from simple soft rubber tubes that pass from a body cavity into a dressing to wide-bore tubes that connect to a collection bag or bottle. Suction drains are thin tubes containing many small holes to help collect fluid or air, which is then drawn into a vacuum bottle.

**dream analysis**

The interpretation of a person’s dreams as part of psychoanalysis or psychotherapy. First developed by Sigmund Freud, it is based on the idea that repressed feelings and thoughts are revealed, in a disguised way, in dreams.

**dreaming**

Mental activity that takes place during sleep. Dreaming is thought to occur only during periods of REM (rapid eye movement) sleep, which last for about 20 minutes and occur four to five times a night. Compared to other phases, the REM phase of sleep is active. Blood flow and brain temperature increase, and there are sudden changes in heart rate and blood pressure.

Dreams usually closely mirror the day’s preoccupations. Dreaming can be seen as a process in which the mental impressions, feelings, and ideas are sorted out. People roused during REM sleep report especially vivid dreams.

**dribbling**

Involuntary leakage of urine from the bladder (see incontinence, urinary) or of saliva from the mouth (drooling). Dribbling of saliva is normal in infants. In adults, it may be due to poorly fitting dentures; alternatively, it may be the result of facial paralysis, dementia, or another disorder of the nervous system, most commonly Parkinson’s disease. Dribbling of saliva may also be caused by an obstruction in the mouth that interferes with swallowing.
drip
See intravenous infusion.

drip, postnasal
See postnasal drip.

driving, health and
Safe driving depends in part on the health of the vehicle’s driver. Any state or medical disorder that affects a driver’s physical condition, or impairs mental faculties such as judgment, alertness, or speed of reaction, increases the risk of injury to the driver and also to other road users and pedestrians.

One of the most obvious hazards is being under the influence of alcohol. There are strict laws regarding the maximum alcohol level allowed, because alcohol is known to impair judgment and to slow reaction times. Illicit drugs (see drug abuse) have a similarly harmful effect. Some prescribed drugs can also affect ability to drive; for example, some antidepressants (used to treat disorders such as hay fever) can cause drowsiness. The combination of drugs and alcohol is more potent than either used alone. Other states that can be hazardous include fatigue and any type of stress reaction such as anger and anxiety. Driving when tired is one of the most common causes of road accidents.

Impaired vision obviously affects a person’s fitness to drive. Various other health problems should be disclosed to the driver’s vehicle licensing authority, and in some cases may preclude driving for a period of time. Drivers who have diabetes mellitus must inform their vehicle licensing authority as well as their insurance company if they begin insulin therapy. Careful monitoring of blood sugar levels is of vital importance, because abnormally high or low levels may impair the person’s judgment or cause loss of consciousness. People who have had a stroke, or who have had a pacemaker fitted, may also be subject to driving restrictions. Stricter regulations are in place for certain groups of drivers, for example people with epilepsy.

Regardless of the medical condition, it is extremely important that the patient contacts the vehicle licensing authority for advice on fitness to drive if there is the least cause for concern.

drooping eyelid
See ptosis.

drop attack
A brief disturbance that affects the nervous system, causing a person to fall to the ground without warning. Unlike in fainting, the person may not lose consciousness, but injuries can occur from the fall. Elderly women make up the group most commonly affected.

CAUSES
The causes are not fully understood, but they may be a form of transient ischaemic attack (TIA) in which there is a fall in blood flow to nerve centres in the brainstem. Elderly men may have a drop attack while passing urine or while standing, possibly due to low blood pressure or an abrupt alteration in heart rhythm. Akinetic seizures (a rare form of epilepsy) are also sometimes described as drop attacks; the sufferer falls to the ground but does not have muscular spasms.

TREATMENT
There is no treatment for drop attacks in elderly people. Akinetic seizures usually respond to anticonvulsant drugs.

drop, foot
See foot-drop.

dropped beat
A type of cardiac arrhythmia (see arrhythmia, cardiac) characterized by the absence of a single ventricular contraction. The next heartbeat often comes slightly early, and is more forceful than usual; this beat is often the one that is noticed, rather than the dropped one. Dropped beat is very common and may be caused by alcohol, caffeine, and some medications. Single, infrequent dropped beats are very unlikely to be due to heart disease.

dropsy
An outmoded term for generalized oedema (fluid accumulation in body tissues). It is not a disease in itself, but a sign of disease, especially of congestive heart failure or kidney disease.

drowning
Death caused by suffocation and hypoxia (a lack of oxygen) associated with immersion in a fluid. Most often, the person inhales liquid into the lungs; but sometimes no liquid enters the lungs, a condition called dry drowning (see drowning, dry). People who are resuscitated after prolonged immersion are said to be victims of “near drowning”. (See also Types of drowning, p. 246.)

MECHANISM OF DROWNING
Initially, automatic contraction of a muscle at the entrance to the windpipe, a mechanism known as the laryngeal reflex, prevents water from entering the lungs; instead, the water enters the oesophagus and stomach. However, the laryngeal reflex impairs breathing and can quickly lead to hypoxia and to loss of consciousness. If the person is buoyant at this point and floats face-up, his or her chances of survival are reasonable because the laryngeal reflex begins to relax and normal breathing may then resume.

FIRST AID AND TREATMENT
An ambulance should be called and the person’s condition assessed. If he or she is not breathing and/or the pulse is absent, resuscitative measures should be started (see artificial respiration; cardiopulmonary resuscitation) and continued until medical help arrives.

Victims can sometimes be resuscitated despite a long period immersed in very cold water (which reduces the body’s oxygen needs). In all cases of successful resuscitation, the person should be sent to hospital, because life-threatening symptoms may develop some hours after rescue if water has passed from the lungs into the blood.

drowning, dry
A form of drowning in which no fluid enters into the lungs. Some fatal drowning cases are “dry”. Victims of dry drowning have a particularly strong laryngeal reflex, which diverts water into the stomach instead of the lungs, but at the same time impairs breathing. As with cases of “wet” drowning, death occurs by suffocation.

drowsiness
A state of consciousness between full wakefulness and sleep or unconsciousness. Drowsiness is medically significant if a person fails to awaken after being shaken, pinched, and shouted at, or wakes but relapses into drowsiness.

Abnormal drowsiness must be treated as a medical emergency. It may be the result of a head injury, high fever, meningitis (inflammation of the membranes surrounding the brain and spinal cord), ureaemia (excess urea in the blood due to kidney failure), or liver failure. Alcohol or drugs may also produce this effect. In a person with diabetes mellitus, drowsiness may be a result of hypoglycaemia (low blood sugar levels) or of hyperglycaemia (high blood sugar levels).
drug
A chemical substance that alters the function of one or more body organs or the process of a disease. Drugs include prescribed medicines, over-the-counter remedies, and various substances (such as alcohol, tobacco, and drugs of abuse) that are used for nonmedical purposes.

CLASSIFICATION AND LICENSING
Drugs normally have a chemical name, an officially approved generic name (see generic drug), and often a brand name. Drugs for medical use are either licensed for prescription by a doctor only or can be bought over the counter at a chemist’s or supermarket.

Most drugs are artificially produced to ensure a pure preparation with a predictable potency (strength). Some drugs are genetically engineered. A drug is classified according to its chemical make-up, or the disorder it treats, or according to its specific effect on the body. All new drugs are tested for their efficiency and safety. In the UK, drugs are licensed by the Medicines and Healthcare products Regulatory Agency (MHRA). A licence may be withdrawn if toxic effects are reported or if the drug causes serious illness.

USES
Drugs can be used to relieve physical or mental symptoms, to replace a natural substance that is deficient, or to stop the excessive production of a hormone or other chemical by the body. Some drugs are given to destroy foreign organisms, such as bacteria or fungi. Others, which are known as vaccines, are given to stimulate the body’s immune system to form antibodies.

METHODS OF ADMINISTRATION
Drugs are given by mouth or injection, or are applied directly or indirectly to the affected site via transdermal, nasal, and other direct routes (for example, to the lungs through an inhaler). Drugs that are injected take effect more rapidly than those taken by mouth because they enter the bloodstream directly, without passing first through the digestive system. There are different routes for injection. The fastest is intravenous; intramuscular is also fast because muscles have a good blood supply; subcutaneous injection is the slowest method, but is easier for self-administration of drugs.

ELIMINATION
Unabsorbed drugs are broken down in the liver. Those taken orally are excreted in faeces; those that have entered the bloodstream are eliminated in urine.

ADVERSE EFFECTS
Most drugs can produce adverse effects. These effects may wear off as the body adapts to the drug. Adverse effects are more likely if there is a change in the absorption, breakdown, or elimination of a drug (caused, for example, by liver disease). Unexpected reactions sometimes occur due to a genetic disorder, an allergic reaction, or the formation of antibodies that damage body tissues. Some drugs interact with food, alcohol, or other drugs.

Many drugs can cross the placenta; some affect the growth and development of the fetus if taken by a pregnant woman. Most drugs can pass into the breast milk of a nursing mother, and some have adverse effects on the baby.

drug abuse
Use of a drug for a purpose other than that for which it is normally prescribed or recommended. Commonly abused drugs include stimulant drugs, such as cocaine and amphetamine drugs; central nervous system depressants, such as alcohol and barbiturate drugs; hallucinogenic drugs, such as LSD; and narcotics (see opioid drugs), such as heroin. Some drugs are abused in order to improve performance in sports (see sports, drugs and; steroids, anabolic).

Problems resulting from drug abuse may arise from the adverse effects of the drug, accidents that occur during intoxication, or from the habit-forming potential of many drugs, which may lead to drug dependence.

drug dependence
Physical or psychological dependence on a drug (see drug dependence).

TYPES
Drug dependence can be psychological or physical, or more commonly both. A person is psychologically dependent if he or she experiences craving or distress when the drug is withdrawn. In physical drug dependence, the body has adapted to the drug, causing the symptoms and signs of withdrawal syndrome when the drug is stopped. These symptoms are relieved if the drug is taken again.

CAUSE
Dependence develops as a result of regular or excessive drug use, and it develops most frequently with drugs that alter mood or behaviour.

SYMPTOMS AND SIGNS
Drug dependence may cause physical problems, for example lung and heart disease from smoking and liver disease from excessive alcohol consumption. Mental problems, such as anxiety and depression, are common during drug withdrawal. Dependence may also be linked with drug tolerance, in which increasing doses of the substance are needed to produce the same effect.

COMPLICATIONS
Complications such as hepatitis or AIDS are a particular risk for people who abuse drugs by injection. Death may occur as a result of taking a contaminated drug, or be due to accidental overdose from taking a purer, more potent preparation than usual.

TREATMENT AND OUTLOOK
Controlled withdrawal programmes are available in special centres and hospitals, which usually offer gradual, supervised reductions in dose. Alternative, less
harmful drugs may be given, as well as treatment for any withdrawal symptoms. Social service agencies and support groups may provide follow-up care. The success of treatment depends on the motivation of the affected person. Problems often recur if people return to the circumstances that originally gave rise to the drug abuse.

**drug eruption**
An adverse, allergic reaction (see allergy) that is provoked by the ingestion or topical application of a particular drug. A drug eruption is usually manifested as a rash on the surface of the skin.

**drug-induced disease**
Any disorder resulting from the use of a drug. Examples include drug-induced *lupus erythematosus*, haemolytic anaemia (see anaemia, haemolytic), and *parkinsonism*. Factors that may increase the risk of drug-induced disease are age, sex, individual sensitivity, underlying disease (especially of the kidneys or liver), and the combination of drugs a patient is taking. Adverse effects associated with the use of medications may lead to hospitalization, disability, or even death. (See also side effect.)

**drug interaction**
The effect of a drug when it is taken in combination with other drugs or with substances such as alcohol.

**drug overdose**
The taking of an excessive amount of a drug, which may cause toxic effects (see drug poisoning).

**drug poisoning**
The harmful effects on the body that occur as a result of an excessive dose of a particular drug.

**INCIDENCE AND CAUSES**
Accidental poisoning most commonly occurs in young children. Child-resistant drug containers have helped to reduce this risk. In adults, drug poisoning usually occurs in elderly or confused people who are unsure about their treatment and dosage requirements. Accidental poisoning may also occur in drug abuse. Deliberate self-poisoning may be a cry for help (see suicide; suicide, attempted).

Drugs that are most commonly taken in overdose include *benzodiazepine drugs* and *antidepressant drugs*.

**TREATMENT**
Anyone who has taken a drug overdose, and any child who has swallowed tablets belonging to someone else, needs immediate medical attention. It is important to identify the drugs that have been taken.

Treatment in hospital may involve washing out the stomach by passing water through a tube introduced into the mouth (see lavage, gastric). Charcoal may be given by mouth to reduce the absorption of the drug from the intestine into the bloodstream. To eliminate the drug, urine production may be increased by an *intravenous infusion*. Antidotes are available only for a few specific drugs. Such antidotes include *naloxone* (for *morphine*) and methionine (for *paracetamol*).

**COMPLICATIONS**
Drug poisoning may cause drowsiness, breathing difficulty, irregular heartbeat, and, rarely, cardiac arrest, fits, and kidney and liver damage. *Antiarrhythmic drugs* can be given to treat heartbeat irregularity. Fits are treated with *anticonvulsant drugs*. Blood tests to monitor liver function and careful monitoring of urine output are carried out if the drug is known to damage the liver or kidneys.

**drug psychosis**
A mental condition in which a person loses contact with reality during or following use of certain drugs (see drug abuse). Drug psychosis may be produced by drugs such as *amphetamine*, *cocaine*, *LSD* (lysergic acid diethylamide) and *cannabis*. The condition may also be caused by prescribed drugs, particularly by high doses of *corticosteroid drugs*.

Other possible effects associated with drug psychosis include abnormal behaviour, *hallucinations*, *delusions*, and extreme emotion, such as excitement or a dazed, unresponsive state. Treatment involves withdrawal from the drug and the use of *antipsychotic drugs* to relieve symptoms.

**drunkenness**
See alcohol intoxication.

**dru sen**
Abnormal yellowish deposits that build up in the *retina* (the light-sensitive layer at the back of the eye), which can lead to a disturbance of central vision. Drusen may be a sign of age-related *macular degeneration*.

**dry drowning**
See drowning, dry.

**dry eye**
See keratoconjunctivitis sicca.

**dry gangrene**
A type of gangrene.

**dry ice**
Frozen carbon dioxide. Carbon dioxide changes from a gas to a solid when cooled, without passing through a liquid phase. Dry ice may be applied to the skin in *cryosurgery*, a freezing technique that is used, for example, to treat warts.

**dry mouth**
See mouth, dry.

**dry socket**
Infection at the site of a recent tooth extraction, causing pain, bad breath, and an unpleasant taste in the mouth. Dry socket occurs when a blood clot fails to

## METHODS OF DRUG ADMINISTRATION

<table>
<thead>
<tr>
<th>How taken</th>
<th>Action</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>By mouth</strong></td>
<td>Drugs are digested and absorbed from the intestine in the same way as nutrients. How quickly the tablet or liquid works depends on how rapidly it is absorbed. This, in turn, depends on such factors as the drug’s composition, how quickly the drug dissolves and the effect of digestive juices on it. Some drugs are inactivated as soon as they reach the liver and never enter the circulation.</td>
</tr>
<tr>
<td><strong>By injection</strong></td>
<td>Drugs given by injection have a very rapid effect and are given if digestive juices would destroy a drug.</td>
</tr>
<tr>
<td><strong>Topical</strong></td>
<td>These drugs have a local effect on the parts of the body that are exposed to them as well as a systemic (generalized) effect if some of the drug is absorbed into the bloodstream from the site of application.</td>
</tr>
</tbody>
</table>
form in the tooth socket after a difficult extraction, such as removal of a wisdom tooth (see impaction, dental). The clot itself may become infected, or infection may already have been present before extraction. The inflamed socket appears dry, and exposed bone is often visible. The socket is irrigated to remove debris and may then be coated with an anti-inflammatory paste. The infection usually clears up within a few days.

**DST-IV**

The fourth edition of the Diagnostic and Statistical Manual of Mental Disorders, published by the American Psychiatric Association. It classifies psychiatric illnesses and is widely used in other countries.

**DTaP/IPV**

A combined vaccine, introduced in 2004, that provides immunity against diphtheria (in a low dose), tetanus, pertussis (whooping cough), and poliomyelitis. It is given to children aged three to five years as part of the childhood immunization programme. (See Typical childhood immunization schedule, p.414.)

**DTaP/IPV/Hib**

A combined vaccine, introduced in 2004, that provides immunity against diphtheria, tetanus, pertussis (whooping cough), poliomyelitis, and Hib. In this vaccine (and in the DTaP/IPV vaccine), the polio and pertussis parts have been altered to minimize the risk of adverse effects.

**HOW IT IS DONE**

The injection is given in three doses to infants at two, three, and four months of age, so that they are protected as soon as possible. (Meningitis C vaccination is given at the same time.) The childhood immunization schedule also includes a preschool booster (see DTaP/IPV), and a further diphtheria, tetanus, and polio booster before leaving school. (See Typical childhood immunization schedule, p.414.)

**PROTECTION**

The vaccine provides a very high level of immunity against diphtheria, tetanus, pertussis, polio, and Hib infections.

**POSSIBLE ADVERSE EFFECTS**

DTaP/IPV/Hib is less likely to cause reactions than the older vaccines. Any side effects are usually mild and tend to occur within 12–24 hours. They include a slightly raised temperature, irritability and fretfulness, and a small lump, redness, and swelling at the injection site. Severe side effects are very rare.

The vaccine should not be given to children who have reacted severely to a preceding dose or to the old DTP vaccine, or to children who could have a severe reaction to neomycin, streptomycin, or polymyxin B (see polymyxins), which may exist in the vaccine in trace amounts.

**DTP vaccine**

An injection providing immunity against diphtheria, pertussis (whooping cough), and tetanus. In 2004, the DTP vaccine was replaced, in the UK, by the DTaP/IPV and DTaP/IPV/Hib vaccines.

**dual personality**

See multiple personality.

**Dubin–Johnson syndrome**

An inherited disorder that is caused by an autosomal recessive genetic trait (see genetic disorders). Dubin–Johnson syndrome is characterized by long-standing, mild jaundice (yellowing of the skin and the whites of the eyes), which may not become apparent until puberty or adulthood. There is an abnormality in the transportation of bilirubin (the main pigment found in bile) from the liver to the biliary system, which causes the bilirubin to accumulate in the liver.

No specific treatment is available. Affected people are advised to avoid drinking alcohol, and to avoid taking a range of medications that are processed by the liver, for example oral contraceptives. Genetic counselling may be offered to prospective parents who have a family history of Dubin–Johnson syndrome.

**Duchenne’s dystrophy**

The most common and severe form of muscular dystrophy.

**duct**

A tube or a tube-like passage leading from a gland to allow the flow of fluids, such as the tear ducts.

**ductal carcinoma**

Any carcinoma (a cancerous tumour arising from cells in an organ’s surface layer or its lining membrane) of a duct (a tube or tube-like passage leading from a gland).

Examples of ducts that are most frequently affected by carcinomas are the pancreatic duct (see pancreas) and the milk ducts in the female breast. Ductal carcinomas of the breast that have not yet spread into the breast tissue can usually be cured by surgery.

**LOCATION OF THE DUODENUM**

The duodenum is about 25 cm long and shaped like a C; it forms a loop around the head of the pancreas.

**Duke’s classification**

A staging system for carcinomas (cancerous tumours arising from cells in an organ’s surface layer or lining membrane) in the lower gastrointestinal tract. Carcinomas of the colon (the main part of the large intestine) or rectum (the muscular tube that connects the large intestine to the anus) are classified according to this system.

**dumbness**

See mutism.

**dumping syndrome**

Symptoms that include sweating, fainting, and palpitations due to the rapid passage of food from the stomach into the intestine. Dumping syndrome (also known as rapid gastric emptying) is uncommon but mainly affects people who have had a gastrectomy (surgical removal of the stomach).

Symptoms may occur within about 30 minutes of eating (early dumping) or after 90–120 minutes (late dumping). Some very anxious people may experience the symptoms of dumping even though their stomach is intact.
hormone release. This may, in or to prevent ). Dydrogesterone is also to the liver (the first feed into oscopy (see diagnosticed by oesophagogastroduoden- vague gastrointestinal symptoms. It is part of the small intestine), producing for a duodenal ulcer (see treatment for duodenitis is similar to that with a flexible viewing instrument. The of the walls of the upper digestive tract also be prevented by lying down for a rest after a large meal. Adding guar gum to food is also sometimes effective.  

duodenal cap  
The upper area of the first part of the duodenum; this is revealed in a barium X-ray examination.

duodenal ulcer  
A raw area in the wall of the duodenum (the first part of the small intestine) due to erosion of its inner surface lining. Duodenal and gastric (stomach) ulcers are types of peptic ulcer, and have similar causes, symptoms, and treatment.

duodenitis  
Inflammation of the duodenum (the first part of the small intestine), producing vague gastrointestinal symptoms. It is diagnosed by oesophagogastroduodenoscopy (see gastroscopy): examination of the walls of the upper digestive tract with a flexible viewing instrument. The treatment for duodenitis is similar to that for a duodenal ulcer (see peptic ulcer).

duodenum  
The first part of the small intestine. The duodenum begins at the duodenal cap, just beyond the pylorus (the muscular valve at the lower end of the stomach). It extends to the ligament of Treitz, which marks the boundary with the second part of the small intestine (the jejunum). (See Location of the duodenum, opposite page.)

The duodenum is about 25 cm long and C-shaped; it forms a loop around the head of the pancreas, liver, and gallbladder feed into it through a small opening. Digestive enzymes in the pancreatic secretions and chemicals in the bile are released into the duodenum through this opening.

duplex kidney  
Two fused kidneys on one side of the body. Another structural abnormality of the kidney is duplex renal pelvis, in which a single kidney has two renal pelvises (urine-collecting chambers). A third possibility is duplex ureter, in which there are two ureters leading from one kidney. The ureters may open into the bladder, or, in females, one may open into the vagina. These malformations arise during formation in the embryo. Surgical correction may be necessary to prevent complications such as infections.

duplex uterus  
Duplication of part or all of the uterus. There may be two uteri joined to one vagina, or two uteri with two vaginas.

A more common condition is septate uterus, in which a band of tissue (septum) divides the uterine cavity into two spaces instead of one.

Dupuytren’s contracture  
A disorder of the hand in which one or more fingers become fixed in a bent position. In about half of the cases, both hands are affected. In most cases there is no apparent cause, but the disease may be, in part, inherited. Men over the age of 40 are most often affected.

The tissues just under the skin in the fingers or palm become thickened and shortened, which causes difficulty in straightening the fingers. Surgery can correct deformity of the fingers, but in some cases the condition recurs.

dura mater  
The outer of the three membranes (meninges) covering the brain.

Duroziez’s disease  
A congenital (present at birth) form of mitral stenosis (a narrowing of the opening of the mitral valve, which is situated on the left side of the heart).

dust diseases  
Lung disorders caused by dust particles inhaled and absorbed into the lung tissues. There, they may cause fibrosis (formation of scar tissue) and progressive lung damage. The main symptoms are a cough and breathing difficulty. It may take at least ten years of exposure to dusts containing coal, silica, talc, or asbestos before serious lung damage develops (see pneumoconiosis). Hyper-sensitivity to moulds on hay or grain may lead to allergic alveolitis.

Preventive measures, such as the installation of dust extraction machinery, have reduced the incidence of dust diseases, and replacements have been found for especially hazardous substances such as asbestos.

DVT  
Deep vein thrombosis (see thrombosis, deep vein).

dwarfism  
See short stature.

dydrogesterone  
A drug that is derived from the female sex hormone progesterone. It is used to treat premenstrual syndrome and certain menstrual problems (see menstruation, disorders of). Dydrogesterone is also given together with an oestrogen drug as hormone replacement therapy to women after or during the menopause. Dydrogesterone may be prescribed to treat endometriosis or to prevent miscarriage. Possible side effects include swollen ankles, weight gain, breast tenderness, and nausea.

dying, care of the  
Physical and psychological care that is given with the aim of making the final months or days of a dying person’s life as free from pain, discomfort, and emotional distress as possible.

Carers may include doctors, nurses, and other medical professionals, counsellors, social workers, clergy, and the person’s family and friends.
DYS-

PHYSICAL CARE
Pain can be relieved by regular low doses of analgesic drugs. Opioid analgesics, such as morphine, may be given if pain is severe. Other methods of pain relief include nerve blocks, cordotomy, and TENS. Nausea and vomiting may be controlled by drugs. Constipation can be treated with laxatives. Breathlessness is another common problem in the dying, and this may be relieved by administering morphine.

Towards the end, the dying person may be restless and may suffer from breathing difficulty due to heart failure or pneumonia. These symptoms can be relieved by drugs and by placing the patient in a more comfortable position.

EMOTIONAL CARE
Emotional care is as important as the relief of physical symptoms. Many people who are terminally ill feel angry or depressed, and feelings of guilt or of regret are common responses. Loving, caring support from family, friends, and others is very important.

HOME OR HOSPICE?
Many terminally ill people would prefer to die at home, and few terminally ill patients need specialized nursing for a prolonged period. Specially trained nurses or health-care workers from a hospital, hospice, or charity may be able to provide additional support for the dying person and his or her carers.

Care in a hospice may be offered. Hospices are small units that have been established specifically to care for terminally ill people and their families.

dys-
A prefix meaning abnormal, difficult, painful, or faulty, as in dysuria (pain on passing urine).

dysarthria
A speech disorder caused by disease or damage to the physical apparatus of speech or to the nerves controlling this apparatus. Affected people can formulate, select, and write out words and sentences grammatically; the problem is with vocal expression only.

CAUSES
Dysarthria is common in many degenerative neurological conditions, such as multiple sclerosis and Parkinson’s disease. It may also result from a stroke, brain tumour, or an isolated defect or damage to a particular nerve. Structural defects of the mouth, as occur in cleft lip and palate, can also cause dysarthria.

TREATMENT
Drug or surgical treatment of the underlying disease or structural defect may improve the person’s ability to speak clearly. Speech therapy is also useful.

dyscalculia
A disorder in which there is difficulty in solving mathematical problems. (See also learning difficulties.)

dyschondroplasia
A rare disorder, also called multiple enchondromatosis or Ollier’s disease, that is present from birth and characterized by the presence of multiple tumours of cartilaginous tissue within the bones of a limb. It is caused by a failure of normal ossification during bone development. The bones are shortened, resulting in deformity. Rarely, a tumour in the bone may become cancerous (see chondrosarcoma).

dysentery
An intestinal infection, causing diarrhoea (often mixed with blood, pus, or mucus) and abdominal pain. There are two distinct forms of dysentery: shigellosis, which is due to shigella bacteria; and amoebic dysentery, which is caused by the protozoan parasite Entamoeba histolytica. The main risk with dysentery is dehydration caused by loss of fluid in the diarrhoea.

dysfunction
An abnormality or impairment in the functioning of an organ or body system. (See also bleeding, dysfunctional uterine; minimal brain dysfunction; psychosexual dysfunction.)

The term “dysfunctional” may be used to describe a poor relationship between two or more people.

dysgraphia
Problems with writing (see learning difficulties).

dyskaryosis
Abnormal changes in the nuclei of cells, particularly in the early stages of cancer. Dyskaryosis may be detected by microscopic examination of cells in procedures such as a cervical smear test.

dyskeratosis
An abnormality in keratinization (the deposition of the tough protein keratin) in the surface of the skin or nails. One form is due to a rare, inherited disorder that is most often caused by an X-linked recessive genetic trait, although autosomal dominant and autosomal recessive forms also exist (see genetic disorders). The condition affects more males than females and first become apparent in childhood.

Dyskeratosis is characterized by premature thickening of epithelial cells (epithelium) in the skin; leukoplakia (raised white patches on the mucous membranes of the mouth or vulva); nail dystrophy (a disorder caused by inadequate nutrition); and pancytopenia (a simultaneous decrease in the number of red cells, (anaemia), white cells (neutropenia), and platelets (thrombocytopenia) in the blood).

dyskinesia
Abnormal muscular movements. These uncontrollable twitching, jerking, or writhing movements cannot be suppressed, and they may affect control of voluntary movements. The disorder may involve the whole body or be restricted to a group of muscles.

Types of dyskinesia include chorea (jerking movements), athetosis (writhing movements), choreoathetosis (a combined form), myoclonus (muscle spasms), tics (repetitive fidgets), and tremors.

Dyskinesia may result from brain damage at birth or may be a side effect of certain drugs (see tardive dyskinesia), which often disappears when the drug is stopped. Otherwise, dyskinesia is difficult to treat. (See also parkinsonism.)

dyslexia
A reading disability characterized by difficulty interpreting written symbols.

CAUSE
Dyslexia is more common in males, and evidence suggests that a specific, sometimes inherited, neurological disorder underlies true dyslexia.

SYMPTOMS
A child with dyslexia has normal intelligence, but his or her attainment of reading skills lags far behind other scholastic abilities.

While many young children tend to reverse letters and words (for example, writing or reading p for q, or was for saw), most soon learn to correct such errors. Dyslexic children continue to confuse these symbols. Letters are often transposed (as in pest for step), and spelling errors are common. The children may even be unable to read words that they can spell correctly.
TREATMENT
It is very important to recognize the problem early to prevent added frustrations. Specific teaching can help an affected child develop “tricks” to overcome the deficit. Avoidance of pressure from parents combined with praise for what the child can do is equally important in helping progress.

dysmenorrhoea
Pain or discomfort experienced during or just before a menstrual period.

TYPES AND CAUSES
Primary dysmenorrhoea is common in teenage girls and young women. It usually starts two to three years after menstruation begins, but often diminishes after the age of 25. The exact cause is unknown. One possibility is excessive production of, or undue sensitivity to, prostaglandins, which are hormone-like substances that stimulate spasms in the uterus.

Secondary dysmenorrhoea is due to an underlying disorder, such as pelvic inflammatory disease or endometriosis, and usually begins in adult life.

SYMPTOMS
Cramp-like pain or discomfort is felt in the lower abdomen, sometimes accompanied by a dull ache in the lower back. Some women also have nausea and vomiting.

TREATMENT
Mild primary dysmenorrhoea is often relieved by analgesic drugs (painkillers). In severe cases, symptoms can usually be relieved by taking oral contraceptives or other hormonal preparations that suppress ovulation. The treatment of secondary dysmenorrhoea depends on the cause of the condition.

dysmoria
An abnormality in the shape of a body tissue or structure.

dyspareunia
Painful sexual intercourse (see intercourse, painful).

dyspepsia
The medical term for indigestion.

dysphagia
The medical term for swallowing difficulty.

dysphasia
A disturbance in the ability to select the words with which to speak and write and/or to understand speech or writing. It is caused by damage to speech and comprehension regions of the brain. (See also aphasia.)

dysphonia
Defective production of vocal sounds in speech, either as a result of disease or of damage to the larynx (voicebox) or to the nerve supply to the laryngeal muscles. (See also larynx, disorders of; speech disorders.)

dysphoria
A feeling of disquiet or restlessness. Dysphoria may be a side effect of certain drugs, or it may be a symptom of a psychiatric disorder.

Gender dysphoria is a persistent feeling that one has been born the wrong sex (see gender identity).

dysplasia
Any abnormality of growth. The term applies to deformities in structures such as the skull and to abnormalities of single cells. Abnormal cell features include the size, shape, and rate of multiplication of cells (see, for example, cervical dysplasia).

dyspnoea
The medical term for shortness of breath (see breathing difficulty).

dysrhythmia, cardiac
A medical term meaning disturbance of heart rhythm, sometimes used as an alternative to arrhythmia (see arrhythmia, cardiac).

dystocia
A term that means difficult or abnormal labour (see childbirth). Dystocia may occur, for example, if the baby is very large, or if the mother’s pelvis is abnormally shaped or too small for the baby to pass through. (See also childbirth, complications of.)

dystonia
Abnormal muscle rigidity, which causes painful spasms, unusually fixed postures, or strange movement patterns. Dystonia may affect a localized area of the body, or may be more generalized. The most common types of localized dystonia are torticollis (painful neck spasm), and scoliosis (an abnormal sideways curvature of the spine), which is caused by an injury to the back that produces muscle spasm. Generalized dystonia may be caused by neurological disorders such as Parkinson’s disease, or it may be a side effect of antipsychotic drugs.

Dystonia may be reduced by treatment with anticholinergic drugs or with benzodiazepine drugs. In some cases, biofeedback training may be helpful. Injections of botulinum toxin into the affected muscles are effective in treating some types of dystonia.

dystrophy
Any disorder in which the structure and normal activity of cells within a body tissue have been disrupted by inadequate nourishment of that part. The cause is usually unknown, but may be poor circulation of blood through the tissue, nerve damage or deficiency of a specific enzyme in the tissue.

Examples of dystrophy include muscular dystrophies and leukodystrophies. Corneal dystrophies, in which cells lining the cornea of the eye are damaged, are a rare cause of blindness.

dysuria
The medical term for pain, discomfort, or difficulty in passing urine (see urination, painful).
The middle ear is cut off from the outside by the eardrum. However, it is not completely airtight; a ventilation passage, called the eustachian tube, runs forwards and downwards into the back of the nose. The eustachian tube is normally kept closed, but it opens by muscular contraction when an individual yawns or swallows.

The middle ear acts as a transformer, passing the vibrations of sound from the air outside (which is a thin medium) to the fluid within the inner ear (which is a thicker medium).

INNER EAR
The inner ear is an intricate series of structures contained deep within the bones of the skull. It consists of a maze of winding passages, collectively known as the labyrinth. The front part, called the cochlea, is a tube that resembles a snail’s shell, containing nerve fibres that detect different sound frequencies. (For more information about how this system works, see hearing.)

The rear part of the inner ear contains three semicircular canals and is concerned with balance. The semicircular canals are connected to a cavity called the vestibule and contain hair cells bathed in fluid. Some of these cells are sensitive to gravity and acceleration; others respond to the positions and movement of the head. Information from the inner ear is conducted to the brain via the vestibulocochlear nerve. (See also disorders of the ear box.)

earache
Pain in the ear, which may originate in the ear itself or may result from a disorder in one of the structures situated

Eales’ disease
A rare condition seen mainly in young men that is characterized by inflammation of the retinal veins and recurrent vitreous haemorrhage (leakage of blood into the vitreous humour, the gel-like substance that fills the rear chamber of the eye). The presence of blood in the vitreous humour may affect vision and lead to headaches. If vision is impaired, laser treatment may be performed to prevent further haemorrhage.
near the ear. Earache is an extremely common symptom, especially in infancy and childhood.

CAUSES
A frequent cause of earache is acute otitis media (infection of the middle ear), which occurs most commonly in young children and results in severe, stabbing pain. There may also be loss of hearing and a raised temperature.

Another common cause of earache is otitis externa (inflammation of the ear canal), which is often caused by infection. Infection can affect the whole canal, or it may be localized, sometimes taking the form of a boil or abscess. The earache may be accompanied by irritation in the ear canal and a discharge of pus.

Intermittent earache may also occur in people with dental problems, tonsillitis, throat cancer (see pharynx, cancer of), pain in the jaw or neck muscles, and other disorders affecting areas near the ear. Earache in such cases occurs because the ear and nearby areas are supplied by the same nerves; the pain is said to be “referred” to the ear.

DIAGNOSIS AND TREATMENT
To determine the cause of earache, the ear is inspected (see ear, examination of). The mouth, throat, and teeth may also be examined.

Analgesic drugs (painkillers) may be prescribed to relieve the pain. Other treatment depends on the underlying cause of the earache. Antibiotic drugs may be prescribed for an infection. Pus in the outer ear may be removed by suction. Pus in the middle ear may be drained through a hole in the eardrum, a procedure known as myringotomy.

ear, cauliflower
See cauliflower ear.

ear, discharge from
Also called otorrhoea, emission of fluid from the ear. Not all discharge is the same; it may be watery or thick, clear or coloured, odourless or foul-smelling, and intermittent or continuous.

CAUSES
A discharge from the ear may be due to an outer-ear infection (see otitis externa). It may also follow perforation of the eardrum (see eardrum, perforated), which is usually due to a middle-ear infection (see otitis media). Rarely, after a skull fracture (see skull, fracture of), cerebrospinal fluid or blood may be discharged from the ear.

DISORDERS OF THE EAR
The ear is susceptible to many disorders, some of which can lead to deafness.

Congenital defects
In rare cases, the ear canal, ossicles (small bones in the middle ear), or pinna (visible part of the ear) are absent or deformed at birth. Rubella (German measles) in early pregnancy can damage the baby’s developing ear, leading to deafness. Most cases of congenital sensorineural deafness (deafness due to problems with the inner ear, nerves, or the brain’s auditory area) are genetic.

Infection
Infection is the most common cause of ear disorders. Infection in the ear canal leads to otitis externa; in the middle ear, it causes otitis media. This can lead to perforation of the eardrum (see eardrum, perforated). Glue ear (buildup of fluid in the middle ear), often due to infection, is the most common cause of childhood hearing difficulties. Viral infection of the inner ear may cause labyrinthitis with severe vertigo or sudden hearing loss.

Injury
Cauliflower ear occurs as the result of one major or several minor injuries to the pinna. Perforation of the eardrum can result from poking objects into the ear or from loud noise. Prolonged exposure to loud noise can cause tinnitus (noises within the ear) and/or deafness.

Pressure changes associated with flying or scuba diving can also cause minor damage (see barotrauma).

Tumours
Acoustic neuroma is a rare, noncancerous tumour of the acoustic nerve that may press on structures in the ear to cause deafness, tinnitus, and problems with balance. In cholesteatoma, skin cells accumulate in the middle ear.

Obstruction
Obstruction of the ear canal is often due to earwax, although in small children, an object may have been pushed into the ear (see ear, foreign body in).

Other disorders
In otosclerosis, a hereditary condition, a bone in the middle ear becomes immobilized, causing deafness. Menière’s disease is a rare condition in which deafness, vertigo, and tinnitus occur due to buildup of fluid in the inner ear. Progressive, age-related hearing loss is a condition known as presbyacusis.

Certain drugs, such as aminoglycoside drugs and some diuretic drugs, can also damage ear function.

INVESTIGATION
Hearing and balance are explored using hearing tests, caloric tests, and electronystagmography. The ear canal and eardrum are viewed with an otoscope.

eardrum, perforated
The rupture or erosion of the eardrum. Perforation of the eardrum can cause brief, intense pain. There may also be slight bleeding, a discharge from the ear (see ear, discharge from), and a reduction in hearing.

CAUSES
Most commonly, perforation occurs as a result of buildup of pus in the middle ear due to acute otitis media (middle-ear infection). Perforation may also be associated with cholesteatoma (accumulation of skin cells and debris in the ear). Another cause is injury, for example from insertion of an object into the ear, a loud noise, barotrauma (damage caused by pressure changes) or a fracture to the base of the skull (see skull, fracture of).
In some cases, a doctor may deliberately puncture the eardrum to drain pus from the middle ear (see myringotomy).

**DIAGNOSIS AND TREATMENT**

Diagnosis is confirmed by examination of the ear (see ear, examination of). Hearing tests may also be performed to assess any hearing loss.

Analgesic drugs (painkillers) may help to relieve any pain and antibiotic drugs may be prescribed to treat or prevent infection. Most perforations heal very quickly, usually within a month. However, if the perforation has failed to heal after about six months, myringoplasty (an operation to repair the eardrum) may be required.

**ear, examination of**

The ear may be examined to investigate the possible causes of earache, discharge from the ear (see ear, discharge from), hearing loss, a feeling of fullness in the ear, disturbed balance, tinnitus (noises within the ear), or swelling of lymph nodes (see glands, swollen) below or in front of the ear.

**HOW IT IS DONE**

The doctor begins by examining the pinna (the visible part of the outer ear) for any evidence of swelling, tenderness, ulceration, or deformity. To view the ear canal and eardrum, an otoscope (a viewing instrument for examining the ear) may be used.

To obtain images of the middle and inner ears, X-rays, or CT scanning or MRI (techniques that produce cross-sectional or three-dimensional images of body structures), may be carried out. Hearing and balance can be assessed by means of hearing tests or caloric tests. Electronystagmography is a technique in which balance is assessed by observing the movements of the eye as water is poured into the ear.

**ear, foreign body in**

Foreign bodies can easily enter the ear canal. Children often insert small objects, such as peas or stones, into their ears, and insects may crawl or fly in.

If people try to remove objects from the ear themselves, they may push the items further into the ear canal and risk damaging the eardrum. Foreign bodies in the ear must always be removed by doctors. This can be done by syringing (see syringing of ears) or by using fine-toothed forceps. Insects can sometimes be floated out using warmed olive oil or lukewarm water.

**ear, nose, and throat surgery**

See otolaryngology.

**ear piercing**

Making a hole in the earlobe or another, usually cartilaginous, part of the external ear to accommodate an earring. Ear piercings are best cleaned twice a day with salt water. Earlobe piercing takes about 4 weeks to heal; cartilage piercing may take 8–12 weeks.

**ears, pinning back of**

See otoplasty.

**earwax**

A yellow or brown secretion, also called cerumen, produced by glands in the outer ear canal. In most people, wax is produced in small amounts, comes out on much wax, and causes no problems. However, some people produce so much wax that it regularly obstructs the canal. Excess earwax may produce a sensation of fullness in the ear and, if the canal is blocked completely, partial deafness. These symptoms are worsened if water enters the ear and makes the wax swell. Prolonged blockage may irritate the skin of the ear canal.

**TREATMENT**

Wax that causes blockage or irritation may come out after being softened with warmed olive oil or almond oil. Otherwise, the wax should first be softened and then removed by a doctor or nurse (see syringing of the ears).

**eating disorders**

Illnesses that are characterized by obsessions with weight and body image. Eating disorders are most common in young adolescent females, but they can also affect males.

In the eating disorder anorexia nervosa, patients, despite being painfully thin, perceive themselves as fat and starve themselves. Binge-eating followed by self-induced vomiting is one of the main features of bulimia, although, in this disorder, weight may be normal. The two conditions sometimes occur together. In morbid obesity, there is a constant desire to eat large quantities of food.

**Ebola fever**

A dangerous and highly contagious viral infection that causes severe haemorrhaging (see bleeding) from the skin and the mucous membranes (the thin, moist tissue that lines body cavities). Ebola fever occurs predominantly in Africa. There is no specific treatment for the disease, which is fatal in many cases.

**eburnation**

The conversion of bone into an ivorylike mass. The cartilage that covers an articulating bone surface wears away, exposing the underlying bone tissue, which becomes increasingly dense and worn. Eburnation is a feature of osteoarthritis.

**EB virus**

See Epstein–Barr virus.

**eczymosis**

The medical term for a bruise that is visible through the skin.

**eccrine gland**

A type of sweat gland.

**ECG**

The abbreviation for electrocardiography, a method of recording the electrical activity of the heart muscle. An ECG is useful for diagnosing heart disorders, many of which produce electrical patterns that deviate from normal. Electrodes connected to a recording machine are placed on the patient’s chest, wrists, and ankles. The machine displays the heart’s electrical activity on a screen or as a trace. (See also ambulatory ECG; exercise ECG.)

**echinacea**

A preparation of the plant genus Echinacea. Three species of echinacea are used in herbal medicine; they are believed to boost the body’s immune system and therefore increase its resistance to bacterial, viral, and fungal infections.

**echocardiography**

A method of obtaining an image of the structure and movements of the heart using ultrasound (inaudible, high-frequency sound waves).

**WHY IT IS DONE**

Echocardiography is a diagnostic technique that is used to detect structural, and some functional, abnormalities of the heart wall, heart chambers, heart valves, and large coronary arteries.

The procedure is also used to diagnose congenital heart disease (see heart disease, congenital), cardiomyopathy (heart muscle disorders), aneurysms (ballooning of the heart or blood vessel walls), pericarditis (inflammation of the membrane that surrounds the heart), and blood clots in the heart.
**ECGLAPSIA**

**ELECTROCARDIOGRAPHY**

Electrocardiography causes no discomfort. Electrodes connected to a recording machine are applied to the chest, wrists, and ankles. The machine displays the electrical activity in the heart as a trace on a moving graph or a screen. Any abnormality is thereby revealed to the doctor, nurse, or paramedic. Normal and abnormal recordings are shown, below right.

An ECG can be taken at home, in the doctor’s surgery, or in the hospital; a recording lasting 24 hours or longer can be obtained from a monitoring device worn by the patient.

**HOW ECG IS DONE**

Small electrodes, connected by leads to the recording machine, are attached to the chest, wrists, and ankles using conducting jelly or pads. Signals from the electrodes produce a trace.

**Normal rhythm**

The heart chambers are contracting regularly.

**Ventricular fibrillation**

Here, the contractions of the lower heart chambers are extremely irregular.

**Complete heart block**

The upper and lower heart chambers are beating independently.

**Atrial fibrillation**

Here, the upper heart chambers are beating fast and irregularly, triggering irregular contraction of the ventricles.

**HOW IT IS DONE**

Echocardiography is harmless and causes no discomfort. A transducer (an instrument that sends out and receives sound signals) is placed on the patient’s chest, or an ultrasound probe is passed into the oesophagus using a flexible endoscope (viewing tube). Ultrasound waves are reflected differently by each part of the heart, resulting in a complex series of echoes. These are viewed on a screen and may be recorded, or the results can be printed out.

**DEVELOPMENTS**

Developments such as multiple moving transducers and computer analysis have helped to provide clear anatomical pictures of the heart.

Doppler echocardiography is used to measure the velocity (speed) of blood flow through the heart. It allows for the assessment of structural abnormalities such as a mitral valve prolapse and septal defects.

**echo-free**

A term used in ultrasound scanning to denote a structure that does not give rise to reflections (echoes) of ultrasound waves. A cyst filled with clear fluid, for example, is echo-free.

**echogenic**

A term used in ultrasound scanning to denote a structure that gives rise to reflections (echoes) of ultrasound waves.

**echolalia**

The compulsive repetition of something spoken by another person. The tone and accent of the speaker are copied as well as the words. Echolalia is sometimes seen in schizophrenia and may occur in people with learning difficulties or autism.

**ECHO virus**

The name for a specific group of RNA viruses. There are 32 types of ECHO virus, and these cause a wide range of conditions, including skin rashes, colds (see cold, common), gastrointestinal disorders, and viral meningitis.

**eclampsia**

An uncommon but serious condition that develops in a woman in late pregnancy, during childbirth, or after delivery. Eclampsia is characterized by hypertension (high blood pressure), proteinuria (protein in the urine), oedema (accumulation of fluid in body tissues), and the development of seizures. The condition is life-threatening for both the mother and the baby.

Eclampsia occurs as a complication of moderate or severe, although not mild, pre-eclampsia.

**SYMPTOMS**

The warning symptoms of impending eclampsia include headaches, confusion, blurred or disturbed vision, and abdominal pain. If untreated, seizures may occur and may be followed by
coma (a state of unconsciousness and unresponsiveness to stimuli). Levels of blood platelets may fall severely, resulting in bleeding; liver and kidney function may also be affected.

TREATMENT AND OUTLOOK
Careful monitoring of blood pressure and proteinuria throughout pregnancy is required to enable prompt treatment of impending eclampsia, and immediate delivery, often by caesarean section, together with antihypertensive drugs and anticonvulsant drugs is needed. Patients may need intensive care to prevent the development of complications, such as kidney failure.

Blood pressure often returns to normal in the months following delivery, although it may remain high. There is a risk of a recurrence of eclampsia in subsequent pregnancies.

econazole
An antifungal drug used as a cream in the treatment of fungal skin infections (such as athlete’s foot and tinea), and in cream or pessary form to treat vaginal candidiasis (thrush). Skin irritation is a rare side effect.

Ecstasy
An illegal designer drug, related to the amphetamine drugs. Ecstasy has a mildly hallucinogenic effect and generates feelings of euphoria, making users feel alert and sociable. In most people, the drug has no ill effects in the short-term, but repeated use carries a risk of liver damage. The most common side effect is hyperthermia (very high body temperature). Taking the drug causes intense thirst; drinking large quantities of water to combat this may result in fatal damage to the body, including brain swelling.

ECT
The abbreviation for electroconvulsive therapy, a treatment for very severe depression. ECT is less commonly used today than it was in the past, since the introduction of newer, more effective antidepressant drugs; however, the procedure usually relieves depression more rapidly than drugs, and it may be life-saving in severe cases that are resistant to other forms of treatment.

In this procedure, an electric current is passed through the brain in order to induce a seizure. ECT is administered under a short-lived general anaesthetic (see anaesthesia, general) and in combination with a muscle-relaxant drug, which reduces the physical effects of the induced seizure. The treatment is usually given once or twice a week, for six weeks. Temporary amnesia (memory loss) is a possible side effect.

ectasia
A term that means widening, usually used to refer to a disorder of a duct. For example, mammary duct ectasia is an abnormal widening of the ducts that carry secretions from the breast tissue to the nipple.

ectomorph
A term formerly used to describe an individual with a tall, thin body, a low level of body fat, slender limbs, small bones, and little muscle mass. (See also endomorph; mesomorph.)

-ectomy
A suffix that denotes surgical removal. For example, tonsillectomy is surgical removal of the tonsils.

ectoparasite
A parasite that lives in or on its host’s skin. An ectoparasite derives nourishment from the skin or by sucking the host’s blood. Various lice, ticks, mites, and some types of fungi are occasional ectoparasites of humans. By contrast, endoparasites live inside the body.

ectopic
A term used to describe a body structure that occurs in an abnormal location or position or a body function that occurs at an abnormal time.

ectopic heartbeat
A contraction of the heart muscle that is out of normal timing. An ectopic heartbeat occurs shortly after a normal beat and is followed by a longer-than-usual interval before the next one.

ECTopic beats can occur in a healthy heart and may be symptomless. Multiple ectopic beats can cause palpitations (awareness of a rapid or forceful heartbeat). When occurring after a myocardial infarction (heart attack), such multiple beats are a sign of damaged heart muscle. They may lead to a condition called ventricular fibrillation, a rapid, uncoordinated, potentially fatal heartbeat.

Multiple ectopic beats that are causing palpitations, or those that occur after a myocardial infarction, are often treated with an antiarrhythmic drug. (See also arrhythmia, cardiac.)

ectopic pregnancy
A pregnancy that develops outside the uterus, most commonly in a fallopian tube, but sometimes in an ovary, the abdominal cavity, or the cervix (neck of the uterus). As the pregnancy develops, it may damage surrounding tissues, causing serious bleeding. An ectopic pregnancy is potentially life-threatening and requires emergency treatment.
ultrasound probe is inserted into the vagina, and it can be confirmed by laparoscopy (internal examination using a viewing instrument).

If the diagnosis is made early on, treatment using the drug methotrexate may be considered. In most cases, surgery, usually minimally invasive surgery, is carried out to remove the embryo (which is usually already dead), the placenta, and any damaged tissue at the site of the pregnancy. If blood loss is severe, blood transfusions may be necessary. An affected fallopian tube is removed if it cannot be repaired.

OUTLOOK
It is still possible to have a normal pregnancy even if one fallopian tube has been removed, although the chances of conception are slightly reduced. Women with two damaged tubes may require in vitro fertilization to achieve an intrauterine pregnancy.

ectopic testis
See testis, ectopic.

ectropion
A turning outwards of the eyelid so that the inner surface is exposed. Ectropion is most common in elderly people, in whom it usually affects the lower lid and is due to weakness of the muscle surrounding the eye.

The condition may also be caused by the contraction of scar tissue in the skin near either lid. Ectropion often follows facial palsy, which causes paralysis of the muscles around the eye.

Even slight ectropion interferes with the normal drainage of tears by distorsion of the opening of the tear duct. Chronic conjunctivitis may result, causing redness, discomfort, and overflow of tears so that the skin becomes damp and inflamed. Constant wiping tends to pull the lid farther from the eye.

Surgery to tighten the affected eyelid may be required.

eczema
An inflammation of the skin, usually causing itching and sometimes scaling or blisters. There are several different types of eczema and some forms are better known as dermatitis (such as contact dermatitis and photodermatitis). Eczema is sometimes the result of an allergy, but is often of unknown cause.

TYPES
Atopic eczema Atopic eczema is a chronic, superficial inflammation that occurs in people who have an inherited tendency towards allergy. The condition is common in babies. An intensely itchy rash occurs, usually on the face, in the elbow creases, and behind the knees. The skin often scales and small red pimples may appear. Infection may occur if the rash is scratched, breaking the skin.

For mild cases, emollients (such as petroleum jelly) help to keep the skin soft. In severe cases, ointments containing corticosteroid drugs may be used. Antihistamine drugs may be prescribed to reduce itching. Excluding certain foods from the diet may help to control the condition. Atopic eczema often clears up on its own as a child grows older.

Nummular eczema Nummular eczema usually occurs in adults and is of unknown cause. It produces round, itchy, scaling patches on the skin that are similar to those of tinea (ringworm). Topical corticosteroids may reduce inflammation, but the eczema is often persistent.

Hand eczema Hand eczema is usually caused by irritant substances such as detergents, but it may occur for no apparent reason. Itchy blisters develop, usually on the palms, and the skin may become scaly and cracked.

Hand eczema usually improves if emollients are used and if cotton gloves with rubber gloves over them are worn when coming into contact with irritants. If the eczema is severe, corticosteroids may be prescribed.

Stasis eczema Stasis eczema occurs in people with varicose veins. The skin on the legs may become irritated, inflamed, and discoloured. The swelling of the legs may be controlled with compression bandages or stockings. Application of ointments containing corticosteroids may give temporary relief.

GENERAL TREATMENT
To reduce irritation and the risk of scratching, a soothing ointment should be applied to the affected areas; these may then be covered with a dressing to prevent scratching. Absorbent, non-irritating materials (such as cotton) should be worn next to the skin; irritants (such as wool, silk, and rough synthetics) should be carefully avoided.

EDD
The abbreviation for expected date of delivery, the date on which a baby is due to be born. The EDD is calculated as 40 weeks from the first day of the woman’s last menstrual period (see period, menstrual). In practice, babies are rarely born exactly on their EDD.

edentulous
A term meaning without teeth, a condition arising either because the teeth have not yet grown or because they have fallen out or been removed by a dentist.

Edwards’ syndrome
A genetic disorder, also known as trisomy 18 syndrome, that is associated with the presence of a third copy of chromosome 18. Edwards’ syndrome affects about three times as many girls as boys.

Characteristics of Edwards’ syndrome include a low birth weight, severe learning difficulties, low-set and malformed ears, a small jaw, hand abnormalities, opacities in the cornea of the eye, congenital heart disease (see heart disease, congenital), hernias, ventricular septal defect (a hole between the lower chambers of the heart), and kidney abnormalities.

Approximately half the babies born with Edwards’ syndrome do not survive beyond the first week of life. Very few infants live longer than a year. People with a family history of Edwards’ syndrome should consider genetic counselling before starting a family.

EEG
The abbreviation for electroencephalography, a method of recording the electrical activity of the brain. A trace of the activity is displayed on a monitor or printed out on a moving strip of paper.

In EEG, small electrodes are attached to the scalp and connected to an instrument that records minute electrical impulses produced by the brain’s activity. By revealing characteristic wave patterns, an EEG can help in diagnosing different types of epilepsy and identifying areas in the brain where abnormal electrical activity develops. (See also How electroencephalography is done box, overleaf.)
effusion

The process by which fluid escapes. The term effusion also describes an abnormal collection of fluid (such as blood, pus, or plasma) in the tissues or a body cavity. An effusion can form as a result of inflammation or changes in pressure within blood vessels; alternatively, it can be due to changes in the blood constituents, such as in nephrotic syndrome (a kidney disorder).

Effusion commonly occurs around the lung (see pleural effusion) or heart (see pericardial effusion) or within joints, causing swelling (see effusion, joint).

effusion, joint

The accumulation of fluid in the space around a joint, resulting in swelling, limitation of movement, and usually also pain and tenderness. All joints are enclosed by a capsule lined with a membrane called the synovium. The synovium normally secretes small amounts of fluid (known as synovial fluid) to lubricate the joint. However, if the synovium is damaged or inflamed (for example, as a result of arthritis), it produces excessive fluid.

The pain and inflammation may be relieved by analgesic drugs (painkillers) and nonsteroidal anti-inflammatory drugs and by having injections of corticosteroid drugs. The swelling usually reduces if the affected joint is rested, bandaged firmly, cooled with ice packs, and kept elevated. In some cases, the excess fluid is drawn out of the joint using a needle and syringe.

egg

See ovum.

ego

The conscious sense of oneself. In Freudian psychoanalytic theory, the ego maintains a balance between the primitive, unconscious instincts of the id, the controls of the superego, and the demands of the outside world.

Ehlers–Danlos syndrome

An inherited disorder of collagen, the most important structural protein in the body. Individuals with Ehlers–Danlos syndrome have abnormally stretchy, thin skin that bruises easily. Wounds are slow to heal and leave paper-thin scars, and the joints are loose and prone to recurrent dislocation. Sufferers bleed easily from the gums and digestive tract.

Ehlers–Danlos syndrome is most commonly inherited in an autosomal dominant pattern (see genetic disorders). There is no known specific treatment for the condition, although unnecessary accidental injury, such as that which may occur in contact sports, should be avoided by sufferers.

Eisenmenger complex

A condition in which deoxygenated blood flows directly back into the circulation rather than through the lungs. This is due to an abnormal connection between the left and right sides of the heart and to pulmonary hypertension (in which there is abnormally high blood pressure in the arteries supplying the lungs). The resultant hypoxia (lack of oxygen in the blood) causes cyanosis (bluish coloration of the skin), fainting, and difficulty in breathing.

Eisenmenger complex occurs most commonly in individuals who have certain uncorrected congenital heart defects (see heart disease, congenital), such as ventricular septal defect.

The diagnosis of Eisenmenger complex may be confirmed by cardiac catheterization (the insertion, under X-ray control, of a thin tube into the heart via a blood vessel). Once the condition has developed, surgical correction of the original defect will not help. Drug treatment may help control the symptoms.
ejaculation
The emission of semen from the penis at orgasm. Just before ejaculation, muscles around the epididymides (ducts in which sperm are stored; see epididymis), the prostate gland, and the seminal vesicles contract rhythmically, forcing the sperm from the epididymides to move forwards and mix with secretions from the seminal vesicles and the prostate. At ejaculation, this fluid is propelled out of the body through the urethra.

Because both semen and urine leave the body by the same route, the bladder neck closes during ejaculation. This not only prevents ejaculate from going into the bladder but also stops urine from contaminating the semen. (See also reproductive system, male.)

ejaculation, disorders of
A group of conditions in which the normal process or timing of ejaculation is disrupted.

TYPES
Premature ejaculation In premature ejaculation, semen emission occurs before or almost immediately following penetration. Premature ejaculation is the most common sexual problem in men, particularly in young men who have only recently become sexually active. It is often due to over-stimulation or to anxiety about sexual performance. If the problem occurs frequently, sexual counselling and techniques for delaying ejaculation may help (see sex therapy).

Inhibited ejaculation This is a rare condition in which erection is normal, or even prolonged, but ejaculation is abnormally delayed or fails to occur. The problem may be psychological in origin, in which case counselling may help, or it may arise as a complication of a disorder such as diabetes mellitus or alcohol dependence. In some cases, inhibited ejaculation occurs as a side effect of certain drugs, such as some antihypertensive drugs and antidepressant drugs.

The cause is treated where possible; if drug treatment is thought to be the cause, a change to another drug may resolve the problem.

Retrograde ejaculation In retrograde ejaculation, the neck of the bladder, which normally closes during ejaculation, stays open. As a result, semen is forced backwards into the bladder and none is expelled from the penis.

Retrograde ejaculation may be due to a neurological disease, surgery on the bladder, or prostatectomy (removal of the prostate gland). There is no treatment, but sexual intercourse with a full bladder can sometimes result in normal ejaculation. If an affected man and his partner wish to have a baby, it is sometimes possible to harvest sperm from the bladder for use in in vitro fertilization. (See also azoospermia; psychosexual dysfunction; sexual problems.)

elastitic bandage
A type of stretchable bandage that is especially useful in the treatment of joint injuries and for swelling of the legs due to varicose veins. An elastitic bandage helps to minimize swelling while not impeding movement.

elevator
The hinge joint formed where the lower end of the humerus (upper-arm bone) meets the upper ends of the radius and ulna (the forearm bones). The elbow is stabilized by ligaments at the front, the back, and the sides. The elbow joint connects the upper arm to the forearm and allows the arm to be bent and straightened, and to be rotated through almost 180 degrees around its long axis without more than a very slight movement of the upper arm.

DISORDERS
Disorders of the elbow include arthritides and various injuries to the joint and its surrounding muscles, tendons, and ligaments. Repeated strain on the tendons of the forearm muscles, where they attach to the elbow, can result in inflammation that is known as episcondylitis. There are two main types of episcondylitis: tennis elbow and golfer’s elbow. Alternatively, a sprain of the ligaments around the elbow joint may occur.

Olecranon bursitis develops over the tip of the elbow in response to local irritation. Strain on the elbow joint can produce an effusion (the accumulation of fluid in a joint) or traumatic synovitis (inflammation of the membranes that line the joint capsule).

A sharp blow on the olecranon process (the bony tip of the elbow, also known as the “funny bone”) may impinge on the ulnar nerve as it passes in a groove in this area, causing temporary discomfort: a pins-and-needles sensation and lancinating pains that shoot down the arm into the fourth and fifth fingers.

A fall onto an outstretched hand or onto the tip of the elbow can cause a fracture or dislocation of the elbow.

elderly, care of the
Appropriate care to help maintain physical and mental deterioration in the elderly. For example, failing vision and hearing are often regarded as inevitable in old age, but removal of a cataract (loss of transparency in the lens of the eye) or use of a hearing-aid can often improve quality of life.

Isolation or inactivity leads to depression in some elderly people. Attending a day-care centre can provide social contact and introduce new interests.

Many elderly people are cared for by family members. Voluntary agencies can often provide domestic help in order to ease the strain on carers. The option of sheltered housing allows independence while providing a degree of supervision and assistance when it is needed. Elderly people who have dementia (loss of normal brain function) or a physical disability may require more supervision, in a residential care or hospital setting. (See also geriatric medicine.)

elective
A term used to describe a procedure, usually a surgical operation, that is not urgent and can be performed at a scheduled time. Elective surgery includes the correction of nonurgent medical conditions, such as haemorrhoids, and some cosmetic procedures, such as rhinoplasty.
electrical injury
Damage to tissues caused by an electric current passing through the body and the associated heat release. The internal tissues of the body, being moist and salty, are good conductors of electricity.

Dry skin provides a high resistance to current flow, but moist skin has a low resistance and thus allows a substantial current to flow into the body. Serious injury or death from domestic voltage levels is therefore more likely to occur in the presence of water.

PHYSICAL EFFECTS
All except the mildest electric shocks may result in unconsciousness. Alternating current (AC) is more dangerous than direct current (DC): it causes sustained muscle contractions, which may prevent the victim from releasing the source of the current. A current as small as 0.1 amp passing through the heart can cause a fatal arrhythmia (irregular heartbeat). The same current passing through the brainstem may cause cessation of the heartbeat and breathing.

Larger currents may cause charring of tissues, especially where the current enters and exits the body.

electric shock treatment
See ECT.

electrocardiography
See ECG.

electrocautery
A technique for destroying tissue using heat produced by an electric current. Electrocautery is used to remove skin blemishes such as warts. (See also cauterization; diathermy; electrocoagulation.)

electrocoagulation
Use of a high-frequency electric current to seal blood vessels by heat, stopping bleeding. Electrocoagulation is used in surgery; the current is delivered through a surgical knife, enabling the surgeon to make bloodless incisions. The procedure is also used to stop nosebleeds and to destroy abnormal blood vessel formations, such as spider naevi, in which case current is applied through a fine needle.

electroconvulsive therapy
See ECT.

electrode
A device through which an electrical current is transmitted or received. In ECG, for example, electrodes are applied to the chest wall to detect electrical impulses from the heart. Other procedures using electrodes include certain types of physiotherapy, in which electrodes are attached to the skin and emit electrical impulses to stimulate the underlying muscles. (See also ECT; electrocautery; electrocoagulation; electrolysis; electronystagmography.)

electroencephalography
See EEG.

electrolysis
Permanent removal of unwanted hair by introducing a short-wave electric current into the hair follicle. The current destroys the hair root either by causing a chemical reaction (a process that is called galvanism) or by generating heat, which seals off the blood vessels supplying the hair (see diathermy).

WHY IT IS DONE
Hair on the face and body can be removed temporarily by shaving or plucking or by the use of depilatory creams, abrasives, or wax preparations. However, electrolysis is the only method of permanent hair removal.

AREAS THAT CAN BE TREATED
With a few exceptions, electrolysis can be safely used on any part of the body. Its use should be avoided on the lower margins of the eyebrows because the skin above the eyelids is very delicate and easily damaged. It is also questionable whether the technique should be used on the armpits due to the risk of bacterial infection. Electrolysis has no harmful effect on the breasts (where hair sometimes grows around the areola, the pigmented area surrounding the nipple) and does not affect breastfeeding. The legs are not well suited to electrolysis because treatment of this extensive area requires so many sessions that the procedure would be very time-consuming and expensive.

NEWER TREATMENTS
Alternative methods of hair removal, which are faster and less painful than electrolysis, are now available.

One new method is a form of laser treatment in which hair follicles are disabled by a laser beam. The treatment can be used on several hundred hair follicles simultaneously. It works best on people with pale skin and dark hair, because the melanin (dark pigment) in the hair absorbs energy from the laser, while the skin (which has little melanin) is relatively unaffected.

Another new technique, known as photo-epilation, involves the use of intense pulsed light to disable hundreds of hair follicles at the same time, with minimal side effects.

electrolyte
A substance whose molecules dissociate (split) into its constituent ions (electrically charged particles) when dissolved or melted. For example, sodium chloride (table salt) dissociates into sodium cations (positively charged ions) and chloride anions (negatively charged ions) when dissolved in water.

electromyography
See EMG.

electronystagmography
A method of recording types of nystagmus (abnormal, jerky movements of the eye) in order to investigate their cause. In electronystagmography, electrical changes caused by eye movements are picked up by electrodes that are placed near the eyes and are recorded on a graph.

electrophoresis
The movement of electrically charged particles that are suspended in a colloid solution under the influence of an electric current. The direction, distance, and rate of movement of the particles vary according to their size, shape, and electrical charge.

Electrophoresis is used to analyse mixtures (to identify and quantify the proteins in blood, for example), and it
may be used as a diagnostic test for multiple myeloma, a bone marrow tumour that produces abnormally high blood levels of a specific antibody (a protein manufactured by the immune system).

**elephantiasis**
A disease that occurs in the tropics and is characterized by massive swelling of the legs, the arms, and, in men, the scrotum (the pouch behind the penis that contains the testes). There is also thickening and darkening of the skin. Most cases of elephantiasis are due to chronic lymphatic obstruction caused by *filariasis* (a worm infestation).

**elimination diet**
A dietary programme used to identify a food allergy or food intolerance. Test foods, such as milk, are gradually omitted from the diet one at a time to see if they are responsible for the symptoms. (See also exclusion diet.)

**ELISA test**
A laboratory blood test used in the diagnosis of infectious diseases. ELISA stands for enzyme-linked immunosorbent assay. (See also immunoassay.)

**elixir**
A clear, sweetened liquid, which often contains alcohol, that forms the basis of many liquid medicines, such as cough remedies.

**ellipsoidal joint**
A type of mobile joint, such as the wrist joint, that allows all types of movement except full rotation.

**Eltroxin**
A brand name for levothyroxine, a synthetic thyroid hormone.

**emaciation**
Abnormal thinness or wasting away of the body, which may be the result of a variety of conditions including malnutrition, worm infestation, or diseases such as tuberculosis or cancer.

**embolectomy**
Surgical removal of an embolus (a fragment of material, often a blood clot, that is carried in the bloodstream and has blocked an artery; see *embolism*).

There are two methods of embolectomy. In one procedure, an incision is made in the affected artery and the embolus is removed through a suction tube. In balloon embolectomy, a balloon catheter (a flexible tube with a balloon at its tip) is passed into the affected blood vessel, to just beyond the embolus. The balloon is inflated and the catheter is withdrawn from the body, bringing the embolus out with it.

**embolism**
Blockage of an artery by an embolus (a fragment of material carried in the bloodstream). An embolus may consist of various substances. It is usually formed from a blood clot. Other substances that may form an embolism include a bubble of air or other gas; a piece of tissue or tumour; a clump of bacteria, bone marrow, cholesterol, or fat; or, rarely, amniotic fluid forced into a woman’s circulation during childbirth.

**TYPES**
A blood clot that has broken off from a larger clot elsewhere in the circulation is the most common type of embolus.

Pulmonary embolism is a disorder that may be due to a blood clot. The condition is usually the result of a fragment breaking off from a deep vein thrombosis (see thrombosis, deep vein) and being carried via the heart to block an artery supplying the lungs. Pulmonary embolism may cause sudden death. Blood clots may form inside the heart after a myocardial infarction (heart attack), or in the atria (upper chambers of the heart) in atrial fibrillation, and then travel to the brain. This results in a cerebral embolism, which is an important cause of stroke (damage to part of the brain due to interruption to its blood supply).

Air embolism, in which a small artery is blocked by an air bubble, is rare. Fat embolism, in which a vessel is blocked by fat globules, is a possible complication of a major fracture of a limb; it occurs when fat is released from the marrow of the broken bone. Amniotic fluid embolism occurs during labour or immediately after delivery of the baby. This rare complication of childbirth is often fatal.

**SYMPTOMS**
Symptoms of an embolism depend on the site of the embolus. Pulmonary embolism can lead to breathlessness and chest pains. If the embolus lodges in the brain, a stroke may occur, affecting speech, vision, or movement. If an embolism blocks an artery to the leg, the limb will become painful and turn pale. If left untreated, gangrene (tissue death) may develop.

In serious cases of fat embolism, heart and breathing rates rise dramatically and there may be restlessness, confusion, and drowsiness.

**TYPES OF EMBOLISM**

<table>
<thead>
<tr>
<th>Embolism Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Cerebral embolism</td>
<td>A blockage of one of the arteries that supply blood to the brain; it is one of the most common causes of stroke.</td>
</tr>
<tr>
<td>Pulmonary embolism</td>
<td>A blockage of one of the arteries that supply blood to the lungs. This may cause chest pain, breathlessness, and sudden death.</td>
</tr>
<tr>
<td>Amniotic fluid embolism</td>
<td>The escape of some of the fluid that surrounds the baby in the uterus into the mother’s circulation. This may cause blockage of an artery in one of her lungs.</td>
</tr>
<tr>
<td>Embolism in leg</td>
<td>An embolism may block one of the arteries that supply blood to the leg. Gangrene may occur below the blockage.</td>
</tr>
</tbody>
</table>
**TREATMENT**

If a severe embolism causes the person to collapse, emergency life-saving measures are undertaken to maintain the breathing and circulation (see cardio-pulmonary resuscitation).

*Embolectomy* (surgical removal of the blockage) may be possible. If the embolus is formed from a blood clot and surgery is not possible, *thrombolytic drugs* (drugs that dissolve blood clots) and *anticoagulant drugs* (drugs that prevent clot formation) may be given.

**embolization**

Deliberate obstruction of a blood vessel using an artificial embolus (a fragment of material carried in the bloodstream) made of material such as gel foam, PVA (resin), liquid sclerosants (hardeners), or medical glue. Embolization is carried out to stop uncontrollable internal bleeding or to cut off the blood supply to a *tumour*, especially a *fibroid*. In the latter case, embolization can relieve pain; cause the tumour to shrivel, making surgical removal easier; or stop the tumour from spreading. Embolization can also be used to block flow through vascular abnormalities such as *haemangiomas*, in both the skin and internal organs.

A *catheter* (flexible tube) is introduced into a blood vessel near the one to be blocked. An embolus is released through the catheter; it lodges inside the vessel, blocking blood flow to the affected area.

**embolus**

A fragment of material, usually a blood clot, that is carried in the bloodstream and obstructs an *artery*. An embolus is life-threatening if it blocks blood flow through a vital artery (see *embolism*).

**embrocation**

A medication rubbed into the skin in order to relieve muscular or joint pain.

**embryo**

The unborn child during the first eight weeks of its development following *conception*; for the rest of the pregnancy it is known as a *fetus*.

Development of the embryo is governed internally by *genes* inherited from the parents and externally by factors such as the mother’s diet and any drugs taken during pregnancy.

**THE FIRST TWO WEEKS**

The embryo develops from an *ovum* (egg) that has been fertilized by a *sperm* (see *fertilization*). It starts as a single cell, but divides several times as it travels along the *fallopian tube* to the *uterus* (womb) to form a spherical mass of cells.

About six days after conception, this mass becomes embedded in the uterus lining. At the site of attachment, the outer layer of cells obtains nourishment from the woman’s blood; this part will later become the *placenta*. In the cell mass, a flat disc forms, consisting of layers of cells from which all the baby’s tissues will form. The *amniotic sac* develops around the embryo.

**THE THIRD WEEK**

Early in the third week, the disc of cells becomes pear-shaped. The head of the embryo forms at the rounded end and the lower spine at the pointed end. A group of cells develops along the back of the embryo to form the notochord, a rod of cells that constitutes the basis for the spine. From this time onwards, the embryo has two recognizable halves that develop more or less symmetrically.

The notochord then furrows and the edges grow towards each other before fusing to form the neural tube. Later, the neural tube will develop into the *brain* and *spinal cord*.

**THE FOURTH WEEK**

During the fourth week, the embryo’s back grows more rapidly than its front, giving it a C-shape. The neural tube extends towards the embryo’s head, where a fold that will eventually form the brain becomes visible.

Developing ears appear as pits and rudimentary eyes form as stalks. Within the embryo, buds of tissue form that will become the lungs, pancreas, liver, and gallbladder. A heart starts to develop in the form of a tube. Outer layers of the embryo begin to form the limb buds and paired bulges appear on the sides of the neural tube that will eventually become the cartilage, bone, and muscle of the back.

**THE FIFTH WEEK**

During the fifth week of pregnancy, the embryo’s external ears become visible; pits mark the position of the nose; the jaws form; and the limb buds extend, becoming flattened at the ends where the hands and feet will develop. Folds of tissue fuse to form the front wall of the chest and abdomen. The *umbilical cord* develops.

**THE SIXTH TO EIGHTH WEEKS**

During weeks six to eight, the embryo’s face becomes recognizably human, the neck forms, the limbs become jointed, and fingers and toes appear. After eight weeks, the embryo is about 2.5 cm long. Most of the internal organs have formed and all the external features are present.

**embryo diagnosis**

Also called preimplantation diagnosis, a procedure carried out on *embryos* at an early stage of development to determine whether they are affected by a *genetic disorder*. Embryo diagnosis may be carried out following *in vitro fertilization* (IVF) if the parents are known to be carriers of a specific disorder.

Several eggs are fertilized; they are grown for a few days in specialized laboratories until the first two or three cell divisions have taken place and the clusters contain approximately eight cells. One cell from each cluster is removed in order for its *DNA* to be analysed. Embryos that are found to be healthy can then be implanted in the mother’s uterus (womb).

**embryology**

The study of the development and growth of the *embryo* and then the *fetus* from *conception* through the months of gestation until birth.

Embryology is an essential part of a medical student’s training because it leads to a greater understanding of the anatomy of an adult and of the ways in which structural defects in the body may arise. For example, the occurrence of congenital heart defects is easier to understand when the stages of fetal heart development are explained. (See also *embryo diagnosis*.)

**embryoma of the kidney**

An alternative name for *Wilms’ tumour*.

**emergency**

Any condition requiring urgent medical treatment, such as *cardiac arrest* (a halt in the pumping action of the heart), or any procedure that must be performed immediately, such as *cardiopulmonary resuscitation*.

**emergency contraception**

See *contraception, emergency*.

**emesis**

The medical term for *vomiting*.

**emetic**

A substance that causes *vomiting*, used to treat some types of poisoning and drug overdose. Emetics act by stimulating the
THE DEVELOPING EMBRYO

From the time of conception until the eighth week, the developing baby is known as an embryo. At conception, the fertilized egg consists of a single cell, the zygote, which contains genetic material from the sperm and the ovum. The zygote divides several times to form a ball of cells, which then implants into the lining of the uterus. At the point of attachment, the outer layer of cells forms the placenta, while a group of cells within one area of the cell ball develops into the embryo. A sac filled with amniotic fluid forms around the embryo to protect it. As the embryo grows, it begins to form features and, by the fifth week, it has developed a recognizable head and limb buds.

Passage to the uterus
The egg is fertilized in one of the fallopian tubes and is carried to the uterus, where it embeds in the uterine lining.

INTERNAL ORGANS AT FIVE WEEKS

All the internal organs (such as the liver, pancreas, stomach, kidneys, heart, lungs, and sex organs) have begun to form by the fifth week. During this critical stage of development, the embryo is highly vulnerable to harmful substances that are consumed by the mother (such as alcohol and medication), which may cause birth defects.

ACTUAL SIZE

Three weeks
The embryo now becomes pear-shaped, with a rounded head, pointed lower spine, and notochord running along its back.

Four weeks
The embryo now becomes C-shaped and a tail is visible. The umbilical cord forms and the forebrain enlarges.

Embryo at about six weeks
The embryo is floating in the amniotic sac. The smaller sac above (the yolk sac) provides nourishment for the early embryo.

ACTUAL SIZE

Six weeks
Eyes are visible and the mouth, nose, and ears are forming. The limbs grow rapidly from initial tiny buds.

Eight weeks
The face is more “human”, the head is more upright, and the tail has gone. Limbs become jointed and digits appear.
part of the brain that controls vomiting and/or by directly irritating the lining of the stomach. The most widely used emetic is *ipecacuanha*.

**EMG**

The abbreviation for electromyogram, a recording of the electrical activity within a muscle.

**WHY IT IS DONE**

An EMG can help to diagnose muscle disorders, such as *muscular dystrophy*, or conditions in which the nerve supply to the muscle is impaired, such as *neuropathy*, *radiculopathy*, or *motor neuron disease*. In cases of nerve injury, the actual site of the nerve damage can often be located.

**HOW IT IS DONE**

Electrical activity is measured during muscle contraction and at rest. Small disc electrodes are attached to the skin over the muscle; alternatively, needle electrodes are inserted into the muscle. The impulses from the muscle are displayed on an oscilloscope screen, which shows muscle contraction and relaxation in the form of a wave pattern and reveals whether or not the muscle activity is normal. A permanent record can be made of the EMG. The procedure has no side effects.

**EMLA**

An acronym for “eutectic mixture of local anaesthetics”. *(The word “eutectic” means “easily melted”.) EMLA is a brand-named cream applied to the skin to produce local anaesthesia (see *anaesthesia, local*). It is used to reduce discomfort before intravenous injection and *venepuncture*, particularly in children, and before treating localized skin conditions such as genital warts (see *warts, genital*).

**emollient**

A substance, such as lanolin or petroleum jelly, that has a soothing and softening effect when applied to the skin. Emollients have a moisturizing effect on the skin because they form an oily film on its surface, which prevents loss of water. Emollients are used in creams, ointments, lotions, and bath additives.

**emotional deprivation**

A lack of sufficient loving attention and of warm, trusting relationships during early childhood, causing normal emotional development to be inhibited. Emotional deprivation may result if *bonding* does not occur in the early months of life or if a child is frequently separated from his or her parents for long periods during the first five years.

Emotionally deprived children may be impulsive, unable to cope with frustration, hungry for attention, and may have impaired intellectual development.

**emotional overlay**

A term used by some doctors to describe physical symptoms that they feel have been worsened by emotional difficulties. For example, it is common for symptoms of a condition to worsen when an individual is unhappy or worried. *(See also *pain*.)

**empathy**

The ability to understand and share the thoughts and feelings of another person. In *psychoanalysis*, the therapist partly relies on empathy to establish a relationship with a patient.

**emphysema**

A disease in which the walls of the alveoli (see *alveolus, pulmonary*) are progressively destroyed, thereby reducing the area of lung available for exchange of gases. The alveoli, of which there are many millions in each lung, are groups of air sacs at the end of bronchioles (tiny air passages). Through their thin walls, inhaled oxygen is passed into the bloodstream and carbon dioxide is removed from the capillaries to be breathed out.

Emphysema usually develops along with chronic *bronchitis*, in a condition known as chronic obstructive pulmonary disease (see *pulmonary disease, chronic obstructive*).

**CAUSES**

In almost all cases, emphysema is a direct result of smoking. In rare cases, an inherited deficiency of a chemical called *alpha,*-antitrypsin in the body results in emphysema and, in a minority of people, also affects the liver (see *alpha,*-antitrypsin deficiency).

Tobacco smoke and other air pollutants are believed to cause emphysema by provoking the release of chemicals within the alveoli that cause damage to the alveolar walls. *Alpha,*-antitrypsin is thought to protect against this chemical damage; therefore, people with a deficiency of this substance are particularly badly affected by emphysema.

The damage is slight at first, but in heavy smokers it becomes progressively worse; the alveoli burst and merge to form fewer, larger sacs with less surface area, which consequently impairs oxygen and carbon dioxide exchange. Over the years the lungs become increasingly less elastic, which further reduces their efficiency.

**SYMPTOMS AND SIGNS**

Initially, there are no symptoms, but as the disease progresses and the lungs suffer damage, there is an increasing shortness of breath. In some people, the chest becomes barrel-shaped as air is trapped in the lungs. There may also be a chronic cough (caused by the accompanying bronchitis) and a slight wheeze.

Eventually (sometimes after many years) the level of oxygen in the blood starts to fall. In some cases, *pulmonary hypertension* (raised blood pressure in the pulmonary artery) develops, leading to *cor pulmonale* (enlargement and strain on the right side of the heart). Affected people start to turn blue due to a lack of oxygen in the blood; their legs subsequently swell as a result of *oedema* (accumulation of fluid in the tissues). Other sufferers are able to compensate for oxygen deficiency to some extent by breathing faster, thereby retaining their normal colouring. Many people show signs falling somewhere between these two extremes.

**DIAGNOSIS**

A diagnosis is made from the patient’s symptoms and signs, from a chest examination, and from various tests. A blood sample from an artery may be analysed to measure the concentration of oxygen and carbon dioxide in the blood; blood oxygen levels may alternatively be measured using an *oximeter*. A blood test for *alpha,*-antitrypsin deficiency may be performed if there is a family history of the disorder. Chest *X-rays* are taken to exclude the possibility of another lung disease being responsible for the symptoms and to determine how great an area of the lungs has been affected. *Pulmonary function tests* are carried out to assess breathing capacity and the efficiency of the alveoli in exchanging gases.

**TREATMENT AND PREVENTION**

Once the damage to the lungs has occurred, there is no treatment that can
reverse it. However, giving up smoking will greatly reduce the rate at which the lungs deteriorate. The efficiency of the remaining lung tissue may be improved in various ways. For example, bronchodilator drugs may be given to widen the bronchioles and patients who are deficient in alpha,-antitrypsin may be given replacement alpha,-antitrypsin therapy.

To treat oedema, diuretic drugs may help to reduce the volume of fluid in the body by promoting its output through increased urine production. If the blood oxygen level is continually low, oxygen therapy at home may be needed.

People who have a localized area of emphysema in one lung may be offered surgery to remove the affected area of tissue, which will allow the remaining lung tissue to re-expand. A single lung transplant operation (see transplant surgery) may be considered if respiratory failure is life-threatening.

**emphysema, surgical**

The abnormal presence of air in tissues under the skin following surgery or injury. Surgical emphysema most commonly occurs as a complication of pneumothorax (the abnormal presence of air in the pleural cavity between the lung and the chest wall).

**empirical treatment**

Treatment that is given simply on the grounds that its effectiveness has been observed in previous, similar cases. Empirical treatment is different to treatment that is based on an understanding of the nature of a disorder and the way in which the particular method of treatment works.

**empyema**

An accumulation of pus in a body cavity or an internal organ. Empyema can occur around a lung as a rare complication of an infection such as pneumonia or pleurisy. The main symptoms are chest pain, breathlessness, and fever. Treatment is generally by aspiration (removal of the pus by suction) and the injection of antibiotic drugs. An operation to open the chest cavity and drain the pus may sometimes be performed.

Empyema of the gallbladder is a complication of cholecystitis (inflammation of the gallbladder), causing abdominal pain, fever, and jaundice (yellowing of the skin and the whites of the eyes). This type of empyema is treated by surgical removal of the gallbladder.

**EMU**

An abbreviation for early morning urine, a specimen of urine collected on the patient’s first visit to the toilet after waking up. This type of urine specimen is often requested in an investigation for tuberculosis affecting the kidney.

**emulsifying ointment**

A type of emollient containing emulsifying wax, white soft paraffin, and liquid paraffin. Emulsifying ointment is used to smooth, soothe, and hydrate the skin in all dry or scaling conditions. Rarely, ingredients such as preservatives may result in skin sensitization.

**enalapril**

An ACE inhibitor drug that is used in the treatment of hypertension (high blood pressure) and heart failure (a reduced pumping efficiency of the heart). The drug inhibits a chemical reaction that causes blood vessels to constrict, and thus allows vessels to dilate (widen); as a result, it lowers blood pressure and reduces the workload of the heart.

One side effect of enalapril is a sudden drop in blood pressure on taking the first dose. For this reason, the patient should rest while the dose is taken and for two or three hours afterwards. More common adverse effects of the drug include headaches and dizziness; these effects should diminish with continued treatment.

**enamel, dental**

The hard outer layer of a tooth (see teeth) that protects the inner structures.

**encephalitis**

Inflammation of the brain, and sometimes also the meninges (the three membranes that cover and protect the brain and the spinal cord), usually due to a viral infection. Encephalitis varies in severity from a mild problem, in which symptoms are barely noticeable, to a serious and potentially life-threatening disorder.

**CAUSES**

Mild cases of encephalitis may be due to glandular fever (see mononucleosis, infectious) or may be a complication of viral diseases such as mumps or measles.

In Europe, the most common cause of life-threatening encephalitis is herpes simplex. In South-east Asia, Japanese B encephalitis, due to a virus spread by mosquitoes, is the most dangerous type. Occasionally, outbreaks of viral encephalitis occur elsewhere in the world; for example, an outbreak of West Nile virus, another mosquito-borne form of the disease, occurred in New York in 1999. People with HIV are particularly at risk from severe viral encephalitis, and may also develop cerebral abscesses (collections of pus in the brain tissue).

**SYMPTOMS**

Mild cases of encephalitis usually develop over several days and may cause only a slight fever and mild headache. In serious cases of encephalitis, the symptoms develop rapidly and include weakness or paralysis; speech, memory, and hearing problems; and a gradual loss of consciousness. Coma (a state of unconsciousness and unresponsiveness to external stimuli) and seizures may also occur. If the meninges are inflamed, certain other symptoms (for example, a stiff neck and abnormal sensitivity to light) may develop (see meningitis).

**DIAGNOSIS AND TREATMENT**

Diagnosis is based on results of blood tests; CT scanning or MRI (techniques that produce cross-sectional or three-dimensional images of the brain); EEG (a method of recording the electrical activity of the brain); lumbar puncture (taking a sample of fluid from the spinal canal for analysis); and, very occasionally, a brain biopsy (removal of a small sample of tissue for analysis).

Encephalitis due to herpes simplex is treated with intravenous infusion of the antiviral drug aciclovir, but there is no known treatment for encephalitis caused by other viral infections.

**encephalitis lethargica**

An epidemic form of encephalitis (brain inflammation). There have been no major outbreaks of the condition since the 1920s, but rare sporadic cases still occur. Symptoms of encephalitis lethargica are those of encephalitis, with additional lethargy and drowsiness.

Many survivors of the initial illness during the major epidemics developed a movement disorder that became known as post-encephalitic Parkinson’s disease.

**encephalocele**

A type of neural tube defect resulting in defects of the brain rather than of the spinal cord, as occurs in spina bifida.

**encephalomyelitis**

Inflammation of the brain and spinal cord, resulting in damage to the nervous system, usually due to a viral infection.
CAUSES
Encephalomyelitis develops as a rare complication of measles or, less commonly, of other viral infections, such as chickenpox, rubella (German measles), or glandular fever (see mononucleosis, infectious). It may also occasionally follow vaccination against rubies.

SYMPTOMS
Symptoms of encephalomyelitis include fever, drowsiness, headache, seizures, partial paralysis or loss of sensation, and, in some cases, coma (a state of unconsciousness and unresponsiveness to internal or external stimuli).

DIAGNOSIS AND TREATMENT
Diagnosis is based on the results of blood tests; CT scanning or MRI (techniques that produce cross-sectional or three-dimensional images of the body structures); EEG (a method of recording the electrical activity of the brain); lumbar puncture (taking a sample of fluid from the spinal canal for analysis); and, rarely, a brain biopsy (removal of a small sample of brain tissue for microscopic analysis).

There is no cure for the disease, but corticosteroid drugs are given to reduce inflammation and anticonvulsant drugs to control seizures.

OUTLOOK
The disease is often fatal; those who survive may suffer permanent damage to the nervous system.

encephalomyelitis, myalgic
Another term for the disorder chronic fatigue syndrome.

encephalopathy
Any disorder affecting the brain, especially chronic degenerative conditions.

TYPES
Wernicke’s encephalopathy is a degenerative condition of the brain caused by a deficiency of vitamin B1 (see Wernicke–Korsakoff syndrome).

Heptac encephalopathy is caused by the effect on the brain of toxins that have built up in the blood as a result of liver failure. It may lead to impaired consciousness, memory loss, a change in personality, tremors, and seizures.

In spongiform encephalopathy, the brain tissue shrinks and spaces develop within it; this leads to severe problems, such as paralysis and dementia. Bovine spongiform encephalopathy (BSE) is a disorder contracted by cattle after they are given feed containing material from sheep or cattle. The cause of BSE is believed to be an infective agent that is known as a prion. Some cases of variant Creutzfeldt–Jakob disease in humans have been attributed to infection with the prions responsible for BSE, which were probably transmitted to humans via consumption of meat products. (See also hypertensive encephalopathy.)

enchondroma
A noncancerous bone tumour that originates in cartilage in the metaphysis (the area in which new tissue is added as the bone grows).

encoding
The first stage in the memory process, also called registration. In this stage, information received by one of the senses (such as hearing or sight) is registered and then modified ready for storage by the brain. The information can then be retrieved when it is needed.

encopresis
A type of soiling in which children pass normal faeces in unacceptable places after the age at which bowel control has been achieved. There is usually an underlying behavioural problem (see behavioural problems in children).

endarterectomy
An operation to remove the lining of an artery affected by atherosclerosis (narrowing due to deposits of fatty material). Removing the diseased lining restores normal blood flow to the part of the body supplied by the artery.

WHY IT IS DONE
Endarterectomy is used to treat cerebrovascular disease (in which the blood supply to the brain is seriously reduced) and peripheral vascular disease (in which blood supply to the limbs is impaired).

HOW IT IS DONE
Endarterectomy is a delicate procedure that may take several hours. The operation may be performed endoscopically (see endoscopy) or by open surgery. In open surgery, the artery is exposed, clamps are applied, an incision is made, and the diseased lining, as well as any thrombus (blood clot) that may have formed, are removed. The incision is closed with stitches.

RESULTS
New lining grows in the artery within a few weeks of surgery. When narrowing of the arteries is widespread (in other words, it is not confined to a single artery), arterial reconstructive surgery may have to be performed.

endarteritis
Inflammation of the inner (intimal) layer of an artery wall. Endarteritis most commonly occurs as a result of a bacterial infection such as syphilis. The causative infection is treated with antibiotic drugs, such as penicillin.

end artery
An artery (a blood vessel that carries blood away from the heart), or the final branch of an artery, that does not communicate with any other arteries. An end artery is therefore the sole supplier of blood to its surrounding tissues. If an end artery is damaged and can no longer supply blood to an area, the tissues of that area may die. End arteries are found in the brain, heart, retina, kidneys, and spleen.

endemic
A term applied to a disease or disorder that is constantly present in a particular region or in a specific group of people. AIDS, for example, has become endemic in central Africa. An endemic disease contrasts with an epidemic, which is not generally present but occasionally affects a large group of people.

endemic goitre
A type of goitre (a swelling of the neck due to enlargement of the thyroid gland) that occurs in certain parts of the world due to a deficiency of iodine in the diet. Iodine is necessary for the production of the thyroid hormones triiodothyronine (T3) and thyroxine (T4). If there is too little iodine in the diet, the thyroid gland compensates for the deficiency by enlarging in order to produce sufficient amounts of thyroid hormones.

Endemic goitre is rare in the developed world. It may be treated using dietary measures alone.

endocarditis
Inflammation of the endocardium (the membrane that lines the inside of the heart), particularly the endocardium lining the heart valves.

CAUSES AND INCIDENCE
Endocarditis is most often caused by infection with bacteria, fungi, or other microorganisms, which may be introduced into the body during surgery (including dental procedures); by intravenous injection using dirty needles; or through breaks in the skin or mucous membranes. The organisms travel in the bloodstream to the heart. As a result, the
lining of the valves becomes inflamed, the valves may be damaged, and blood clots may form on the affected areas.

People whose endocardium has previously been damaged by disease are particularly vulnerable to endocarditis, as are those with artificial heart valves or some forms of congenital heart disease. This is because clots that form on the injured surface trap the causative microorganisms, which then multiply rapidly at the site of damage.

Intravenous drug users are vulnerable to endocarditis, even if their hearts are healthy, because microorganisms from a dirty syringe or from unclean skin at the site of injection can be introduced into the bloodstream.

Those with a suppressed immune system are at increased risk of endocarditis due to a lowered resistance to infection; organisms that would normally be harmless can cause serious infection.

SYMPTOMS

Endocarditis may be either subacute or acute. In the subacute form, symptoms are often general and nonspecific; they may include fatigue, feverishness, and vague aches and pains. On physical examination, the only evident abnormality may be a heart murmur.

Acute endocarditis, which occurs less frequently, develops suddenly and causes shortness of breath, severe chills, high fever, and a rapid or irregular heartbeat. The infection quickly progresses and may destroy the heart valves, leading to heart failure.

DIAGNOSIS AND TREATMENT

Endocarditis is diagnosed by physical examination and analysis of blood samples. Tests performed on the heart may include ECG (measurement of the heart’s electrical activity) and echocardiography (an ultrasound technique that produces detailed images of the heart). Echocardiography shows the structure and movement of the heart and can reveal any collections of infected material on the valves or in a chamber of the heart.

Treatment is with high doses of antibiotic drugs, usually given intravenously. Antibacterial drugs are given as preventive treatment for those people at risk. Heart-valve surgery may be needed to replace a damaged valve.

endocardium

The innermost of the three layers of the heart wall. The endocardium is formed of endothelial cells and is continuous with the linings of the blood vessels.

endocervix

The mucous membrane (layer of thin, moist tissue) that lines the cervical canal. The cervical canal connects the uterus to the vagina and runs through the centre of the cervix (the neck of the womb). (See also endometrium.)

endocrine gland

A type of gland that secretes hormones directly into the bloodstream rather than through a duct. The thyroid gland, pituitary gland, ovaries, testes (see testis), and adrenal glands are all endocrine glands. The endocrine glands in the body make up the endocrine system. (See also exocrine gland.)

endocrine system

The collection of glands around the body that produce hormones (chemical substances necessary for normal body functioning). These glands include the thyroid gland, pancreas, testes (see testis), ovaries, and adrenal glands. Hormones that are produced by these glands are responsible for numerous bodily processes, including growth, metabolism, sexual development and function, and response to stress.

Any increase or decrease in the production of a specific hormone interferes with the process it controls. To prevent under- or overproduction, hormone secretion from many endocrine glands is regulated by the pituitary gland; the pituitary gland is, in turn, influenced by the hypothalamus in the brain according to a feedback mechanism (see Control of hormone production box, overleaf).

endocrinology

The study of the endocrine system, or hormonal system, including the investigation and treatment of its disorders. A physician who specializes in diseases and
ENDOCRINE SYSTEM

The system consists of a collection of hormone-producing glands. Many of these glands are regulated by trophic (stimulating) hormones secreted by the pituitary. The pituitary is itself influenced by hormones secreted by the hypothalamus in the brain. Shown here are the principal glands, with a note on the hormones they produce.

**Pancreas**
This gland secretes insulin and glucagon, which control the body’s utilization of glucose.

**Adrenal cortex**
When stimulated by ACTH (adrenocorticotrophic hormone), the adrenal cortex produces hydrocortisone, which has widespread effects on metabolism; it also produces androgen hormones and aldosterone, which maintains blood pressure and the body’s salt balance.

**Ovaries**
In females, the ovaries produce estrogen and progesterone, which influence many aspects of female physiology. This hormone production is controlled by gonadotrophin hormones, secreted by the pituitary.

**Pituitary gland**
The pituitary gland secretes hormones that stimulate the adrenals, the thyroid, pigment-producing skin cells, and the gonads; it also secretes growth hormone, antidiuretic hormone, prolactin, and oxytocin.

**Thyroid gland**
This gland produces the hormones thyroxine, triiodothyronine, and calcitonin, which stimulate metabolism, body heat production, and bone growth. Thyroid activity is controlled by TSH (thyroid-stimulating hormone), secreted by the pituitary.

**Parathyroid glands**
These glands, at the back of the thyroid, secrete parathyroid hormone, which maintains the calcium level in the blood.

**Testes**
In males, the testes produce testosterone in response to gonadotrophins secreted by the pituitary. A combination of gonadotrophins and testosterone stimulates sperm production and the development of other male characteristics.

CONTROL OF HORMONE PRODUCTION

Production of too much or too little hormone by a gland is prevented by feedback mechanisms. Variations in the blood level of the hormones are detected by the part of the brain known as the hypothalamus, which prompts the pituitary to modify its production of the appropriate trophic (gland-stimulating) hormones accordingly.

1. The production of hormone by the target gland (in this illustration, the thyroid gland) and of trophic hormone by the pituitary gland is normal.

2. If hormone production by the target gland rises, the feedback effect causes less trophic hormone to be produced, which tends to return the situation to normal.

3. If hormone production by the target gland drops, the feedback lessens and more trophic hormone is produced, which tends to return the situation to normal.
disorders of the endocrine glands and the hormones that they secrete is called an endocrinologist.

**endodontics**
A branch of dentistry concerned with the causes, prevention, diagnosis, and treatment of disease and injury that affect the nerves and pulp in teeth and the supportive tissues in the gum. Common endodontic procedures are root-canal treatment and pulpotomy.

**endogenous**
A term that refers to a disease or disorder that arises within the body. For example, an endogenous infection may occur if bacteria from the anus invade the urinary tract. Most disorders are exogenous (caused by external factors).

**endogenous depression**
A term formerly used for a type of depression (feelings of sadness, hopelessness, and a lack of interest in life) originating from biological factors in an individual. In contrast, “reactive depression” was seen to result from a stressful or emotional event or period of life. In many cases, however, depression is a combination of both of these types.

**endolymph**
The fluid contained within the membranous labyrinth (the structures in the inner ear that help to control balance). Endolymph flows around the labyrinth as the body moves, causing nerve receptors in the labyrinth to send signals to the brain about the motion of the body. A significant increase in the volume of endolymph in the labyrinth may occur in Ménière’s disease.

**endometrial ablation**
A treatment for persistent menorrhagia (heavy menstrual bleeding) involving removal of the endometrium (the inner lining of the uterus). In this procedure, endoscopy is used to view the interior of the uterus, while the endometrium is removed by diathermy (heat treatment), laser, or a microwave probe (MEA). Endometrial ablation can only be carried out if the woman has no desire to become pregnant in the future.

**endometrial biopsy**
A procedure in which a small sample of tissue is taken from the endometrium (the inner lining of the uterus) and sent for microscopic analysis. Endometrial biopsies are used to detect areas of abnormal tissue such as tumours (see uterus, cancer of). Samples may be taken during hysteroscopy (examination of the interior of the uterus with a viewing instrument) or collected using a small vacuum device that is introduced through the cervix. Mild cramping pains may be a side effect.

**endometrial cancer**
See uterus, cancer of.

**endometriosis**
A condition in which fragments of the endometrium (the lining of the inside of the uterus) are found in other parts of the body, usually in the pelvic cavity. Endometriosis can cause infertility in up to two in five affected women.

**INCIDENCE AND CAUSES**
Endometriosis most commonly occurs in women who are aged between 25 and 40. The cause of the disorder is not clear. In some cases, it is thought to be due to the failure of certain fragments of the endometrium, shed during menstruation, to leave the body. Instead, they travel up the fallopian tubes and into the pelvic cavity, where they can adhere to and grow on any pelvic organ. These displaced patches of endometrium continue to respond to hormones that are produced in the menstrual cycle and bleed each month.

**SYMPTOMS**
The symptoms of endometriosis vary greatly. Some women have no symptoms, but the disorder most commonly causes abnormal or heavy menstrual bleeding. There may be severe abdominal pain and/or lower back pain during menstruation. Other possible symptoms include dyspareunia (see intercourse, painful), diarrhoea, constipation, and pain during defaecation.

The internal bleeding causes pain and is followed by healing, which produces internal scarring. Bleeding into an ovary may result in a blood-filled ovarian cyst.
(known as a “chocolate cyst” because of its appearance). Endometrial tissue may be deposited in the muscular wall of the uterus (myometrium); this condition is called adenomyosis. In rare cases, there is bleeding from the rectum during menstruation.

**DIAGNOSIS AND TREATMENT**

**Laparoscopy** (examination of the abdominal cavity with a viewing instrument) confirms the diagnosis. Certain drugs (including danazol, progestagen drugs, gonadorelin analogues, or the combined oral contraceptive pill) may be given to prevent menstruation. Local ablation of the endometrial deposits, using either laser treatment or electrocautery (the application of heat produced by an electrical current), may sometimes be needed.

If the woman is fertile, pregnancy often results in significant improvement. A **hysterec- tomy** (surgical removal of the uterus) and **oophorec- tomy** (surgical removal of the ovaries) may be offered if the woman does not have plans to have children.

**endometritis**

Inflammation of the endometrium (the inner lining of the uterus) resulting from infection. Endometritis is a feature of pelvic inflammatory disease (PID). It may also be a complication of abortion or childbirth, occur after insertion of an IUD, or be the result of a sexually transmitted infection.

Symptoms of endometritis include fever, vaginal discharge, and lower abdominal pain. Treatment includes removing any foreign body (such as an IUD or retained placental tissue) and antibiotic drugs.

**endometrium**

The inner lining of the uterus. The endometrium contains numerous glands and gradually increases in thickness during the menstrual cycle (see menstruation) until ovulation (release of an egg from the ovary) occurs. The surface layers of the endometrium are shed during menstruation if conception does not take place.

**end morph**

A term formerly used to describe an individual with a round head and a large abdomen; short arms and legs with slender wrists and ankles; weak muscular and skeletal development; and a large proportion of body fat. (See also ectomorph; mesomorph.)

**end organ**

The specialized structure occurring at the end of a peripheral nerve that acts as a receptor for a particular sensation. An example of an end organ is one of the taste buds in the tongue.

**endorphins**

A group of pain-relieving protein molecules that are produced by the body. Endorphins relieve pain by activating opiate receptors in the nervous system. They have a similar chemical structure to the pain-relieving drug morphine. In addition, endorphins are thought to be involved in the body’s response to stress, as well as in regulating intestinal contractions, determining mood, and controlling the release of certain hormones from the pituitary gland. (See also enkephalins.)

**endoscope**

A tubelike viewing instrument, with lenses and a light source attached, that is inserted into a body cavity for the purposes of investigating or treating disorders (see endoscopy). Endoscopes are named according to their use, and they can be flexible or rigid, depending on the part of the body to be examined. A selection of the common types of endoscope and their uses are shown in the illustrated box at right.

**endoscopy**

Examination of a body cavity by means of an endoscope (a rigid or flexible viewing tube) for the purposes of diagnosis and/or treatment. The technique makes use of both fibre-optics and video technology and enables almost any hollow structure in the body to be inspected directly. Many procedures that formerly required major surgery can now be performed much more simply and safely by endoscopy.

**USES**

Endoscopes are named according to the part of the body for which they are being used (see endoscopes box). The endoscope is inserted via a natural body opening, such as the mouth or vagina, or into a small incision. Endoscopy is also used in diagnosis to inspect hollow organs. The organ may be photographed and a biopsy (removal of a small sample of tissue for microscopic analysis) may be performed. Endoscopy can be repeated safely at frequent intervals to allow monitoring the progress of a condition and the response to treatment.

Many operations are now being performed by passing surgical instruments down an endoscope. The procedure is valuable in the treatment of acute emergencies, such as bleeding from the stomach or the removal of foreign bodies from the lungs. Operations such as female sterilization, the treatment of torn ligaments or cartilage within the knee joint, and the treatment of chronic infections of the nasal sinuses, are all routine endoscopic procedures. (See also minimally invasive surgery.)

**endothelium**

The layer of cells that lines the heart, blood vessels, and lymphatic ducts (see lymphatic system). Endothelial cells are squamous (thin and flat), providing a smooth surface that aids the flow of blood and lymph and helps to prevent the formation of thrombi (blood clots). (See also epithelium.)

**endotoxin**

A poison produced by certain bacteria that is not released until the death of those bacteria. Endotoxins cause fever when they are released in infected people. They also make the walls of the capillaries (the smallest blood vessels) more permeable, causing fluid to leak into the surrounding tissue. This sometimes results in a reduction in blood pressure, a condition called endotoxic shock. (See also enterotoxin; exotoxin.)

**endotracheal tube**

A tube that is passed into the trachea (windpipe) through the nose or mouth to enable delivery of oxygen during artificial ventilation or anaesthetic gases (see anaesthesia) during surgery. An inflatable cuff around the lower end of the endotracheal tube prevents any secretions or stomach contents from entering the lungs.

**end stage**

The most advanced stage of a disease, in which an affected organ or system is no longer able to carry out its normal functions. In these circumstances, the damage done to the body cannot be reversed; therefore, treatment is aimed at improving the patient’s condition wherever possible and at relieving the symptoms (see palliative care). In some cases, a machine may be able to take over the function; for example, in end-stage kidney failure, filtering of the blood may be carried out by a dialysis...
A typical flexible fibre-optic endoscope consists of a bundle of light-transmitting fibres. At one end is the head (featuring a viewing lens and steering device) and a power source. The tip has a light, a lens, and an outlet for air or water. Side channels enable attachments to be passed to the tip. In some endoscopes the tip may contain a camera that transmits a picture electronically to a screen. A rigid endoscope is a straight, narrow viewing tube that has a light source attached to it.

**FLEXIBLE ENDOSCOPE**

**Procedure for endoscopy**

The endoscope is inserted through a natural opening (here, the mouth during gastroscopy); the patient may be sedated. A tiny camera at the tip of the endoscope relays an image of the area under investigation via a monitor and eyepiece. Minor procedures, such as biopsy (removal of a tissue sample for analysis), may be carried out using very fine surgical instruments passed down the endoscope.
machine. The term “end stage” is used in relation to many conditions, including cancer, advanced kidney failure, and chronic lung diseases.

**enema**
A procedure in which fluid is passed into the rectum through a tube that has been inserted into the anus. An enema may be performed as a treatment, to prepare the intestine for surgery, or as an aid to diagnosis.

**WHY IT IS DONE**
An enema may be given to clear the intestine of faeces, either to relieve constipation or in preparation for intestinal surgery. Enemas may also be used to administer medicine, such as corticosteroid drugs in the treatment of the inflammatory bowel condition ulcerative colitis. A barium enema is used to diagnose disorders of the large intestine (see barium X-ray examinations).

**HOW IT IS DONE**
Anaesthesia is not required, although the procedure may cause slight discomfort because the fluid stretches the intestine. The patient lies on his or her side with the hips raised on a pillow. A catheter (flexible tube), with a soft, well-lubricated tip, is gently inserted into the rectum and the enema fluid, warmed to prevent a sudden contraction of the intestine, is slowly introduced through it. Treatment doses are often packaged with their own applicators.

**energy**
The capacity to do work or effect physical change. Nutritionists use the term to refer to the fuel content of a food.

There are many different forms of energy, including light, sound, heat, chemical, electrical, and kinetic, and most of them play a role in the body. For instance, the retina (the light-sensitive inner layer at the back of the eye) converts light energy to electrical nerve impulses, making vision possible. The body’s muscles use chemical energy obtained from food to produce kinetic energy, movement, and heat.

**MEASUREMENT**
Energy is measured in units called calories and joules. Because these units are extremely small, more practical units used in dietetics (nutritional science) are the kilocalorie (kcal, 1,000 calories) and kilojoule (kJ, 1,000 joules). Carbohydrates and proteins provide 4 kcal per gram (g), whereas fats provide 9 kcal per g (see metabolism).

**ENERGY AND BODY WEIGHT**
Energy is needed to maintain the heart-beat, lung function, and constant body temperature. The rate at which these processes use energy, while the body is at rest, is called the basal metabolic rate (BMR). Any actions, such as movement or food digestion and absorption, increase energy expenditure above the BMR.

An individual’s energy requirement increases during periods of growth and during pregnancy and breast-feeding.

**ENEMA**
A procedure in which fluid is passed into the rectum through a tube that has been inserted into the anus. An enema may be performed as a treatment, to prepare the intestine for surgery, or as an aid to diagnosis.

**energy requirements**
The amount of energy needed by an individual for cell metabolism, muscular activity, and growth. This energy is provided by the chemical breakdown of fats, carbohydrates, and proteins supplied by food in the diet and by stored nutrients in the liver, muscles, and adipose tissue.

**ENERGY EXPENDITURE**
Energy is needed to maintain the heart-beat, lung function, and constant body temperature. The rate at which these processes use energy, while the body is at rest, is called the basal metabolic rate (BMR). Any actions, such as movement or food digestion and absorption, increase energy expenditure above the BMR.

An individual’s energy requirement increases during periods of growth and during pregnancy and breast-feeding.

**ENERGY STORAGE AND USE**
In general, the energy liberated from the breakdown of food is stored as chemical energy in ATP (adenosine triphosphate) molecules. The stored energy is then available to power processes that consume energy, such as muscle contraction or the repair and maintenance of body structures.

**Engelmann’s disease**
A rare, progressive, inherited form of bone dysplasia (a growth abnormality). In affected individuals, the bones become abnormally long and thick, which usually results in abnormal stature and, sometimes, in delayed walking (see walking, delayed). There may also be muscle wasting, pain or weakness in affected limbs, delayed puberty, and hypogonadism (underactivity of the testes or ovaries).

The disease is inherited in an autosomal dominant pattern (see genetic disorders) and affects more males than females. It is usually diagnosed in the first few years of life. There is no specific treatment available, although nonsteroidal anti-inflammatory drugs may be given to relieve pain.

**engorgement**
Overfilling of the breasts with milk. Engorgement is common a few days after childbirth, when the milk supply arrives quickly and forcibly. Engorgement causes the breasts and nipples to become swollen and tender, and can make breast-feeding difficult. The problem can be relieved by expressing milk.

**enhancement**
The process of augmentation. The term may be used of improvements made to body structures or functions, or may mean increasing the clarity of images in diagnostic imaging methods. For example, immunoenhancement is the process by which the body’s immune response is increased by the use of antibodies (proteins made by the immune system).

**enkephalins**
A group of small protein molecules produced in the brain and by nerve endings elsewhere in the body (in the digestive system and adrenal glands, for example). Enkephalins have an analgesic (painkilling) effect and are also thought to affect mood. They are similar to endorphins but have a slightly different chemical composition and are released by different nerve endings.

**enlarged prostate gland**
See prostate, enlarged.

**enophthalmos**
A sinking inwards of the eyeball. Enophthalmos is most commonly caused by fracture of the eye socket or shrinkage of the eye due to the formation of scar tissue following injury.
ENT
The abbreviation for ear, nose, and throat (see otorhinolaryngology).

Entamoeba
A genus of amoebae (see amoeba), some of which are parasites of the human digestive tract.

Worldwide, *Entamoeba histolytica* is the most serious cause of amoebic disease, particularly in tropical areas. It is responsible for *amoebiasis* (amoebic dysentery), a disease in which the tissues of the intestinal lining are destroyed, causing the formation of *ulcers* in the intestines; and *abscesses* may form in the liver.

*Entamoeba gingivalis* is found in the mouths of humans and is associated with periodontal disease (any disorder of the tissues that surround and support the teeth) and *gingivitis* (inflammation of the gums). *Entamoeba coli* is a harmless intestinal parasite.

enteral feeding
A type of feeding that involves introducing nutrients directly into the intestines via a tube passed either through the abdominal wall or through a nostril and down the throat. Food may be provided in a partially broken-down form so that it does not need to be digested before being absorbed in the intestines. Enteral feeding is a useful method of feeding people with intestinal disorders, particularly inflammatory bowel disorders such as *Crohn’s disease*. (See also *feeding, artificial*.)

enteric
Relating to or affecting the *intestine* (the main part of the digestive tract, which extends from the exit of the stomach to the anus).

enteric-coated tablet
A tablet whose surface is covered with a substance that is resistant to the action of *stomach* juices. Enteric-coated tablets pass undissolved through the stomach into the small intestine, where the covering dissolves and the contents are absorbed. Such tablets are used either when the drug might harm the stomach lining (as may occur with certain corticosteroid drugs) or when the stomach juices may affect the efficacy of the drug (as with sulphasalazine).

enteric fever
An alternative name for *typhoid fever* or *paratyphoid fever*.

enteritis
Inflammation of any part of the *intestine*, particularly the small intestine. Enteritis may be due to infection, particularly *giardiasis* and *tuberculosis*, or to *Crohn’s disease*. Enteritis usually causes diarrhoea. (See also *colitis, gastroenteritis*.)

enteritis, regional
Another name for *Crohn’s disease*.

enterobacteria
A group of rod-shaped, gram-negative (*see Gram’s stain*) bacteria that live in the human or animal *intestine* (the principal part of the digestive tract, which extends from the exit of the stomach to the anus).

Some types of enterobacteria live harmlessly in the intestine. Several other types, however, cause intestinal diseases, with symptoms of diarrhoea and/or vomiting. Certain types are also responsible for urinary infections such as *cystitis*, which may occur when bacteria from the intestines gain access to the urethra. Examples of common enterobacteria include *Escherichia coli*, *Salmonella*, *Yersinia*, *Enterobacter*, and *Shigella*.

enterobiasis
The medical term for *threadworm infestation* of the intestines.

enterocle
A type of *hernia* in which part of the small intestine protrudes through a weakened area of the upper vaginal wall. An enterocle may develop when the muscles in a woman’s vaginal canal become stretched, damaged, or weakened by any of the following: pregnancy, childbirth, surgery, or aging.

Pelvic floor exercises may help to improve the condition, but surgery may be needed to tighten the muscles. In some cases, *hysterectomy* (removal of the uterus) may be the best treatment. (See also *hernia repair*.)

*Enterococcus*
A genus of gram-positive (see *Gram’s stain*) bacteria of the Streptococcales family. Enterococci are normally found in the human or animal *intestine* (the principal part of the digestive tract, which extends from the exit of the stomach to the anus).

They rarely cause problems in the intestine, but *urinary tract infections*, caused by enterococci entering the urethra, are common. If the bacteria spread in the bloodstream they can cause *septicaemia* (blood poisoning) and infective *endocarditis* (inflammation of the membrane lining the inside of the heart). The infections are usually treated with *antibiotic drugs*.

enterocolitis
A combination of *enteritis* (inflammation of the small intestine) and *colitis* (inflammation of the colon). Possible causes include inflammatory bowel disorders such as *Crohn’s disease*.

enteropathic
A term used to describe any condition or organism related to disease of the *intestine* (the main part of the digestive tract, extending from the exit of the stomach to the anus). Enteropathic bacteria, for example, are species that may cause intestinal disease; enteropathic arthritis is joint inflammation associated with *inflammatory bowel disease*.

enteropathy, gluten
See *coeliac disease*.

enterostomy
An operation in which a portion of small or large *intestine* is joined to another part of the gastrointestinal tract or to the abdominal wall. For example, when part of the colon (large intestine) is brought through an incision in the abdominal wall to allow the discharge of faeces into a bag attached to the skin, the operation is called a *colostomy*; when the ileum (the last section of the small intestine) is used, the procedure is called an *ileostomy*.

enterotoxin
A type of *toxin* released by certain *bacteria* that inflames the intestinal lining, leading to diarrhoea and vomiting. Enterotoxins cause the symptoms of *cholera* and *staphylococcal food poisoning* (see *staphylococcal infections*). (See also *endotoxin, exotoxin*.)

Entonox
A brand name for a mixture of *nitrous oxide* and oxygen used to produce pain relief without loss of consciousness.

entrapment neuropathy
A condition, such as *carpal tunnel syndrome*, in which local pressure on a nerve causes muscle pain, numbness, and weakness in the area of the body supplied by that nerve.
entropion
A defect of the eyelids in which the edges of the lids turn inwards, causing the lashes to rub against the cornea (the transparent dome that forms the front of the eyeball) and the conjunctiva (the membrane that covers the white of the eye and the inside of the eyelid).

CAUSES
Entropion may be congenital (present from birth), especially in overweight babies. In addition, it is common in elderly people, due to weakness of the muscles around the lower eye, allowing the lower lid plate to turn inwards. Entropion of the upper or lower lid may also be caused by scarring, such as that due to trachoma.

COMPLICATIONS AND OUTLOOK
Entropion in babies does not disturb the eye and usually disappears within a few months. In later life, entropion can cause irritation, conjunctivitis, damage to the cornea, or problems with vision. Surgery to correct entropion can prevent such conditions.

ENT surgery
The abbreviation for ear, nose, and throat surgery (see otorhinolaryngology).

enucleate
To remove an organ, a tumour, or another structure surgically in such a way that it comes out cleanly and completely. A common example of enucleation is the removal of an eyeball while leaving the other structures in place in the eye socket.

enuresis, nocturnal
The medical term for bedwetting. It is a common condition in children, and boys are slightly more likely than girls to be affected. The problem tends to run in families.

CAUSES
Usually, enuresis results from slow maturation of nervous system functions concerned with bladder control. It may also result from psychological stress. In a small number of bedwetters, there is a physical cause, such as a structural abnormality of the urinary tract. Diabetes mellitus or a urinary tract infection may cause bedwetting in a child who was previously dry. In cases due to physical problems, the child also has difficulty with daytime bladder control (see incontinence, urinary).

INVESTIGATION AND TREATMENT
If a child wets the bed persistently, tests, including urinalysis, may be performed to rule out a physical cause. For bedwetting that is not caused by a physical disorder, treatment starts with training the child to pass urine regularly during the day. Systems such as rewarding the child for each dry night (for example, by putting stars on a chart) are often successful. Getting the child to go to the toilet just before bed may be helpful.

Punishing a child for bedwetting, however, will not help, and may actually worsen the problem by making the child anxious.

Alarm systems, known as buzzer and pad systems, that involve placing a humidity-sensitive pad in the child’s bed are available. The child is woken by the alarm if urine is passed and eventually learns to wake before starting to pass urine.

The drug desmopressin is a synthetic form of antidiuretic hormone (see ADH) that may occasionally be given to reduce the amount of water that is excreted by the kidneys. Desmopressin is useful on the occasional nights when a child needs to stay dry, such as when staying overnight with friends.

environmental medicine
The study of the effects on health of natural environmental factors, such as climate, altitude, sunlight, and the presence of various minerals. Environmental medicine overlaps somewhat with occupational medicine, in which the effects on people of their working environments are studied.

CLIMATE
The symptoms of particular types of illness may be affected by certain climates. For example, sufferers from chest disorders, such as chronic bronchitis and asthma, usually obtain some relief from their symptoms in a warm,
relatively dry climate. Most respiratory complaints, in contrast, are more common during the winter.

**ALITUDE**

Although mountainous regions have much less atmospheric pollution, they are not necessarily beneficial to health because the air becomes thinner as altitude increases. People with a chest condition who ascend in a few days from sea level to 1,500 m may find that their breathing difficulty worsens. Above about 3,000 m, breathing becomes difficult even for healthy people. Rapid ascent from sea level to 3,600 m or higher carries a risk of altitude sickness (see *mountain sickness*), which can cause sleeplessness, nausea, coma (a state of unconsciousness and unresponsiveness to stimuli), or death.

Sustained life seems to be impossible above 6,000 m because at that level the blood cells increase in number to compensate for the lack of oxygen. This increase puts strain on the heart and causes a predisposition to thrombosis (abnormal blood clotting).

**SUNLIGHT**

Fair-skinned people who live in sunny climates may suffer ill effects from repeated exposure to sunlight (see *sunlight, adverse effects of*), including premature wrinkling of the skin and an increased risk of cataract (loss of transparency of the lens of the eye). There is also an increased risk of developing skin cancers, such as malignant melanoma (see *melanoma, malignant*) and basal cell carcinoma, as well as the precancerous condition solar keratosis. These risks have been increased by damage caused by environmental pollutants to the protective layers of ozone in the upper atmosphere. Health risks from sunlight may be reduced by protection of the skin, such as by using sunscreens.

**MINERALS**

Variations in the distribution of certain minerals in the environment are known to have an effect on health. For example, there is a higher-than-average incidence of cancer in areas where the radioactive gas radon is emitted from granitic rocks. In contrast, there is a lower-than-average incidence of tooth decay (see *caries, dental*) in populations in regions where the water has a high fluoride content.

**enzyme**

A protein that regulates the rate of a chemical reaction in the body. There are thousands of enzymes, each with a different chemical structure. It is this structure that determines the specific reaction regulated by the enzyme.

Every cell in the body produces various types of enzymes; different sets of enzymes occur in different tissues, reflecting their specialized functions. For example, the pancreas produces the digestive enzymes lipase, protease, and amylase, and among the numerous enzymes produced by the liver are some that metabolize drugs.

In order to function properly, many enzymes need an additional component, known as a coenzyme, which is often derived from a *vitamin* or *mineral*.

**ENZYMES AND INHIBITION**

Enzyme activity is influenced by many factors. One of these factors is the action of drugs. Liver enzyme activity is increased by certain drugs, such as *barbiturate drugs*, which affect the rate at which other drugs are metabolized by the liver cells. This effect, which is called enzyme induction, is responsible for a variety of important drug interactions (see *drug*).

Conversely, drugs inhibit or block enzyme action. Some *antibiotic drugs* destroy bacteria by blocking bacterial enzymes while leaving human enzymes unaffected. Similarly, some *anticancer drugs* act by blocking enzyme activity in tumour cells, affecting normal body cells to a lesser degree.

**ENZYMES AND DISEASE**

Measuring enzyme levels in the blood can be useful in diagnosing certain disorders. For example, the level of heart muscle enzymes is raised following a *myocardial infarction* (heart attack) because the damaged heart muscle releases enzymes into the bloodstream, and muscle enzyme levels are raised in *muscular dystrophy*.

Many inherited metabolic disorders, including *phenylketonuria, galactosaemia*, and *G6PD deficiency*, are caused by defects in, or deficiencies of, enzymes. Abnormal enzymes or levels can be detected in tests on blood or other body fluids.

**ENZYMES AND TREATMENT**

Enzymes can play a valuable role in treating certain diseases. Pancreatic enzymes may be given to aid digestion in people who have *malabsorption* related to pancreatic disease.

Enzymes such as *streptokinase* and alteplase (see *tissue-plasminogen activator*) are used to treat acute *thrombosis* and *embolism* (conditions that cause blockage of blood vessels) by dissolving clots.

---

**THE ACTION OF ENZYMES**

An enzyme is a protein that acts as a catalyst for a chemical change in the body (that is, it greatly speeds up the rate at which the change occurs). The change may be a small modification to the structure of a substrate (the particular chemical on which the enzyme acts) in a body tissue, the splitting of a substrate, or the joining of two substrates.

---

**eosinophil**

A type of leukocyte (*white blood cell*) that plays a role in allergic responses (see *allergy*) and fighting parasitic infections.

**ependymoma**

A rare brain tumour of the glioma type (arising from supporting glial cells in the nervous system) that occurs most commonly in children.
ephedrine
A drug that mimics the effects of the neurotransmitter noradrenaline (norepinephrine). Ephedrine is prescribed as a decongestant drug to treat nasal congestion. It may also be used to treat some cases of low blood pressure that are due to drug actions or disease.

epicanthic fold
A vertical fold of skin extending from the upper eyelid to the side of the nose. Epicanthic folds are common in East Asian people but rare in other races, except in babies, in whom they usually disappear as the nose develops. Abnormal epicanthic folds are a feature of Down's syndrome. If desired, the folds can be removed by cosmetic surgery.

epicardium
The outermost of the three layers that form the wall of the heart. The epicardium is a smooth membranous structure that envelops the myocardium (the muscle layer of the heart).

epicondyle
Any bony outgrowth to which tendons are attached (for example, at the lower end of the humerus (upper-arm bone) where it forms part of the elbow joint). Overuse of muscles, leading to repeated tugging on the tendons, can result in pain and inflammation at an epicondyle (see epicondylitis).

epicondylitis
Painful inflammation of an epicondyle, and specifically one of the bony prominences of the elbow at the lower end of the humerus (upper-arm bone). Epicondylitis is the result of overuse of the forearm muscles, which causes repeated tugging on the tendons at their point of attachment to the bone.

Epicondylitis that affects the prominence on the outer elbow is called tennis elbow. When the prominence on the inner elbow is affected the condition is called golfer's elbow.

epidemic
A term applied to a disease that for the majority of the time is rare in a community but that suddenly spreads rapidly to affect a large number of people.

Epidemics of new strains of influenza are common, occurring periodically when the influenza virus changes to a form to which the population has no resistance. (See also endemic.)

epidemiology
The branch of medicine that is concerned with the occurrence and distribution of disease, including infectious diseases (such as cholera or influenza) and noninfectious diseases (such as cancer and heart disease).

In epidemiological studies, the members of a population are counted and described in terms of such variables as race, sex, age, social class, and occupation. The incidence and prevalence of the disease of interest are then determined. These observations may be repeated at regular intervals in order to detect changes over time. The result is a statistical record that may reveal links between particular variables and distribution of disease.

In comparative epidemiological studies, two or more groups are chosen. For example, in a study of the link between smoking and lung cancer, one group may consist of smokers and the other of nonsmokers; the proportion with cancer in each group is calculated. In such cases, the epidemiologist is careful to make the two groups as identical as possible in all other relevant respects, and will carefully match factors such as age, sex, and weight.

definitions and treatment
The thin outermost layer of the skin.

epidermoid cyst
A harmless nodule under the skin’s surface that contains yellow, cheesy material. The terms epidermoid cyst and sebaceous cyst are often used interchangeably.

epidermolysis bullosa
A group of rare, inherited conditions, varying widely in severity, in which blisters appear on the skin after minor injury or occur spontaneously.

CAUSES
Epidermolysis bullosa is caused by a genetic defect that may show either an autosomal dominant or an autosomal recessive pattern of inheritance (see genetic disorders).

DIAGNOSIS AND TREATMENT
The conditions can be diagnosed by means of a skin biopsy (the removal of a small sample of tissue for microscopic analysis).

There is no specific treatment for the condition, but injury to the skin should be avoided and protective measures should be taken to prevent the rubbing of affected areas when blisters appear.

The outlook varies from gradual improvement in mild cases to progressive disease in the most severe cases.

epididymal cyst
A harmless, usually painless, swelling in the epididymis (the coiled tube at the back of the testis). Small cysts are fairly common in men over the age of 40 and need no treatment. Rarely, they enlarge or become tender, causing discomfort. In such cases, it may be necessary for the cysts to be surgically removed.

epididymis
A long, coiled tube that runs along the back of the testis and connects the vas efferentia (small tubes leading from the testis) to the vas deferens (the sperm duct that leads to the urethra). Sperm cells, which are produced in the testis, mature as they pass slowly along the epididymis, until they are capable of fertilizing an egg, and they are then stored until ejaculation takes place.

Disorders of the epididymis include epididymal cysts (fluid-filled swellings in the epididymis) and epididymo-orchitis (inflammation of the testis and epididymis). Infection or injury can block the epididymis; if both testes are affected, infertility may result.
epididymitis
See epididymo-orchitis.

epididymo-orchitis
Acute inflammation of a testis and epididymis (coiled tube that runs along the back of the testis). Epididymo-orchitis causes acute pain and swelling at the back of the testis, and, in severe cases, swelling and redness of the scrotum.

The inflammation is caused by infection. Often, there is no obvious source of the infection, but sometimes the cause is a bacterial urinary tract infection that has spread via the vas deferens (the sperm duct leading to the urethra) to the epididymis.

Treatment is with antibiotic drugs. If there is an underlying urinary tract infection, its cause needs to be investigated. (See also orchitis.)

epidural anaesthesia
A method of administering pain relief in which a local anaesthetic (see anaesthesia, local) is injected into the epidural space (the space around the spinal cord) in the middle and lower back. Epidural anaesthesia numbs the nerves that supply the chest and lower body. The technique is widely used to relieve pain during and after surgery, as well as during childbirth.

epigastric hernia
A hernia (protrusion of an organ or tissue) through a weakened area in the upper central abdominal wall. The hernia may appear as a lump in the centre of the upper abdomen, between the base of the sternum (breastbone) and the navel. (See also hernia repair.)

epiglottis
The flap of cartilage lying behind the tongue and in front of the entrance to the larynx (voice box). The epiglottis is usually upright to allow air to pass through the larynx and into the rest of the respiratory system. During swallowing, it tilts downwards to cover the entrance to the larynx, preventing food and drink from being inhaled into the trachea (windpipe).

epiglottitis
A potentially life-threatening infection causing inflammation and swelling of the epiglottis (the flap of cartilage at the back of the tongue that closes off the windpipe during swallowing). The swollen epiglottis obstructs breathing and can cause death by suffocation if the condition is not treated promptly.

Epiglottitis is now rare due to the routine immunization of infants against Haemophilus influenzae, the bacterium that causes the condition.

epilepsy
A tendency to have recurrent seizures. Seizures are defined as transient neurological abnormalities that are caused by abnormal electrical activity in the brain. Human activities, thoughts, and emotions are normally the result of the regulated and orderly electrical excitation of nerve cells in the brain. During a seizure, a chaotic and unregulated electrical discharge causes various physical and mental symptoms.

CAUSES
In many people with epilepsy, the cause is unclear, although a genetic factor may be involved. In other cases, seizures may be the result of brain damage from a head injury; birth trauma; brain infection (such as meningitis or encephalitis); brain tumour; stroke (damage to part of the brain caused by an interruption to its blood supply); drug or alcohol intoxication; or a metabolic disorder.

SYMPTOMS
Many people who suffer from epilepsy do not have any symptoms between seizures. Some people experience an aura (a peculiar “warning” sensation) shortly beforehand. In some cases, a stimulus such as a flashing light triggers a seizure. Epileptic seizures may occur more frequently during times of illness or stress.

TYPES
Epileptic seizures can be classified into two broad groups: generalized and partial seizures.

Generalized seizures These seizures cause loss of consciousness and may affect all areas of the brain. There are two main types of generalized seizure: tonic–clonic (formerly grand mal) and absence (petit mal) seizures.

During a tonic–clonic seizure, there may initially be an aura, then the body becomes stiff and consciousness is lost. Breathing may be irregular or may stop briefly, then the body jerks uncontrollably. The episode usually ends spontaneously after a few minutes. The person may be drowsy and disoriented for a few hours afterwards, however, and may have no memory of the event. Prolonged tonic–clonic seizures are potentially life-threatening.

Absence seizures occur mainly in children. Periods of altered consciousness last for only a few seconds and there are no abnormal movements of the body. This type of seizure may occur hundreds of times daily.

Partial seizures These seizures are caused by abnormal electrical activity in a more limited area of the brain. They may be simple or complex.

In simple partial seizures, consciousness is not lost and an abnormal twitching movement, tingling sensation, or hallucination of smell, vision, or taste occurs, lasting several minutes.

In one type of partial seizure, called temporal lobe epilepsy, conscious contact with the surroundings is lost. The sufferer becomes dazed and may behave oddly. Typically, the person remembers little, if anything, of the event.

DIAGNOSIS
In order to make a diagnosis, a doctor needs as much information as possible about the seizures. The patient may not be able to recall the events, so an accurate account from a witness may be necessary. Examination of the nervous system is normally carried out between seizures. An EEG (a method of recording the activity of the brain), CT scanning or MRI of the brain, and blood tests may also be carried out.
TREATMENT
While a seizure is happening, any witnesses should make the surrounding area safe (for example, by removing hazardous objects) and ensure that the person can breathe while unconscious. Clothing around the neck should be loosened, and a soft item, such as a folded piece of clothing, should be placed under the head. Otherwise, witnesses should simply let the attack run its course. Once the convulsions have stopped, the person should be placed in the recovery position. A person having a seizure should never be restrained, and should never have anything put into his or her mouth.

Anticonvulsant drugs usually stop or reduce the frequency of recurrent seizures. The drugs may have unpleasant side effects, however, so the doctor will take care to find the one drug that works best for that patient. With very severe epilepsy, a combination of drugs may be needed to control seizures. If no seizures occur after two or three years of treatment, and depending on their cause, the doctor may suggest reducing or stopping the drug treatment.

Women who are taking anticonvulsant drugs and are planning a pregnancy will need to have their treatment reviewed before conceiving. They may need to change to another drug to reduce the risk of a fetal abnormality. Stopping treatment is not usually an option because seizures can be profoundly damaging to the fetus.

Surgery may be considered if a single area of damage to the brain is causing the seizures and drug treatment has not proved effective.

OUTLOOK
Epilepsy that develops during childhood may sometimes disappear soon after adolescence.

Affected adults can enjoy relatively normal lives, but may be restricted in their choice of work. For example, it is inadvisable for people with epilepsy to have occupations involving heights or operating dangerous machinery. In addition, there are certain restrictions on driving vehicles (see driving, health and). People with epilepsy are legally required to contact their vehicle licensing agency, who will explain the relevant restrictions.

Many people with epilepsy carry a special card, tag, or bracelet, such as those produced by Medic-Alert, which states that they have the condition. Affered people should also advise their family, friends, and colleagues what to do if a seizure occurs.

epiloia
See tuberous sclerosis.

epinephrine
An alternative name for adrenaline.

EpiPen
A brand name for an assembled needle and syringe containing a dose of adrenaline (epinephrine) that is used for rapid administration to prevent or treat life-threatening allergic reactions (see anaphylactic shock). The EpiPen is designed for people who are prone to such reactions to use on themselves; it delivers the adrenaline directly into a muscle, usually a thigh muscle.

Anyone known to be at risk of an anaphylactic reaction should carry an EpiPen with them at all times and be taught how to administer it. An affected person’s family, as well as other close contacts, such as teachers, colleagues, and friends, should also be aware of how to use the EpiPen.

epiphora
See watering eye.

epiphyseal fracture
A fracture (break) at the point where the epiphysis (the end section of a long bone) meets the diaphysis (the main shaft of the bone). This type of break may affect the subsequent growth of the fractured bone.

epiphyseal plate
The disc that separates the epiphysis (the end section of a long bone) from the diaphysis (the main shaft of the bone). During the period of growth, the epiphyseal plate is composed of cartilage (connective tissue formed of collagen). This cartilage is gradually replaced by bone as a result of ossification, a process by which cartilage cells multiply and absorb calcium to develop into bone.

epiphysis
The end section of a long bone (such as the femur in the legs, or the humerus in the arms) that is separated from the diaphysis (the main shaft of the bone) by the epiphyseal plate.

Problems that affect the epiphysis or the epiphyseal plate during the period of growth, such as inflammation (a condition called epiphysitis), may retard the growth of the affected bone and cause it to become deformed.

epiphysis, slipped
See femoral epiphysis, slipped.

episcleritis
A localized patch of inflammation that affects the outermost layers of the sclera (white of the eye) in an area immediately underneath the conjunctiva (the transparent membrane that covers the sclera).

Episcleritis is usually of unknown cause and mainly affects middle-aged men. It may, at times, be a complication of rheumatoid arthritis. The inflammation may cause a dull, aching pain and there may be photophobia (abnormal sensitivity of the eyes to light).

The disorder usually disappears by itself within a week or so, but it may recur. Symptoms may be relieved by using eye-drops or ointment containing a corticosteroid drug.

episiotomy
A surgical procedure in which an incision is made in the perineum (the tissue between the vagina and the anus) in
order to facilitate the delivery of a baby. After delivery, the severed tissues are stitched back together.

WHY IT IS DONE
An episiotomy is advisable if the perineum fails to stretch over the baby’s head and/or a large perineal tear is likely. The procedure prevents ragged tears that would be more painful, more difficult to repair, and more likely to lead to complications. Episiotomy is usually necessary in a forceps delivery, because the instruments occupy additional space in the vagina, and in a breech delivery, in which there is little opportunity for gradual stretching of the perineal tissues.

In most cases, however, the naturally elastic vagina should not have to be cut to allow a normal delivery.

episplasias
A rare congenital (present from birth) abnormality in which the opening of the urethra (the tube through which urine is excreted from the bladder) is not in the glans (head) of the penis but is on its upper surface. In some cases, the penis also curves upwards. Surgery is carried out during infancy, using tissue from the foreskin to reconstruct the urethra. (See also hypospadias.)

epistaxis
A medical term for nosebleed.

epithelioma
A noncancerous tumour arising from the epithelium, the tissue that covers the outer surface of the body and forms the membranous lining of internal organs. In some cases, an epithelioma may become cancerous, in which case it becomes known as a carcinoma.

epithelium
The layer of cells that covers the entire surface of the body and lines most of the structures within it. Epithelial cells vary in shape according to their function. There are three basic shapes: squamous (thin and flat), cuboidal, and columnar. These structures may vary further. For example, in the respiratory tract, epithelial cells bear brushlike filaments called cilia that create a current in the surrounding fluid. This current propels dust particles from inhaled air back up the bronchi (the large air passages in the lungs) and the trachea (windpipe).

Most internal organs lined with epithelium are covered with only a single layer of cells, but the skin, which is subjected to more trauma, consists of many layers including a dead outer layer of cells that is constantly being shed. Structures that are not lined with epithelium are the blood vessels, the lymph vessels (see lymphatic system), and the inside of the heart, which are lined with endothelium, and the chest and abdominal cavities, which are lined with mesothelium.

epoetin
A genetically engineered preparation of the hormone erythropoietin, which is produced by specialized cells in the kidneys and stimulates the bone marrow to produce red blood cells.

Epoetin may be used in the treatment of anemia (a reduced level of the oxygen-carrying pigment haemoglobin in the blood) due to the lack of erythropoietin that occurs in kidney failure. It is also used to boost the level of red blood cells before surgery; the patient donates blood to be used during or after the surgery beforehand. Epoetin may also be used as an alternative to blood transfusions in major orthopaedic (bone) surgery.

Epstein–Barr virus
A virus that belongs to the herpesvirus family. The Epstein–Barr virus (EBV) may cause glandular fever (see mononucleosis, infectious); after the initial infection, the virus remains dormant in the cells of the immune system and may later be reactivated. Epstein–Barr virus is one of the few viruses with a proven role in the development of cancerous tumours. In Africa, it is associated with Burkitt’s lymphoma, and in Southeast Asia it is associated with cancer of the nasopharynx (see nasopharynx, cancer of). Epstein–Barr virus may also cause lymphomas to develop in patients who have undergone transplant surgery.

Other disorders that are associated with Epstein–Barr virus include some cases of acute hepatitis. In people with AIDS, the virus may lead to the development of a condition called oral hairy leukoplakia; this condition is characterized by roughened, white patches on the sides of the tongue.

Erb–Charcot disease
A rare condition resulting from spinal cord damage due to syphilis (a sexually transmitted bacterial infection). The symptoms include numbness, a sensation of pins and needles, and muscle weakness in the legs.

Erb’s palsy
Weakness or paralysis of the muscles in the upper arm and shoulder. Erb’s palsy results from damage to the upper roots of the brachial plexus (a collection of nerve trunks formed from nerve roots near the top of the spine). Such an injury may occur during birth if excess pressure is applied to the baby’s head during a difficult delivery, causing the fifth cervical root of the spinal cord to be damaged. It may also result from a road traffic accident, particularly in motorcycle riders, when an impact forces the head and neck to one side and severely strains the nerves on the opposite side. Erb’s palsy is characterized by an arm that is rotated inwards at the shoulder and hangs limp down one side of the body.

ERCP
The abbreviation for endoscopic retrograde cholangiopancreatography, which is an X-ray procedure used for examining the biliary system and the pancreatic duct. ERCP is used mainly when other imaging techniques, such as ultrasound scanning, CT scanning, or MRI, fail to provide sufficiently detailed images of these body structures.

HOW IT IS DONE
An endoscope (a flexible viewing tube with a lens and a light attached) is passed down the oesophagus, through
the stomach, and into the duodenum (the upper part of the small intestine). A catheter (a fine, flexible tube) is passed through the endoscope into the common bile duct and pancreatic duct. Finally, a contrast medium (a substance opaque to X-rays) is introduced through the catheter to make the pancreatic duct and the biliary system visible on X-rays.

If a disease or disorder is detected during the procedure, it can sometimes be treated at the same time. For example, it may be possible to relieve a blockage due to a gallstone.

erectile dysfunction

Inability to achieve or maintain an erection; commonly known as impotence.

erection

The hardness, swelling, and elevation of the penis that occurs in response to sexual arousal or physical stimulation. The erectile tissue of the penis becomes engorged with blood as the blood vessels within it dilate. Muscles around the vessels then contract and keep blood in the penis, thereby maintaining the erection.

errection, disorders of

Conditions in which the erection of the penis is disrupted. Such conditions include total or partial failure to attain or maintain an erection (see impotence), persistent erection in the absence of sexual desire (see priapism), and curving of the penis during erection (see chordee).

ergocalciferol

An alternative name for vitamin D₂ (see vitamin D).

ergometer

A machine that measures and records the amount of physical work undertaken by the body and the body’s response to a controlled amount of exercise. An ergometer makes continuous recordings, both during and after activity, of heart rate and rhythm (using an ECG); blood pressure; rate of breathing; and volume of oxygen taken in from the air.

ergometrine

A drug given after childbirth, miscarriage, or abortion to reduce the loss of blood from the uterus (womb). Ergometrine works by causing blood vessels in the uterine wall to contract, thereby reducing bleeding. The drug is often given in combination with oxytocin, which stimulates uterine contractions.

eroticism

The character and emotive nature of sexual excitement. Sexual arousal may be stimulated by erotic thoughts, by touching the erogenous zones, and by a variety of other sensations (such as the look and feel of certain clothes).

eruption

The process of breaking out, as of a skin rash or a new tooth. (See also eruption of teeth; eruptive phase.)
when an individual has been sitting too close to a fire. The condition is most common in elderly women. Dryness and itching can often be relieved by use of an emollient (soothing cream). The redness fades in time but may not disappear entirely.

**erythema infectiosum**
See *fifth disease.*

**erythema marginatum**
A pink rash that appears and disappears spontaneously and that may affect any area of the body except the face. Erythema marginatum is a characteristic sign of *rheumatic fever.*

**erythema migrans**
A red, circular rash that occurs as a result of infection with *Lyme disease.* Erythema migrans first appears at the site of a bite from an infected tick. The rash then expands, over a period of days or weeks, to form a large, round patch. Erythema migrans is most commonly found on the thighs, groin, or trunk, or in the armpit.

**erythema multiforme**
Acute inflammation of the skin, and sometimes of the mucous membranes (the thin, moist tissue that lines body cavities), that is sometimes accompanied by generalized illness. Erythema multiforme means “skin redness of many varieties”.

**CAUSES**
Erythema multiforme can develop as an adverse reaction to certain drugs or it may accompany certain viral infections (for example, *herpes simplex*) or bacterial infections (such as *streptococcal infections*). Other possible causes of erythema multiforme are pregnancy, *vaccination,* and *radiotherapy.* However, about half of all cases occur for no apparent reason.

**SYMPTOMS**
A symmetrical rash of red, frequently itchy, spots erupts on the skin of the limbs and, occasionally, on the face and the rest of the body. The spots may blister or form raised, pale-centred weals known as target lesions. People suffering from erythema multiforme may have a fever, sore throat, headache, and/or diarrhoea.

In a more severe form of erythema multiforme, known as *Stevens–Johnson syndrome,* the mucous membranes of the mouth, eyes, and genitals are all affected and become ulcerated.

**TREATMENT**
Treatment for erythema multiforme depends on the underlying cause. Any causative drug treatment will be withdrawn and any underlying condition will be treated if possible. *Corticosteroid drugs* may be given to reduce the inflammation. People suffering from Stevens–Johnson syndrome are also given *analgesic drugs* (painkillers) and may need intensive care.

**erythema nodosum**
A condition characterized by reddish-purple, tender swellings on the legs. Erythema nodosum is usually associated with another illness.

**CAUSES**
The most common cause of erythema nodosum is a *streptococcal infection* of the throat. However, the condition is also associated with other diseases, mainly *tuberculosis* and *sarcoidosis,* and...
may occur as a reaction to some drugs, particularly sulphonamide drugs, penicillin drugs, and salicylate drugs. Sometimes there is no apparent cause.

**SYMPTOMS**
The swellings, which may range from 1 to 10 cm in diameter, are shiny and tender and occur on the fronts of the shins, the thighs, and, less commonly, the arms. Joint and muscle pains and fever also usually occur.

**TREATMENT**
Successful treatment of any underlying condition clears the swellings. Bed rest, analgesic drugs (painkillers), and, occasionally, corticosteroid drugs may also be necessary. The condition usually subsides within about a month.

**erythematous**
Characterized by erythema (redness of the skin).

**erythrasma**
A bacterial skin infection, caused by the organism Corynebacterium, that affects the groin, armpits, and skin between the toes. Raised, irregularly shaped, discoloured patches appear in the affected areas. Erythrasma is most common in people who have diabetes mellitus. The condition generally clears up following a course of treatment with the antibiotic drug erythromycin.

**erythrocyte**
Another name for a red blood cell.

**erythroderma**
See exfoliative dermatitis.

**erythrogenic toxin**
A poisonous protein produced by streptococcal bacteria that causes the red rash in scarlet fever.

**erythromelalgia**
A rare condition, also known as Gerhardt–Mitchell disease, that principally affects the extremities of the body, most commonly the feet. Erythromelalgia usually first appears in middle age. It may be associated with polycythæmia (an increase in the total red cell mass of the blood), thrombocytosis (an increase in the number of platelets in the blood), gout (a metabolic disorder that causes attacks of arthritis), and neurological disease.

Erythromelalgia is characterized by severe attacks of burning pain and mottled redness of the skin; it may be triggered by heat. Attacks of the condition can be relieved by elevating the affected limb and applying something cold, such as an ice pack, to it. No specific treatment is available, but aspirin may relieve the condition in some cases.

**erythromelalgia**
Diffuse erythema (redness) and atrophy (wasting) of the skin of the lower limbs. The cause of erythromelalgia is unknown.

**erythromycin**
An antibiotic drug used in the treatment of skin, chest, throat, and ear infections. Erythromycin is given to people with these conditions who are allergic to penicillin drugs. In addition, it is particularly useful in the treatment of pertussis (whooping cough) and legionnaires’ disease. The drug may be taken in tablet form, liquid form, or intravenously. Possible adverse effects include nausea, diarrhoea, and an itchy rash.

**erythrovirus**
A virus formerly known as parvovirus. Infection with a strain of erythrovirus causes fifth disease in humans.

**escape beat**
An automatic heartbeat that occurs after an abnormally long pause in the heart rhythm. An escape beat is therefore a delayed beat that terminates a longer cycle than normal.

**eschar**
A scab that forms on the surface of skin that has been subject to damage, for example by a burn.

**Escherichia coli (E.coli)**
A bacterium (see bacteria) that is normally found in the intestines but can cause illness under some circumstances.

Types of E. coli are often the cause of traveller’s diarrhoea, which is usually a mild illness. Bacteria that enter the bladder through the urethra are a common cause of urinary tract infections. Some strains of E.coli, however, can cause serious food-borne infections that may result in haemolytic–uraemic syndrome (a condition in which red blood cells are destroyed and kidney function becomes impaired).

**Esmarch’s bandage**
A broad rubber bandage that is wrapped around the elevated limb of a patient to force blood out of the blood vessels towards the heart. This action creates a blood-free area, so surgery on the limb can be performed more easily.

The patient is anaesthetized (see anaesthesia), then the Esmarch’s bandage is wrapped around the fingers or toes upwards. An inflatable tourniquet (a device used to compress blood vessels) is then applied to the upper arm or thigh to stop blood from returning to the limb. The Esmarch’s bandage is removed, leaving the inflated tourniquet in position during surgery.

**esotropia**
An alternative term for a convergent squint, in which one eye looks directly at an object while the other eye turns inwards. (See also exotropia.)

**ESR**
The abbreviation for erythrocyte sedimentation rate, which is the rate at which erythrocytes (red blood cells) sink to the bottom of a test tube.

**WHY IT IS DONE**
The ESR is increased if levels of fibrinogen (a type of protein) in the blood is raised. Fibrinogen is raised in response to a range of illnesses, including inflammation, especially when this is caused by infection or by an autoimmune disease. The ESR is also increased if levels of antibodies (proteins manufactured by the immune system) are very high, as occurs in multiple myeloma. ESR is therefore useful for helping to diagnose these conditions as well as in monitoring their treatment.

**HOW IT IS DONE**
Whole blood collected from the patient is mixed with anticoagulant (a chemical that prevents the blood from clotting) in a test tube. In one method, the blood is left undisturbed at a constant temperature for one hour. The red blood cells, which can be seen as a dark red clump, settle to the bottom of the tube, leaving the clear, straw-coloured plasma at the top. The ESR is the number of millimetres the red cells fall in one hour.

**essential amino acids**
The nine amino acids required for protein synthesis, growth, and development, that cannot be made by the body and must be obtained in the diet.

**essential fatty acids**
The fatty acids that cannot be synthesized by the body and must therefore be obtained in the diet.
**essential food factors**

Any substances that are essential for normal functioning of the body but cannot be synthesized by the body itself, so must be obtained through the diet. Examples of essential food factors are most *vitamins* and *minerals* and *essential amino acids*.

**essential hypertension**

*Hypertension* (high blood pressure) that occurs without known cause.

**estradiol**

The most important *oestrogen hormone*, which is essential for the healthy functioning of the female reproductive system and for breast development. In its synthetic form, estradiol is used to treat the symptoms and complications of the menopause (see *hormone replacement therapy*) and to stimulate sexual development in female *hypogonadism* (underactivity of the ovaries).

**estriol**

One of the *oestrogen hormones*. Estriol is the predominant oestrogen produced during pregnancy. Synthetic estriol is prescribed to treat the symptoms and complications of the menopause (see *hormone replacement therapy*) as well as to stimulate sexual development in female *hypogonadism* (underactivity of the ovaries).

**estrone**

An *oestrogen hormone*. Synthetic estrone is used to treat the symptoms and complications of the menopause (see *hormone replacement therapy*).

**ESWL**

The abbreviation for extracorporeal shock wave *lithotripsy*.

**ethambutol**

A drug used in conjunction with other drugs to treat *tuberculosis*. Ethambutol rarely causes side effects, but it may sometimes result in inflammation of the *optic nerve*, leading to blurred vision.

**ethanol**

The chemical name for the *alcohol* that is present in alcoholic drinks.

**ether**

A colourless liquid that produces unconsciousness when inhaled. Ether was the first general anaesthetic (see *anaesthesia, general*) to be introduced.

**ethics, medical**

See *medical ethics*.

**ethinylestradiol**

A synthetic form of the female sex hormone *estradiol*. Ethinylestradiol is most often used in *oral contraceptives*, in which it is combined with a *progestogen drug*. Rarely, it is used in *hormone replacement therapy*.

**ethmoidal sinus**

One of the air-containing spaces in the ethmoid bone behind the nose (see *sinus*, *facial*).

**ethmoid bone**

A bone that forms part of the floor of the cranium (skull) and contributes to the root of the nasal cavity and to the orbits (eye sockets). The *olfactory nerves*, which are responsible for smell, pass through holes in part of the ethmoid bone called the cribriform plate.

**ethosuximide**

An *anticonvulsant drug* used in the treatment of absence (petit mal) seizures (see *epilepsy*). Ethosuximide may cause nausea and vomiting and, in rare cases, affects the production of blood cells in bone marrow (see *anaemia, aplastic*).

**ethyl alcohol**

Another name for ethanol, the alcohol in alcoholic drinks.

**ethyl chloride**

A colourless liquid that is used as an *analgesic drug* (painkiller). Ethyl chloride is applied to the skin as a spray to numb an area before minor surgery is carried out or to relieve muscle pain. The substance is also used in the treatment of *larva migrans*, a hookworm infestation.

**etidronate, disodium**

A *bisphosphonate drug* used to treat bone disorders (see *bone, disorders of*), such as *Paget’s disease* and *osteoporosis*. Disodium etidronate works by reducing the activity of bone cells, thereby halting the progress of the disease. Side effects of the drug are generally mild.

**etretinate**

A *retinoid* drug, chemically related to *vitamin A*, that is used mainly in the treatment of severe *psoriasis* (a skin disease characterized by thickened patches of red, inflamed skin). Also known as *acitretin*, etretinate is also occasionally used in the treatment of other disorders that cause excessive skin thickening, such as *ichthyosis*. It reduces the production of keratin, the protein that forms the hard, outer layers of the skin.

Etretinate can cause liver damage and a rise in blood fats. The drug must not be taken during pregnancy because it can cause damage to the fetus.

**eucalyptus oil**

A substance distilled from the leaves of eucalyptus trees. Because of its aromatic smell and refreshing taste, it is used as a flavouring. It is also used in cough and cold remedies, when it may be applied as a rub, inhaled as vapour, or incorporated in tablets.

There is little evidence that eucalyptus oil has any curative properties, although it may relieve symptoms.

**eugenics**

The science that is based on the improvement of the human race and the quality of human life through the principles of *genetics*. Modern eugenics is primarily concerned with the study (and, where possible, the elimination) of genetic disease (see *genetic disorders*).

**Eulenburg’s disease**

A rare, nonprogressive, inherited disorder, also called congenital paramyotonia, in which there is prolonged contraction of muscle fibres (see *myotonia*) when the patient is exposed to the cold. The muscles of the limbs, eyelids, and tongue may be affected. Eulenburg’s disease shows an autosomal dominant pattern of inheritance (see *genetic disorders*) and may be caused by a disorder of potassium *metabolism*.

**eunuch**

A man whose testes (see *testis*) have been removed or destroyed so that he is sterile and lacks male hormones. A male who has been castrated before *puberty* will have broad hips, narrow shoulders, and undeveloped male secondary *sexual characteristics* (such as a small penis, a feminine distribution of body hair, and a high-pitched voice).

**euphoria**

A state of confident wellbeing. Euphoria is a normal reaction to personal success, but it can also be induced by certain drugs, including prolonged use of *corticosteroid drugs*. Euphoria that has
Eustachian tube

The passage that runs from the middle ear into the back of the nose, just above the soft palate (part of the roof of the mouth). The eustachian tube is lined with a smooth, moist, mucous membrane.

**FUNCTION**

The eustachian tube acts as a drainage channel from the middle ear and maintains hearing by opening periodically to regulate air pressure. The lower end of the tube opens during swallowing and yawning, allowing air to flow up to the middle ear, equalizing the air pressure on both sides of the eardrum.

**DISORDERS**

When a viral infection, such as a cold, causes blockage of the eustachian tube, equalization cannot occur, resulting in severe pain and temporary impairment of hearing. A person with a blocked eustachian tube who is subjected to rapid pressure changes may suffer from barotrauma (pressure damage to the eardrum and other structures). Glue ear (the accumulation of secretions in the middle ear) or chronic otitis media (middle-ear infection) may occur if the tube is blocked, preventing adequate drainage from the middle ear.

These conditions, which often result in partial hearing loss, are much more common in children. This is partly because their adenoids are larger and more likely to cause a blockage if they become infected and partly because children’s eustachian tubes are shorter than those of adults.

**euthanasia**

The use of medical knowledge to end a life painlessly in order to relieve suffering. Voluntary euthanasia refers to action taken to end life at the patient’s own request. In the UK, it is illegal to take active measures to end a person’s life; however, the withdrawal of treatment that would prolong life may be considered under some circumstances.

**euthyroid**

A term used to describe a person whose thyroid gland is functioning normally. The term “euthyroid” is used especially to refer to someone who has been successfully treated for either hypothyroidism (underactivity of the thyroid) or hyperthyroidism (overactivity of the thyroid).

**Evan’s syndrome**

An uncommon autoimmune disorder in which the body wrongly makes two antibodies (immune system proteins): one that attacks healthy red blood cells (see anaemia, haemolytic) and one that destroys platelets (tiny cells in the blood that play a vital role in blood clotting). The spleen is usually the main site of cell destruction.

The anaemia can cause tiredness and pallor, and the deficiency of platelets may lead to bruising and a tendency to bleed easily. The haemolysis (red cell destruction) causes jaundice (yellowing of the skin and the whites of the eyes).

A blood transfusion may be needed in the early stages of the condition. Corticosteroid drugs may be prescribed to control haemolysis and platelet destruction. In severe cases, the spleen may be removed (see splenectomy). The antibodies may eventually disappear after several months or years.

**evening primrose oil**

An oil extracted from the seeds of the plant Oenothera biennis, commonly called evening primrose. The oil contains an anti-inflammatory substance known as gamolenic acid and is believed by some to be of benefit in treating eczema and premenstrual syndrome.

**eversion**

Turning outwards. The term is used medically to describe a type of ankle injury or deformity in which the foot is turned outwards.

**evidence-based medicine**

The use of medical or surgical treatments that have been evaluated for effectiveness and safety by clinical research. The research involves randomized controlled trials and often includes meta-analysis, in which the results from several trials are combined.

**Evista**

A brand name for raloxifene, a drug that is prescribed for the prevention and treatment of osteoporosis in postmenopausal women.

**evoked potential**

The electrical signal generated when a sensory area, such as a nerve, a muscle, or the retina (the light-sensitive inner layer at the back of the eye), is stimulated. Tests to record evoked potentials are used to diagnose problems affecting the conduction of signals along sensory nerves. (See also evoked responses.)

**evoked responses**

The tracing of electrical activity in the brain in response to a specific external stimulus. The evoked responses procedure is similar to that for an EEG (electroencephalography).

The technique is used to check the functioning of various sensory systems (such as sight, hearing, or touch). The information obtained can be used to
reveal abnormalities caused by inflammation, pressure from a tumour, or other disorders, and to help confirm a diagnosis of multiple sclerosis.

Ewing's sarcoma
A rare malignant form of bone cancer. Ewing's sarcoma arises in a large bone, usually the femur (thigh bone), tibia, (shin), humerus (upper-arm bone), or a pelvic bone, and spreads to other areas at an early stage. The condition is most common in children between ten and 15 years of age.

SYMPTOMS
A bone affected by Ewing's sarcoma is painful and tender. It may also become weakened and fracture easily. Other symptoms include weight loss, fever, and anaemia (a reduced level of the oxygen-carrying pigment haemoglobin in the blood).

DIAGNOSIS AND TREATMENT
The sarcoma can be diagnosed by X-rays and biopsy (removal of a small sample of tissue for microscopic analysis). If cancer is found, the whole skeleton is examined by X-rays and radionuclide scanning, and the lungs viewed by CT scanning, to determine if, and how far, the cancer has spread.

Treatment of Ewing's sarcoma is with radiotherapy and anticancer drugs. The outlook depends on how far the cancer has spread.

exanthema
A skin eruption or rash, or a disease in which a skin eruption or rash is a prominent feature, such as measles, scarlet fever, or roseola infantum.

exchange transfusion
A treatment for haemolytic disease of the newborn, a severe disorder resulting from rhesus incompatibility between a pregnant mother and her baby and causing destruction of red blood cells in the baby. This condition leads to dangerously high levels of the pigment bilirubin in the baby's blood as well as severe anaemia (a reduced level of the oxygen-carrying pigment haemoglobin in the blood). Exchange transfusion is used to treat both these symptoms by replacing the infant's blood with rhesus-negative donor blood.

excimer laser
A computer-controlled laser used to reshape the cornea (the transparent dome that forms the front of the eyeball). The laser removes very thin layers of tissue from the corneal surface (see LASIK; PRK). The technique is used to correct myopia (shortsightedness), hypermetropia (longsightedness), and some other vision disorders.

excision
The surgical cutting out of diseased tissue, such as a breast lump or gangrenous skin, from surrounding healthy tissue. (See also excisional biopsy.)

excisional biopsy
A type of biopsy that involves the removal of an entire area of affected tissue, together with a margin of adjacent healthy tissue, for microscopic analysis in a laboratory.

exclusion diet
A dietary programme that is used to identify a particular food allergy or food intolerance. Food is initially limited to a very restricted choice until symptoms improve; test foods, such as milk, are then reintroduced one at a time, at intervals of several days, to see if there is an adverse reaction. The reintroduction of such a test food is known as a food challenge. Individuals on an exclusion diet are asked to keep a daily record of their symptoms from at least a week before starting the diet until the end of the programme. An exclusion diet should never be attempted without the advice of a doctor, dietitian, or nutritionist because it can result in serious nutritional deficiencies.

excoriation
Injury to the surface of the skin or to a mucous membrane (the thin, moist tissue that lines body cavities) caused by physical abrasion, such as scratching.

excretion
Any abnormal raised growth on the surface of the body, such as a wart.

excretion
The discharge of any waste material from the body. Examples of such waste material are the by-products of digestion, waste products from the repair of tissues, and excess water.

organs of excretion
The kidneys excrete urine, which contains excess nitrogen (as urea), together with excess water, salts, some acids, and most drugs. The liver excretes bile, which contains waste products and bile pigments formed from the breakdown of red blood cells. Some of the bile is passed from the body in the faeces. The large intestine excretes undigested food, some salts, and excess water in the form of faeces. The lungs discharge carbon dioxide and water vapour into the air. Sweat glands excrete salt and water onto the surface of the skin as a method of regulating the body's temperature.

exencephaly
A developmental defect of the cranium (skull) in which part of the bone is absent, leaving the brain exposed or allowing it to protrude. This defect is incompatible with survival.

exenteration
The surgical removal of all organs and soft tissue in a body cavity, usually to arrest the growth of a cancer. Exenteration is sometimes used in ophthalmology when the eye and the contents of the eye socket are removed.

exercise
Any physical activity performed to improve health. Exercise may be taken for recreation or to correct a physical injury or deformity (see physiotherapy).

types of exercise
Different types of exercise have different effects on the body. Some forms (aerobic exercises) improve the fitness
of the cardiovascular and respiratory systems; some forms improve flexibility; some increase muscular strength; and some improve physical endurance.

During aerobic exercise, such as jogging or swimming, the heart and lungs work faster and more efficiently to meet the muscles’ increased demand for oxygen. Regular aerobic exercise improves the condition of both the cardiovascular and respiratory systems.

Exercises such as weight training increase muscle strength and endurance. Activities such as yoga and pilates improve flexibility. For further information on the effects of exercise, see the illustrated box below.

**THE EFFECTS OF EXERCISE**

Exercise produces many changes in different body organs. Muscles receive an increased blood flow because of their greater energy requirements, and the heart and lungs work faster and more efficiently to keep the body tissues well supplied with blood. These changes are controlled by the release of the chemicals adrenaline and noradrenaline from the sympathetic nervous system.

**The lungs**
The rate and depth of breathing increase to ensure a sufficient flow of oxygen from the lungs into the blood. This increase in breathing also helps to remove additional carbon dioxide produced by the muscle cells during exercise.

**Bones**
Regular exercise helps to maintain the strength and density of the bones and so prevents or slows the development of the bone disease osteoporosis.

**COMMON TYPES OF EXERCISE**

<table>
<thead>
<tr>
<th>Aerobic</th>
<th>Isometric</th>
<th>Isotonic</th>
<th>Isokinetic</th>
</tr>
</thead>
<tbody>
<tr>
<td>Aerobic exercise is activity in which the body continuously needs to take in additional oxygen to meet the muscles’ increased demands. Regular aerobic exercise improves the performance of the cardiovascular and respiratory systems. Jogging, swimming, and cycling are examples of aerobic exercise.</td>
<td>Isometric exercise is exercise without movement, in which one group of muscles exerts steady pressure against either an immovable object or an opposing group of muscles. It is an effective means of increasing muscle strength, but does not exercise the cardiovascular system or help in muscular endurance.</td>
<td>Isotonic exercise is exercise with movement, in which muscle tension is more or less constant and the body works against its own weight or external weights. Isotonic exercise includes weight training and calisthenics (repetitive movements with little or no equipment). It increases muscle strength, size, and endurance.</td>
<td>Isokinetic exercise involves both isotonic and isometric exercise. The muscles move reasonably heavy loads, but are also put through their full range of movement. Isokinetics combines strength training with some aerobic exercise, but requires specialist equipment.</td>
</tr>
</tbody>
</table>
exhalation
The medical term for the process of breathing out (see breathing).

exhaustion
Extreme mental or physical tiredness in which a person lacks energy. The state of exhaustion may come about as a result of overactivity or prolonged insomnia (difficulty in falling or staying asleep) or it may be a symptom of a mental or physical disorder, such as anxiety, stress, severe anaemia, or prolonged labour. (See also heat exhaustion.)

exhibitionism
The habit of deliberately exposing the genitalia as a deviant sexual act. This type of behaviour is almost always confined to men. Psychotherapy or behaviour therapy may help to treat persistent offenders.

existential psychotherapy
An uncommon form of psychotherapy in which emphasis is placed on spontaneous interactions and feelings rather than on rational thinking. The psychotherapist is involved in the therapy to the same extent as the patient.

exocrine gland
A gland that secretes substances through a duct (a tube or passage) either onto the inner surface of an organ or the outer surface of the body. Examples of exocrine glands include the salivary glands and the sweat glands. The release of exocrine secretions can be triggered by a hormone or a neurotransmitter. (See also endocrine gland.)

exogenous
A term referring to a disease or disorder that has a cause external to the body. Examples are infection, poisoning, or injury. (See also endogenous.)

exophthalmic goitre
An alternative name for the thyroid gland disorder Graves’ disease.

exophthalmos
Protrusion of one or both eyeballs caused by a swelling of the soft tissues within the eye socket.

appearance of exophthalmos
An alternative name for the thyroid gland disorder Graves’ disease.

CAUSES
Exophthalmos is most commonly associated with Graves’ disease, which also causes thyrotoxicosis (overactivity of the thyroid gland). Other causes include an eye tumour, an aneurysm (ballooning of an artery), or inflammation behind the eye.

SYMPTOMS
Exophthalmos may restrict eye movement and cause double vision. In severe cases, increased pressure in the socket may restrict blood supply to the optic nerve, causing blindness. The eyelids may be unable to close, and vision may become blurred due to drying of the cornea (the transparent dome that forms the front of the eyeball).

TREATMENT AND OUTLOOK
In exophthalmos due to thyroid disease, treatment of the thyroid disorder may relieve the exophthalmos; however, exophthalmos may persist even if thyroid function returns to normal.

With early treatment, normal vision is usually restored. Occasionally, surgery may be required to relieve pressure on the eyeball and optic nerve.

exostosis
The most common type of noncancerous bone tumour, in which there is an outgrowth of bone tissue. Exostosis develops most commonly at one end of the femur (thigh bone) or the tibia (shin). The condition may be due to hereditary factors or to prolonged pressure on a particular bone.
SYMPTOMS
In most cases, exostosis produces no symptoms. Often it is recognized only after an injury, when it appears as a hard swelling. Occasionally, the tumour presses on a nerve, causing pain or weakness in the affected area.

DIAGNOSIS AND TREATMENT
Diagnosis can be confirmed by X-rays. The tumour may be surgically removed if it is causing symptoms or for cosmetic reasons.

exotoxin
A poison, released by certain types of bacteria (including tetanus bacilli and diphtheria bacilli), that enters the bloodstream and causes widespread effects around the body. Exotoxins are among the most poisonous substances known.
Infections by tetanus, diphtheria, and some other bacteria that release life-threatening exotoxins can be prevented by immunization with vaccines consisting of detoxified exotoxins. Treatment of such infections usually includes administration of antibiotic drugs and an antitoxin to neutralize the exotoxin. (See also endotoxin; enterotoxin.)

exotropia
An alternative term for a divergent squint, in which one eye is used for detailed vision and the other is directed outwards. (See also esotropia.)

expectorants
Cough remedies that encourage expectoration (the coughing up of sputum).

expectoration
The coughing up and spitting out of sputum (phlegm). (See also cough.)

expiratory reserve volume
The extra volume of air expired in the fullest possible exhalation; this amount is in addition to the volume that is normally expelled when a person is at rest. The expiratory reserve volume may be measured in pulmonary function tests.

expiratory stridor
An abnormal noise that is heard when a person exhales. Expiratory stridor may occur if the vocal cords are partially obstructing the flow of air or if there is an obstruction in the trachea (the windpipe) or bronchi (see bronchus), which are the main airways to the lungs. Expiratory stridor may occur either alone or with inspiratory stridor.

expire
To exhale (breathe out air from the lungs). The term also means “to die”.

expired gas
Any gas that has been expelled from the lungs. Expired gas usually contains a high proportion of carbon dioxide. It may also contain other substances, such as alcohol and carbon monoxide, that are carried in the circulation.

exploratory surgery
Any operation carried out to investigate or examine part of the body to discover the extent of known disease or to establish a diagnosis. Advances in imaging, such as MRI (a technique that produces cross-sectional or three-dimensional images of body structures), have reduced the need for exploratory surgery.

exposure
A term used to describe the effects on the body of being subjected to very low temperatures, or to a combination of low temperatures, wetness, and high winds. The primary danger in these conditions is hypothermia (a sharp fall in body temperature).
The term is also used to describe subjection to radiation, to environmental pollutants, or to infectious diseases.

expressing milk
A technique sometimes used by women who are breast-feeding, for removing milk from the breasts. The technique may be needed if the woman’s breasts are overfull (see engorgement). A woman may also want to express milk so that it can be given to the baby in her absence or so that an infant who is unable to feed at the breast (due to prematurity, for example) can still benefit from breast milk. Milk can either be expressed by hand or using a breast pump. The milk may also be frozen for later use.

expressive dysphasia
A type of dysphasia (disturbance in the ability to use and/or understand words) in which the person can understand others and knows what he or she wishes to say, but has difficulty putting thoughts into words. (See also aphasia; speech; speech disorders; speech therapy.)

exsanguinate
To remove, withdraw, or deprive the body of circulating blood. Exsanguination usually results from severe internal or external bleeding. It can also be performed during surgery to create a blood-free area for the procedure. (See also Esmarch’s bandage.)

extrophy of the bladder
A rare birth defect in which the bladder is inside-out and is open to the outside of the body through a space in the lower abdominal wall. There are also, usually, other defects, such as epispadias in males (in which the opening of the urethra is on the upper surface of the penis) and failure of the pubic bones to join at the front. Untreated, an affected child constantly leaks urine.
Surgical treatment involves reconstructing the bladder and closing the abdominal wall. If the bladder is very small, it is removed and the urine diverted (see urinary diversion).

extensor
Any muscle that moves a joint in order to straighten a limb. An example of an extensor muscle is the triceps muscle in the arm, which straightens the elbow.

external cardiac massage
Rhythmic pressure applied to the chest in order to maintain circulation if a person’s heart has stopped beating. The lower breastbone is squeezed repeatedly with the heels of the hands, in order to compress the heart (see cardiac massage). External cardiac massage may be used in first aid, as part of cardiopulmonary resuscitation.

external fixation
The insertion of pins through the skin to hold together parts of a broken bone (see fracture). The pins are held in place by an external metal frame. Usually, the affected limb can be used within a few days; the frame and pins are removed under anaesthesia when the bone has healed. (See also internal fixation.)

external haemorrhoids
Haemorrhoids (dilated veins) that form around the outside of the anus. Haemorrhoids are commonly known as piles. The condition is sometimes associated with internal haemorrhoids, those that develop higher up inside the anal canal. If the blood in an external haemorrhoid clots, the resulting swelling is termed a perianal haematoma. This condition is very painful but usually disappears within about five days. (See also haemorrhoidectomy; internal haemorrhoids.)
extracorporeal circulation
Circulation of blood outside the body through a machine that temporarily assumes an organ’s functions. Examples of extracorporeal circulation include the use of a heart–lungs machine, during open heart surgery, to keep blood moving around the body and carry out carbon dioxide–oxygen exchange, and extracorporeal dialysis.

extracorporeal dialysis
Haemodialysis performed through an artificial kidney to remove the substances that are normally excreted in the urine (see dialysis).

extracorporeal gas exchange
A technique in which blood is diverted out of the body and through an “artificial lung” to aid respiration. It involves a procedure called extracorporeal membrane oxygenation (ECMO), in which blood is passed over an artificial membrane and takes up oxygen, and the removal of waste carbon dioxide. Extracorporeal gas exchange is used to treat severe respiratory failure, in addition to mechanical ventilation.

extracorpuscular
A term meaning “situated or occurring outside the corpuscles (minute bodies or cells)”. Extracorpuscular refers particularly to the environment outside the blood cells (for example, it may be used for agents that attack red blood cells from outside; see anaemia, haemolytic).

extraction, dental
The removal of one or more teeth by a dentist.

WHY IT IS DONE
Dental extraction may be performed when a tooth is severely decayed or too badly broken to be repaired or when an abscess (see abscess, dental) has formed. Teeth may also be removed if there is dental crowding or malocclusion (an incorrect bite); if they are loose due to severe gum disease; or if they are preventing another tooth from erupting through the gum (see eruption of teeth).

HOW IT IS DONE
For most extractions, local anaesthesia is used (see anaesthesia, dental). A general anaesthetic (see anaesthesia, general) may be used to extract badly impacted wisdom teeth (see impaction, dental), to extract several teeth at once, or for extremely anxious or disabled patients or young children.

Teeth are usually extracted with dental forceps, which are designed to grasp the root of the tooth. When gentle but firm pressure is applied, the blades cut through the periodontal ligaments (the tough, fibrous membranes supporting the tooth in its socket), the socket is gradually expanded, and the tooth is removed. Occasionally the root fractures during this procedure and may need to be removed separately.

In difficult extractions, for example if the tooth is impacted, if the crown is missing, or if the roots are very curved, some gum and bone may need to be removed from around the tooth before the tooth is extracted and the gum is sutured (stitched).

COMPLICATIONS
Most extractions take place without complications. If bleeding does not stop after extraction of a tooth, suturing of the tissue around the socket may be necessary.

Occasionally, if a blood clot (see blood clotting) fails to form in the empty tooth socket, or if the blood clot is dislodged, dry socket (infection in the tooth socket) develops.

extradural haemorrhage
Bleeding into the space between the inner surface of the skull and the external surface of the dura mater (the outer layer of the meninges, the protective covering of the brain).

CAUSE
Extradural haemorrhage most commonly occurs as a result of a heavy blow to the side of the head that fractures the skull (see skull, fracture of) and ruptures an artery running over the surface of the dura mater.

SYMPTOMS
A haematoma (a collection of clotted blood) forms and enlarges, increasing pressure inside the skull. Symptoms result several hours or sometimes even days after the injury. These symptoms may include headache, drowsiness, vomiting, paralysis affecting one side of the body, and seizures.

If left untreated, extradural haemorrhage may be life-threatening.

DIAGNOSIS AND TREATMENT
CT scanning or MRI (techniques that produce cross-sectional or three-dimensional images of body structures) are used to confirm the diagnosis. Treatment may consist of craniotomy (drilling holes in the skull), draining the blood clot, and clipping shut the ruptured blood vessel.

extrapyramidal disease
Any of a group of disorders that are the result of damage to, or degeneration of, parts of the extrapyramidal system (nerve pathways that link motor nerve nuclei within the brain). Extrapyramidal diseases disrupt the execution of voluntary movements; these diseases are characterized by uncontrollable movements, changes in muscle tone, and postural disturbances. Examples of extrapyramidal disease include Huntington’s disease, Parkinson’s disease, and some types of cerebral palsy.

extrapyramidal system
A network of nerve pathways that links the surface of the cerebrum (main mass of the brain) with motor nerve nuclei in the basal ganglia, and parts of the brainstem. This system influences and modifies electrical impulses sent from the brain to initiate movement in skeletal muscles.

Damage or degeneration of components in the extrapyramidal system may be caused by extrapyramidal disease. It may also occur as a side effect of taking phenothiazine drugs.

extrasystole
A contraction of the heart that is independent of the heart’s normal rhythm. Extrasystole arises in response to an electrical impulse in a part of the heart other than the sinoatrial node (see ectopic heartbeat).

extrauterine pregnancy
An alternative term for an ectopic pregnancy.

extravasation
The leakage and spread of fluid, usually from blood vessels or lymph vessels, into the surrounding tissues. Extravasation has a variety of causes, including injury, burns, and inflammation.

extravascular
Situated or occurring outside the vessels. The term refers particularly to the blood vessels (see circulatory system) and lymph vessels (see lymphatic system). Extravascular fluid is that fluid that exists outside the circulation, in the body tissues.

extrinsic allergic alveolitis
Inflammation and thickening of the tiny air sacs in the lungs that is caused by an allergy to inhaled organic dusts (see alveolitis).
**extrinsic asthma**

Any form of *asthma* precipitated by an environmental factor. Extrinsic asthma is usually due to an *allergy* to a foreign substance, such as inhaled particles, certain foods, or a particular drug.

**extrinsic factor**

An alternative name for *vitamin B₁₂*.

**extrovert**

A person whose main interest is in other people and the outside world. Extroverts are active, sociable, and have many interests. (See also *introvert, personality*.)

**exudation**

The discharge of fluid from *blood vessels* into surrounding tissues. Exuded fluid (exudate) contains *cells* and *protein*.

Most exudates are a result of inflammation. In inflamed tissue, the small blood vessels widen and tiny pores in the vessel walls enlarge, allowing fluid and cells (mainly *white blood cells*) to escape.

**exudation cyst**

A *cyst* (a fluid-filled lump or swelling) formed when an existing body cavity fills with fluid due to *exudation*. A *hydrocele* (fluid-filled swelling in the scrotum) is an example of an exudation cyst.

**exudative retinitis**

See *Coat’s disease*.

**eye**

The organ of sight. The eye is a complex organ, consisting of a series of structures that focus an image on to the *retina* (the light-sensitive inner layer at the back of the eye) and nerve cells that convert this image into electrical impulses. These impulses are carried by the *optic nerve* to the visual cortex (an area on the back surface of the brain concerned with *vision*) for interpretation.

The eyes work in conjunction with one another, under the control of the brain. They align themselves on a particular object so that a clear image of the object is formed on each retina. If necessary, the eyes may sharpen the image by altering focus using an automatic process called *accommodation*, which changes the shape of the *lens*.

**EYE BALL**

The eyeballs lie in pads of fat within the bony *orbits* (eye sockets) that provide protection from injury. Each eyeball is

---

**ANATOMY OF THE EYE**

The eye is a complex organ that focuses light rays to form an image on the retina, the light-sensitive inner layer at the back of the eyeball. The cornea and lens focus the rays. The pupil controls the amount of light entering the eye and the ciliary body alters the shape of the lens to adjust the focus. The retina has millions of nerve cells that respond to light; they convert the image into a pattern of nerve impulses, which are transmitted to the brain via the optic nerve.

**movement of the eye**

Movement of each eyeball occurs as the result of contraction of one or more of the muscles attached around it. There are six of these muscles, each of which pulls the eye in a specific direction.
moved by six delicate muscles. The eye has a tough, white outer layer known as the sclera. At the front of the sclera, the cornea (a transparent, thin-walled dome) serves as the main “lens” of the eye and does most of the focusing.

Behind the cornea is a shallow chamber filled with watery fluid (called the aqueous humour), at the back of which is the iris (the coloured part of the eye) with its pupil (circular opening), which appears black. Tiny muscles alter the size of the pupil in response to changes in light intensity in order to control the amount of light entering the eye.

Behind the iris, and in contact with it, is the crystalline lens, which is suspended by fibres from a circular ring of muscle: the ciliary body. Contraction of the ciliary body changes the shape of the lens, enabling fine focusing.

The main cavity of the eye contains a clear gel (the vitreous humour) and is located directly behind the lens. On the inside of the back of the eye is the retina, a complex structure of nerve tissue that is extremely sensitive to light. The retina requires a constant supply of oxygen and glucose. To meet this need, a thin network of blood vessels, the choroid plexus, lies immediately under it. The choroid is continuous at the front with the ciliary body and the iris; these three parts constitute the uveal tract.

**CONJUNCTIVA AND EYELID**

The eyeball is sealed off by a transparent, flexible membrane called the conjunctiva, which is attached to the skin at the corners of the eye and forms the inner lining of the eyelids. The conjunctiva contains mucus-secreting glands. These, together with the meibomian glands in the eyelids (which secrete an oily fluid), provide the tear film that protects the cornea and conjunctiva. Blinking, a protective reflex, helps to spread the tear film evenly over the cornea to enable clear vision.

**eye, artificial**

A prosthesis used to replace an eye that has been surgically removed. An artificial eye is worn purely for cosmetic and psychological reasons and fits neatly behind the eyelids into the cavity from which the natural eye was removed. Some movement of the artificial eye may be achieved by attaching the muscles that normally move the eye to the remaining conjunctival membrane (see conjunctiva) or to a plastic implant placed in the eye socket.

Often called “glass eyes”, artificial eyes were once made of glass; now an easily mouldable plastic material is used.

**eye-drops**

Medication in solution that is used in the treatment of eye disorders or to aid in their diagnosis. Examples of drugs given in this form are antibiotic drugs, antihistamine drugs, drugs used either to dilate (widen) or constrict (narrow) the pupil, the circular opening in the centre of the iris, and corticosteroid drugs.

A specified number of eye-drops are applied to the inside of the lower eyelid after the lid has been drawn down using the tip of a clean finger. Blinking helps to spread the medicated solution evenly around the eyeball.

**eye, examination of**

An inspection of the structures of the eyes, either as part of a vision test or to make a diagnosis when an eye disorder is suspected.

---

### DISORDERS OF THE EYE

Many eye disorders are minor, but some can cause loss of vision unless treated. (See also disorders of the cornea box; disorders of the retina box.)

**Congenital defects**

Squint (misalignment of the eyes) may be congenital (present at birth). Other examples of congenital defects are nystagmus (uncontrollable, jerky eye movements), albinism (absence of pigment in the iris), and developmental defects affecting the cornea and retina. A rare birth defect is microphthalmos (abnormally small size of one or both eyes). Cataract (opacity of the lens) can sometimes be seen in newborn infants.

**Infection**

Conjunctivitis (inflammation of the conjunctiva) is the most common eye infection. Trachoma (a persistent disease of the cornea or conjunctiva) or severe bacterial conjunctivitis can impair vision. Corneal infections can lead to blurred vision or corneal perforation if not treated early. Endophthalmitis (infection within the eye) can occur as a result of injury to the eye or infection elsewhere in the body.

**Impaired blood supply**

Narrowing, blockage, or inflammation of retinal blood vessels may cause visual loss.

**Tumours**

Malignant melanoma of the choroid is the most common cancerous tumour of the eye. Retinoblastoma (a cancer of the retina) most commonly affects children. Basal cell carcinoma affects the eyelid and may result from excessive exposure to sunlight.

**Nutritional disorders**

Various vitamin deficiencies affect the eyes. Vitamin A deficiency may lead to xerophthalmia (corneal and conjunctival dryness), night blindness, or, eventually, keratomalacia (corneal softening and disintegration).

**Autoimmune disorders**

Uveitis (inflammation of the iris, choroid, and/or ciliary body) may be caused by infection or an autoimmune disorder (in which the body’s immune system attacks its own tissues), such as ankylosing spondylitis and sarcoidosis.

**Degeneration**

Macular degeneration of the retina is common in elderly people, as is cataract.

**Focusing disorders**

Myopia (shortsightedness), hypermetropia (longsightedness), and astigmatism are relatively common. Presbyopia is a progressive, age-related loss of the ability to focus at close range. Amblyopia (poor vision in one eye unrelated to structural abnormality) is often due to squint.

**Other disorders**

Glaucoma (increased pressure within the eyeball), can lead to permanent visual loss. In retinal detachment, the retina lifts away from the eye’s underlying layer.

### INVESTIGATION

An ophthalmoscope and slit-lamp are used to view the eye. Vision is evaluated using Snellen charts and refraction tests.
EYE, FOREIGN BODY IN

WHY IT IS DONE
Eye examinations are used to determine the cause of visual disturbance or of other symptoms relating to the eye. They are also used to assess whether corrective devices, such as glasses or contact lenses, are necessary. Eye tests are essential to discover certain serious eye disorders, such as glaucoma (in which the fluid in the eye is at abnormally high pressure), because such disorders may be symptomless in the early stages and only detectable during an eye examination.

HOW IT IS DONE
An eye examination usually begins with a physical inspection of the eyes, the eyelids, and the surrounding skin. Eye movements are usually checked and the examiner looks for squint (misalignment of the eye).

Visual acuity (sharpness of vision) in each eye is investigated using a Snellen chart, the standard eye test wall chart. Refraction testing (using lenses of different strengths) may then be performed to determine precisely what glasses or contact lenses, if any, are required.

An investigation of the visual fields (the extent of peripheral vision) may also be carried out, especially in suspected cases of glaucoma or a variety of neurological conditions.

CONDUCTING AN EYE EXAMINATION

In an eye examination, the ophthalmologist checks the external appearance, eye movement, visual acuity, visual field, and colour vision. The eyes are checked for the presence of a squint, abrasions, and ulcers. Applanation tonometry and a refraction test may also be carried out.

Colour vision is occasionally checked because loss of colour perception is a sign of certain disorders of the retina (the light-sensitive inner layer at the back of the eye) or of the optic nerve (which transmits impulses from the retina to the brain). In order to check for abrasions or ulcers, the conjunctiva (the transparent membrane covering the white of the eye and inside of the eyelids) and the cornea (the transparent dome that forms the front of the eyeball) may be stained with fluorescein (an orange dye).

Applanation tonometry (measurement of the pressure within the eye) is an essential test for glaucoma.

EQUIPMENT
The ophthalmoscope is an instrument used to examine the inside of the eye, particularly the retina.

The slit-lamp microscope, with its illumination and lens magnification, allows for examination of the conjunctiva, the cornea, the front chamber of the eye, the iris (the coloured part of the eye) and the lens (the component that is responsible for focusing).

To obtain a full view of the lens and the structures behind it, the pupil (the circular opening in the centre of the iris) must be widely dilated by using special eye-drops.

eye, foreign body in

Any material on the surface of the eye or under the eyelid, or an object that penetrates the eyeball.

CAUSES
Particles of dust are the most common type of foreign body to enter the eye. Occasionally, a fragment of metal, plastic, or wood may be deflected into the eye. Rarely, an object travelling at high speed may penetrate the eyeball.

SYMPTOMS AND COMPLICATIONS
A foreign body may cause irritation, redness, increased tear production, and blepharospasm (uncontrollable closure and squeezing of the eyelid). Some foreign bodies left within the eyeball may release damaging substances into the eye, resulting in blindness. Other foreign bodies may remain intact but cause infection that can lead to loss of sight. Sympathetic ophthalmitis is a rare condition that may threaten sight even in the uninjured eye.

TREATMENT
Foreign bodies on or in the conjunctiva (the transparent membrane covering the white of the eye and lining the inside of the eyelids) can usually be flushed out with water. However, medical attention is needed if the object has penetrated the eyeball. The doctor may drop fluorescein (an orange dye) into the eye to reveal the presence of any corneal abrasions or sites of penetration. Ultrasound scanning or an X-ray of the eye may also be performed.

Anaesthetic eye-drops may be applied and a spatula used to remove an object from the cornea (the transparent dome that forms the front of the eyeball). The eye may then be covered with a patch. Antibiotic drugs may be prescribed to fight infection.

eye injuries

Eye injuries may be caused by a blow to the eye or penetration of a foreign body (see eye, foreign body in). However, the eye often escapes serious injury because it is protected by the surrounding bone and the rapid blink reflex.

A blow to the eye may cause tearing of the iris (the coloured part of the eye) or the sclera (the white of the eye), with collapse of the eyeball and potential blindness. Minor injuries may lead to a vitreous haemorrhage (bleeding into the gel-filled cavity behind the lens); hyphaema (bleeding into the front chamber of the eye); retinal detachment; or injury to the trabeculum (the chan-
nel, which drains fluid from the eye, which can lead to glaucoma (a sudden increase in fluid pressure in the eyeball).

Injuries to the centre of the cornea (the transparent dome that forms the front of the eyeball) impair vision by causing scarring. Damage to the lens (the component of the eye responsible for focusing) may cause a cataract (loss of transparency) to form.

**eyelashes**

Hairs that are arranged in rows at the edge of each eyelid and normally curve outwards. The purpose of the eyelashes is to prevent dust and debris from entering the eye. The lashes become finer and fewer as a person ages.

Growth in an abnormal direction may be due to injury to the eyelid or, more commonly, to an infection. Severe blepharitis (inflammation of the lid margins) may destroy the roots of the lashes. *Trachoma*, an infection in which the lid can be distorted by scarring, may lead to trichiasis, in which the lashes turn inwards and rub against the cornea (the transparent dome that forms the front of the eyeball).

**eye, lazy**

A popular term for amblyopia (in which normal vision has failed to develop in an otherwise healthy eye). The term "lazy eye" also refers to a convergent squint (in which one eye turns inwards).

**eyelid**

A fold of tissue at the upper or lower edge of an orbit (eye socket). The eyelids are held in place by ligaments attached to the socket's bony edges. They consist of thin plates of fibrous tissue (called tarsal plates) covered by muscle and a thin layer of skin. The inner layer is covered by an extension of the conjunctiva (the transparent membrane that covers the white of the eye). Along the edge of each lid is a row of eyelashes. Immediately behind the eyelashes are the openings of ducts that lead from the meibomian glands, which secrete the oily fluid in tears.

The eyelids act as protective shutters, closing almost instantly as a reflex action if anything approaches the eye. They also spread the tear film across the cornea (the transparent dome that forms the front of the eyeball).

**DISORDERS**

Disorders affecting the eyelids include a chalazion (a swelling of a meibomian gland), blepharitis (inflammation of the edge of the eyelid), and a sty (a small abscess at the root of one of the lashes).

Certain disorders affect the shape and position of the eyelids. These include entropion (in which the eyelid margin turns inwards), ectropion (in which the eyelid margin turns outwards), and ptosis (in which the eyelid droops down, covering all or part of the eye).

Myokymia (twitching of the eyelid) is common, and usually caused by fatigue. Blepharospasm (prolonged contraction of the eyelid) is usually due to a condition such as photophobia (abnormal sensitivity of the eyes to sunlight) or a foreign body. The skin of the eyelid is a common site for a basal cell carcinoma.

**eyelid, drooping**

See ptosis.

**eyelid surgery**

See blepharoplasty.

**eye, painful red**

A common combination of eye symptoms that may be due to any of various eye disorders.

Conjunctivitis (inflammation of the conjunctiva, the transparent membrane covering the white of the eye) is the most common cause of redness and irritation in the eye. Uveitis (inflammation of the iris, choroid, and/or ciliary body) is a common cause of dull, aching pain; this may be due to swelling in the front part of the eye and spasm in muscles around the iris (the coloured part of the eye). The redness is caused by widening of blood vessels around the iris.

Another cause of pain and redness in one eye is acute closed-angle glaucoma (a sudden increase in pressure within the eyeball). The pain is severe and may be accompanied by nausea, vomiting, and blurred vision. Increased blood flow in the surrounding blood vessels causes redness in the white of the eye.

There are additional causes of painful red eye including keratitis (inflammation of the cornea, the outer protective layer of the eye), which usually occurs as a result of a corneal ulcer, and a foreign body in the eye (see eye, foreign body in).

**eye-strain**

A common term used to describe aching or discomfort in or around the eye. Eye-strain is usually due to a headache caused by fatigue, tiredness of muscles around the eye, sinusitis, blepharitis

(inflammation of the eyelid margins), or conjunctivitis (inflammation of the conjunctiva, the transparent membrane that covers the whites of the eye).

**eye teeth**

A common name for the canine teeth.

**eye tumours**

Tumours of the eye are rare. However, when eye tumours do occur, they are usually painless and cancerous.

**TYPES AND TREATMENT**

Retinoblastoma This is a cancerous tumour of the retina (the light-sensitive inner layer at the back of the eye) that may occur in one or both eyes and most often affects children. Retinoblastoma may be treated by radiotherapy, laser treatment, or cryosurgery (freezing), but the eye may have to be removed to prevent spread of the tumour.

Malignant melanoma This form of cancer occurs in the choroid (the layer of tissue between the retina and the sclera, the white of the eye) and usually affects middle-aged or elderly people. There are no symptoms in the early stages, but the tumour eventually causes retinal detachment and distortion of vision. Small malignant melanomas can be destroyed by laser treatment, but the eye may need to be removed to prevent spread of the tumour.

Secondary eye tumours If cancer elsewhere in the body spreads to the eye, secondary tumours develop. Symptoms depend on a tumour’s location and growth rate. Secondary eye tumours may be controlled by radiotherapy; however, the primary tumour will need to be treated separately.

Basal cell carcinoma This is the most common type of tumour of the eyelid. It may be caused by excessive exposure to sunlight. The tumour usually has a crusty central crater and a hard rolled edge. In the early stages, a basal cell carcinoma of the eyelid may be treated by surgery, radiotherapy, or cryosurgery. If the tumour becomes large, the eyelid may need to be removed.
Fabry’s disease
A rare inherited disorder caused by a deficiency of alpha-galactosidase A, an enzyme (a protein that acts as a catalyst) necessary for the metabolism of certain lipids (fats) in the body. Without the enzyme, lipid molecules accumulate in the tissues, especially in the nerves, heart, and kidneys.

Fabry’s disease is inherited as an X-linked recessive trait (see genetic disorders) and therefore affects males more commonly than females.

SYMPTOMS
Among the first symptoms to develop, often in childhood, are pain and discomfort in the hands and feet as a result of damage to the peripheral nerves. As the condition progresses, heart and kidney function may become impaired. Female carriers usually show only mild symptoms.

TREATMENT AND OUTLOOK
Hand and feet pain is treated with carbamazepine. Sufferers usually survive into adulthood but are at risk from strokes, heart attacks, and kidney damage.

face-lift
A cosmetic operation to smooth out wrinkles and lift sagging skin on the face to make it look younger. The effect is achieved by making an incision near or along the hairline on each side of the face, lifting the skin off the face, and then removing the excess skin. The edges of skin are then stitched back together within the hairline.

Some bruising of the face is common following the procedure, and there may be some discomfort. Stitches are removed three to five days after the operation. In most cases, the scars, which fade within about a year, are hidden by natural crease lines or by the hair. The effect of a face-lift usually lasts about five years.

In a few cases, satisfactory healing does not occur because blood accumulates under the skin or because of infection that leads to severe scarring.

facial nerve
The seventh cranial nerve, which arises from structures in the brainstem and sends branches to the face, neck, salivary glands, and outer ear.

The facial nerve performs both motor and sensory functions. It controls the neck muscles and those of facial expression; it stimulates the secretion of saliva; and it conveys sensory information from the tongue and from the outer ear.

Damage to the facial nerve results in weakness of the facial muscles (see facial palsy) and, in some cases, loss of taste. Such damage is probably most often due to a viral infection but may also occur in stroke.

facial pain
Pain in the face may be due to any one of a variety of causes or may occur for no known reason.

CAUSES
Injury to the face, such as by blows or cuts, is a common cause of facial pain. Facial pain is also commonly due to infection. Sinusitis (inflammation of the air spaces in the facial bones) can cause pain around the eyes and in the cheek bones. The onset of mumps can cause pain in the cheeks before swelling is apparent; the pain is in front of and/or below the ears. Pain from a boil in the nose or ear may also be felt in the face.

Problems with the teeth and jaws are another common cause of facial pain. Such problems include severe tooth decay (see caries, dental), an abscess (see abscess, dental), impacted wisdom teeth (see impaction, dental), or partial dislocation of the jaw (see jaw, dislocated).

Damage to one of the nerves that supply the face can also produce severe pain. Conditions resulting from nerve damage include the stabbing pain that precedes the rash of herpes zoster (shingles) and the intermittent shooting pain of trigeminal neuralgia, which usually affects the cheek, lip, gum, or chin on one side and is often brought on by touching the face or chewing.

A disorder elsewhere in the body may cause referred pain in the face. For example, in angina pectoris (chest pain due to impaired blood supply to the heart muscle), pain may also be felt in the jaw. During a migraine headache, pain may also occur on one side of the face. Facial pain that occurs for no apparent reason may occasionally be a symptom of depression.

TREATMENT
Analgesic drugs (painkillers) can provide temporary relief from pain, but severe or persistent facial pain requires medical attention.

facial palsy
Weakness of the facial muscles as a result of damage to, or inflammation of, the facial nerve. The condition is usually temporary and affects only one side of the face.

CAUSES
Facial palsy is most often due to Bell’s palsy, which occurs for no known reason. Less commonly, the condition is associated with herpes zoster (shingles) affecting the ear and facial nerve. Facial palsy may also result from surgical damage to this nerve, or compression of the nerve by a tumour.

SYMPTOMS
Facial palsy usually develops suddenly. The eyelid and the corner of the mouth on one side of the face droop, and there may be pain in the ear on that side. The ability to wrinkle the brow or to close
the eye may be lost, and smiling is distorted. Depending on which nerve branches are affected, the sense of taste may be impaired or sounds may seem to be unnaturally loud.

TREATMENT
In many cases, facial palsy clears up without treatment. Pain can be relieved by taking analgesics (painkillers), and exercising the facial muscles may aid recovery. It may be necessary to tape the eyelid shut at bedtime in order to avoid the risk of corneal abrasion.

Bell’s palsy may be treated with corticosteroid drugs to reduce inflammation and speed recovery. Re-routing or grafting of nerve tissue may help people suffering from palsy caused by an injury or a tumour.

facial spasm
An uncommon disorder in which the muscles that are supplied by the facial nerve twitch frequently. Facial spasm, which predominantly affects middle-aged women, is of unknown cause.

facial tic
See facial spasm.

facies
A term used to denote facial expression, which is often used as a guide to a person’s health. For example, the typical facies seen in a child with enlarged adenoids is open-mouthed because of difficulty breathing through the nose.

The term “facies” may also be used to refer to a particular surface of a body structure, part, or organ.

facioscapulohumeral dystrophy
An autosomal dominant genetic disorder that causes muscle weakness and wasting. The condition first appears in childhood or adolescence. The muscle wasting chiefly affects the face, shoulder girdle, arms, and later the pelvis and legs.

factitious disorders
A group of disorders in which a patient’s symptoms mimic those of a true illness but which have been invented by, and are under the control of, the patient. There is no apparent cause other than a wish for attention; the desire to assume the role of a patient may be an escape from everyday life in order to be cared for and protected.

The most common disorder of this type is Munchhausen’s syndrome, which is characterized by physical symptoms. The sufferer may aggravate existing physical problems or even inflict self-injury. In Ganser’s syndrome, symptoms differ from malingering, in which a person claims to be ill for a particular purpose (for example, in order to obtain time off work).

factor V
One of the blood proteins that maintains the balance between the blood clotting too easily or too slowly after an injury. About 5 per cent of the population have an inherited mutation in the gene controlling factor V production, known as factor V Leiden. They are at increased risk of deep-vein thrombosis (see thrombophilia), particularly if taking the oral contraceptive pill or going on long aircraft journeys.

factor VIII
One of the blood proteins involved in blood clotting. People with haemophilia have a reduced level of factor VIII in their blood and, consequently, have a tendency to abnormal bleeding and to prolonged bleeding when injured.

People with severe haemophilia require regular treatment with concentrates of factor VIII. This treatment reduces the bleeding tendency and allows the affected person a normal quality of life.

factor IX
A protein in blood that plays an important role in the clotting mechanism. A deficiency of factor IX causes a rare genetic bleeding disorder known as Christmas disease.

fad
See food fad.

faecal fistula
See fistula.

faecal impaction
A condition in which a large mass of hard faeces cannot be evacuated from the rectum. It is usually associated with long-standing constipation. Faecal impaction is most common in very young children and in elderly people, especially those who are bedridden.

The main symptoms are an intense desire to pass a bowel movement; pain in the rectum, anus, and centre of the abdomen; and, in some cases, watery faeces that are passed around the mass (and may be confused with diarrhoea).

Treatment of faecal impaction is with enemas or, in cases where these are ineffective, by manual removal of the faecal mass.

faecal incontinence
See incontinence, faecal.

faecalith
A small, hard piece of impacted faeces that forms in a diverticulum (a sac in the wall of the intestine). A faecalith is harmless unless it forms a blockage at the entrance to the sac, which causes diverticulitis, or to the appendix, which causes appendicitis.

faecal occult blood test (FOBT)
A test, also known as a stool guaiac test, that is used to check for the presence of hidden blood in the faeces (see occult blood, faecal). FOBT is a screening test that may be carried out because such bleeding may be one of the earliest indications of colorectal cancer (see colon, cancer of; rectum, cancer of). One example of a commonly used brand of FOBT is Hemoccult.

faecal vomiting
The vomiting of matter that resembles faeces, either in appearance or odour or both. Faecal vomiting is a symptom of serious intestinal obstruction (see intestine, disorders of).

faeces
Waste material from the digestive tract that is solidified in the large intestine and expelled through the anus. Faeces are composed of indigestible food residue (dietary fibre), dead bacteria, dead cells shed from the intestinal lining, intestinal secretions such as mucus, bile from the liver (which is the substance that gives faeces their brown colour), and water.

Examination of the faeces plays an important part in the diagnosis of disorders of the digestive tract, such as malabsorption. Samples of faeces may be examined physically for their colour, odour, consistency, or for the presence of blood. A special test, known as a faecal occult blood test (FOBT), is used to detect concealed blood in the faeces (see occult blood, faecal). Microscopic examination may be carried out to detect pus, parasites, or microorganisms. Chemical tests may be performed to assess the excretion of fat. (See also faeces, abnormal.)
faeces, abnormal

Faeces that differ from normal in their colour, odour, consistency, or content. Abnormal faeces may be an indication of a disorder of the digestive system or a related organ, such as the liver. A change in the character of faeces, however, is most often the result of a change in diet.

Diarrhoea (frequent passage of liquid or very loose faeces) may simply be due to anxiety. However, it may be the result of an intestinal infection (see gastroenteritis), an intestinal disorder (such as ulcerative colitis or Crohn's disease), or irritable bowel syndrome. Loose stools may also be an indication of malabsorption (impaired absorption of nutrients by the small intestine).

Constipation (infrequent passage of very hard faeces) is generally harmless. Constipation that develops unexpectedly, however, may be caused by a disorder of the large intestine, such as cancer (see colon, cancer of).

Pale faeces may be caused by diarrhoea, a lack of bile in the intestine as a result of bile duct obstruction, or a disease that causes malabsorption (such as coeliac disease). In malabsorption, the paleness is caused by the high fat content of the faeces. This type of faeces may be oily, foul-smelling, and difficult to flush away.

Dark faeces may result from taking iron tablets. If the faeces are black, however, there may be bleeding in the upper digestive tract.

Faeces that contain excessive mucus are sometimes associated with constipation or with irritable bowel syndrome. Enteritis, dysentery, or a tumour of the intestine (see intestine, tumours of) may also lead to the passage of excess mucus, often accompanied by blood.

Blood in the faeces differs in appearance depending on the site of bleeding. Bleeding from the stomach or duodenum is usually passed in the form of black, tarry faeces (see melena). Blood from the colon is red and is usually passed at the same time as the faeces. Bleeding from the rectum or anus, which may be due to tumours or to haemorrhoids (piles), is usually bright red. Occasionally, however, it may not even be visible (see occult blood, faecal). (See also rectal bleeding.)

faeces, blood in the

See faeces, abnormal; occult blood, faecal; rectal bleeding.

Fahrenheit scale

A temperature scale in which the melting point of ice is 32° and the boiling point of water is 212°. On this scale, normal body temperature is 98.6°F, which is equivalent to 37° Celsius (C). To convert a temperature in Fahrenheit to its Celsius equivalent, subtract 32 and multiply by 0.56 (or ½). To convert a Celsius temperature to Fahrenheit, multiply by 1.8 (or ⅔) and then add 32. (See also Celsius scale.)

Fahr's disease

A rare, degenerative neurological disorder that is characterized by the appearance of abnormal calcium deposits and is associated cell loss in certain areas of the brain. Fahr's disease may be familial, in which it shows either an autosomal recessive or autosomal dominant pattern of inheritance (see genetic disorders). In many cases, however, the cause of the disorder is unknown.

Symptoms of Fahr’s disease include progressive dementia (deterioration in brain function) and the loss of acquired motor skills. Increased muscle stiffness and restricted movements may also develop. Possible complications include athetosis, characterized by slow, involuntary, writhing movements, or chorea, characterized by irregular, rapid, jerky movements. There may also be gradual deterioration of eyesight.

Individual symptoms of Fahr’s disease are treated where possible, but there is no cure.

causes

Episodes of fainting are often due to a vasovagal attack—an episode in which overstimulation of the vagus nerve (which controls vital organs such as the lungs and heart) causes slowing of the heartbeat and a fall in blood pressure, thereby reducing the flow of blood to the brain. Attacks are usually preceded by sweating, nausea, dizziness, and weakness, and are commonly the result of pain, stress, shock, a stuffy atmosphere, or prolonged coughing. Fainting may also result from postural hypotension (low blood pressure), which may occur when a person stands still for a long time or stands up suddenly. This problem is common in elderly people, in those with diabetes mellitus, and in those taking antihypertensive drugs or vasodilator drugs.

TREATMENT

In most cases, recovery from fainting occurs when normal blood flow to the brain is restored. This restoration usually happens within minutes because the loss of consciousness results in the person falling into a lying position, which restores the flow of blood to the brain. Medical attention is required in cases of prolonged unconsciousness or repeated attacks of fainting.

faith-healing

The supposed ability of certain people to cure disease by a healing force inexplicable to science.

falciparum malaria

The most severe form of malaria, which is caused by the parasitic protozoan Plasmodium falciparum.

fallen arches

One of the causes of flat-feet. Fallen arches can develop as a result of weakness of the muscles that support the arches of the foot.

fallopian tube

One of the two tubes that extend from the uterus to each ovary. The fallopian tube transports eggs and sperm and is where fertilization takes place.

structure

The funnel-shaped fallopian tube is about 10 cm long. It opens into the uterus at one end. The other end, which is divided into fimbriae (fingerlike projections), lies close to the ovary. The tube has muscular walls lined by cells with cilia (hairlike projections).
LOCATION OF THE FALLOPIAN TUBES

Situated in the pelvis, each tube extends from the upper part of the cavity of the uterus to an ovary.

**FUNCTION**
The fimbriae take up the egg after it is expelled from the ovary. The beating cilia and muscular contractions propel the egg towards the uterus. After sexual intercourse, sperm swim up the fallopian tube from the uterus. The lining of the tube and its secretions sustain the egg and sperm, encouraging fertilization to take place and nourish the egg until it reaches the uterus.

**DISORDERS**
The fallopian tube may become inflamed, usually as a result of a bacterial sexually transmitted infection (see pelvic inflammatory disease); this can, in some cases, lead to infertility. Ectopic pregnancy (the development of an embryo outside the uterus) is another serious disorder that most commonly occurs in a fallopian tube. This arises when there is a delay in the passage of the fertilized egg along the tube, usually as a result of scarring or blockage. Implantation occurs in the fallopian tube wall, but it is too thin to sustain growth, and as the pregnancy progresses, the tube may rupture and cause internal bleeding. The pregnancy must be terminated.

**Fallot’s tetralogy**
See tetralogy of Fallot.

**fallout**
See radiation hazards.

**falls in the elderly**
The tendency to fall over increases steadily with age. This increased probability of falling is due to a gradual slowing down of reflex actions; an elderly person who trips is frequently too slow to prevent a fall.

**CAUSES**
Falls may simply be accidents, which are commonly the result of obstructions on the ground (such as loose floor coverings), or they may be caused by medical problems. Various medical conditions that are common in elderly people increase the risk of falls. Examples of such conditions are poor sight, walking disorders, cardiac arrhythmia (an irregular heartbeat), hypotension (low blood pressure), and Parkinson’s disease (a movement disorder). Taking sleeping drugs or tranquilizer drugs may also increase the risk of falls. Falls sometimes herald the onset of a serious illness, such as pneumonia.

**COMPLICATIONS**
Broken bones (see fracture) are a common complication of falls, especially in women. Not only do women have more falls, but they are also more likely to suffer fractures because the strength of their bones may be reduced through osteoporosis (loss of bone density).

Falls may sometimes have serious indirect consequences in elderly people. Anyone who falls and lies on the floor for more than an hour, especially if it is cold, may develop hypothermia (low body temperature). A fall, or the fear of falling, can also have adverse psychological effects, causing a once active person to become demoralized and housebound.

**PREVENTION**
Falls may be prevented by taking common-sense measures such as ensuring that floors are free of clutter, good lighting is available, suitable footwear is worn, floor coverings and wiring are safe, and handrails are secure. For elderly people who live alone, personal alarms are available that can be worn round the neck at all times; in the event of a fall the alarm button can be pressed to summon help.

**false negative**
A test result that wrongly suggests that a particular disease or condition is not present. For example, a false negative mammography result is one that suggests breast tissue is healthy when, in fact, a breast cancer is present.

**false positive**
A test result that wrongly suggests that a certain disease or condition is present. For example, a false positive mammography result appears to reveal a breast cancer, but subsequent tests do not find any evidence of disease.

**false pregnancy**
See pregnancy, false.

**false teeth**
See denture.

**false vocal cord**
One of two folds of tissue in the larynx (voice-box) that are situated above the true vocal cords but which are not involved in the production of speech.

**famciclovir**
An antiviral drug used to treat viral infections such as herpes zoster (shingles) and genital herpes simplex. Minor side effects can include nausea, vomiting, and headache.

**familial**
A term applied to a characteristic or disorder that runs in families, that is, it occurs in more members of a particular family than would be expected from the occurrence in the population as a whole. An example of a familial characteristic is male-pattern baldness (see alopecia); an example of a familial disorder is hyperlipidaemia (abnormally high levels of fats in the blood).

**familial adenomatous polyposis (FAP)**
See polyposis, familial adenomatous.

**familial cystinuria**
See cystinuria.

**familial goitre**
See goitre.

**familial hypercholesterolaemia**
An inherited disorder of lipoprotein metabolism (see fats and oils) that is characterized by a high level of the fatty substance cholesterol in the blood. An individual suffering from familial hypercholesterolaemia lacks the low density lipoprotein receptors in the liver that remove excess cholesterol from the
blood. The condition shows an auto-
somal dominant pattern of inheritance (see genetic disorders).

Raised levels of cholesterol in the blood lead to the early development of atherosclerosis (an accumulation of fatty deposits on the inner walls of the arteries), coronary artery disease, and other vascular diseases. Treatment, which must continue long term, is with lipid-lowering drugs, including statins, along with a diet that is low in cholesterol and a weight-reduction regime.

familial Mediterranean fever
An inherited condition that affects cer-
tain Sephardic Jewish, Armenian, and
Arab families. The cause of familial
Mediterranean fever is unknown. Sym-
toms usually begin between the ages of five and 15 years, and include recurrent episodes of fever, abdominal and chest pain, and arthritis. Red skin swellings sometimes occur, and affected people may also suffer from psychiatric prob-
lems. Attacks usually last from 24 to 48 hours but may be longer. Between attacks there are usually no symptoms.

Although there is no specific treat-
ment for familial Mediterranean fever, those
known to suffer from the condi-
tion can reduce the incidence of
attacks by taking colchicine, a drug that is
usually used to treat gout. Death may
eventually occur from amyloidosis, a
complication of the condition.

familial screening
Screening of a family in which one member is affected by an inherited
disorder. Looking for evidence of in-
creased susceptibility to a disorder may involve testing for a specific gene
defect (as is the case for cystic fibrosis),
which will also help specialists deter-
mine the chances of family members
having an affected child.

Alternatively, tests may be carried out to detect a risk factor for a disor-
der; for example, if a person has a
heart attack at an early age, his or her
relatives may be tested for hyper-
lipidaemia (high levels of fats in the
blood), a condition that increases the
risk of coronary artery disease.

In addition to being tested for a par-
cular disorder, the relatives of an
affected person may be offered regular
check-ups so that any abnormal signs
may be detected as early as possible and
the necessary treatment started
without any delay.

family planning
The deliberate limitation or spacing of
births. Strategies for family planning
include the different methods of con-
traception. (See also birth control.)

family therapy
A form of psychotherapy, designed to
help someone with mental health
problems, that is aimed at the whole
family rather than just the individual
sufferer. The therapist arranges regular
meetings with the family to encourage
discussion and understanding and to
find out what feelings lie behind the
way family members deal with each
other in everyday life. The main theory
behind family therapy is that improv-
ing the functioning of the family unit
will benefit the individual’s health.

famotidine
An H₂ receptor antagonist drug that pro-
motes healing of peptic ulcers and
reduces inflammation of the oesophagus (see oesophagitis). Famotidine acts
by suppressing production of stomach
acid. Side effects are uncommon, but
may include headaches and dizziness.

Fanconi’s anaemia
A rare type of aplastic anaemia (see
anaemia, aplastic) in which the bone
marrow, which normally makes all of
the types of blood cells, produces
abnormally low numbers of the cells.

Fanconi’s syndrome
A rare kidney disorder that usually
occurs in childhood. In Fanconi’s syn-
drome, various important chemicals,
such as amino acids, phosphate, calcium,
and potassium, are lost in the urine. The
results of these losses include failure to
thrive, stunting of growth, and bone
disorders such as rickets.

Possible causes include several rare
inherited abnormalities of body chem-
istry and an adverse reaction to certain
drugs, such as tetracycline that has
passed its “use-by” date.

If an underlying chemical abnormal-
ity is detected and can be corrected, the
affected child may resume normal
growth. Alternatively, a kidney transplant
may be possible.

fantasy
The process of imagining events or
objects that are not actually occurring
or present. The term also refers to the
mental image itself.

Fantasy can give the illusion that wish-
es have been met. In this sense, it
provides satisfaction and can be a
means of helping people to cope when
reality becomes too unpleasant. Fan-
tasy can also stimulate creativity.

Psychoanalysts believe that certain
fantasies are unconscious and represent
primitive instincts; these fantasies are
presented to the conscious mind in the
form of symbols.

farmer’s lung
An occupational disease affecting the
lungs of farm workers. Farmer’s lung is
a type of allergic alveolitis, in which
affected people develop hypersensitivity
(an excessive reaction of the immune
system) to certain moulds or fungi
that grow on hay, grain, or straw. The
causative organisms thrive in warm,
damp conditions, and outbreaks are
most common in areas of high rainfall.

SYMPTOMS
Symptoms typically develop about six
hours after exposure to dust contain-
ing fungal spores. They include
shortness of breath, headache, fever,
and muscle aches. In acute attacks, the
symptoms last for about a day. Repeat-
ed exposure to spores may lead to a
chronic form of the disease, causing
permanent scarring of lung tissues.

DIAGNOSIS AND TREATMENT
Diagnosis of farmer’s lung may involve
a chest X-ray; pulmonary function tests;
and blood tests for a specific antibody
to the fungus.

Corticosteroid drugs relieve the symp-
toms of the condition. Further expos-
ture to the spores of the fungus should
be avoided. Complete recovery is likely
if the disease is diagnosed before per-
manent lung damage has occurred.
(See also fibrosing alveolitis.)

farmer’s skin
Premature aging of the skin caused by
prolonged exposure to sunlight. Fea-
tures of farmer’s skin include a lack of
elasticity, wrinkling, dryness, thinning
(sometimes with thicker areas), and
excessive skin pigmentation.

fascia
Fibrous connective tissue that surrounds
many structures in the body. One layer
of the tissue, known as the superficial
fascia, envelops the entire body just
beneath the skin. Another layer, the
deep fascia, encloses muscles, forming
a sheath for individual muscles and
separating them into groups; it also holds in place soft organs such as the kidneys. Thick fascia in the palm of the hand and sole of the foot have a cushioning, protective function.

**fasciculation**
Spontaneous, irregular, and usually continual contractions of a muscle that is apparently at rest. Unlike the contractions of *fibrillation*, fasciculation is visible through the skin.

Minor fasciculation, such as that occurring in the eyelids, is common and is no cause for concern. However, persistent fasciculation with weakness in the affected muscle indicates damage to the nerve cells in the spine that control the muscle, or to the nerve fibres that connect the spinal nerves to the muscle; *motor neuron disease* is one such disorder.

**fasciitis**
Inflammation of a layer of *fascia* (fibrous connective tissue), causing pain and tenderness. Fasciitis is usually the result of straining or injuring the fascia surrounding a muscle; it most commonly affects the sole of the foot. The condition may occur in people who suffer from *ankylosing spondylitis* (a rheumatic disorder affecting the spine) or those with *Reiter's syndrome* (inflammation of the urethra, conjunctivitis, and arthritis).

Treatment of fasciitis involves resting the affected area and protecting it from pressure. A local injection of a corticosteroid drug may be given. If fasciitis is part of a widespread disorder of the joints, treatment of this condition will generally improve symptoms. (See also *necrotizing fasciitis*.)

**fascioliasis**
A disease affecting the liver and bile ducts that is caused by infestation with the *liver fluke* species *Fasciola hepatica*. Fascioliasis is acquired through eating plant food (such as watercress) contaminated with the larvae of the fluke. Treatment is with *anthelmintic drugs*.

**fasciotomy**
An operation to relieve pressure on muscles by making an incision in the *fascia* (fibrous connective tissue) that surrounds them.

Fasciotomy is usually performed to treat *compartment syndrome*, a painful condition in which constriction of a group of muscles causes obstruction of blood flow; it gives the muscles space in which to expand. The procedure is also sometimes performed as a surgical emergency after an injury has resulted in muscle swelling or bleeding within a muscle compartment.

**fasting**
Abstaining from all food and drinking only water. In temperate conditions and at moderate levels of physical activity, a person can survive on water alone for more than two months; however, without consuming either food or drink, death usually occurs within about ten days.

**EFFECTS ON THE BODY**
In the absence of food, the energy that is needed in order to maintain essential body processes is supplied by substances stored in the body tissues. About six hours after the last meal, the body starts to use *glycogen* (a carbohydrate stored in the liver and muscles). This process continues for about 24 hours, after which time the body obtains energy from stored fat and by breaking down protein in the muscles. If fasting continues, the body's *metabolism* slows down in an attempt to conserve energy, and the fat and protein stores are consumed more slowly.

In the initial stages of fasting, weight loss is rapid. It then slows down, not only due to the slowing of the metabolism, but also because the body begins to conserve its salt supply, resulting in the retention of water in the tissues. This accumulated fluid causes *oedema* (swelling), which principally affects the legs and abdomen.

In prolonged fasting, the ability to digest food may be impaired because the stomach stops secreting digestive juices. Prolonged fasting also halts the production of sex hormones, causing amenorrhoea (the absence of menstruation) in women.

**fat**
A substance that is composed of one or more *fatty acids*. Fat is the main form in which energy is stored by the body. A layer of fat, known as *adipose tissue*, lies directly beneath the skin and surrounds various internal organs. Excess amounts of fat are deposited under the skin in *obesity*. (See also *fats and oils*.)

**fatal**
Causing, or ending in, death.

**fat atrophy**
Localized loss of fatty tissue beneath the skin. Fat atrophy can occur at injection sites in people with type 1 (insulin-dependent) *diabetes mellitus*. A particular pattern of fat atrophy also develops in some people being treated with *antiretroviral drugs* for HIV infection or *AIDS* (see lipodystrophy).

**fatigue**
See tiredness.

**fat pad**
A localized collection of fatty tissue. Fat pads are normally found in parts of the body that need cushioning and protection, such as behind the eyelids, around the kidneys, behind the knees, under the heel bone, and in the cheeks (especially in infants). Abnormal fat pads may be noncancerous tumours (see *lipoma*) or may develop in certain disorders, such as *lipodystrophy*.

**fats and oils**
Nutrients that provide the body with its most concentrated form of *energy*. Fats are the largest group of *lipids*, and are compounds containing chains of carbon and hydrogen atoms with very little oxygen. Chemically, they consist mostly of *fatty acids* combined with *glycerol*. Fats are usually solid at room temperature, while oils are liquid.

**TYPES**
Fats and oils are divided into two main groups – saturated and unsaturated – depending on the proportion of hydrogen atoms they contain. If the fatty acids contain the maximum possible quantity of hydrogen, the fats are saturated. If some sites on the carbon chain are unoccupied by hydrogen, they are unsaturated. Monounsaturated fats are unsaturated fats with only one site that could take an extra hydrogen atom; if many sites are vacant, the fats are polyunsaturated. Animal fats, such as those in meat and dairy products, are largely saturated; vegetable fats tend to be unsaturated.

**FAT AND HEALTH**
The amount and types of fat in the diet have important implications for health. A diet containing a large amount of fat, particularly saturated fat, is linked to obesity and an increased risk of *atherosclerosis* (deposition of fat on the walls of arteries) and of subsequent *coronary artery disease* and *stroke*. Other serious disorders related to the consumption
of excess fat include cancers of the breast, colon, and prostate and type 2 diabetes mellitus.

**USES IN THE BODY**

Some dietary fats, mainly triglycerides (combinations of glycerol and three fatty acids), are sources of the fat-soluble vitamins A, D, E, and K and also of essential fatty acids.

Triglycerides are the main form of fat stored in the body. These stores act as an energy reserve; they also provide insulation and a protective layer for delicate organs such as the heart and kidneys. Phospholipids are structural fats found in cell membranes. Sterols, such as cholesterol, are found in animal and plant tissues; they have a variety of functions, and are essential for making hormones or vitamins. Phospholipids and sterols are made in the body from nutrients provided in the diet.

**FAT METABOLISM**

Dietary fats are first emulsified (reduced to microscopic particles) by bile salts before being broken down by lipase, a pancreatic enzyme. They are absorbed via the lymphatic system before entering the bloodstream.

To be carried in the blood, the lipids become bound to proteins; in this state, they are known as lipoproteins. There are four classes of lipoprotein: chylomicrons; high-density lipoproteins (HDLs); low-density lipoproteins (LDLs); and very low-density lipoproteins (VLDLs). LDLs and VLDLs contain large amounts of cholesterol, which they carry through the bloodstream and deposit in tissues; they are sometimes referred to as bad fats. HDLs, known as good fats, pick up cholesterol and carry it back to the liver for processing and excretion. High levels of LDLs are associated with atherosclerosis, whereas HDLs have a protective effect. (See also nutrition.)

**fatty acids**

Organic acids, containing carbon, oxygen, and hydrogen, that are constituents of fats and oils. There are more than 40 fatty acids found in nature; they are distinguished from one another by their constituent numbers of carbon and hydrogen atoms.

Certain fatty acids cannot be synthesized by the body and must be provided by the diet. These substances, sometimes collectively termed essential fatty acids, are linoleic, linolenic, and arachidonic acids. Strictly speaking, only linoleic acid is truly essential, because the body can make the other two from linoleic acid obtained from food. (See also nutrition.)

**fatty degeneration**

A general term describing the accumulation of fat within the cells of tissues damaged by disease.

**fatty diarrhoea**

See steatorrhoea.

**fatty liver**

A condition in which fat accumulates within the liver cells. The most common cause of fatty liver is excessive consumption of alcohol which, if continued, eventually leads to cirrhosis. However, if the drinking of alcohol stops, the fat clears from the liver. Fatty liver can also occur in association with obesity, diabetes mellitus, starvation, and in some cases of chronic ill-health.

**favism**

A disorder that is characterized by an extreme sensitivity to the broad bean Vicia faba (fava bean). If an affected person eats these beans, a chemical in the bean causes rapid destruction of red blood cells, leading to a severe type of anaemia (see anaemia, haemolytic).

Favism is uncommon except in some areas of the Mediterranean. It is a sex-linked genetic disorder. Affected people have G6PD deficiency, a defect in a certain chemical pathway in their red blood cells that normally helps protect the cells from injury.

Children with a family history of favism can be screened for the disorder at an early age. If the condition is found, they must avoid fava beans as well as certain drugs, including some antimalarial drugs and antibiotic drugs, that can have a similar effect on their red blood cells.

**febrile**

Feverish or related to fever. Febrile convulsions, for example, occur mainly in young children with high temperatures (see convulsion, febrile).

**febrile convulsion**

See convulsion, febrile.

**feedback**

A self-regulating mechanism that controls certain body processes, such as hormone and enzyme production.

If, for example, levels of a hormone are too high, output of any substance that stimulates the hormone’s release is inhibited; the result is reduced hormone production (negative feedback). The reverse process (positive feedback) restores the balance if the levels of a hormone become too low. (See also endocrine system.)

**feeding, artificial**

The administration of nutrients other than by mouth, usually by way of a tube passed through the nose into the stomach or small intestine. If long-term artificial feeding is anticipated, a tube is inserted directly into the stomach or upper small intestine during endoscopic surgery (see gastroscopy). This is called enteral feeding. If the gastrointestinal tract is not functioning, nutrients must be introduced directly into the bloodstream (see infusion, intravenous). This type of feeding is known as parenteral nutrition.

**TUBE FEEDING**

Tube feeding may be necessary for people who have difficulty swallowing, or gastrointestinal disorders (for example, conditions resulting in malabsorption), or disorders affecting the nervous system or kidneys. Premature babies often require tube feeding if their suckling reflexes are undeveloped, as do critically ill patients due to their increased nutritional requirements.

Food mixtures, or preparations of nutrients, are given through a tube that is passed through the patient’s nostril and down to the stomach or duodenum. There are two methods of feeding: continuous drip feeding, and bolus feeding (in which set amounts of nutrients are given at regular intervals throughout the day). In both methods, the rate of delivery of the food can be controlled by a pump.

**INTRAVENOUS FEEDING**

Intravenous feeding is usually given when large areas of the small intestine have been damaged by disease or have been surgically removed. Nutrient preparations are given and are inserted into a large central vein near the heart, via a catheter (a thin, flexible tube) that is buried under the skin.

**feeding, infant**

A person grows more rapidly in his or her first year than at any other time in life. A good diet is essential for healthy growth and development.
**FEEDING AN INFANT: INTRODUCING SOLIDS**

The age at which an infant should be weaned on to solids depends entirely on the individual. There is no real need to feed solid foods to an infant below the age of six months unless he or she is consistently hungry. The following is a flexible guide:

<table>
<thead>
<tr>
<th>Age</th>
<th>Time</th>
<th>Food</th>

</tbody>
</table>

**WARNING** Avoid eggs, fish, and citrus fruit (including juice) before six months. Nuts should not be given to babies under six months, and whole nuts should not be given under five years. Avoid gluten before six months. Parents should be especially careful about feeding their children foods containing gluten or peanuts because serious allergies to these products are common.
female

An individual with two X sex chromosomes. Females are also characterized by the presence of a vagina and vulva (see sexual characteristics, primary).

female catheter

A short catheter (flexible tube) that can be inserted into a woman’s bladder through the urethra for the purpose of withdrawing urine.

feminization

The development of female secondary sexual characteristics in a male (such as breast enlargement and fat deposits beneath the skin and loss of facial hair). The condition is due either to a hormonal disorder or to hormone therapy. (See also demasculinization; intersex; masculinization; sex determination; sexual characteristics, secondary; testicular feminization syndrome.)

femoral artery

A major blood vessel that supplies oxygenated blood to the leg. The femoral artery is formed in the pelvis from the iliac artery, which is the terminal branch of the aorta. It then runs from the groin down the front of the thigh, and passes behind the knee to become the popliteal artery, which branches supplying the skin convey sensation; the branches supplying the muscles stimulate contraction of the quadriceps muscle, thereby straightening the knee.

Damage to the femoral nerve (which impairs the ability to straighten the knee) is usually the result of a slipped disc in the lumbar region of the spine (see disc prolapse). Damage may also result from a dislocation of the hip or from a neuropathy.

femoral hernia

A type of hernia that occurs in the groin area, at the point where the femoral artery and femoral vein pass from the lower abdomen to the thigh. Women who are overweight or who have had several pregnancies are at risk of femoral hernia because their abdominal muscles are weakened.

femoral nerve

One of the main nerves of the leg. The nerve fibres that form the femoral nerve emerge from the lower spine (the condyles) that distribute the weight-bearing load through the knee joint. On the outer side of the upper femur is a protuberance called the greater trochanter.

The shaft of the femur is surrounded by muscles that move the hip and knee joints. The shaft is also well supplied with blood vessels; therefore, a fracture can result in considerable blood loss.

femur, fracture of

A break in the femur (the thigh bone). The symptoms, treatment, and possible complications of a fracture depend on whether the bone has broken across its neck (the short section between the top of the shaft and the hip joint) or across the shaft.

FRACTURE OF NECK OF FEMUR

This type of fracture, which is often called a broken hip, is very common in elderly people, especially in women with the bone disorder osteoporosis (loss of bone density). It is usually associated with a fall. In a fracture of the neck of the femur, the broken bone ends are often considerably displaced; in such cases there is usually severe pain in the hip and groin, making standing impossible. Occasionally, the broken bone ends become impacted (pushed together). In this case, there is less pain, and walking may be possible.

The diagnosis is confirmed by X-ray. If the ends of the bone are displaced, an operation is necessary, either to realign the bone ends and fasten them together, or to replace the entire head and neck of the femur with an artificial substitute (see hip replacement). If the bone ends are impacted, the fracture may heal naturally, but surgery may still be recommended.

A possible complication is damage to the blood supply to the head of the femur, resulting in the disintegration of the bone in that area (see avascular necrosis). Osteoarthritis may develop in the hip joint after fracture of the femur neck. In elderly people, immobility
and surgery may result in complications, such as pneumonia, that are not directly related to the fracture site.

**FRACTURE OF SHAFT OF FEMUR**

Fracture of the bone shaft usually occurs when the femur is subjected to extreme force, such as that occurring in a traffic accident. In most cases, the bone ends are considerably displaced, causing severe pain, tenderness, and swelling. With a fractured femoral shaft there is often substantial blood loss from the bone.

The diagnosis is confirmed by X-ray. The fracture is usually repaired by surgery in which the fractured ends of the bone are realigned and fastened together with a metal pin. Sometimes, however, the bone ends can be realigned by manipulation and surgery is unnecessary. After realignment, the leg is supported with a splint and put in traction to hold the bone while it heals.

Complications include failure of the bone ends to unite or fusion of the broken ends at the wrong angle; infection of the bone; or damage to a nerve or artery. A fracture of the lower shaft can cause permanent knee stiffness.

**fenbufen**

A nonsteroidal anti-inflammatory drug (NSAID) that is used to relieve pain and stiffness caused, for example, by rheumatoid arthritis, osteoarthritis, and gout. Fenbufen is also used to reduce pain and to help speed recovery following muscle and ligament sprains.

In common with many NSAIDs, fenbufen can cause irritation of the stomach lining (see gastritis) and may also cause a rash.

**fenestration**

A surgical procedure in which an artificial opening, or window, is created in a sheath or a membrane. For example, fenestration may involve removal of part of the wall of a cyst to prevent fluid reaccumulating.

**fenoprofen**

A nonsteroidal anti-inflammatory drug (NSAID) that is used to relieve pain and stiffness caused, for example, by rheumatoid arthritis, osteoarthritis, and gout. Fenoprofen is also used to treat muscle and ligament sprains; it reduces pain and helps to speed recovery.

In common with many NSAIDs, fenoprofen may cause irritation of the stomach lining (see gastritis).

**fentanyl**

An opioid analgesic drug that is given by injection to provide pain relief during surgery and to enhance general anaesthesia (see anaesthesia, general). Fentanyl is also used in the form of a skin patch to control the severe chronic pain of conditions such as cancer.

In common with other opioid drugs, fentanyl has side effects that include depressed breathing, constipation, nausea, and vomiting. The use of patches containing fentanyl may be associated with local irritation of the skin.

**ferritin**

A complex of iron and protein, found mainly in the liver and spleen. Ferritin is the principal form in which iron is stored in the body.

**ferrous fumarate**

A form of iron given in an oral preparation to treat iron-deficiency anaemia. Ferrous fumarate can cause diarrhoea, constipation, and abdominal pain.

**ferrous sulphate**

Another name for iron sulphate.

**fertile period**

The period during a woman’s menstrual cycle when conception is most likely to occur. The fertile period is usually between three and five days in duration, beginning just before ovulation. Ovulation occurs about 14 days before a new menstrual cycle begins.

**fertility**

The ability to produce children without undue difficulty. Fertility depends on both male and female partners.

**MALE FERTILITY**

A man’s fertility depends on the production of normal quantities of healthy sperm in the testes (see testis). This ability depends on adequate production of gonadotrophin hormones by the pituitary gland, situated at the base of the brain. Fertility in males is also dependent on the ability to achieve an erection and to ejaculate semen into the vagina during sexual intercourse.

Males become fertile at puberty and usually remain so, although to a lessening degree, well into old age.

**FEMALE FERTILITY**

A woman’s ability to conceive depends on normal ovulation (the monthly production of a healthy ovum, or egg, by an ovary) and the ovum’s unimpeded passage down a fallopian tube towards the uterus; on thinning of the mucus surrounding the mouth of the cervix, to enable sperm to penetrate; and on changes in the lining of the uterus that prepare it for the implantation of a fertilized ovum.

These processes, in turn, depend on normal production of gonadotrophins by the pituitary gland, and of the sex hormones oestrogen and progesterone by the ovaries.

Women become fertile at puberty and remain so (although to a lessening degree as they become older) until the menopause, which usually occurs between 45 and 55 years of age. (See also fertility drugs; infertility.)

**fertility drugs**

A group of hormonal or hormone-related drugs that are used to treat some types of infertility.

In women, fertility drugs may be given when the abnormal production of hormones by the pituitary gland or ovaries (see ovary) disrupts ovulation (the release of an ovum, or egg, from an ovary) or causes mucus around the cervix to become so thick that sperm cannot penetrate it. Treatment with the drug clomifene, which may continue over a number of months, can help to bring about ovulation in women whose pituitary glands do not produce sufficient hormones for ovulation to occur naturally. If this treatment fails to produce ovulation, treatment with follicle-stimulating hormone (FSH), followed by an injection of human chorionic gonadotrophin (HCG), may be given in order to stimulate ripening of the ovum and ovulation. (See also gonadotrophin hormones.)

Treatment with fertility drugs must be monitored carefully in order to avoid overstimulation of the ovaries. Symptoms of overstimulation may include nausea, vomiting, abdominal swelling, and the development of massive ovarian cysts. The condition is potentially life-threatening.

Fertility drugs are generally less effective in men but may be used when abnormal hormone production by the pituitary gland or testes interferes with...
THE PROCESS OF FERTILIZATION

Fertilization occurs when the head of a sperm penetrates a mature ovum. After penetration, the nuclei (which contain the genetic material) of the sperm and ovum fuse and the body and tail of the sperm drop off. The newly fertilized ovum, called a zygote, then forms an outer layer that is impenetrable to other sperm. The zygote undergoes repeated cell divisions as it passes down the fallopian tube. By the time it reaches the uterus, it has grown into a solid ball of cells called a morula. It then develops an inner cavity with a small cluster of cells to one side; this is called a blastocyst.

Sperm and ovum
A single sperm penetrates the ovum, thereby fertilizing it. To achieve this, the sperm releases enzymes that dissolve a path through the ovum's outer layers.

FERTILE PERIOD

Ovulation occurs halfway through the menstrual cycle (13 to 16 days before the start of a period), after which the released ovum is available for fertilization for about two days. Sperm can also live for about two days, so the peak fertile period is about four days (two pre- and two post-ovulation).

Peak and possible fertile periods
Although the peak fertile period is about four days, the possible fertile period may last seven to 12 days, due to variations in how long the ovum and sperm can survive and the timing of ovulation. The illustration shows the peak and maximum possible fertile periods in a 28-day cycle.

JOURNEY OF THE SPERM

When semen is ejaculated into the vagina, as many as 500 million sperm are released, most of which are capable of fertilizing an ovum. But, as they travel upwards (propelled by their whiplike tails), more than half are killed by acidic vaginal secretions; many more die during the journey up through the cervix and uterus and into the fallopian tubes. The journey can take from less than half-an-hour to five hours and, in the end, only a few thousand sperm have survived.
the production of sperm. Low sperm production may be treated with gonadotrophins (FSH or HCG). (See also testosterone.)

fertilization
The union of a sperm and an ovum (egg cell). In natural fertilization (see the illustrated box), the sperm and ovum unite in the woman’s fallopian tube following sexual intercourse.

Fertilization may also occur as a result of semen being artificially introduced into the cervix (see artificial insemination) or it may take place in a laboratory (see in vitro fertilization).

festinating gait
An involuntary style of walking in which a person moves, often on tiptoe, with progressively shortening and accelerating steps. A festinating gait is a feature of an individual suffering from the movement disorder parkinsonism.

fetal alcohol syndrome
A rare combination of birth defects that occur as a result of continued, excessive alcohol consumption by the baby’s mother during pregnancy.

The affected baby has diminished growth, a small head and brain, and small eyes. He or she may also have a cleft palate, a small jaw, heart defects, and joint abnormalities. As a newborn, the baby sucks poorly, sleeps badly, and is irritable due to alcohol withdrawal.

Some affected babies die during the first few weeks of life. Those who survive may experience delayed mental development and are, to some degree, mentally and physically handicapped.

fetal circulation
Blood circulation in the fetus is different from the normal circulation after birth (see circulatory system). The fetus neither breathes nor eats, so oxygen and nutrients are obtained, via the placenta and umbilical cord, from the mother’s blood. The other fundamental difference in circulation is that blood bypasses the lungs in the fetus.

Oxygen and nutrients enter the fetal blood through the placenta, an organ embedded in the inner lining and wall of the uterus and connected to the fetus by the umbilical cord. The maternal and fetal circulations are separated by a thin membrane in the placenta, which allows the exchange of nutrients and waste products.

for reoxygenation and elimination of carbon dioxide and other wastes. In rare cases, the foramen ovale or ductus arteriosus fails to close after birth, causing a congenital heart disorder (see heart disease, congenital).

fetal death
See stillbirth.

fetal distress
The physical stress experienced by a fetus during labour as a result of not receiving enough oxygen. During each contraction, the uterus tightens and thus reduces the oxygen supply from the placenta to the fetus. If there are also problems, such as pressure on the umbilical cord or the mother losing blood, there may be an inadequate amount of oxygen reaching the fetus.

MONITORING
Various monitoring techniques may be used during childbirth to detect signs of fetal distress. A cardiotocograph (see fetal heart monitoring) will record whether the baby’s heart rate is slow or if it is failing to show normal variability. Acidosis (high acidity in the body), which indicates that the oxygen supply to the fetus is inadequate, can be detected in a sample of blood taken from the baby’s scalp. Signs of meconium (fetal faeces) in the amniotic fluid can also be an indication of fetal distress.

DELIVERY
Fetal distress sometimes occurs as a temporary episode, but, if acidosis is severe, the distressed fetus may need to be delivered promptly by caesarean section, forceps delivery, or vacuum extraction. (See also childbirth.)

fetal heart monitoring
The use of an instrument to record and/or listen to an unborn baby’s heartbeat during pregnancy and labour.

WHY IT IS DONE
The fetal heart is checked routinely during pregnancy with a fetal stethoscope or Doppler ultrasound scanning. Additional monitoring is carried out if tests indicate that the placenta is not functioning normally or if the baby’s growth is slow. Uterine contractions or other stimuli, such as reflex kicking, increase the heart rate in a healthy fetus; the midwife or obstetrician can detect this using a fetal heart monitor. During labour, monitoring can detect fetal distress, in which oxygen deprivation causes abnormalities in the fetal heart rate.
HOW IT IS DONE

The most simple form of fetal heart monitoring involves using a special fetal stethoscope. Cardiotocography, a more sophisticated electronic version, is a procedure that produces a continuous paper recording of the heartbeat and a recording of the uterine contractions. The heartbeat is picked up either externally by an ultrasound transducer strapped to the mother’s abdomen or, as an alternative during labour, internally by an electrode attached to the baby’s scalp that passes through the vagina and cervix. The mother’s uterine contractions are measured and recorded by an external pressure gauge strapped to the mother’s abdomen, or by an internal plastic tube inserted through the vagina into the amniotic fluid.

fetal movement

Movements made by a developing fetus in the uterus, which can usually be detected by the mother from between about the 16th and 20th weeks of pregnancy. Fetal movement at this stage may feel like a gentle “flutter” to the mother; later in pregnancy the fetus becomes more robust in its movements and may kick as it moves around in the amniotic sac. Some fetuses are more active than others. In late pregnancy, to monitor fetal well-being, the number of movements may be recorded on a “kick chart”.

fetishism

Reliance on special objects in order to achieve sexual arousal. The objects need not have an obvious sexual meaning; they may include shoes, rubber or leather garments, and parts of the body such as the feet or ears.

Fetishism usually has no obvious cause. According to psychoanalysts, the origin may be a childhood fixation of sexual interest upon some aspect of the mother’s appearance. Treatment is necessary only if the behaviour leads to distress or is causing persistent criminal acts.

fetoscopy

A procedure for directly observing a fetus inside the uterus using a fetoscope, which is a type of endoscope (a tubelike viewing instrument). Fetoscopy allows a close-up look at the fetus, particularly the face, limbs, genitals, and spine, and is used to diagnose various congenital abnormalities before birth.

DEVELOPMENT OF THE FETUS

By the 32nd week of pregnancy, the internal organs of the fetus are almost fully mature and it is perfectly formed. In most cases, the fetus has turned to lie head-down in the pelvis.

GROWTH OF THE FETUS FROM 8 TO 40 WEEKS

Between the eighth week and term (the 40th week), the length of the fetus (from crown to rump) increases by 20 times and its weight increases by about 1,700 times.

The technique carries some risks, so it is performed only when other tests, such as ultrasound scanning, detect an abnormality. By attaching additional instruments, doctors can use the fetoscope to take samples of fetal blood or tissue for analysis and to perform surgical procedures, such as insertion of a catheter into the fetal bladder. (See also amniocentesis; chorionic villus sampling.)

fetus

The unborn child from the end of the eighth week after conception until birth. For the first eight weeks, the unborn child is called an embryo.

The fetus develops in the mother’s uterus in a sac filled with amniotic fluid, which cushions it against injury. The oxygen and nutrients required by the fetus are supplied via the placenta, an organ embedded in the inner wall of the uterus that is attached to the fetus by the umbilical cord.

FEV

See forced expiratory volume.

fever

Known medically as pyrexia, elevation of body temperature above the normal level of 37°C in the mouth and 0.6°C lower in the axilla (armpit). A fever may be accompanied by symptoms such as shivering, sweating, a headache, thirst, lower in the axilla (armpit). A fever may be accompanied by symptoms such as shivering, sweating, a headache, thirst, or viral infections, such as influenza. Most fevers are caused either by bacterial infections, such as tonsillitis, or by viral infections, such as influenza. In such cases, proteins called pyrogens are released when the white blood cells fight the microorganisms that are responsible for the infection (see immune system). Pyrogens act on the temperature-controlling centre in the brain, causing it to raise the temperature of the body in an attempt to destroy the invading microorganisms.

Fever may also occur in other conditions where infection is not present. Such conditions include dehydration, thyrotoxicosis (a condition that results from overactivity of the thyroid gland), lymphoma (a tumour of the lymphatic system), and myocardial infarction (heart attack).

TREATMENT

Drugs such as aspirin, other nonsteroidal anti-inflammatory drugs, or paracetamol may be given to reduce fevers that are due to infections. Otherwise, treatment is directed at the underlying cause; for example, antibiotic drugs are given to treat a bacterial infection.

feverfew

The common name for the plant Tanacetum parthenium, which is used in herbal medicine for the treatment of headache and migraine.

fibrates

A type of lipid-lowering drug that is used to treat high blood levels of triglycerides or cholesterol.

fibre, dietary

The indigestible plant material in food. Dietary fibre includes certain types of polysaccharide, cellulose, hemicellulose, lignin, and gums and pectins (see carbohydrates). Humans do not have the enzymes necessary to digest these substances, so the material passes through the digestive system virtually unchanged and cannot be used as a source of energy.

Some components of dietary fibre hold water, thereby adding bulk to the faeces and aiding bowel function. For this reason, dietary fibre can be effective in treating constipation, diverticular disease, and irritable bowel syndrome. A high-fibre diet can help to reduce blood cholesterol levels. Certain high-fibre foods, such as fruit and vegetables, are also beneficial in protecting against cancers. Unrefined carbohydrate foods, including wholemeal bread, cereals, and root vegetables, are very rich in dietary fibre. (See also nutrition.)

fibre-optics

The transmission of images through bundles of thin, flexible glass or plastic threads. Light from a powerful external source is conducted along the length of the fibre, without losing its intensity, by a process known as total internal reflection. Fibre-optics have led to the development of endoscopes, instruments that enable structures deep within the body to be viewed directly.

fibrillation

Localized, spontaneous, rapid contractions of muscle fibres that can affect both skeletal and heart muscle.

In skeletal muscle, fibrillation generally occurs when a nerve supplying a muscle is destroyed, causing the muscle to become weak and waste away. Unlike fasciculation (muscular quivering), fibrillation in skeletal muscle is not visible through the skin; instead, the contractions can be detected using an EMG (electromyogram).

Fibrillation in the heart muscle is caused by disruption to the spread of nerve impulses through the wall of one of the chambers of the heart. Either the upper chambers (see atrial fibrillation) or the lower chambers (see ventricular fibrillation) of the heart may be affected. The condition can be detected by the use of an ECG (electrocardiogram). Fibrillation in heart muscle has the

GOOD SOURCES OF FIBRE (per 100g portion)

Essential for the efficient working of the digestive system, fibre is usually eaten as fruit or grains. Among the best sources are bran, apricots, prunes, and wholemeal bread. Eating sufficient fibre in food can reduce constipation. The recommended daily intake is 25 to 30 grams.

<table>

potential to be serious because it impairs the ability of the chambers to contract efficiently.

**fibrin**
A substance that is produced in the blood during the process of **blood clotting**. Fibrin is formed from a dissolved protein called fibrinogen. It forms long filaments that bind clumps of platelets and other blood cells into a mass that plugs the bleeding point, thereby preventing further blood loss.

**fibrinogen**
A protein that is present in blood and which is converted into fibrin during the **blood clotting** process.

**fibrinolysis**
The breakdown of fibrin, the principal component of any blood clot. Fibrin is a stringy protein that is formed in blood as the end product of coagulation (see **blood clotting**).

Blood also contains a fibrinolytic system, which is activated in parallel with the coagulation system when a blood vessel is damaged. The fibrinolytic system prevents the formation of clots in undamaged blood vessels, thereby preventing a blockage in these vessels, and it acts to dissolve a clot once healing of a broken blood vessel wall has taken place.

**Thrombosis** (abnormal formation of blood clots) occurs in situations in which there is a disturbance in the normal balance between the coagulation and fibrinolytic mechanisms.

Drugs that achieve the effect of fibrinolysis (see **thrombolytic drugs**) can be used to treat certain disorders, such as **pulmonary embolism** and **myocardial infarction**, in which blood clots block the circulation.

**fibrinolytic drugs**
Another name for **thrombolytic drugs**, which are used to dissolve blood clots.

**fibroadenoma**
A noncancerous fibrous tumour most commonly found in the breast. Fibroadenomas occur most often in women under the age of 30 and in black women. Multiple tumours may develop in one or both breasts.

Fibroadenomas of the breast are painless, firm, round lumps that are usually between 1 and 5 cm in diameter and movable. Although the cause of fibroadenomas is not fully understood, their development in the breast is believed to be linked to the sensitivity of breast tissue to female sex hormones. The lumps tend to grow more quickly during pregnancy, probably due to the increased levels of female sex hormones.

A sample of tissue from the lump is removed and examined to confirm the diagnosis (see **biopsy**). Fibroadenomas are harmless and do not require treatment unless they become very large or cause discomfort.

**fibroadenosis**
An outdated term for the general lumpiness that is a normal feature of some women’s breasts. Cyclical changes in hormone levels often lead to the appearance of lumps in the breasts, and the lumpiness is more obvious before a menstrual period.

Lumpy breasts do not increase the risk of developing breast cancer. However, a new solitary, discrete **breast lump** should be assessed by a doctor to rule out the possibility of breast cancer. (See also **mammary dysplasia**.)

**fibrocystic disease**
A term that is used to refer either to the inherited disorder **cystic fibrosis** or to general lumpiness of the breasts (see **fibroadenosis**).

**fibroid**
A slow-growing and noncancerous tumour that is found in the wall of the **uterus**. A fibroid is composed of smooth muscle and **connective tissue**. There may be one or more fibroids, and they may range in size from as small as a pea to as large as a grapefruit. Fibroids are common, appearing most often in women between the ages of 35 and 45.

**CAUSE**
The cause of a fibroid is thought to be related to an abnormal response to **oestrogen hormones**. **Oral contraceptives** that contain oestrogen can cause enlargement of fibroids, as can **pregnancy**. Decreased production of oestrogen after the **menopause** usually causes any fibroids to shrink.

**SYMPTOMS**
In many cases, there are no symptoms. If a fibroid enlarges and projects into the cavity of the uterus, it may cause heavy or prolonged periods. A large fibroid may exert pressure on the bladder, causing frequent passing of urine, or on the bowel, causing backache or constipation. Fibroids that distort the uterine cavity may cause recurrent miscarriage or infertility. Rarely, a fibroid may become twisted, resulting in sudden pain in the lower abdomen.

**DIAGNOSIS AND TREATMENT**
Fibroids that do not cause symptoms are often discovered during a routine pelvic examination. Ultrasound scanning can confirm the diagnosis.

Small, symptomless fibroids generally require no treatment, but regular examination may be needed to assess growth. Surgery or microwave **endometrial ablation** (MEA) is required for fibroids causing serious symptoms. In some cases, they can be removed with a hysteroscope (a tubelike viewing instrument with surgical attachments) under general anaesthesia (see **anaesthesia, general**), leaving the uterus intact. Removal of fibroids usually results in regained fertility. Sometimes, however, a hysterectomy (removal of the uterus) is required.

**fibroma**
A noncancerous tumour of the cells that form **connective tissue**. For example, a neurofibroma is a tumour of the cells that surround nerve fibres (see **neurofibromatosis**). Treatment is only needed if there are symptoms.

**fibromyalgia**
Pain and stiffness in the muscles, which is often associated with disturbance of sleep. Fibromyalgia is most common in women aged between 40 and 60 years. The condition is also known as **chronic widespread pain** (CWP) and was formerly referred to as fibrositis. Medical investigation usually fails to reveal any underlying cause and, for this reason, some doctors do not recognize fibromyalgia as a medical condition. However, the lives of affected people are often severely disrupted.
The muscles most commonly affected are those in the neck, shoulders, chest, back, buttocks, and knees. There is usually no restriction of movement. Attacks are generally worse in cold, damp weather. Exhaustion and disturbed sleep are common.

Use of analgesic drugs (painkillers), hot baths, and massage usually relieves pain and stiffness. Antidepressant drugs, such as amitriptyline, are often effective in improving sleep and relieving pain.

**fibroplasia**

The formation of fibrous tissue, which is a process that occurs normally during the healing of a wound, that may occur abnormally in some tissues. In one form of the condition, known as retroental fibroplasia, fibrous tissue develops behind the lens of the eye and causes blindness. This type of fibroplasia is usually seen only in newborn premature babies and is the result of excessive treatment with oxygen.

**fibrosarcoma**

A rare, cancerous tumour of the cells that make up connective tissue (the material that surrounds body structures and holds them together). A fibrosarcoma may develop from a non-cancerous fibroma or may be cancerous from the start.

Treatment of a fibrosarcoma is by surgical removal and/or radiotherapy. However, this may be only temporarily successful if cells from the tumour have already spread through the bloodstream to initiate growths elsewhere in the body.

**fibrosing alveolitis**

Inflammation and thickening of the walls of the alveoli (the tiny air sacs in the lungs; see alveolus, pulmonary) that results in scarring of lung tissue (see interstitial pulmonary fibrosis). Fibrosing alveolitis most frequently occurs in people over the age of 60.

Usually, fibrosing alveolitis is a long-term disorder, that develops over months or years. Rarely, an acute form occurs that develops rapidly over a few days or weeks. Both forms tend to become progressively worse and are difficult to treat.

**CAUSES**

In some cases, fibrosing alveolitis is the result of an autoimmune disorder (in which the immune system attacks the body’s own tissues) and may be associated with such conditions, particularly rheumatoid arthritis and systemic lupus erythematosus. Other causes of the condition may include radiotherapy of the organs in the chest and treatment with anticancer drugs. In many cases, however, the cause is unknown; the condition is then known as idiopathic pulmonary fibrosis.

**SYMPTOMS**

Symptoms of fibrosing alveolitis include shortness of breath, a persistent dry cough, and joint pains. As the condition progresses, breathing becomes increasingly difficult, especially during vigorous exercise. In severe cases, there is increased risk of respiratory failure and chronic heart failure. Some people with the disorder are more susceptible to lung cancer.

**TREATMENT**

Treatment of the condition involves corticosteroid drugs combined with other immunosuppressant drugs to slow the progress of lung damage. Home oxygen therapy may be used to assist breathing. For some people, a lung transplant may be life-saving.

**fibrosis**

An overgrowth of scar tissue or connective tissue. Fibrous tissue may be formed as an exaggerated healing response to infection, inflammation, or injury. Fibrosis may also result from a lack of oxygen in a tissue, usually due to inadequate blood flow through it (in heart muscle damaged by a myocardial infarction, for example).

In fibrosis, specialized structures (for example, kidney or muscle cells) are replaced by fibrous tissue, which results in impaired function of the organ concerned. An overgrowth of fibrous tissue can compress hollow structures, a situation that occurs in retroperitoneal fibrosis, in which the ureters (tubes draining urine from the kidneys into the bladder) become blocked. Fibrous tissue formed within a muscle after a tear causes shortening of the muscle and disruption of the normal contraction of its fibres. The likelihood of further tears occurring is increased unless the muscle is stretched and exercised.

**fibrositis**

A former term for fibromyalgia.

**fibrous adhesion**

See adhesion.

**fibula**

The outer and thinner of the two long bones of the lower leg. The fibula is much narrower than the other lower-leg bone, the tibia (shin), to which it runs parallel and to which it is attached at both ends by ligaments. The top end of the fibula does not reach the knee, but the lower end extends below the tibia and forms part of the ankle joint.

The main function of the fibula is to provide an attachment for the muscles. It provides little supportive strength to the lower leg.

**FRACTURE**

The fibula is one of the most commonly broken bones. A fracture of the fibula just above the ankle may occur with a severe ankle sprain as a result of a violent twisting movement. Pott’s fracture is a fracture at this location combined with dislocation of the ankle and sometimes with fracture of the tibia.

To confirm a fracture of the fibula, X-rays are taken. In some cases, the lower leg is immobilized in a plaster cast to allow the bone to heal. If a fracture occurs in the middle portion of the fibula, however, immobilization may not be needed. If the fracture is severe (especially if it is accompanied by dislocation of the ankle), surgery may be necessary to fasten the broken pieces of bone with pins.

**LOCATION OF THE FIBULA**

The fibula lies beside the tibia on the outside of each lower leg.
A fractured fibula may take up to six weeks to heal, depending on its severity and the age of the patient.

**fifth disease**
An infectious disease that often causes a widespread rash. Fifth disease, which is also known as slapped cheek disease or erythema infectiosum, principally affects children and is caused by a strain of *erythrovirus*. Erythrovirus is transmitted in airborne droplets from the coughs and sneezes of individuals who are carrying the infection, but it may occasionally be transmitted through a blood transfusion. Many children do not develop symptoms; in other children, the rash appears seven to 14 days after infection. The rash of fifth disease starts on the cheeks as separate, rose-red, raised spots, which subsequently converge to give the characteristic appearance of the condition. Within a few days, the rash spreads in a lacy pattern over the limbs, but only sparsely on the trunk. The rash is frequently accompanied by mild fever and generally clears up after approximately ten days.

Adults, who contract the disease only rarely, tend to be more severely affected than children. They may have joint pain and swelling that lasts for up to two years. Infection may bring a temporary halt to the production of red blood cells in the bone marrow (known as an aplastic crisis); it can therefore have serious implications for people with *anaemia*.

The only treatment for the infection is with drugs to reduce the fever. In most cases, the condition clears up within two weeks. However, people at risk of anaemia may need hospital treatment. One attack of erythrovirus confers lifelong immunity.

**fight-or-flight response**
The arousal of the sympathetic part of the *autonomic nervous system*, generally in response to fear. *Adrenalin* (epinephrine), *noradrenalin* (norepinephrine), and other hormones are released from the adrenal glands and nervous system, leading to a raised heart rate, pupil dilation, and increased blood flow to the muscles. These responses make the body more efficient in either fighting or fleeing the apparent danger. Prolonged or excessive fight-or-flight responses occur as part of *anxiety disorders*.

**figure-of-eight bandage**
A *bandage* that is wrapped over itself a number of times to resemble the figure eight. A figure-of-eight bandage is often used in first aid to support the elbows, wrists, knees, and ankles, particularly if the joint is to be kept in a flexed position.

**filariasis**
A group of tropical diseases, caused by various parasitic worms or their larvae, which are transmitted to humans by insect bites. Adult female worms, which may measure anything between 2 and 50 cm, produce many thousands of larvae, which are carried through the body in the bloodstream. Blood-sucking insects (primarily certain species of mosquito) ingest the larvae while feeding on blood from infected people and transmit them by biting others.

Filariasis is prevalent in tropical Africa, Indonesia, the South Pacific, coastal Asia, southern Arabia, Mexico, and Guatemala.

**TYPES AND SYMPTOMS**
Some species of worm live in the lymphatic vessels (see *lymphatic system*). Swollen *lymph nodes* and recurring fever are early symptoms of the disease. Inflammation of lymph vessels results in localized *oedema* (the accumulation of fluid in the tissues, causing swelling). After repeated infections, the affected area, which is commonly a limb or the scrotum, becomes very enlarged; in addition, the skin becomes thick, coarse, and fissured, resulting in a condition known as *elephantiasis*.

The larvae of another type of worm invade the eye, causing blindness (see *onchocerciasis*). A third type of larva, which may sometimes be seen and felt moving beneath the skin, causes *loiasis*, characterized by irritating and sometimes painful areas of oedema called calabar swellings.

**DIAGNOSIS AND TREATMENT**
A diagnosis of filariasis is confirmed by microscopic examination of the blood (see *blood tests*). The *anthelmintic drugs* diethylcarbamazine or ivermectin generally cure the infection, but they may also cause certain side effects, however, such as fever, sickness, muscle pains, and increased itching.

**PREVENTION**
The drug diethylcarbamazine can be given as a preventative measure; and the use of insecticides and protective clothing are useful protection against insect bites. (See also *roundworms; insects and disease*.)

**filling defect**
An abnormal finding on *contrast X-rays* due to a lesion occupying space within a hollow organ. Normally, in contrast X-rays, a radio-opaque dye (a contrast medium) is introduced into a hollow body structure, such as the intestine,
and X-rays are taken; the dye outlines the shape of the structure. Anything that protrudes into the cavity of a body structure, such as polyps in the large intestine or a tumour in the bladder, will prevent the area from filling with the contrast medium, and will produce a distorted shape on the X-ray.

**filling, dental**

The process of replacing a chipped or decayed area of tooth with an inactive material. The term may also be used to describe the restorative material itself.

Amalgam, a hard-wearing mixture of silver, mercury, and other metals, is often used for back teeth. Tiny amounts of mercury released from such fillings are believed by some to cause health problems. However, a link has yet to be scientifically established.

If a front tooth is chipped, bonding (see bonding, dental), in which plastic or porcelain tooth-coloured material is attached to the surface of the tooth, may be used.

**WHY IT IS DONE**

When enamel is damaged, bacteria can invade the dentine beneath and eventually attack the pulp (inner tissue containing blood vessels and nerves), causing the tooth to die. Teeth are therefore repaired, where possible, at the first signs of damage to prevent decay. Filling also restores a tooth’s original shape, which is important for appearance and also for a correct bite.

**HOW IT IS DONE**

If the filling required is large or in a sensitive area, the dentist numbs the surrounding gum with a local anaesthetic (see anaesthesia, dental). Any soft, decayed material is removed with sharp instruments. A high-speed drill is used to remove harder material and to shape a hole that will hold the filling securely. While the dentist works, a suction tube placed in the patient’s mouth draws away saliva and produces water to cool the end of the drill.

If the pulp is almost exposed, the bottom of the cavity is lined with a sedative paste to protect the sensitive pulp from pressure and temperature changes. If one or more of the walls of the tooth is missing through extensive decay, a steel band may be placed around the tooth to support the filling. The dentist then mixes the amalgam or other filling material, and packs it into the cavity, smoothing the surface. The material hardens over 24 hours.

**Amalgam fillings** have a limited life and may need to be replaced after about ten years. Occasionally, a filling needs to be replaced sooner if decay has spread under the filling or the filling has become dislodged or fractured.

**film**

A thin, transparent sheet of cellulose acetate or similar material, coated with a light- or radiation-sensitive emulsion, on which images such as X-rays are produced. The term is also used to describe any thin layer or coating, such as the covering of tears on the eyeball. (See also blood film.)

**film badge**

A device that enables hospital staff to monitor their exposure to radiation. Film badges are worn by people working in X-ray and radiotherapy departments. The badge consists of a piece of photographic film in a holder, which is worn on the clothing. The film has a fast (sensitive) emulsion on one side and a slow emulsion on the other. Small doses of radiation blacken only the fast emulsion; higher doses start to blacken the slow emulsion and make the fast emulsion turn opaque.

**finmбриae**

A fringe of threadlike or fingerlike filaments, such as those that make up the ends of the fallopian tubes that open on to the ovaries (see ovary). During ovulation, the finmbriae guide the egg (see ovum) into the tube.

**finasteride**

A specific enzyme inhibitor drug that prevents the conversion of testosterone into the more potent male hormone dihydrotestosterone. Finasteride is used in the treatment of noncancerous enlargement of the prostate (see prostate, enlarged); it shrinks the gland, thereby improving urine flow. It is also used to treat male pattern baldness in men. Side effects include impotence and reductions in libido and semen volume.

**fine tremor**

A tremor (an involuntary trembling or oscillating movement) characterized by very small and rapid vibrations.

**finger**

One of the digits of the hand. Each finger has three phalanges (finger bones), and the thumb has two. The phalanges join at hinge joints moved by muscle tendons that flex (bend) and extend (straighten) the finger. The tendons are covered by synovial sheaths that contain fluid, enabling the muscles to work without friction. A small artery, vein, and nerve run down each side of the finger. The entire structure is enclosed in skin with a nail at the tip.

**DISORDERS**

Finger injuries are common, especially lacerations, fractures, and ruptures of the tendons. Mallet finger is a condition that occurs when the extensor tendon along the back of the finger is pulled away from its attachment after a blow to the fingertip.

Infections may occur in the finger pulp at the tip; paronychia (infection of the tissue around a nail) sometimes follows a minor cut.

Inflammation that is due to rheumatoid arthritis or osteoarthritis may affect the joints of the fingers, causing stiffness, pain, swelling, and deformity. In addition, the flexor tendons, which run along the front of the fingers, may become inflamed and stuck in the tendon sheath, causing a condition known as trigger finger.

Altered control of the muscles in the walls of the blood vessels and impaired blood supply to the hands and fingers may cause Raynaud’s disease. Dactylitis is a spindle-shaped swelling of the fingers...
that is found in sickle-cell anaemia. Swelling of the fingers is also a rare feature of tuberculosis and syphilis.

Clubbing of the fingers is a sign of chronic lung disease or of certain forms of congenital heart disease. Tumours of the finger are rare, but they may occur in chondromatosis, a condition that is characterized by multiple noncancerous tumours of the cartilage.

Congenital finger disorders include syndactyly (fused fingers), polydactyly (extra fingers), missing fingers, or a webbed appearance of the hand that is caused by a deep membrane between the fingers.

Finger-joint replacement
A surgical procedure in which one or more artificial joints (made of metal, plastic, or silicone rubber) are used to replace finger joints that have been destroyed by disease, usually by rheumatoid arthritis or osteoarthritis.

How it is done
Usually, several finger joints are treated at the same time. An incision is made to expose the joint; the ends of the two diseased bones in the joint are cut away, along with diseased cartilage. An artificial joint is then inserted into the bone ends. The finger is immobilized in a splint until the wound has healed. After about ten days, the dressings are removed and the patient is encouraged to exercise the fingers and resume normal activities.

Results
Finger-joint replacement is usually successful in relieving arthritic pain and enabling the patient to use his or her hands again. However, it rarely restores normal movement.

Fingerprint
An impression that is left on a surface by the pattern of fine curved ridges on the skin of the fingertip. These ridges occur in four patterns: loops, arches, whorls, and compounds (which are combinations of the other three). No two people (not even identical twins) have the same fingerprints.

First aid
The immediate treatment of any injury or sudden illness before professional medical care can be provided. Most first aid consists of treating minor injuries and burns, and fractures. Sometimes, however, emergency life-saving first aid treatment may be needed.

The aims of first-aid treatment in an emergency are to preserve life; to protect the individual from further harm; to provide reassurance; to make the victim comfortable; to arrange for medical help; and to find out as much as possible about the circumstances of the accident or injury.

Various techniques can be used to achieve these aims. For example, the recovery position helps to maintain an open airway in an unconscious person who is breathing; artificial respiration is necessary if a person is not breathing. Cardiopulmonary resuscitation is essential if a person is not breathing and has no heartbeat. Heavy bleeding, which can result in shock, may be controlled by applying pressure at appropriate pressure points.

Fish oil
A product occurring naturally in some species of oily fish, such as mackerel. Fish-oil preparations, which are rich in omega-3 fatty acids, are used as lipid-lowering drugs.

Fissure
A cleft or groove, which can be either normal or abnormal. A dental fissure is a naturally occurring defect in the enamel of a tooth in which tooth decay (see caries, dental) commonly arises. The sylvian fissure is one of the deep folds that separate the temporal lobe of the brain from the frontal and parietal lobes. An anal fissure is a tear occurring in the anal canal.

Fissure sealant
A substance that is bonded to the biting surface of a tooth to seal any naturally occurring fissures (clefts or grooves) in the enamel and to help prevent tooth decay (see dental caries). Treatment with fissure sealant may be offered as a preventive measure to children whose molar teeth have recently emerged (see eruption of teeth).

Fistula
An abnormal passage leading from an internal organ to the body surface or connecting two organs. Fistulas may rarely be congenital (present from birth), or they may be acquired as a result of tissue damage.

Congenital types include tracheoesophageal fistulas, branchial fistulas (see branchial disorders), and thyroglossal fistulas (see thyroglossal disorders).

Acquired fistulas may result from infection, injury, or cancer. Fistulas between the intestine and the skin may occur in the inflammatory bowel condition Crohn's disease; these fistulas may allow the intestinal contents to escape to the skin through an opening, in which case they are known as faecal fistulas. Fistulas of the urinary tract, which open from the urethra or bladder to the perineum (the area between the anus and genitals), may be the result of radiotherapy to the pelvis, or they may be caused by a difficult childbirth. Such fistulas may cause leakage of urine (see incontinence, urinary) or urinary tract infection.

Certain types of arteriovenous fistula (between an artery and a vein) are surgically constructed to provide ready access to the circulation in people who are having dialysis.

Treatment
Identifying the cause of a fistula, and treating it if possible, is the first line of action. Some types of fistula close spontaneously but most need surgery. In faecal fistulas, a temporary colostomy may be necessary to divert faeces away from the affected area.

Fit
See seizure.

Fitness
The capacity for performing physical activities without exhaustion. Fitness depends on strength (the ability to exert force for pushing, pulling, lifting), flexibility (the ability to bend, stretch, and twist through a full range of movements), and endurance (the ability to maintain a certain amount of effort for a certain period of time).

How fitness is achieved
Cardiovascular fitness is the precondition for all other forms of fitness; for this reason, regular aerobic exercise (see aerobics), which makes the body's use of oxygen more efficient, is the basis of any fitness programme. Specific activities, such as weight training or yoga, can help to develop strength and flexibility when included in a programme (see exercise). Although fitness training has cumulative effects that build up over many months (provided that there is a sustained increase in activity levels), the effects are specific to the muscles used and the ways in which they are used. A variety of activities is therefore necessary to achieve overall fitness.
BENEFITS OF FITNESS

When the body is fit, the maximum work capacity and endurance are increased. A fit person has a better chance of avoiding coronary artery disease as well as of preventing the effects of aging and chronic disease.

The strength, endurance, and efficiency of the heart is also increased by exercise. A fit heart pumps 25 per cent more blood per minute when at rest, and over 50 per cent more blood per minute during physical exertion, than an unfit heart. A fit person’s heart normally beats 60 or 70 times a minute; an unfit person’s heart beats 80 to 100 times per minute.

fitness testing

A series of exercises designed to determine an individual’s level of fitness, primarily his or her cardiovascular fitness and muscle performance. Fitness testing is often carried out before a person starts an exercise programme to evaluate its safety and suitability or to monitor progress thereafter.

A physical examination is usually performed, including measurement of body fat, height, and weight. Blood and urine tests may be done, including an analysis of blood cholesterol. The performance of the heart is measured by taking the pulse before, during, and after aerobic exercise such as step climbing, riding a stationary bicycle, or running on a treadmill. The more efficient the heart, the slower it works during exercise and the quicker it returns to normal afterwards.

Another test involves measuring a person’s overall performance in a standard exercise. This is most suitable for monitoring progress through an exercise programme and for setting goals. The test may be based either on measuring the distance covered in a fixed time or the time needed to cover a fixed distance. (See also aerobics; exercise.)

fixation

In psychoanalytic theory, the process by which an individual becomes, or remains, emotionally attached to real or imagined objects or events that occurred during early childhood. If the fixations are powerful, resulting from traumatic events, they may lead to immature and inappropriate behaviour. Regression to these events is regarded by some analysts as the basis of certain emotional disorders.

The word “fixation” also describes the alignment and stabilization of fractured bones. Fixation may be external, as with a plaster cast, or internal, using pins, plates, or nails introduced surgically into the injured area.

fixative

A chemical agent, such as formaldehyde, that is used for the hardening and preservation of tissue specimens prior to microscopic analysis (see histology).

fixed pupil

An abnormal pupil (the circular opening in the centre of the iris) that does not react to light or adjust on accommodation (the process by which the eye focuses on objects). A fixed pupil may be symptomatic of various eye disorders (see eye, disorders of), such as acute glaucoma and uveitis, or, rarely, of a brain tumour in which brainstem structures that control eye reflexes are compressed. Both pupils being fixed and dilated is a sign of brain death.

fixed-rate pacemaker

An artificial cardiac pacemaker (a device that sends electrical impulses to the heart to maintain a regular heartbeat) that is set to pace at a single rate regardless of the patient’s own heart rate. Fixed-rate pacemakers are still used in some clinical and diagnostic settings, and may be appropriate for the elderly. For active people, rate-responsive pacemakers (see demand pacemaker) are often a better choice; these devices deliver electrical stimuli as required and at a rate to match the patient’s level of activity.

flaccid

Lacking in firmness or characterized by a loss of muscle tone.

flail chest

A type of chest injury that usually results from a traffic accident or from violence. In flail chest, several adjacent ribs are broken in more than one place, producing a piece of chest wall that moves in the opposite way to normal as the victim breathes: when the victim inhales, and the rib cage expands, the flail segment moves inwards, and during exhalation it moves outwards.

The injury may severely impair the efficiency of breathing and may lead to respiratory failure and shock. It makes breathing and coughing very painful, which can increase the risk of chest infection and lung collapse (see atelectasis).

Emergency treatment involves turning the person on to the affected side or firmly strapping the flail segment. In severe cases, artificial ventilation is needed until the chest wall has become stable and the ribs have healed.

flat-feet

A condition, usually affecting both feet, in which the arch of the foot is absent and the sole rests flat on the ground. The arches normally form gradually as the supportive ligaments and muscles in the soles develop; they are usually not fully formed until about the age of six. In some people, however, the ligaments are lax, or the muscles in the feet are weak, and the feet therefore remain flat. Less commonly, the arches of the feet may not form because of a hereditary defect in bone structure.

Flat-feet can be acquired in adult life because of fallen arches, sometimes as the result of a rapid increase in weight. Weakening of the supporting muscles and ligaments of the feet may occur in certain neurological or muscular diseases, such as poliomyelitis.

In most cases, flat-feet are painless and require no treatment, although in some cases the feet may ache on walking or standing. Arch supports can be worn in the shoes for comfort and special exercises can be used to help strengthen weakened ligaments and muscles. A small number of affected children require an operation to correct the bones in the feet.

flatulence

Abdominal discomfort or fullness that is relieved by belching or by passing wind through the anus. Flatulence is a feature of many gastrointestinal conditions, such as irritable bowel syndrome and gallbladder disorders.

When an individual is in an upright position, most swallowed air passes back up the oesophagus to be expelled through the mouth. When a person is in a prone position, the air may pass through the intestine and anus instead. Gas formed in the intestine is passed only through the anus.

flatus

Gas, commonly known as “wind”, that is passed via the anus. Gas is formed in the large intestine by the action of
bacteria on carbohydrates and amino acids in food. The gas consists of hydrogen, carbon dioxide, and methane. Air may be swallowed while eating and enter the stomach or intestine. Large amounts of gas may cause flatulence (abdominal discomfort), which may be relieved by the passage of wind or by defaecation (passing faeces).

**flatworm**
Any species of worm that has a flattened shape. Two types of flatworm are parasites of humans: cestodes (tape-worms) and trematodes (schistosomes, flukes; see liver fluke; schistosomiasis).

**flea bites**
See insect bites.

**fleacaineide**
An antiarrhythmic drug used in the treatment of tachycardia, atrial fibrillation, and arrhythmias associated with conditions such as Wolff–Parkinson–White syndrome (an abnormality of heart rhythm). Flecainide is given, in the form of tablets or injection, to people who are physically resistant to or intolerant of other treatments. The treatment is always started in hospital.

Side effects include dizziness, visual disturbances, and worsening of the existing arrhythmia or development of a new type. In rare cases, nausea, vomiting, urticaria (nettle rash), vertigo, and jaundice occur.

**flexor**
Any muscle that acts to flex a joint. An example of a flexor muscle is the biceps muscle, in the upper arm, which contracts to bend the elbow.

**flies**
See insects and disease.

**floaters**
Small fragments that are perceived to be floating in the field of vision. Floaters move rapidly with eye movement but drift slightly when the eyes are still. They do not usually affect vision.

The majority of floaters are the result of shadows cast on the retina by microscopic structures in the vitreous humour (the jellylike substance behind the lens of the eye). In older people, the vitreous humour tends to shrink slightly and detach from the retina, often resulting in conspicuous floaters, which usually decrease over time.

**HOW TO USE DENTAL FLOSS**
Floss should be used as an adjunct to toothbrushing to remove plaque and food particles from gaps between teeth and around gums. Care should be taken to avoid damaging the gum margins, and floss should never be reused.

1. Break off a generous length of floss (about 50 cm) and wrap the ends around one finger of each hand.

2. Holding the floss taut, guide it gently into the gap between the teeth until it reaches the gum line. Then rub the sides of each tooth with the floss using an up-and-down motion.

**flossing, dental**
The removal of plaque (see plaque, dental) and food particles from between the teeth using soft nylon or silk thread or tape. Dental floss may be waxed or unwaxed. Flossing should be carried out as an adjunct to toothbrushing.

**flu**
See influenza.

**fluconazol**
A penicillin drug usually used to treat staphylococcal infections.

**fluconazole**
An antifungal drug used in the treatment of candidiasis (thrush), a fungal infection that commonly affects the vagina or the mouth. Although generally well tolerated, fluconazole may sometimes cause nausea and diarrhoea.

**fluctuant**
A term used to describe the movement within a swelling when it is examined by touch. It is a sign that the swelling contains fluid. The term is often used to describe an abscess.

**fluid retention**
The excessive accumulation of fluid in body tissues. Mild fluid retention is a common feature of premenstrual syndrome, but it disappears with the onset of menstruation. A more severe case of fluid retention may be associated with an underlying heart, liver, or kidney disorder (see ascites; nephrotic syndrome; oedema). Diuretic drugs may be used to treat fluid retention.
**fluke**
A type of flattened worm, also known as a trematode, that may infest humans or animals. The two main diseases caused by flukes are *liver fluke* infestation, which occurs worldwide, and *schistosomiasis*, a debilitating disease that is common in tropical countries.

**flunitrazepam**
A type of benzodiazepine drug that is used as a sleeping drug in the treatment of insomnia. The effects of flunitrazepam may persist into the following day. Pro-longed use of this drug may result in dependence (see drug dependence). Also known as Rohypnol, or the “date-rape” drug, flunitrazepam is a controlled drug.

**fluorescein**
A harmless orange dye (that glows green in contact with defective cells when blue light is shone on it) used in ophthalmology to aid the diagnosis of certain eye disorders. Fluorescein can be applied to the front of the eye to detect abrasions of the conjunctiva or cornea. It is also given intravenously during fluorescein angiography in order to detect abnormalities of the blood vessels in the retina (the light-sensitive inner layer at the back of the eye), which occur in such conditions as macular degeneration and diabetic retinopathy.

**fluoridation**
The addition of fluoride to the water supply as a means of reducing the incidence of dental caries (tooth decay). Some areas have naturally high levels of fluoride in the drinking water; in other areas, however, fluoride is added to bring the concentration up to the recommended level. In the UK, decisions to add fluoride to drinking water are made by the local authorities.

**fluoride**
A mineral that helps to prevent dental caries (tooth decay) by strengthening tooth enamel (see teeth), making it more resistant to acid attacks. Fluoride may also reduce the acid-producing ability of microorganisms in plaque.

Fluoride that is ingested during the formation of teeth has a lifelong beneficial effect because it is incorporated into the developing tooth substance. In the UK, fluoride is added to the water supply, and fluoridation has led to a decrease in the incidence of tooth decay among children.

Fluoride is also beneficial to both children and adults when it is applied directly to the teeth as part of dental treatment or used in the form of a mouthwash or toothpaste. However, the ingestion of excess fluoride as the teeth are forming can lead to fluorosis (staining of the tooth enamel).

**fluorosis**
Mottling or staining of the tooth enamel (see teeth) that is caused by the ingestion of excess fluoride as the teeth are formed. In severe cases of fluorosis the enamel develops brown stains. This occurs principally in areas in which the fluoride level in water exceeds the recommended level or if additional supplements are taken.

**fluourouracil**
An antineoplastic drug used in the treatment of cancers of the breast, bladder, ovaries, and intestine.

**flupentixol**
An antipsychotic drug used to treat schizophrenia and similar illnesses. It is also sometimes prescribed for depression. Side effects of the drug most commonly include blurred vision, nausea, a rapid heartbeat, dizziness, and Parkinsonism.

**flurazepam**
A type of benzodiazepine drug that is used as a sleeping drug in the treatment of insomnia. The drug’s effects may persist the following day. Prolonged use may result in dependence (see drug dependence).

**flurbiprofen**
A nonsteroidal anti-inflammatory drug that is used particularly to ease the symptoms of musculoskeletal disorders, such as rheumatoid arthritis.

**flush**
Reddening of the face, and sometimes of the neck, caused by dilation of the blood vessels near the skin surface.

Flushing may occur during fever or as a result of embarrassment. Hot flushes are common at the menopause.

**fluticasone**
A corticosteroid drug taken in the form of an inhaler to control asthma, as a nasal spray to relieve the symptoms of allergic rhinitis (see rhinitis allergic), and as an ointment or cream to treat dermatitis and eczema.

Side effects are rare, but may include nosebleeds when the drug is taken as a nasal spray, candidiasis (thrush) of the mouth and throat when taken as an inhaler, and skin irritation when taken as an ointment or cream.

**Flynn–Aird syndrome**
A rare, inherited disorder that is characterized by atrophy (wasting away) of the muscles and skin, ataxia (incoordination and clumsiness), and dementia. Other symptoms of Flynn–Aird syndrome include tooth decay (see caries, dental), stiffness in the joints, retinitis pigmentosa (degeneration of the rods and cones of the retina), peripheral neuropathy (a peripheral nerve disorder), cataracts, and progressive loss of hearing. Flynn–Aird syndrome shows an autosomal dominant pattern of inheritance (see genetic disorders).

**foam, contraceptive**
See spermicides.

**focal point**
The point at which light rays converge after passing through a lens. In people with normal vision, light rays from a viewed object converge on the light-sensitive retina after passing through the cornea and lens, producing a clear image. In shortsightedness, the focal point occurs in front of the retina and the image is blurred; in longsightedness, it occurs beyond the retina, with the same result.

**foetus**
An alternative spelling for fetus.

**Foley catheter**
A type of catheter (flexible tube) that is fed through the urethra into the bladder and used for the continuous drainage of urine (see catheterization, urinaiy). A Foley catheter is kept in place within the bladder by means of a balloon at its tip that is inflated with either air or liquid.
**folic acid**

A vitamin that is essential for the production of red blood cells by the bone marrow. Folic acid is contained in a variety of foods, particularly liver and raw vegetables; adequate amounts are usually included in a normal diet.

During pregnancy, folic acid is very important for fetal growth, the development of the nervous system, and the formation of blood cells. The incidence of neural tube defects is reduced if a woman takes folic acid supplements before conception and during the first 12 weeks of pregnancy.

Folic acid deficiency is a cause of megaloblastic anaemia, which produces symptoms such as headaches, fatigue, and pallor. Deficiency can occur during any serious illness or can be the result of a nutritionally poor diet, especially in people who consume large amounts of alcohol.

**folie à deux**

A French term that is used to describe the unusual occurrence of two people sharing the same psychotic illness (see psychosis). Often the two people are closely related and share one or more paranoid delusions. If the sufferers become separated, one of them usually rapidly loses the symptoms, which have been imposed by the dominant, and genuinely psychotic, partner.

**folk medicine**

Any form of medical treatment that is based on popular tradition, such as the charming of warts or the use of copper bracelets to treat rheumatism.

**follicle**

A small cavity in the body. For example, a hair follicle is a pit in the skin from which a single strand of hair emerges. Another example is an ovarian follicle, which is a fluid-filled cavity in the ovary in which an ovum (egg) develops.

**follicle-stimulating hormone**

A gonadotrophin hormone that is produced by the pituitary gland and acts on the ovary or testis. In women, follicle-stimulating hormone (FSH) causes an egg follicle to start maturing in the ovary in the first week of the menstrual cycle, ready for ovulation. In men, FSH stimulates sperm production in the testes. FSH is given medically to treat certain types of infertility.

**folliculitis**

Inflammation of one or more hair follicles as a result of a staphylococcal infection. Folliculitis can occur almost anywhere on the skin, but the condition most commonly affects the neck, armpits, thighs, or buttocks, causing a boil; it may also affect the bearded area of the face, producing pustules (see syphilis barbae). Treatment of folliculitis is with antibiotics. Because the infection is easily spread, careful hygiene is important, and an affected individual should wash any clothes worn next to the skin daily in boiling water until the condition has cleared up.

**fomites**

Inanimate objects (for example, bed linen, clothing, books, or telephone receivers) that are not in themselves harmful but which may be capable of harbouring harmful microorganisms or parasites and, therefore, of conveying an infection from one person to another. Fomites principally transmit respiratory infections, such as influenza. The singular form of the word fomites is “fomes”.

**fontanelle**

Either one of two membrane-covered spaces between the bones of a baby’s skull. At birth, the skull bones are not yet fully fused, and two soft areas can be felt through the scalp. These are the anterior fontanelle, which is diamond-shaped and usually closes up by age 18 months, and the posterior fontanelle, which is triangular and closes up within the first two months.

It is normal for the fontanelles to become tense and bulge out when a baby cries. Persistent tension at other times, however, may indicate an abnormality, particularly hydrocephalus (the accumulation of fluid in the skull). A sunken fontanelle may be a sign of dehydration. If a fontanelle is abnormally large or takes a long time to close, the cause may be a brain abnormality or a disorder, such as rickets, affecting the skull bones. Early closure of the fontanelles results in a deformity called craniostenosis.

Occasionally, a third fontanelle is present between the other two; this is a feature of Down’s syndrome. Sometimes a baby may have extra bones in the anterior fontanelle, but this is not abnormal. These extra bones fuse into the skull when the gap between them closes.

**food additives**

Any substance that is added to food for the purposes of preservation or to improve its acceptability in terms of taste, colour, or consistency.

**TYPES AND USES**

Additives fall into five main groups: those that preserve food; those that affect texture; those that affect appearance and taste; added nutrients, such as vitamins; and miscellaneous additives, such as rising and glazing agents, flour improvers, and anti-foaming agents. For further information on the many different types of food additives, see the table opposite.

Preservatives, such as sodium nitrate, are added to food to control the growth of bacteria, moulds, and yeasts. Other additives, such as antioxidants, can improve the keeping quality of food by preventing any undesirable chemical changes within it; for example, antioxidants prevent rancidity in some foods containing fat.

Additives that improve the texture of food include thickeners, emulsifiers, stabilizers, and gelling agents. Lecithin, which occurs naturally in all animal and plant cells, is an emulsifier that is added to margarine to prevent separation.

The appearance and taste of many foods and drinks may be improved through the use of colourings, flavourings, sweeteners, and flavour enhancers. Artificial sweeteners, such as saccharin and aspartame, may be used instead of sugar, especially in products that are aimed at people trying to lose weight. Many colourings are natural (for example, beetroot red).

**RISKS**

Certain additives may produce an allergic reaction in some individuals, although this is relatively rare. Some substances, particularly food colourings
such as tartrazine, may be a contributory factor in behavioural problems in children, but this is difficult to confirm.

**food allergy**

An inappropriate or exaggerated reaction of the immune system to a food. Sensitivity to cows’ milk protein is a fairly common food allergy in young children. Other foods that are commonly implicated in food allergy are nuts (particularly peanuts), wheat, fish, shellfish, and eggs. Food allergy is more common in those who suffer from other forms of allergy or hypersensitivity, such as asthma, allergic rhinitis, and eczema.

**FOOD ADDITIVES**

Most additives approved by the EU have been given an E number, which must be listed by type and name and/or by number on food labels. Some examples of food additives and foods in which they are used are shown below. Antioxidants improve the keeping qualities of certain foods by preventing undesirable chemical changes. Preservatives also improve keeping quality, but by inhibiting growth of microorganisms. Emulsifiers and stabilizers improve the texture of foods. Sweeteners improve palatability and reduce dental problems associated with excess sugar intake.

*Warning: may produce reactions in susceptible people*

Immediate reactions, which occur within an hour (or sometimes only minutes) of eating the trigger foods, include swelling of the lips, tingling in the mouth or throat, vomiting, abdominal distension, abnormally loud bowel sounds, and diarrhoea. Serious food allergies can cause anaphylactic shock, which requires immediate self-injection with adrenaline (epinephrine). The only effective treatment for food allergy is avoidance of the offending food. (See also food intolerance.)

**food-borne infection**

Any infectious illness caused by eating food contaminated with viruses, bacteria, worms, or other organisms.

There are two mechanisms by which food can become infected. Firstly, many animals that are kept or caught for food may harbour disease organisms in their tissues or organs; if meat or milk from such an animal is eaten without being thoroughly cooked or pasteurized, the organisms may cause illness in their human host. In the UK, the only common infection of this type is food poisoning. Secondly, food may be contaminated with organisms spread from an infected person or animal, usually by flies moving from faeces to food (see Food poisoning box overleaf).

Immunization is available against certain food- and water-borne infections, such as typhoid fever.

**food challenge**

The controlled reintroduction into the diet of a food suspected of causing symptoms. Food challenges are usually attempted after a person has already been following an exclusion diet.

**food fad**

A like or dislike of a particular food or foods that is taken to extremes. A food fad may lead to undue reliance on, or avoidance of, a particular food. Fads are common in toddlers, adolescents, and people who are under stress. When a food fad becomes obsessive or persistent, however, it may indicate a serious eating disorder. (See also anorexia nervosa; bulimia.)

**food intolerance**

An adverse reaction to a food or an ingredient of food that occurs each time an individual eats the substance. Food intolerance does not have a psychological cause; it is not the result of
Some animals, including cows, pigs, poultry, and shellfish, harbour disease organisms (such as bacteria, viruses, worms, and parasites) in their tissues; these organisms may cause infection if meat, fish, or dairy products are consumed raw or are improperly cooked. Beef, pork, and fish tapeworm infestations, salmonella poisoning, and (rarely) brucellosis can be transmitted in this way. Adequate pasteurization of milk and the inspection of meat and fish before they go on sale prevent most infections and infestations of this type from occurring. Thorough preparation and cooking of meat, fish, shellfish, poultry, and eggs further reduce the risk of infection.

FOOD CONTAMINATION

Intestinal infections may be spread from person to person if organisms in faeces contaminate food, either directly or indirectly. Contamination can occur if vegetable crops are sprayed with sewage, if flies settle on faeces and then on food, or if food is handled by a person who has not washed his or her hands.

Contaminating organism
The photograph (left), taken through an electron microscope, shows a typical Salmonella bacterium. The organism uses its many flagellae (whiplike structures) to move. Salmonella is a common contaminant of poultry, eggs, and egg products and may cause severe food poisoning.

food poisoning: and it does not involve the immune system.

Food intolerance is commonly of unknown cause. Certain foods may be poorly tolerated as a result of impaired digestion and absorption, which may be associated with disorders of the pancreas or of the biliary system (which produce digestive juices to break down food). Some individuals have a genetic deficiency of a specific enzyme, such as lactase (which is required for the digestion of lactose, the sugar that occurs in milk); on drinking milk, those people with lactose intolerance develop abdominal cramps, flatulence, and loose stools.

food poisoning
A term used to describe any gastrointestinal illness of sudden onset that is likely to have been caused by contaminated food or water. Most cases of food poisoning are caused by contamination of food or water by bacteria, viruses, or parasites. The illness is more common in hot weather.

Food poisoning is usually suspected when, for example, several members of a household (or customers at a particular restaurant) become ill after eating the same food.

BACTERIAL CAUSES

The bacteria commonly responsible for food poisoning belong to the groups SALMONELLA, CAMPYLOBACTER, and E. COLI, certain strains of which are capable of multiplying rapidly in the intestines to cause widespread inflammation. Food poisoning may also be caused by LISTERIA (see LISTERIOSIS).

Certain farm animals, especially poultry, commonly harbour the bacteria that are responsible for food poisoning. If frozen poultry is incompletely thawed before being cooked, or if it is not cooked thoroughly, it is liable to cause food poisoning. Eggs laid by affected poultry may also contain disease-causing bacteria. Fresh eggs are unlikely to be heavily contaminated. However, but eggs that are kept for more than a couple of weeks should be thoroughly cooked before being eaten. Bacteria may also be transferred to food from the excrement of infected animals or people; the bacteria can be transmitted either by flies or through poor personal hygiene.

Some types of bacteria cause the formation of toxins, which may be difficult to destroy even after thorough cooking. For example, the organism CLOSTRIDIUM PERFRINGENS is resistant to heat, and it may survive in precooked foods, such as pies, that have been incorrectly stored. BOTULISM is an uncommon, life-threatening form of food poisoning that is caused by a bacterial toxin. The foods most likely to cause botulism are home-preserved fruit, vegetables, and fish.

VIRAL CAUSES

The viruses that are most commonly responsible for food poisoning are...
astrovirus, rotavirus, and a small round-structured virus (SRSV), which affects shellfish. This form of poisoning can occur when raw or partly cooked foods have been in contact with water that has been contaminated by human excrement.

**OTHER INFECTIVE CAUSES**

The protozoan parasite Cryptosporidium (see cryptosporidiosis), which principally affects farm animals, can be passed on to humans through drinking water supplies, swimming pools, or by direct contact with infected animals. People with HIV infection or AIDS are particularly susceptible to contracting this type of food poisoning.

**NONINFECTIVE CAUSES**

There are a number of noninfective causes of food poisoning including poisonous mushrooms and toadstools (see mushroom poisoning), fresh fruit and vegetables contaminated with high doses of insecticide, and chemical poisoning from some foods, such as fruit juice, that are stored in containers made partly from zinc.

Certain foods, such as puffer fish, considered a delicacy in Japan, or cassava, a staple food in many tropical countries, can also cause moderate to lethal poisoning if improperly cooked or prepared.

**SYMPTOMS**

The onset of symptoms depends on the cause of poisoning. Symptoms usually develop within 30 minutes in cases of chemical poisoning, between one and 12 hours in cases of bacterial toxins, and between 12 and 48 hours with most bacterial and viral infections.

Symptoms of food poisoning usually include diarrhoea, nausea and vomiting, stomach pain, and, in severe cases, shock and collapse. Botulism affects the nervous system, causing visual disturbances, difficulty with speech, paralysis, and vomiting.

**DIAGNOSIS**

The diagnosis of bacterial food poisoning can usually be confirmed from examination of a sample of faeces. Chemical poisoning can often be diagnosed from a description of what the person has eaten, and from analysis of a sample of the suspect food.

**TREATMENT**

Mild cases can be treated at home by replacement of lost fluids (see rehydration therapy). In severe cases, or when the very young or elderly are affected, hospital treatment may be necessary. If poisoning by a chemical or bacterial toxin is suspected, the stomach may be washed out (see lavage, gastric).

Except for botulism and some cases of mushroom poisoning, most food poisoning is not serious; recovery usually occurs within about three days. Some strains of E. coli can seriously damage red blood cells, causing kidney failure (see haemolytic–uraemic syndrome). (See also cholera; dysentery; seafood poisoning; typhoid fever.)

**PREVENTION**

Some simple measures can virtually eliminate the risk of food poisoning. Hands should always be washed before food is handled, and fresh fruit and vegetables should be rinsed in clean water. Cutting boards and implements that have been used for raw meat should be washed with hot water before being used for other foods. Meat, poultry, and eggs must be cooked thoroughly. Raw and cooked foods should be stored well apart in the refrigerator, and raw meat should be kept in the coldest part. Advice should be sought when preparing unfamiliar foods.

**FOOT**

The foot has two vital functions. The first of these functions is to support the weight of the body in standing or walking; the second function of the foot is to act as a lever that propels the body forwards.

**STRUCTURE**

The largest bone of the foot, the heel-bone (see calcaneus), is joined to the ankle bone (the talus). The tarsal bones are located in front of the talus and calcaneus and they are jointed to the five metatarsal bones. The bones of the toes are called the phalanges; the big toe has two phalanges and all the remaining toes have three.

Tendons passing around the ankle connect the muscles that act on the various bones of the foot and toe. The main blood vessels and nerves pass in front of and behind the inside of the ankle to supply the foot. The undersurface of a normal foot forms a natural arch that is supported by ligaments and muscles. Fascia (fibrous tissue) and fat form the sole of the foot, which is covered by a layer of tough skin.

**DISORDERS**

Injuries to the foot often result in fracture of the foot bones (the metatarsals and phalanges). The calcaneus may fracture following a fall from a height on to a hard surface.

Congenital foot abnormalities are fairly common and include club-foot (see talipes), flat-feet, and claw-foot. A bunion is a common deformity of the foot in which a thickened bursa (fluid-filled pad) lies over the joint at the base of the big toe.

Corns are small areas of thickened skin that are usually caused by tightly fitting shoes. Verrucas (see plantar warts) develop on the soles of the feet. Athlete’s foot is a fungal infection that affects the skin between the toes, causing it to become very itchy, sore, and cracked.

Gout is a relatively common type of arthritis that often affects the joint at the base of the big toe or one of the joints in the foot. An ingrowing toenail (see toenail, ingrowing) commonly occurs on the big toe and may lead to inflammation and infection of the surrounding tissues (see paronychia).

Foot-drop is the inability to raise the foot properly causing it to drag along the ground when the person is walking. The condition may occur as a result of damage to the muscles in the leg that are responsible for performing this movement or, alternatively, to the nerves that supply these muscles.
foot-drop
A condition in which the foot cannot be raised properly and hangs limp from the ankle, causing it to catch on the ground when the affected person is walking.

Neuritis (inflammation of a nerve) affecting the nerves that supply the foot muscles is a common cause. This condition may be due to diabetes mellitus, multiple sclerosis, or a neuropathy (nerve disease). Weakness in the foot muscles can also result from pressure on a nerve at the point where it leaves the spinal cord, due to a disc prolapse or a tumour. Damage to the muscles in the leg from an injury may also be a cause of foot-drop.

The underlying cause is treated, but in many people the weakness persists. A lightweight plastic caliper splint may be used to keep the foot in place when the person is walking.

foramen
A natural opening in a bone or other body structure, usually to allow the passage of nerves or blood vessels. For example, the foramen magnum is a hole in the base of the skull through which the spinal cord passes.

Forbes–Albright syndrome
A condition that is characterized by amenorrhoea (the absence of menstruation) and galactorrhoea (the production of breast milk) that is not associated with pregnancy. Forbes–Albright syndrome is usually the result of a pituitary tumour that secretes excessive amounts of the hormone prolactin. Treatment with the drug bromocriptine may suppress prolactin production. However, surgical removal of the tumour may be necessary.

forced expiratory volume
The maximum volume of air that can, over a given period of time, be forcibly exhaled from the lungs, usually over one second. Forced expiratory volume (FEV) tests are often carried out in conjunction with forced vital capacity (FVC) tests to check for a variety of lung disorders. (See also pulmonary function tests.)

A low result may indicate one of a variety of disorders, including chronic obstructive pulmonary disease (see pulmonary disease, chronic obstructive) and diminished lung volume, such as that found in emphysema.

forced vital capacity
The largest volume of air that can be expired following a deep inhalation. Forced vital capacity (FVC) is one of the variables measured in a lung function test (see pulmonary function tests), which is carried out to check for a variety of lung disorders.

forceps
A tweezerlike instrument that is used for handling tissues or equipment during surgical procedures. Various types of forceps have been designed for specific purposes. For example, forceps that are used for holding and removing wound dressings have scissor handles to make manipulation easier; tissue forceps have fine teeth at the tip of each blade so that body tissues can be handled delicately during surgery. (See also forceps delivery.)

forceps delivery
The use of specially designed forceps (see forceps, obstetric) to ease out the baby’s head during a difficult birth (see childbirth).

WHY IT IS DONE
Forceps delivery is used if the mother is overtired or unable to push out her baby unaided, or if the baby is showing signs of fetal distress. Forceps are also used to control the baby’s head once the body has been delivered in breech delivery to prevent an overly rapid birth. They may also be used if the baby’s head is stuck in the middle of the mother’s pelvis and needs to be rotated to make delivery possible.

HOW IT IS DONE
The mother is given a painkiller and anaesthesia (making a cut in the perineum) is usually needed for a forceps delivery. The forceps blades are placed on either side of the baby’s head, just in front of the ears, and gentle traction is applied to bring about delivery of the baby.

Recovery and care for mother and child is usually the same as after a vaginal delivery.

forceps, obstetric
Surgical instruments that are used in forceps delivery to deliver the head of a baby in a difficult labour and birth.

Obstetric forceps are of various types but basically consist of two blades that cup around the baby’s head.

Fordyce’s disease
A fairly common condition consisting of raised yellow patches on the lips and gums and in the lining of the mouth. The patches are composed of misplaced sebaceous glands. The disease is also known as Fordyce’s granules. The condition is not serious and does not usually need treatment.

forebrain
The foremost, and largest, of the main divisions of the brain. The forebrain is responsible for controlling many of the brain’s higher functions, including conscious thought.

foreign body
An object that is present in an organ or passage of the body but should not be there. A foreign body may enter the body accidentally (for example, by inhalation or swallowing), or it may be introduced deliberately (for example, a child pushing a bead into a nostril). The most common sites for
foreign bodies include the airways (see choking), ears (see ear, foreign body in), eyes (see eye, foreign body in), rectum, and vagina.

foremilk
The breast milk that is produced at the beginning of a feed (see breast-feeding). Foremilk is bluish in appearance; it contains lactose and proteins, but little fat. (See also hindmilk.)

forensic medicine
The branch of medicine that is concerned with the law, especially criminal law. A forensic pathologist is a doctor who specializes in the examination of bodies when it appears that death was the result of unnatural causes. Forensic specialists may examine victims of alleged sexual assault.

Forensic scientists use laboratory methods to study body fluids (such as blood and semen) found on or near the victim and compare them with samples obtained from suspects. Forensic scientists are also trained in ballistics and in the identification of fibres from materials such as clothing. In addition, forensic scientists may advise on blood groups and genetic fingerprinting in certain legal investigations.

forensic psychiatry
A branch of psychiatry specializing in the diagnosis of mental illness related to criminal behaviour.

foreplay
A sexually stimulating activity that commonly precedes sexual intercourse but may also occur independently. Foreplay can involve any of a range of activities, including kissing, caressing, and oral sex.

foreskin
The popular name for the prepuce, which is the loose fold of skin that covers the glans (head) of the penis when it is flaccid and which retracts during erection.

At birth, the foreskin is attached to the glans and is not retractable. It separates from the glans during the first three to four years of life. The foreskin may be removed (see circumcision) for religious or medical reasons.

DISORDERS
In phimosis, the foreskin remains persistently tight after the age of five, causing difficulty in passing urine and ballooning of the foreskin. There may also be recurrent balanitis (infection of the glans). Erection is frequently painful, which is why the condition is often discovered only at puberty. In paraphimosis, the foreskin becomes stuck in the retracted position, causing painful swelling of the glans that requires emergency treatment.

foremilk
A term that is commonly used to refer to the amniotic fluid (the “waters”) that is discharged from the uterus when the part of the amniotic sac in front of the presenting part of the fetus ruptures just before childbirth. This may happen before or after the onset of labour. (See also hindwaters.)

forgetfulness
The inability to remember (see memory). (See also amnesia.)

formaldehyde
A colourless, pungent, irritant gas. In medicine, a solution of formaldehyde and a small amount of alcohol in water, a preparation known as formalin, is used as a preserving medium for tissue specimens or to harden them before they are stained and examined. Formalin is also used as a disinfectant.

forme fruste
The term that is used to describe any disease that does not follow its usual course. One example of forme fruste is when certain characteristic symptoms of the disease fail to appear; another example is when the progression of the disorder terminates at an earlier stage than expected.

formication
An unpleasant sensation, as though ants were crawling over the skin. This feeling may occur following abuse of certain drugs, such as alcohol or morphine. Scratching of the skin in an attempt to relieve the sensation can sometimes cause a rash to develop, which may result in an incorrect diagnosis of skin disease.

formula, chemical
A way of expressing the constituents of a chemical in symbols and numbers. Water, for example, has the formula H2O, indicating that each molecule is composed of two atoms of hydrogen (H2) and one of oxygen (O).

formulary
A book of formulae. The term “formulary” is commonly used to refer to a publication that lists drug preparations and their components and effects. The contents of a formulary may be decided by a group of medical professionals who are working together to ensure similar patterns of drug usage.

fossa
A depression or hollow area. Examples include the posterior fossa, which is an area at the back of the base of the brain occupied by the cerebellum, and the cubital fossa, which is the hollow at the front of the elbow joint.

Fothergill’s disease
An alternative name for trigeminal neuralgia, a disorder of the trigeminal nerve (the fifth cranial nerve, which supplies the facial muscles).

fovea
An area situated near the centre of the retina that has the highest concentration of light-sensitive cells. The fovea allows detailed vision. (See also colour vision.)
The pimpls of Fox–Fordyce disease are caused by the obstruction and rupture of apocrine ducts in the epidermis (the outermost layer of the skin). Treatment with topical retinoids (derivatives of vitamin A) and antibiotic drugs may help to relieve symptoms in patients who have suffered from the disease in the long term.

**fracture**

A break in a bone. Fractures most often occur across the width of a bone, but can be lengthwise, oblique, or spiral.

**TYPES**

There are two main types of fracture: closed (simple) or open (compound). In a closed fracture, the broken bone ends remain beneath the skin and little of the surrounding tissue is damaged; in an open fracture, one or both of the bone ends project through the skin. If the ends of the bone have moved out of alignment, which can occur in either a closed or an open fracture, the fracture is termed “displaced”.

Fractures may be further divided according to the pattern of the break: for example, transverse or spiral fractures of long bones. In a greenstick fracture, the break is not through the full width of the bone. This type of fracture occurs only in children because their bones are more pliable. In an avulsion fracture, a small piece of bone is pulled off by a tendon.

**CAUSES**

Most fractures are the result of a sudden injury that exerts more force on the bone than it can withstand. The force may be direct, for example when a finger is hit by a hammer, or indirect, for example when twisting the foot exerts severe stress on the shin.

In some diseases, such as osteoporosis and certain cancers, the bone is weakened to such an extent that even a minor injury, or occasionally no injury at all, can cause the bone to break; this is known as a pathological fracture. Compression fractures of the vertebrae are common in people suffering from osteoporosis. Elderly people are most prone to fractures because they are more likely to fall and their bones are very fragile.

**SYMPTOMS AND SIGNS**

Common sites of fracture include the hand, wrist (see Colles’ fracture), ankle joint, clavicle (collarbone), and the neck of the femur (see femur, fracture of). There is usually swelling and tenderness at the fracture site. The pain is often severe and is usually made worse by movement.

**DIAGNOSIS AND TREATMENT**

X-rays can confirm the presence of a fracture. Bone begins to heal soon after it has broken, so the first aim of treatment is to ensure that the bone ends are aligned. Displaced bone ends are moved back into position, under general anaesthesia, by manipulation either through the skin or through an incision. The bone is then immobilized. In some cases, the ends of the bone may be fixed with metal pins or plates.

**RECOVERY AND COMPLICATIONS**

Most fractures heal without any problems. Healing is sometimes delayed because the blood supply to the affected bone is inadequate (as a result of damaged blood vessels) or because the bone ends are not sufficiently close together. If the fracture fails to unite, internal fixation or a bone graft may be needed. Osteomyelitis (infection of bone tissue) is a possible complication of open fractures.

Physiotherapy plays an important part in rehabilitation following a fracture because complete immobility of a bone for a prolonged period can result in loss of muscle bulk in that area and stiffness in nearby joints.

(See also fracture, dental; humerus, fracture of; jaw, fractured; march fracture; Pott’s fracture; radius, fracture of; rib, fracture of; skull, fracture of; Smith’s fracture; stress fracture; ulna, fracture of.)

**fracture, dental**

A break in a tooth (see teeth) most commonly caused by falling onto a hard surface or by being hit in the mouth with a hard object. Fractures may involve the crown or the root of a tooth, or both.

Fractures of the enamel can usually be repaired by bonding (see bonding, dental); in some cases, a replacement crown may be fitted (see crown, dental). Pulpotomy (removal of part of the pulp of the tooth) may be performed in cases where the pulp is damaged. Root fractures may be treated by splinting (see splinting, dental), root-canal treatment, or removal of the tooth (see extraction, dental).

**fragile X syndrome**

An inherited defect of the X chromosome that causes learning difficulties. The disorder occurs within families according to an unusual X-linked recessive pattern of inheritance (see genetic disorders). Although fragile X syndrome principally affects males, females can also inherit the disorder. Both men and women can be carriers without having any signs of the disorder.

In addition to having learning difficulties, affected people may have a prominent nose and jaw, and increased ear length; they are also prone to epileptic seizures and behavioural difficulties. Males tend to have large testes. Some carriers may also show intellectual impairment.

The condition cannot be treated, but affected children may benefit from speech therapy, specialist education, and help from a psychologist for any accompanying behavioural problems. Life expectancy is normal, but affected boys usually need lifelong care. Couples who have a family history of fragile X syndrome may wish to seek genetic counselling when planning to have a child.

**Fragmin**

A brand name for dalteparin, which is a low molecular weight heparin (an anticoagulant drug that is used in the prevention and treatment of abnormal blood clotting).

**Fraley’s syndrome**

A rare condition in which the uppermost renal calyces in the kidney (part of the central region where urine collects before passing out of the kidney) are compressed; this is usually caused by some of the blood vessels that supply the area. Abdominal pain, back pain in the area of the kidney, and blood in the urine are usually the main symptoms. Possible complications of this syndrome include recurrent urinary tract infections and kidney stones formation (see calculus, urinary tract).

**Franceschetti’s syndrome**

A rare genetic disorder, also known as Treacher–Collins syndrome, that causes severe facial malformations. The condition is congenital (present from birth). The nose, cheek bones, lower jaw, and chin are deformed, and the child may have a receding chin (see micrognathia). There is a pronounced droop to the outer corners of the eyes. Surgery to reconstruct abnormal features results in significant improvement in appearance and function.
FRANESCHETTI’S SYNDROME

FRACTURES: TYPES AND TREATMENT

There are two main types of fracture: simple (closed) and compound (open). Within these two categories are several other types, three of which are illustrated to the right.

Simple fracture
The broken bone does not break the skin. Because organisms do not come into contact with the fracture, infection is rare.

Compound fracture
A sharp piece of bone punctures the skin and is therefore exposed to organisms. There is a high risk of infection.

Greenstick fracture
This type usually occurs in children. Sudden force causes only the outer side of the bent bone to break.

Comminuted fracture
The bone shatters into more than two pieces. This fracture is usually caused by severe force, such as in a car accident.

Transverse fracture
This may result from a sharp, direct blow or be a stress fracture caused, for example, by prolonged running.

REPAIR OF FRACTURES

There are various ways of repairing fractures depending on the particular bone, the severity of the fracture, and the age of the patient.

Internal fixation
The photograph (left) shows the repair of a fracture in the hip. A metal pin has been inserted through the neck of the femur and is held in place by a plate screwed to the shaft.

External fixation
Immobilization may be achieved by means of a plaster cast (above) or, in cases such as an unstable fracture of the tibia (left and above left), through the use of metal pins inserted into bone on either side of the break and locked into position on an external metal frame.

THE BONE HEALING PROCESS

After a fracture, the bone starts to heal immediately. Any displacement of the bone ends must therefore be corrected without delay to minimize deformity.

1 A blood clot forms between the bone ends, sealing off the ends of the damaged vessels.

2 Macrophages (immune system cells) invade the fracture site to remove wound debris. Fibroblasts then create a mesh to form a base for new tissue.

3 New bone (callus) is laid down between the ends of the bones and over the fracture line.

4 Remodelling takes place, with denser, stronger bone being laid down. New blood vessels have formed.

5 Over a period of weeks, the bone returns to its former shape.
FRASER’S SYNDROME

Fraser’s syndrome
An inherited condition in which there is cryptophthalmos (absence of the opening between the upper and lower eyelids) together with malformations of the ear; cleft palate (see cleft lip and palate); narrowing of the larynx (the voice-box); syndactyly (fusion of two or more fingers or toes); imperforate anus (see anus, imperforate); cardiac defects, kidney malformation; and genital masculinization in females. Fraser’s syndrome is inherited as an autosomal recessive genetic trait (see genetic disorders).

Many babies born with Fraser’s syndrome die within the first year of life. For those who survive, surgery to the eyelids and corneas may provide some degree of vision and eyelid movement.

fraternal twins
An alternative term for dizygotic twins.

freckle
A tiny patch of pigmentation that occurs on sun-exposed skin. Freckles tend to become more numerous with continued exposure to sunlight. A tendency to freckling is inherited and occurs most often in fair and red-haired people. Freckles are harmless.

free-floating anxiety
An all-pervasive feeling of apprehension or tension with no apparent cause. Free-floating anxiety is often associated with generalized anxiety disorder.

Freeman–Sheldon syndrome
A rare congenital disorder with the following characteristics: sunken eyes; under-development of the cartilage of the nose; pursed lips; various skeletal malformations; and muscle weakness. Intelligence and life expectancy are normal. Freeman–Sheldon syndrome is usually inherited as an autosomal dominant genetic trait (see genetic disorders). Affected children may need corrective surgery to improve deformities of the face, hands, or feet.

free radicals
Highly active molecules that bind to and destroy body cells. Free radicals can be formed as a result of the effects of external sources such as smoke, sunlight, and food. They are produced in the body principally as a result of the chemical reactions involved in metabolism. They are thought to contribute to the cumulative damage to body cells that occurs with aging and to the development of cancers and possibly heart disease. Free radicals and their effects may be neutralized by antioxidants, such as vitamin C and vitamin E.

frenulum
Any fold of tissue or mucous membrane that limits the movement of an organ or part of the body. One example of a frenulum is the fold of mucous membrane on the inside of the upper lip that connects the lip to the gum; another example is the attachment of the foreskin to the glans (head) of the penis.

frequency
See urination, frequent.

Freudian slip
A slip of the tongue or a minor error of action that could betray what the person really wanted to say or do.

Freudian theory
A discipline that was developed by Sigmund Freud (1856–1939), a Viennese neurologist. The theory developed out of Freud’s treatment of neurotic patients using hypnosis and, later, the interpretation of their dreams. The Freudian theory formed the basis of the technique of psychoanalysis.

Freud believed that an individual’s feelings, thoughts, and behaviour were controlled by unconscious wishes and conflicts originating in childhood. Problems are said to occur when the desires are not fulfilled or if conflicts remain unresolved into adulthood.

The essence of Freud’s theory concerns early psychological development, particularly sexual development. Freud defined three developmental stages: oral, anal, and genital (representing the areas of the body on which the infant’s attention becomes fixed at different ages). He also identified three components of personality: the id, the ego, and the superego (based respectively on pleasure, reality, and moral and social constraints). (See also psychoanalytic theory; psychotherapy.)

frier’s balsam
A brand name for the aromatic liquid tincture of benzoin. Friar’s balsam is used with hot water as a steam inhalation to help relieve nasal congestion, acute rhinitis, and sinusitis, as well as to loosen coughs. Friar’s balsam is available over the counter.

Friedreich’s ataxia
A rare inherited disease in which degeneration of nerve fibres in the spinal cord causes loss of coordinated movement and balance.

SYMPTOMS
Symptoms tend to appear between the ages of five and 15 years. Early signs of the condition include difficulty in walking and deformities of the lower legs and feet, such as claw-foot. The difficulty in movement then extends to the arms and trunk. Once symptoms have developed, the disease becomes progressively more severe; the muscles then weaken and waste away. A gradual loss of sensation occurs in the extremities, which may eventually spread to other parts of the body; speech becomes slow and slurred; and nystagmus (involuntary, jerky eye movements) is common.

Other symptoms include chest pain, shortness of breath, and palpitations. Many people with Friedreich’s ataxia develop heart problems, such as cardiomyopathy (disease of the heart muscle) and abnormalities of the heart rhythm (see arrhythmia, cardiac).

TREATMENT AND OUTLOOK
Treatment can help with the symptoms but cannot alter the course of the disease. Braces or surgery may be used to correct deformities, physiotherapy may help to maintain movement for as long as possible, and drugs can be given for heart conditions. However, most affected people die in early adulthood.

frigidity
A lack of desire for sexual contact or an inability to become aroused during stimulation (see sexual desire, inhibited). (See also orgasm, lack of.)

frontal
A term referring to the front part of an organ (for example, the frontal lobe of the brain).

frostbite
Damage to body tissues caused by extremely cold temperatures. Frostbite can develop at any temperature below freezing; the lower the temperature, the more rapidly the frostbite will develop. The risk of frostbite is increased by windy conditions.

Frostbite can affect any part of the body, but the extremities (the nose, ears, fingers, and toes) are most susceptible and tend to be affected first.
People who have impaired circulation, such as those with diabetic vascular disease, are at increased risk.

**SYMPTOMS**
The first symptom of frostbite is a pins-and-needles sensation, followed by complete numbness in the affected region. The affected skin appears white, cold, and hard; it may then become red and swollen.

**TREATMENT AND OUTLOOK**
Treatment of frostbite involves rewarming the affected areas by immersion in warm water (ensuring that it is not too hot to touch), then applying bandages. When warmed, mildly affected tissues become red, swollen, and sore. If frostbite is more severe, blisters appear, and the area becomes very painful.

If the damage is restricted to the skin and the tissues that immediately underlie it, rewarming may result in complete recovery of the tissues. Recovery from frostbite damage usually occurs within about six months, but some lasting sensitivity to extreme temperatures is common. However, following severe frostbite, symptoms including stiffness, pain, and numbness may persist indefinitely.

If blood vessels are affected by frostbite, gangrene (tissue death) may follow. In such circumstances, amputation may be necessary.

**frottage**
A sexual deviation in which an individual rubs his or her body against another person in order to achieve sexual arousal. Typically, this activity is carried out within a crowd of people (such as on a crowded train) where a man rubs his (clothed) genitals against a woman’s buttocks or thigh.

**frozen section**
A method of preparing a biopsy specimen (a sample of tissue removed for microscopic analysis) that can provide a rapid indication of whether or not a tissue is cancerous.

**WHY IT IS DONE**
Frozen section may be used for the purpose of determining whether breast lumps are cancerous. The technique can also be used to check whether thyroid or intestinal tumours are cancerous and to diagnose lymphomas (cancerous tumours of lymphoid tissue).

**HOW IT IS DONE**
Frozen section may be undertaken during an operation in order that the results can be used to determine the appropriate surgical treatment. The surgeon removes a sample of tissue and sends it to the pathology laboratory for analysis. The sample is quickly frozen in liquid nitrogen, cut into very thin sections, placed on a glass slide, and stained so that the cells can be examined under the microscope. The entire process takes about 20 minutes. Information about the sample is then conveyed to the operating theatre.

**frozen shoulder**
Stiffness and pain in the shoulder that limits normal movement of the joint. In severe cases of frozen shoulder, the shoulder may be completely rigid, and pain may be intense.

**CAUSES**
Frozen shoulder is caused by inflammation and thickening of the lining of the joint capsule. In some cases, it occurs following a minor injury to the shoulder. Frozen shoulder can also occur if the shoulder is kept immobilized for a long period of time, such as following a stroke. In many cases, however, the disorder develops for no apparent reason.

The condition is more common in people over the age of 40. People with diabetes mellitus are also more susceptible to developing frozen shoulder.

**TREATMENT**
Moderate symptoms of frozen shoulder can be eased by exercise, by taking analgesic drugs (painkillers) and nonsteroidal anti-inflammatory drugs for the relief of pain and inflammation, and by applying ice-packs. However, in severe cases of frozen shoulder, corticosteroid drugs may need to be injected into the affected joint.

Manipulation of the joint under general anaesthesia can restore mobility. However, this treatment carries the risk of increasing pain initially.

**OUTLOOK**
Recovery is often slow, and the shoulder may remain stiff for some months, but it is usually back to normal and pain-free within two years.

**fructose**
A simple sugar (monosaccharide) that is naturally present in honey and certain fruits. Fructose and glucose are the two components of sucrose (table sugar).

Fructose can be converted into energy as easily as glucose but, unlike glucose, fructose metabolism is not dependent on insulin. For this reason, fructose can prove an important element in the diet of people suffering from diabetes mellitus.

**frusemide**
An alternative name for furosemide, a diuretic drug.

**frustration**
A deep feeling of discontent and tension as a result of unresolved problems or unfulfilled needs, or because the individual’s path to a goal is blocked. In some people, frustration can lead to regression (childlike behaviour), aggression, or depression.

**FSH**
An abbreviation for follicle-stimulating hormone, a gonadotrophin hormone produced by the pituitary gland.

**FTT**
The abbreviation for failure to thrive in infants and children. A child who fails to grow at the appropriate rate needs tests to determine the cause.

**Fuchs’ spots**
 Pigmented spots that develop on the retina (the light-sensitive inner layer at the back of the eye). The condition sometimes occurs in people who suffer from a severe degree of myopia (shortsightedness).

**Fuchs’ syndrome**
A slowly progressing disease that usually affects both eyes and which may be hereditary. The condition is also known as Fuchs’ corneal dystrophy. Fuchs’ syndrome occurs when cells in the innermost layer of the cornea (the transparent front part of the eyeball) gradually deteriorate. Fuchs’ syndrome may result in pain and severe visual impairment.

There is no preventive treatment for the disease. In some cases, a corneal transplant may eventually be necessary to restore sight.

**Fusithalmic eye drops**
A brand of eye drops containing fusidic acid, an antibiotic drug. The drops are used for bacterial conjunctivitis.

**fugue**
An episode of altered consciousness in which a person purposefully wanders away from home or work and,
in some cases, adopts a new identity. Afterwards, the person has no recollection of what has occurred.

Fugues may last for hours or days. During a short fugue, the sufferer may be confused and agitated. During a fugue lasting for days, behaviour may appear normal but there may be accompanying symptoms, such as hallucinations, feelings of unreality, and unstable mood.

Fugues are rare. Possible causes include dissociative disorders, temporal lobe epilepsy, depression, head injury, and dementia. (See also amnesia.)

**fulminant**

A term used to describe a disorder that develops and progresses suddenly and with great severity. A virulent infection, a severe form of arthritis, or a cancer that has spread rapidly is often described as being fulminant.

**fungi**

Simple parasitic life-forms that include yeasts, moulds, mushrooms, and toadstools. The fungi that are responsible for causing disease can be divided into two groups: filamentous fungi and yeasts. Filamentous fungi are made up of branching threads known as hyphae, which form a network called a mycelium. Mushrooms and toadstools are the reproductive structures (known as fruiting bodies) of a filamentous fungus that has spread in dead matter or soil. Yeasts are unicellular organisms.

**fungi and disease**

The majority of fungi are either completely harmless or actually beneficial to human health. However, there are a number of fungi that can cause illness and disease.

The fruiting bodies of some fungi contain toxins that may cause poisoning if they are eaten (see mushroom poisoning). Certain other fungi infect food crops and also produce toxins that may cause food poisoning. The best known of these fungi is a species that infects cereals and produces ergot, a toxin that constricts blood vessels. Another fungus that sometimes grows on peanuts and produces aflatoxin, a poison and carcinogen.

The inhaled spores of some fungi can cause allergic alveolitis, a persistent allergic reaction in the lungs. Farmer’s lung, which is caused by spores from mouldy hay, is an example of such a reaction. Fungal spores are sometimes responsible for various other allergic disorders, such as allergic rhinitis (hay-fever) and asthma.

Some fungi are capable of invading the body and forming colonies in various parts of the body such as the lungs, the skin, or sometimes in a variety of tissues throughout the body, leading to conditions that range from mild irritation to severe, even fatal, widespread infection (see fungal infections) and illness. For further information, see Fungal Diseases box and illness. For further information, see Fungal Diseases box and opposite. (See also candidiasis.)

**fungicidal**

A term used to describe the ability to kill fungi (see antifungal drugs).
funny-bone
A popular term for the small area at the back of the elbow where the ulnar nerve passes over a prominence of the humerus (upper-arm bone).
A blow to the nerve causes acute pain, numbness, and a tingling sensation in the forearm and hand.

furosemide
A diuretic drug used in the treatment of oedema (the accumulation of fluid in body tissues) and heart failure. Furosemide belongs to a group of drugs known as loop diuretics, which cause a rapid, temporary increase in the output of urine. When given by injection, furosemide has a very rapid effect; it may therefore be used in emergencies to relieve pulmonary oedema (a buildup of fluid around the lungs).
Furosemide increases the rate at which potassium is excreted from the body, which may cause headaches, dizziness, and muscle cramps. In order to prevent excessive potassium loss, doctors frequently give potassium supplements, or alternatively potassium-sparing diuretics, in combination with the drug.

furuncle
An alternative term for a boil.

fusidic acid
A type of antibiotic drug that is used in the treatment of a variety of bacterial infections that are resistant to penicillin drugs. Fusidic acid is commonly used in preparations applied to localized areas of skin in conditions such as impetigo. The drug is also used in eye and ear preparations.

FVC
The abbreviation for forced vital capacity. (See also forced expiratory volume.)

Fybogel
A brand name for a bulk-forming laxative drug.
G6PD deficiency

An X-linked disorder in which an abnormal gene causes a deficiency of G6PD (the enzyme glucose 6 phosphate dehydrogenase) in red blood cells. In a healthy person, this enzyme contributes to a chemical process that protects the cells from damage. G6PD deficiency makes the red cells prone to damage or destruction by infectious illness or by certain drugs or foods.

The disorder most commonly affects southern European and black men. Women are unaffected but they can carry the abnormal gene and are at risk of passing it on to their sons.

Some drugs, such as certain antimalarial drugs and antibiotics, may precipitate haemolyis (destruction of red cells) in people with the abnormal gene; see the table below for drugs that may pose this risk. In one form of G6PD deficiency, called favism, haemolyis may be triggered by a chemical in broad beans, and affected people must avoid eating them.

After taking a precipitating drug or food, or during an infectious illness, an affected person develops symptoms of anaemia (see anaemia, haemolytic), such as jaundice, fatigue, headaches, and shortness of breath (which may occur even after mild exertion).

G6PD deficiency is diagnosed with a blood test. There is no specific treatment available, but symptoms provoked by a drug or food can, however, be prevented by avoiding that substance.

GABA

The abbreviation for gamma-amino butyric acid. This chemical is a neurotransmitter (a chemical released from nerve endings that relays messages within the nervous system). GABA controls the flow of nerve impulses by blocking the release of other neurotransmitters, such as noradrenaline and dopamine, that stimulate electrical activity in the nerve cells; as a result, this activity is inhibited.

The action of GABA is enhanced by benzodiazepine drugs, anticonvulsant drugs, and possibly alcohol. In contrast, it has been suggested that people with Huntington’s disease (an inherited disorder that causes a loss of brain function and abnormal movements) suffer degeneration of GABA-secreting brain cells, leading to overstimulation of the basal ganglia (an area of the brain that helps coordinate movement) and producing the typical symptoms.

gabapentin

An anticonvulsant drug used either alone or with other anticonvulsants to treat some types of epilepsy. Common side effects include drowsiness, dizziness, unsteadiness, and fatigue.

gag reflex

An automatic impulse to retch, brought about by the autonomic nervous system in response to a particular stimulus, such as a foreign object touching the back of the throat. The reflex protects the airway from becoming blocked by debris. If a person becomes unconscious, however, the gag reflex may be lost, and the person may be at risk of choking.

gait

A term used to describe the manner or style of walking. Gait varies from one person to another. An abnormal gait, or an unusual change in the gait, may indicate a neuromuscular or brain disorder (such as Parkinson’s disease). (See also festinating gait.)

galactocoele

A breast cyst that contains milk or a milky substance. A galactocoele can be caused by obstruction of a milk duct in the breast during breast-feeding. In most cases, it occurs at the end of breast-feeding when milk is allowed to stagnate in the breast. The swelling may occasionally become infected, leading to a breast abscess. Usually, no treatment is needed; the fluid is reabsorbed, or can be expelled by massaging the breast towards the nipple.

galactokinase deficiency

A rare, inherited condition in which there is a deficiency of galactokinase, an enzyme involved in the breakdown of galactose (a simple sugar that is derived from the milk sugar lactose). Galactokinase deficiency is an autosomal recessive genetic disorder. The condition leads to a form of galactosaemia (the inability of the body to convert galactose into glucose, another simple sugar). The only manifestation of galactokinase deficiency galactosaemia is cataracts, which usually become apparent in affected babies within the first few weeks of life.

galactorrhoea

The spontaneous, persistent production of breast milk by a woman who is not pregnant or breast-feeding, or, very rarely, by a man. Lactation (milk production) is initiated by a rise in the level of prolactin, a hormone produced by the pituitary gland. Galactorrhoea is caused by excessive secretion of prolactin due to a pituitary tumour or to another endocrine disorder, such as hypothyroidism. It may also be caused by some antipsychotic drugs.

As well as triggering breast milk production, excess prolactin may adversely affect the ovaries, causing amenorrhoea (absence of menstrual periods) or

</table>

*These drugs do not usually cause problems in the type of G6PD deficiency that affects black people.
infertility. If the underlying cause is a pituitary tumour, there may be symptoms associated with the tumour, such as headaches and visual disturbances.

Treatment with bromocriptine suppresses prolactin production, but the underlying cause of the disorder may also require treatment.

galactosaemia
A rare, inherited condition in which the body is unable to convert galactose (a simple sugar that is derived from the milk sugar lactose) into glucose (another simple sugar) due to the absence of a particular enzyme (a protein that acts as a catalyst to speed up a reaction) in the body. The diagnosis is confirmed by urine and blood tests. An affected person must avoid milk products, and use lactose-free milk, throughout life.

Galactosaemia causes no symptoms at birth, but jaundice, diarrhoea, and vomiting may develop after a few days, and the baby fails to gain weight. If untreated, the disorder may result in liver disease, cataracts (opacities in the lenses of the eyes), and learning difficulties.

The great majority are mixed. The formation of gallstones results from middle age onwards, an increasing occurrence of gallstones may sometimes give rise to symptoms.

The digestive system can function normally without a gallbladder, and its removal has few known long-term adverse effects.

Metabolic disorders
The principal disorder, with which most other gallbladder problems are associated, is the formation of gallstones. Every year thousands of people develop gallstones. Women are affected up to four times as often as men, depending on their age and ethnicity. The formation of gallstones results from a metabolic problem in which the chemical composition of bile (the digestive juice stored in the gallbladder) is altered. There are three main types of gallstone: stones formed from the fatty substance cholesterol; stones made from bile pigments; and mixed gallstones, which contain both cholesterol and pigments. The great majority are mixed.

Gallbladder
A small, muscular, pear-shaped sac, situated just beneath the liver, in which bile is stored and concentrated.

Bile, which is produced by the liver, enters the gallbladder via the hepatic and cystic ducts. When food passes from the stomach into the duodenum (the first part of the small intestine), gastrointestinal hormones make the gallbladder contract. This causes it to release the bile, via the common bile duct, into the duodenum, where it aids the breakdown of fats contained in the food. (See also biliary system.)

gallbladder cancer
A rare cancer that occurs mainly in the elderly. It is usually associated with gallstones, but affects only a tiny proportion of those people with gallstones. Gallbladder cancer may cause jaundice and tenderness in the abdomen, but it is often symptomless.

The diagnosis is confirmed by ultrasound scanning. Treatment is by surgical removal of the tumour, but if the cancer has spread to the liver by the time it is detected, the outlook is poor.

DISORDERS OF THE GALLBLADDER
The gallbladder rarely causes problems in childhood or early adulthood but, from middle age onwards, an increasing occurrence of gallstones may sometimes give rise to symptoms.

The digestive system can function normally without a gallbladder, and its removal has few known long-term adverse effects.

Metabolic disorders
The principal disorder, with which most other gallbladder problems are associated, is the formation of gallstones. Every year thousands of people develop gallstones. Women are affected up to four times as often as men, depending on their age and ethnicity.

The formation of gallstones results from a metabolic problem in which the chemical composition of bile (the digestive juice stored in the gallbladder) is altered. There are three main types of gallstone: stones formed from the fatty substance cholesterol; stones made from bile pigments; and mixed gallstones, which contain both cholesterol and pigments. The great majority are mixed. Only about 20 per cent of affected people experience symptoms or complications; many carry “silent” gallstones, producing no symptoms. Attempts by the gallbladder to expel the stone or stones, however, can cause severe biliary colic (abdominal pain).

Infection and inflammation
If a gallstone lodges in the gallbladder outlet, trapped bile may irritate and inflame the lining, and bile may become infected. This disorder is called acute cholecystitis. The first symptom may be biliary colic, followed by fever and abdominal tenderness.

Repeated attacks of biliary colic and acute cholecystitis can lead to chronic cholecystitis, in which the gallbladder becomes shrunken and thick-walled and ceases to function. Rarely, it may become inflamed when no gallstones are present: a condition called acalculous cholecystitis.

Cholecystitis can proceed to empyema, in which the gallbladder fills with pus; a high fever and severe abdominal pain may result.

Congenital and genetic defects
Abnormalities that may be present from birth include absence of the gallbladder, an oversized gallbladder, or two gallbladders. These defects, however, rarely cause problems.

Tumours
Gallbladder cancer usually occurs in a gallbladder that contains gallstones. This cancer is, however, extremely uncommon compared to the high prevalence of gallstones.

Other disorders
In rare cases where the gallbladder is empty and a stone obstructs its outlet, the gallbladder may become distended and filled with mucus secreted by its lining. A gallbladder with this problem is known as a mucocele.

INVESTIGATION
Gallbladder problems are investigated by physical examination and imaging techniques such as ultrasound scanning, radionuclide scanning, or cholecystography. Blood tests may also be carried out.
gallium
A metallic element whose radioactive form is used in radionuclide scanning (a technique using a tiny amount of a radioactive substance to obtain images of internal organs). Gallium is injected into the bloodstream before a scan in order to reveal areas of inflammation, such as those that occur in cancers, abscesses, osteomyelitis, and sarcoidosis.

gallstone ileus
See ileus, gallstone.

gallstones
Lumps of solid matter found in the gallbladder (the sac under the liver where bile is stored) or in the bile ducts (which connect the gallbladder and liver to the duodenum). Most gallstones are made of cholesterol and bile pigments from the breakdown of red blood cells.

CAUSES AND INCIDENCE
Gallstones develop due to a disturbance in the chemical composition of bile. They are rare in childhood and become increasingly common with age. Women are affected more than men. Risk factors for developing gallstones include a high-fat diet and being overweight.

SYMPTOMS
Most gallstones cause no symptoms. Any symptoms often begin when a stone lodges in the gallbladder outlet. This problem causes biliary colic (intense pain in the upper right area of the abdomen or between the shoulderblades), nausea, and sometimes indigestion and flatulence. Possible complications include cholecystitis (inflammation of the gallbladder) and bile duct obstruction.

DIAGNOSIS AND TREATMENT
Gallstones are usually diagnosed by ultrasound scanning, X-ray oral cholecystography, or cholangiography.

Stones that are not causing symptoms are usually left alone. In other cases, the gallbladder and stones may be surgically removed by cholecystectomy. Ultrasonic shock waves (see lithotripsy) are sometimes used to shatter gallstones; the fragments pass into the intestines and cause no further problems. Drugs such as ursodeoxycholic acid can dissolve some gallstones if taken over several months, but further stones may form once the treatment is stopped.

gamete
A sex cell. Gametes are found in the reproductive systems of adults: sperm are formed in the testes in males, and an ovum (egg cell) is released approximately every month from the ovaries in females. Sperm and ovum come together during fertilization to create offspring. (See also meiosis.)

gamete intrafallopian transfer (GIFT)
A technique for assisting conception (see infertility) in women. It can only be used if a woman has functioning fallopian tubes. In GIFT, ova (eggs) are removed from the woman’s ovary during laparoscopy (viewing of the interior of the abdomen) and mixed with sperm in the laboratory. The mixed eggs and sperm are introduced into one of the fallopian tubes, where fertilization takes place. A fertilized egg may then become implanted in the uterus.

Gamgee tissue
The brand name for a material consisting of a thick layer of highly absorbent cotton wool enclosed in gauze. Gamgee tissue may be used for padding and compression of soft-tissue injuries, but may also be used on open wounds, such as ulcers, to aid the healing process by applying compression and soaking up body fluids.

gamma aminobutyric acid
See GABA.

gamma camera
A piece of equipment used to generate diagnostic images in radionuclide scanning. A tiny amount of a radioactive substance is introduced into the body (usually by injection) and taken up by the tissues to be examined. The gamma camera detects radiation emitted by the material and displays its pattern of distribution as an image on a monitor.

gamma-globulin
A substance that contains antibodies against a specific infection. Injections of gamma-globulins provide temporary protection against diseases such as chickenpox and tetanus. (See immunization; immunoglobulin injections.)

gamolenic acid
An essential fatty acid found in evening primrose oil and starflower (borage) oil. Gamolenic acid may be taken for premenstrual syndrome and eczema. Very large doses may cause abdominal pain and loose stools.

ganciclovir
An antiviral drug that is used to treat severe cytomegalovirus infection. Such a condition occurs in those people whose immune system is impaired or suppressed because they have AIDS, they are taking immunosuppressant drugs, or have had an organ transplantation.

Ganciclovir is toxic and produces a range of side effects, including nausea; diarrhoea; abdominal pain; weakness; and suppression of blood cell formation in the bone marrow. For this reason, it is used only when the benefits are likely to outweigh the risks.

ganglia
The plural form of ganglion.

ganglion
A group of nerve cells that have a common function; for example, the basal ganglia in the brain are concerned with the control of muscular movements.

The term is also used to describe a fluid-filled swelling associated with the sheath of a tendon. A ganglion may disappear spontaneously; if necessary, it may be drained or removed surgically.

gangrene
Death of tissue, usually caused by loss of the blood supply. Gangrene may affect a small area of skin or a large portion of a limb.

SYMPTOMS AND TYPES
Pain is felt as the tissues are dying, but once dead they become numb. The affected tissue turns black. There are two types of gangrene: dry and wet.

In dry gangrene, the tissue dies as it has no blood supply. The gangrene does not spread. Dry gangrene may be caused by arteriosclerosis, diabetes mellitus, thrombosis, frostbite, or an embolism.

Gangrene of the foot
This shows a gangrenous foot, with areas of dead tissue and blackening of the skin on the big toe.
Wet gangrene develops when an area of dry gangrene, or a wound, becomes infected by bacteria. Redness, swelling, and oozing pus may occur around the blackened tissues. The gangrene spreads, and the area gives off an unpleasant smell. A virulent type called gas gangrene is due to a bacterium that destroys muscles and produces a foul-smelling gas.

**Treatment**
Treatment of dry gangrene involves attempting to improve the circulation to the affected area before the tissues die. Antibiotic drugs can prevent wet gangrene from setting in.

To treat wet gangrene, amputation of the affected part and the surrounding tissue may be necessary.

**Ganser’s syndrome**
A rare factitious disorder in which an individual seeks, either consciously or unconsciously, to mislead others about his or her mental state and may simulate symptoms of psychosis.

**Gardnerella vaginalis**
A bacterium that is often found in the vaginal discharge of women with bacterial vaginosis.

**gargle**
A liquid preparation to wash and freshen the mouth and throat. Some gargles contain antiseptics or local anaesthetics to relieve sore throats.

**gargoylism**
Another name for Hurler’s syndrome, in which the facial features are coarsened.

**gas-and-air**
A mixture of nitrous oxide and oxygen that is mainly used for temporary pain relief in emergencies or during labour.

**gas gangrene**
A rare but life-threatening form of gangrene (tissue death), usually due to infection by the bacterium *Clostridium perfringens*. This organism thrives in anaerobic environments, where there is little or no oxygen, such as dying tissue.

Gas gangrene develops suddenly and normally occurs at the site of a recent, serious wound. The bacteria multiply in the damaged tissue, producing toxins that release a gas, and spread incredibly rapidly to healthy tissue.

The affected area is swollen and painful, and pale or reddish-brown in colour. Gas collects in the tissues, causing a crackling sensation if the area is pressed. Other symptoms that develop early in the infection include sweating, fever, and anxiety. If left untreated, the condition may lead to shock (failure of blood circulation), kidney failure, coma, and even death.

**Penicillin drugs** destroy the bacteria at the edges of the gangrene, but all of the diseased tissue needs to be surgically removed. Amputation of an affected limb may be required, in some cases, to control the spread of infection. Hyperbaric oxygen treatment, in which the patient is exposed to oxygen at high pressure, may help to kill the bacteria.

**Gastrectomy**
Removal of the whole stomach (total gastrectomy) or of part of the stomach (partial gastrectomy). Total gastrectomy is used to treat some stomach cancers. Partial gastrectomy used to be a treatment for peptic ulcers (ulcers of the stomach or duodenum) but has largely been replaced by drug treatment.

A person who has had a gastrectomy may experience fullness and discomfort after meals. Possible postoperative complications include the regurgitation or vomiting of bile, which may lead to inflammation of the stomach or the oesophagus; diarrhoea; and dumping syndrome (sweating, nausea, dizziness, and weakness after meals, due to food leaving the stomach too quickly). Other complications include malabsorption (a reduced ability to absorb nutrients), which may lead to anaemia or osteoporosis (loss of bone density). After a total gastrectomy, patients cannot absorb vitamin B₁₂ and need injections of the vitamin for the rest of their lives.

**Gastric erosion**
A break in the surface layer of the membrane that lines the stomach. Gastric erosions occur in some cases of gastritis (inflammation of the stomach lining). Many result from ingestion of irritants such as alcohol, iron tablets, or aspirin. The physical stress of serious illness, injuries such as burns, or major surgery may also cause erosions to develop.

Often there are no symptoms, but erosions may bleed, causing vomiting of blood or blood in the faeces. Persistent loss of blood may lead to anaemia.

Gastric erosions are diagnosed by gastroscopy (inspection and examination of the stomach via a flexible viewing instrument; an endoscope).

They usually heal in a few days when treated with antacid drugs, H₂-receptor antagonists, or proton pump inhibitors (see ulcer-healing drugs). Drugs that block the production of stomach acid are often given to people who are at high risk of developing erosions, such as those receiving intensive care.

**Gastric lavage**
See lavage, gastric.

**Gastric ulcer**
A raw area in the stomach wall caused by a breach of the lining (see gastric erosion) that penetrates into the tissues. A gastric ulcer is a type of peptic ulcer (ulcer of the stomach or duodenum).

**Gastrin**
A hormone produced by cells in the stomach lining. Gastrin causes the stomach to release in emergency or during labour. A mixture of anaesthetics contain antibiotics. Amputation of the affected part and the surrounding tissue may be necessary.

**Gastrointestinal hormones**

**Gastritis**
Inflammation of the stomach lining due to irritation of the tissues. The condition may be acute or chronic.

Acute gastritis may be due to infection with the *Helicobacter pylori* bacterium. It may also be caused by drugs, usually nonsteroidal anti-inflammatory drugs such as aspirin; alcohol; or severe physical stress, such as burns or major surgery.

Chronic gastritis is most often due to *H. pylori* infection but may be due to prolonged irritation by smoking, alcohol, or bile; by an autoimmune disorder that damages the stomach lining (see anaemia, megaloblastic); or by degeneration of the lining with age.

Symptoms include discomfort in the upper abdomen, nausea, and vomiting. In acute gastritis, the faeces may be blackened by blood lost from the stomach (see melena); in chronic gastritis, slow blood loss may lead to anaemia (see anaemia, iron-deficiency), resulting in symptoms such as pallor, tiredness and breathlessness.

Diagnosis of gastritis is made through gastroscopy (examination of the stomach lining with a flexible viewing instrument), during which a biopsy (removal of a tissue sample for analysis) may be performed. Ulcer-healing drugs and antibiotics may be prescribed to treat *H. pylori* infection. Anaemia will be treated. There is no treatment for gastritis due to an autoimmune disorder, however.
gastroenteritis

Inflammation of the stomach and intestines, usually causing sudden upsets that last for two or three days. Dysentery, typhoid fever, cholera, food poisoning, and travellers’ diarrhoea are all forms of gastroenteritis. Gastroenteritis may be caused by a variety of bacteria, bacterial toxins, viruses, and other organisms in food or water. There are also a number of non-infectious causes, such as food intolerance and certain irritant drugs.

The usual symptoms are appetite loss, nausea, vomiting, cramps, and diarrhoea. Their onset and severity depend on the cause; symptoms may be mild, or may be so severe that dehydration, shock, and collapse occur.

Mild cases usually require rest and rehydration therapy only. For severe illness, treatment in hospital may be necessary, with fluids given by intravenous infusion. Antibiotic drugs may be given for some bacterial infections, but others need no specific treatment.

gastroenterology

The study of the digestive system and the diseases and disorders that affect it.

gastroenterostomy

Surgery that is performed to create a connection between the stomach and the jejunum (the middle two thirds of the small intestine), sometimes combined with a partial gastrectomy (the removal of the lower part of the stomach). The operation, formerly carried out to treat duodenal ulcer (see peptic ulcer), is now rarely performed.

gastrointestinal hormones

A group of hormones released from specialized cells in the stomach, pancreas, and small intestine that control various functions of the digestive organs. Gastrin, secretin, cholecystokinin, and vasoactive intestinal poly peptide are the best known of these hormones (see Hormones in the digestive tract), but new hormones are still being discovered.

gastrointestinal tract

The part of the digestive system consisting of the mouth, oesophagus, stomach, and intestines. These structures together form a long tube through which food passes as it is digested.

gastro-oesophageal reflux disease (GORD)

The medical term for acid reflux.

HORMONES IN THE DIGESTIVE TRACT

Hormones released from endocrine cells in the stomach, pancreas, and intestine aid digestion by stimulating the release of bile from the gallbladder and enzymes from the pancreas into the duodenum.

**Gastrin**

Secreted mainly by cells in the stomach in response to eating food (especially protein), gastrin causes the stomach to produce more acid and stimulates contraction of muscle in the wall of part of the stomach, ileum, and colon. This contraction propels food through the digestive tract.

**Secretin**

Secreted by the lining of the duodenum in response to acid entering from the stomach, secretin acts on the pancreas to increase the output of bicarbonate, which neutralizes acid from the stomach. It also increases the release of enzymes from the pancreas.

Gastroscopy

Examination of the stomach via a flexible endoscope (a viewing instrument) inserted through the mouth. The oesophagus and duodenum (the first part of the small intestine) are also inspected; for this reason, the procedure is more accurately called an oesophagogastroduodenoscopy. The patient is often sedated throughout.

Gastroscopy is used to investigate bleeding, or other disorders, of the oesophagus, stomach, or duodenum. Attachments to the gastroscope enable a biopsy (removal of a tissue sample for analysis) to be carried out, as well as treatments such as laser treatment. A gastroscope may also be used to ease the passage of a gastric feeding tube through the skin (see gastrostomy).

Gastrostomy

A surgically created opening in the stomach (see gastrostomy). The condition is treated by regular injections of the missing enzyme.

gauze

An absorbent, open-weave fabric, usually made of cotton. Sterilized gauze is often used to clean wounds, or applied as a dressing to soak up fluids from wounds. It is not used on areas of damaged tissue such as burns or ulcers, because it may stick to the surface and dislodge new tissue when it is removed.

gavage

Feeding of liquids through a nasogastric tube, which is passed into the stomach through the nose (see feeding, artificial).

The term “gavage” can also refer to hyperalimentation (treating a patient by feeding beyond appetite requirements).

gel

A jelly-like suspension consisting of small, insoluble particles that are dispersed through a liquid. Gels are often

---

GASTROENTERITIS
used as bases for topical skin treatments, particularly those that are used on the face and scalp.

gemfibrozil
A drug that lowers the level of fats in the blood. Gemfibrozil is usually given to people with hyperlipidaemia after dietary measures have failed to reduce blood fat levels. It may cause nausea and diarrhoea, and should not be taken by people with liver disease.

gender identity
An individual's inner feeling of masculinity or femaleness. Gender identity is not necessarily the same as biological sex. It is fixed within the first two to three years of life and is reinforced during puberty; once established, it cannot usually be changed.

A minority of people have persistent feelings of discomfort about their sexual identity. This condition is called gender dysphoria; in the most severe cases, a person may feel that he or she is the wrong sex (see transsexualism).

gene
A particular area of DNA, the material within cells that governs the physical characteristics, development, and functioning of an individual. DNA is a very long, chain-like structure that exists in the nucleus of a cell. Each strand has about 30,000 pairs of genes, arranged on 23 pairs of chromosomes. All body cells (except egg and sperm cells) contain identical sets of genes because they are all derived, by a process of division, from a single fertilized egg.

During growth and cell repair, cells divide to form two identical new cells, each containing a full set of genes (see mitosis). Gametes (cells involved in reproduction), however, undergo a different form of division, called meiosis; as a result, they contain just one gene from each pair, so that each parent contributes half of the genetic material used to form an offspring.

GENE FUNCTION
Each gene controls or influences a specific feature or process in the body. Genes act by directing the manufacture of specific proteins (see What genes are and what they do, overleaf). Many proteins are involved in forming body structures, or in regulating particular chemical processes (see enzyme). Certain proteins, however, are made solely to influence other genes by switching them “on” or “off”. The genes that make these regulatory proteins are called control genes.

The whole complex process of development and growth is regulated by the sequential switching “on” and “off” of particular genes. The activities of control genes also determine the specialization of cells. Within any cell, some genes are active and others are idle, according to the cell’s particular function; for example, nerve cells and liver cells will have different sets of active and idle genes. If the control genes are disrupted, however, cells lose their specialist abilities and multiply out of control; this is the probable mechanism by which cancers develop (see carcinogenesis; oncogenes).

GENE MUTATION
Occasionally, when new cells are formed, a fault occurs in the copying process, leading to a mutation (change). The mutant gene is then passed on each time the cell subsequently divides. Disorders that result from such mutant genes are known as genetic disorders.

ALLELES
The gene at any particular location on a chromosome can exist in any of various forms, called alleles. If the effects of a specific allele mask those of the allele at the same location on its partner chromosome, that allele is described as dominant; the masked allele is recessive. (See also genetic code; inheritance.)

gene mapping
A process by which the location of particular genes on each chromosome is determined. In some cases, gene location gene can be found by certain tests.
WHAT GENES ARE AND WHAT THEY DO

Genes are units of DNA (the material that controls the body’s growth, structure, and functions) contained in every cell. They exert their effects by directing the manufacture of proteins. All of a person’s genes come from his or her parents. The physical differences between people, such as in eye, hair, and skin colour, arise from slight differences in gene structure.

DNA PRINTOUT

Through painstaking laboratory research, the exact structure of many genes is now known.

DNA base sequence
This printout shows a small part of the sequence in the gene that codes for the protein trypsin, a digestive enzyme.
Alternatively, the positions of genes that are close to one another on one chromosome (and so are usually passed on together) may be found by a process called linkage analysis. The information is shown as a diagram of a chromosome with the gene locations marked on it.

**general anaesthetic**
See anaesthesia, general.

**generalized anxiety disorder**
A psychiatric illness characterized by chronic and persistent apprehension and tension that has no particular focus. There may also be various physical symptoms such as trembling, sweating, lightheadedness, and irritability.

The condition can be treated with psychotherapy, antidepressants, or with drugs such as beta blockers or sedatives that relieve symptoms but do not treat the underlying condition. (See anxiety; anxiety disorders.)

**general paralysis of the insane**
An outdated term describing the mental and physical deterioration of untreated or unsuccessfully treated syphilis.

**general practice**
The term used in the UK for the provision of personal medical care outside a hospital setting. Doctors who provide it are called general practitioners (GPs). This form of health-care is now more commonly known as primary care.

**generic drug**
A medicinal drug that is marketed under its official medical name (its generic name) rather than under a patented name (its brand name). Most drugs are now prescribed under their generic names.

**gene therapy**
A treatment in which copies of a normal gene are inserted into the DNA of a person's cells to help fight cancer or to counter the effects of a faulty gene.

Gene therapy is most likely to be successful in the treatment of autosomal recessive diseases (see Disorders due to single gene defects), such as cystic fibrosis, which are caused by a pair of defective genes. When a normal copy of the gene is introduced into the body, it overrides the abnormal ones and corrects the condition. It is less successful, however, in treating autosomal dominant disorders, such as Huntington’s disease, in which a faulty gene...
overides a normal one. In these cases, the abnormal gene must be removed and is then replaced by a normal copy.

The copies of the normal gene can be introduced into the body in various ways. In one technique, a person’s white blood cells are grown in a culture with a retrovirus containing the normal gene and then reintroduced into the body, where they multiply. An alternative method, currently being tried to treat cystic fibrosis, involves packaging normal DNA in tiny liposomes, which are added to an aerosol spray. The spray is inhaled and the liposomes bind to the walls of cells in the lung tissue and the normal gene is activated.

Research is also being carried out to assess the potential of gene therapy in treating cancer. In certain forms of cancer, a gene called p53 (which controls programmed cell death) is faulty, allowing cells to multiply uncontrollably to form a tumour. The introduction of a normal p53 gene may prompt the death of these abnormal cells.

**genetically modified foods**
Food or food constituents that are derived from plants whose genetic material has been deliberately altered in order to modify certain characteristics. In genetic modification, DNA is isolated from one organism and inserted into the DNA of another (the recipient).

The procedure is intended to be beneficial; for example, transferred DNA may enable recipient plants to be more resistant to pests, which is likely to increase crop yields. There may also be disadvantages, however. Ecological and health concerns about GM foods are the subjects of ongoing debate.

**genetic code**
The inherited instructions, contained in genes, that specify the activities of cells and thereby the development and functioning of the body. Each gene in a chromosome contains the coded instructions for a cell to make a protein that has a specific function in the body.

The DNA that makes up genes consists of two long, intertwined strands, each comprising a sequence made up of four chemicals called nucleotide bases (see nucleic acids). These four bases are adenine, thymine, cytosine, and guanine (often abbreviated to A, T, C, and G). They are joined in pairs (base-pairs), thus linking the two strands of the DNA molecule. The sequence of these bases along the DNA strands makes up the genetic code. During protein synthesis, RNA (ribonucleic acid) is used to help read this code and create the protein.

**genetic counselling**
Medical guidance offered to people who have a known risk of having a child with a genetic disorder, such as cystic fibrosis, or who are at increased risk of developing a genetic disorder themselves. The counsellor will examine individual and family medical histories and, in some cases, arrange for tests such as chromosome analysis and genetic probes.

Genetic counselling enables people to make informed decisions about their future, particularly parenthood. If there is a significant risk of a couple having an affected child, doctors may be able to offer pre-implantation genetic testing with in vitro fertilization (see embryo diagnosis), or antenatal diagnosis, to optimise the chances of their having a healthy child. If parents already have an affected child, genetic counselling will provide information on the outlook for that child.

**genetic disorders**
Any disorder caused, wholly or partly, by one or more faults in a person’s DNA. Genetic disorders may be congenital (present at birth) or may become apparent later in life. Many of them are familial (shared by various people in the same family). A child may, however, be born with a genetic disorder when there is no previous family history.

A genetic disorder can occur in two different ways: one or both parents have a defect in their own genetic material that is then inherited by the child, or a mutation occurs during the formation of the ovum or sperm cell.

The disorders fall into three broad categories: chromosomal abnormalities, single gene defects, and multifactorial defects. Chromosomal abnormalities involve a child having an abnormal number of whole chromosomes (as in Down’s syndrome), or extra or missing bits of chromosomes. Single gene defects are rare, and are caused by one abnormal gene or pair of genes. Multifactorial disorders are thought to be due to the effects of several genes combined with environmental influences.

**SINGLE GENE DEFECTS**
There are two main forms of single gene defect. In sex-linked disorders, the defective gene is carried on one of the sex chromosomes – almost always the X chromosome. In autosomal disorders, the defective gene is carried on one of the other 44 chromosomes. These disorders are subdivided into autosomal dominant and autosomal recessive disorders. See Disorders due to single gene defects (previous page) for examples.

Another, rare group of single gene defects involves the mitochondrial DNA, which exists outside the nuclei.

**X-linked recessive disorders**
The most common type of sex-linked disorder, X-linked recessive disorders are caused by a defective gene on an X chromosome. Haemophilia and colour blindness (see colour vision deficiency) are this type.

Women have two X chromosomes; men have only one, inherited from their mothers. When a woman inherits one defective gene, its effect is masked by the normal gene on her other X chromosome and she has no abnormality. She is, however, capable of passing the gene on to her children, and is called a carrier. On average, carriers transmit the defective gene to half their sons, who are affected, and to half their daughters, who become carriers. In males, therefore, the mothers of their sons both have a 50 per cent chance of passing the defective gene on to their children.

**autosomal dominant disorders**
In these conditions, the defective gene is dominant in relation to the equivalent normal gene, so only one copy needs to be present in order to cause an abnormality. People who have an autosomal dominant disorder carry one normal copy and one defective copy of the affected gene, and are termed heterozygotes. Affected people have a 50 per cent chance of passing the defective gene on to their children.

**autosomal recessive disorders**
The defective gene that causes an autosomal recessive disorder is recessive in relation to the normal gene, so two faulty copies of the gene are required to cause an abnormality. People who have the disorder carry two identical defective copies of the gene, and are called homozygotes. In most cases, both parents of an affected individual are heterozygotes: they carry one copy of the defective gene and one copy of the normal gene.

**MITOCHONDRIAL DISORDERS**
In rare cases, a defect in a specific area of mitochondrial DNA causes diseases.
Such disorders include certain myopathies (muscle disorders), neuropathies (nerve disorders), and some cases of degeneration of the retina, and deafness. These disorders are always passed on from the mother, because sperm cells have very few or no mitochondria.

**MULTIFACTORIAL DISORDERS**
A wide range of disorders, including asthma, diabetes mellitus, and most forms of hyperlipidaemia are thought to result from the cumulative effects of several faulty genes, together with environmental factors. The pattern of inheritance in these disorders is less straightforward than that in chromosomal abnormalities or single gene defects.

**genetic drift**
Chance fluctuation in gene frequency within a finite, isolated sample of a population over a number of generations. The chance of random variation increases as the population size decreases because, in a large population, the random nature of the transmission of alleles (various forms of a gene at a particular location) will tend to average out.

**genetic engineering**
A branch of genetics concerned with the alteration of genetic material in an organism in order to produce a desired change in the organism’s characteristics. Genetic engineering has mainly been used to mass-produce a variety of substances that are useful in medicine.

A gene responsible for making a useful protein is identified and isolated. It is then inserted into “host” cells (most commonly bacteria or yeast); this altered DNA is called recombinant DNA. The host cells reproduce rapidly to form a colony of cells containing the gene. This colony produces the protein in large amounts. The human hormones insulin and growth hormone and proteins, such as factor VIII (used to treat haemophilia), are made in this way. Genetic engineering is also used in gene therapy.

**genetic fingerprinting**
A technique that can be used to demonstrate relationships between people (for example in paternity testing) or, in forensic investigations, to identify a suspect.

DNA contains a genetic code (“genetic fingerprint”) that is unique to each individual, except in the case of identical twins. DNA can be extracted from any material containing body cells, such as blood or semen. Its code can then be analysed in comparison with that of a sample from another person, or from the scene of a crime.

**genetic probe**
A specific fragment of DNA used in laboratory tests to determine whether a particular genetic defect is present in a person’s DNA. The probe contains the same structure as the abnormal gene and, when added to a sample of the person’s DNA, will bind to that gene if it is present. A radioactive or fluorescent marker may be added to the probe so that it can easily be detected.

Genetic probes are mainly used in antenatal diagnosis of genetic disorders, and in determining whether people with a family history of a genetic disorder carry the defective gene themselves (see familial screening).

**genetics**
The study of inheritance (the transmission of characteristics from one generation of an organism to the next). Genetics involves determination of the chemical basis for inheritance of particular characteristics, and investigating the causes of similarities and differences between individuals of a particular species or between different species.

Branches of human genetics include population genetics, which studies the relative frequency of various genes in different human races; molecular genetics, which is concerned with the structure, function, and copying of DNA; and clinical genetics, which is concerned with the study and prevention of genetic disorders.

**genetic screening**
See familial screening.

**genital herpes**
See herpes, genital.

**genitalia**
The reproductive organs, especially those that are external. The male genitalia include the penis, testes (situated within the scrotum), prostate gland, seminal vesicles, and associated ducts, such as the epididymis and vas deferens. The female genitalia include the ovaries, fallopian tubes, uterus, vagina, clitoris, vulva, and Bartholin’s glands.

**genitalia, ambiguous**
A group of conditions, also known as intersex, in which an individual’s external sex organs are not clearly male or female, or in which the organs appear to be those of the opposite chromosomal sex. Cases of ambiguous genitalia may result from an abnormality of the sex chromosomes or a hormonal genitalia (see hermaphroditism; sex determination; adrenal hyperplasia, congenital).

**genital phase**
A term used in psychoanalytic theory to refer to a stage of a person’s psychosexual development. The genital phase begins at around the ages of 3–5 years. (See also anal phase; oral phase.)

**genital ulcer**
An eroded area of skin on the genitalia. There are various possible causes. The most common cause of genital ulcers is a sexually transmitted infection, particularly genital herpes (see herpes, genital) or syphilis. Chancroid and granuloma inguinale are tropical bacterial infections that cause genital ulcers. Lymphogranuloma venereum is a bacterial infection (Chlamydia) producing genital blisters. Behçet’s syndrome is a rare condition that causes tender, recurrent ulcers in the mouth and on the genitals. Cancer of the penis or vulva may first appear as a painless ulcer with raised edges.

**genital warts**
See warts, genital.

**genito-urinary medicine**
The branch of medicine concerned with sexually transmitted infections and their effects on the body.

**genome, human**
The complete set of human genetic material. The human genome consists of 23 chromosomes, which, together, contain about 30,000 genes. All cells (except for egg and sperm cells) contain two sets of the 23 chromosomes, one inherited from the father and the other from the mother.

The Human Genome Project, an international research programme, was launched in 1990 with the aim of identifying all the genes in the human body. The project was finally completed in the year 2003.

**genotype**
The entire genetic makeup of an individual, or group of related individuals, as opposed to the individual’s observable characteristics (see phenotype). The term is also used to describe the set of
alleles (any of various forms of a gene) at a specific location within a chromosome; the genetic information carried by alleles determines a particular characteristic of that organism.

gentamicin
An antibacterial drug given by injection to treat serious infections such as meningitis and sepsis (blood poisoning). Gentamicin can result in damage to the kidneys or the inner ear if the dosage is not carefully controlled.

The drug is also used in various eye and ear-drops but is unlikely to cause serious side effects when taken in these types of preparation.

gentian violet
A purple dye used to make bacteria visible under a microscope. Gentian violet was also formerly used as an antiseptic.

genu valgum
The medical term for knock-knee.

Genu varum
The medical term for bowleg.

Geriatric medicine
The medical speciality concerned with the care of elderly people, also known as “care for the elderly”. This group require specialist medical care because they respond to illness and treatment in a different way from younger people. Physical and mental decline due to aging can mean that illnesses are more severe in older people, and people may have two or more diseases at once. In addition, the liver and kidneys become less efficient at breaking down and excreting drugs, so drug dosages for elderly people must be carefully controlled to avoid dangerous side effects.

Geriatric medicine relies on an integrated team of health-care workers, including a doctor (or a specialist called a geriatrician), nurse, physiotherapist, and occupational therapist. This team helps older people to maintain independence and health, and to cope after illness or injury. (See also rehabilitation.)

germ
The popular term used to describe any microorganism that causes disease, such as viruses and bacteria.

German measles
The common name for the viral infection rubella.

germ cell
An embryonic cell with the potential to develop into a spermatozoon or ovum. The term also describes a gamete (mature sex cell) or any cell that is undergoing gametogenesis (the process by which gametes are formed).

germ cell tumour
A growth comprised of immature sperm cells in the male testis or of immature egg cells (see ovum) in the female ovary. A seminoma is one type of germ cell tumour (see testis, cancer of).

Gerontology
The study of developmental, biological, medical, psychological, and sociological aging. (See also geriatric medicine.)

Gerstmann’s syndrome
A neurological disorder involving a writing disability such asagraphia, together with the inability to understand mathematical calculations, to distinguish right from left, and to identify the fingers (a type ofagnosia). Many sufferers also experienceaphasia (complete loss of language skills). The syndrome may occur after a stroke or damage to the left parietal lobe of the brain, but the precise cause is unknown.

Gerstmann–Straussler syndrome
A rare, inherited type of human spongiform encephalopathy, the group of degenerative brain disorders to which Creutzfeldt–Jakob disease belongs. Gerstmann–Straussler syndrome is believed to be caused by infection with a prion (slow virus).

The disease is characterized by ataxia (loss of balance) and dementia and is not usually evident before early adulthood. It progresses more slowly than Creutzfeldt–Jakob disease, but there is no cure, and death usually occurs within three to five years.

Gestalt theory
A school of psychology that emphasizes the viewing of personal experiences as a whole rather than breaking them down into collections of stimuli and responses. Gestalt therapy aims to increase self-awareness by looking at all aspects of a person in his or her environment.

Gestation
The period that lasts approximately nine months between conception and the birth of a human baby; it is the time during which the infant develops in the uterus. (See also embryo; fertilization; fetus; pregnancy.)

gestational diabetes
Diabetes mellitus that develops during pregnancy, usually clearing up after delivery (see diabetic pregnancy).

gestodene
A progestogen drug that is used with the oestrogen drug ethinylestradiol in low-strength combined oral contraceptives. Gestodene is reported to carry a slightly increased risk of venous thromboembolism (the blockage of a blood vessel by a fragment of a blood clot) in comparison with older drugs.

Ghon’s tubercle
An abnormal area in the lung, also known as a Ghon’s focus, that is produced by infection with tuberculosis in a person who has not previously been exposed to the disease. Often, a Ghon’s tubercle heals without causing symptoms, but in some cases it may result in tuberculosis that spreads via the lymphatic system, in the bloodstream, or in the air sacs of the lungs. A healed tubercle may become calcified, and may be discovered during a routine chest X-ray.

Gianotti–Crosti syndrome
A characteristic, harmless response of the skin to certain viral infections, including hepatitis B infection, Epstein Barr virus (see mononucleosis, infectious), and coxsackievirus. In this condition, a papular (lumpy) rash develops on the face, buttocks, and limbs and lasts for several weeks. The condition mainly affects children between the ages of six months and twelve years.

Symptoms and signs
There may be no noticeable symptoms. Alternatively, there may be a mild temperature, and swelling of the lymph nodes in the armpits and groin that persists for some months. The liver may become enlarged.

Diagnosis and treatment
Blood tests and liver function tests are carried out to investigate liver function and detect possible causative viruses. There is no specific treatment, but a mild, topical corticosteroid cream may be prescribed for itching. The rash usually fades in two to eight weeks.

giant cell arteritis
An alternative name for temporal arteritis.
giardiasis
An infection of the small intestine caused by the protozoan (single-celled) parasite Giardia lamblia. Giardiasis is spread by eating or drinking contaminated food or water or through direct contact with an infected person.

SYMPTOMS
Most of those infected have no symptoms. If, however, symptoms do occur, they begin between one and three weeks after infection. They include diarrhoea, and wind, as well as faeces that are foul-smelling, greasy, and tend to float in the toilet. Abdominal discomfort, cramps, and swelling, loss of appetite, and nausea may also occur. In some cases, giardiasis may become chronic.

DIAGNOSIS AND TREATMENT
The infection is diagnosed from microscopic examination of a faecal sample or by a jejunal biopsy (removal of a small sample of tissue from the middle section of the small intestine for analysis).

Acute giardiasis usually clears up without treatment but the drug metronidazole quickly relieves symptoms and helps to prevent the spread of infection. Infection can be prevented in the first place by avoiding food or water that could possibly be contaminated.

gibbous
A term meaning “humped”, as in a gibbous spine, which curves outwards (see kyphosis). A deformity called a gibbus (an extreme hunch in the back) was once a common condition caused by tuberculosis of the spine.

giddiness
See dizziness.

GIFT
See gamete intrafallopian transfer.

gigantism
Excessive growth (especially in height) during childhood or adolescence that results from overproduction of growth hormone by a tumour of the pituitary gland (see pituitary tumours). If untreated, the tumour may compress other hormone-producing cells in the gland, causing symptoms of hormone deficiency (see hypopituitarism).

People with gigantism may be treated with a drug that blocks the release of growth hormone, such as bromocriptine, or they may have to have surgery or radiotherapy to remove or destroy the pituitary tumour. (See also acromegaly.)

Gilles de la Tourette’s syndrome
A rare inherited neurological disorder that is transmitted by an autosomal dominant gene (see genetic disorders).

Gilles de la Tourette’s syndrome is more common in males and starts in childhood with repetitive grimaces and tics. Involuntary barks, grunts, or other noises may appear as the disease progresses. In some cases, the sufferer has episodes of compulsively using foul language (a condition called coprolalia).

People with Tourette’s syndrome usually have it their whole lives; in some sufferers antipsychotic drugs may help to relieve some of the symptoms.

Gilbert’s disease
A common inherited condition that affects the way in which bilirubin is processed by the liver. Usually there are no symptoms, but jaundice may be brought on by unrelated illnesses. Sufferers are otherwise healthy and no treatment is necessary.

gingivectomy
The surgical removal of part of the gum margin. Gingivectomy may be used to treat severe cases of gingival hyperplasia (thickening of the gums) or to remove pockets of infected gum in advanced cases of periodontitis (gum disease). Gingivectomy is usually performed by a dentist under local anaesthesia.

gingivitis
Inflammation of the gums. Gingivitis is usually due to a build-up of plaque around the base of the teeth. Toxins produced by bacteria in the plaque irritate the gums, causing them to become infected, swollen, tender, and reddish-purple in colour. Gingivitis may also result from injury to the gums, usually through rough toothbrushing or flossing. Pregnant women and people with diabetes mellitus are especially susceptible to the disorder.

Gingivitis can be reversed; good oral hygiene is the main method of preventing and treating it. If left untreated, however, it may lead to damage of the gum tissue, which may in turn lead to chronic periodontitis (an advanced stage of gum disease). Acute ulcerative gingivitis (see gingivitis, acute ulcerative) may develop in people who have chronic gingivitis, particularly those with a lowered resistance to infection.
gingivitis, acute ulcerative

Painful infection and ulceration of the gums. Acute ulcerative gingivitis is uncommon, primarily affecting people aged between 15 and 35. It is caused by abnormal overgrowth of bacteria that usually exist harmlessly in small numbers in gum crevices. Predisposing factors include poor oral hygiene, smoking, throat infections, and stress. In many cases, the disorder is preceded by gingivitis or periodontitis.

The gums become sore and bleed easily. Crater-like ulcers, which bleed spontaneously, develop on the gum tips between teeth. There may be a foul taste in the mouth, bad breath, and swollen lymph nodes (see glands, swollen). The infection may spread to the lips and the inside of the cheeks (see noma). A hydrogen peroxide mouthwash can relieve the inflammation. Scaling is then performed to remove plaque. In severe cases, the antibacterial drug metronidazole may be given to control infection.

Example of gingivitis

The gums around the bases of the upper teeth are puffy, shiny, and tender and overhang the teeth margins. Affected gums often bleed when brushed.

gingivostomatitis

Inflammation of the gums and mouth. Gingivostomatitis is often due to a viral infection, particularly herpes simplex. The condition can also be due to a bacterial infection or an adverse reaction to a prescribed drug. (See also cold sore.)

gland

A group of specialized cells that manufacture and release chemical substances, such as hormones and enzymes.

There are two main types of gland: endocrine and exocrine. Endocrine glands do not have ducts and release their secretions directly into the bloodstream; examples include the pituitary, thyroid, and adrenal glands. Exocrine glands have ducts and release their secretions to the surface or interior of the body. Examples include the sebaceous glands, which secrete sebum onto the surface of the skin, and the salivary glands, which secrete saliva into the mouth. The pancreas releases endocrine and exocrine secretions (for example insulin and cholecystokinin, respectively).

Lymph nodes are sometimes called glands, particularly when they are enlarged due to infection (see glands, swollen). Strictly speaking, this is incorrect usage because lymph nodes do not secrete chemicals.

glanders

An infection of horses caused by the bacterium Pseudomonas mallei. It rarely affects humans. Symptoms include fever and general aches and pains. Skin ulcers may develop and, if bacteria enter the lungs, pneumonia may occur. In severe cases, septicaemia (blood poisoning) may follow. Treatment is with antibiotics.

glands, swollen

Enlargement of the lymph nodes (which are commonly called “glands”), due to inflammation and/or proliferation of white blood cells within them. Swollen lymph nodes are a common symptom, especially in children. They are usually caused by a minor infection or an allergic reaction (see allergy).

Rare causes include cancer affecting the lymph nodes (see Hodgkin’s disease; lymphoma) or cancer of the white blood cells (see leukaemia).

glandular fever

See mononucleosis, infectious.

glans

The head of the penis. The glans is covered by a loose fold of skin called the prepuce (foreskin), which retracts when the penis becomes erect; in some males, this skin is removed by circumcision.

The term “glans” may also be applied to the tip of the clitoris in females.

Glanzmann–Riniker syndrome

A severe, inherited immunodeficiency disorder (failure of the body’s immune system to fight infection). The condition is more common in males. Inheritance is either autosomal recessive or X-linked (see genetic disorders).

In Glanzmann–Riniker syndrome, the blood contains virtually no B-lymphocytes (a type of white blood cell) and, as a result, antibodies (proteins produced by B-lymphocytes to destroy invading microorganisms) fail to form.

The condition is evident from early infancy, when an affected child fails to thrive. It is characterized by absence of the thymus (a gland that forms part of the immune system) and susceptibility to bacterial, and viral infections. Symptoms and signs include watery diarrhoea and lung abscesses. Children do not normally survive beyond the first two years of life.

glare

The discomfort that results from bright light entering the field of vision (see eye) either directly or by reflection from another surface, such as a computer screen or a stretch of water. The light hits the retina and reduces central vision.

glasses

Devices, worn on the face, that contain lenses to correct focusing errors in the eyes and thereby achieve clear vision.

Lenses are made of glass or plastic, and the shape and thickness of a lens are chosen during a vision test. Convex lenses (which curve outwards) are needed for hypermetropia, or longsightedness, and
concave lenses (which curve inwards) for myopia, or shortsightedness (see Why glasses are used box, right). Most lenses are single-vision, but bifocal, trifocal, and varifocal lenses are becoming popular. Tinted lenses protect the eyes from sunlight. (See also bifocal; contact lenses.)

glass eye
See eye, artificial.

glass test
A test for meningitis that involves pressing a clear glass against a rash. If the rash remains visible through the glass, it may be a form of purpura (leaking of blood beneath the skin), which sometimes occurs in meningitis.

glaucoma
A condition in which the intraocular pressure (fluid pressure inside the eyes) causes impaired vision. Aqueous humour (watery fluid) is secreted into the front of the eye by the ciliary body (a structure behind the iris) to maintain the eye’s shape and nourish the tissues. Excess fluid drains away at the edge of the iris. In glaucoma, however, this excess fluid may not be able to escape. It causes compression and obstruction of the blood vessels that supply the retina and the optic nerve. This, in turn, may destroy nerve fibres and cause gradual loss of vision.

TYPES, CAUSES, AND SYMPTOMS
The most common form of glaucoma is chronic simple (open-angle) glaucoma. It rarely occurs before the age of 40, and tends to run in families. In this condition, the outflow of aqueous humour is gradually blocked over a period of years, causing a slow rise in pressure. There are often no symptoms until visual loss is advanced.

In acute (closed-angle) glaucoma, the outflow of aqueous humour is rapidly blocked, and the pressure rises suddenly. This may cause a severe, dull pain in and above the eye, fogginess of vision, and the perception of haloes around lights at night. Nausea and vomiting may occur, and the eye may become red with a dilated pupil.

Congenital glaucoma is due to an abnormality in the drainage angles of the eyes that develops before birth. Glaucoma can also be caused by injury or an eye disease such as uveitis or lens dislocation.

A less common form, called normal-pressure or low-tension glaucoma, occurs in people whose intraocular pressure is normal or only slightly raised but causes

WHY GLASSES ARE USED
Glasses compensate for certain visual defects in which the lens of the eye does not focus light correctly on to the retina, at the back of the eyeball. For hypermetropia (longsightedness) or presbyopia, convex (or plus) lenses are needed. Myopia (shortsightedness) requires concave (or minus) lenses.

LONGSIGHTEDNESS
Before correction
Longsightedness occurs when focusing power is inadequate. Light from distant objects is focused on to the retina, but light from close objects is focused behind it.

After correction
Convex magnifying (or plus) lenses cause light rays to converge (bend together). As a result, they focus the light from close objects correctly on to the retina.

SHORTSIGHTEDNESS
Before correction
The focusing power of the eye is too great. Light from close objects is focused correctly; however, light from distant objects is focused in front of the retina, and the objects appear blurred.

After correction
Concave weakening (or minus) lenses cause light rays to diverge (bend apart). As a result, they focus the light from distant objects correctly on to the retina.

ASTIGMATISM
In astigmatism, the surfaces of the cornea, rather than being a hemisphere as normal, are steeper in one direction than in the others; as a result, the light rays in one meridian (plane) are out of focus. Lenses to correct astigmatism are designed with additional curvature in one meridian, then set accurately in the frame of the glasses so that the steepest curves correspond to the flattest meridian of the cornea. As a result, they cancel out the effects of the distortion in the cornea. Both concave and convex lenses can be designed to correct astigmatism.
GLEASON’S SCORE

Acute closed-angle glaucoma
This type of glaucoma is caused by an unduly narrow angle between the iris and the back of the peripheral cornea. Dilation of the pupil may therefore lead to a sudden complete blockage of the outflow, which, in turn, causes a rapid increase in pressure in the eyeball.

DIAGNOSIS AND TREATMENT
Tonometry is used to check for glaucoma by measuring the pressure within the eye. Ophthalmoscopy may show depression of the head of the optic nerve due to the increase in pressure. Tests of the visual field will be needed to assess whether vision has already been damaged, because longstanding or severe glaucoma can result in loss of peripheral vision (see tunnel vision). Prompt treatment is essential to prevent permanent loss of vision.

Chronic simple glaucoma can usually be controlled with eye-drops, such as timolol, or tablets that reduce pressure in the eye. Treatment needs to be continued for life. If drugs are ineffective, surgery or laser treatment can unblock the drainage channel at the edge of the iris or create an artificial channel.

Acute glaucoma requires emergency drug treatment, often in hospital. Surgery or laser treatment may be needed in order to prevent a further attack. The usual procedure is iridectomy, in which a small opening is made at the edge of the iris so that aqueous humour can drain more easily.

Treatment for normal-pressure glaucoma is the same as for open-angle glaucoma, but is aimed at reducing the intraocular pressure to an even lower level than normal.

Gleason’s score
A system of grading prostate cancer cells (see prostate, cancer of) to determine the most appropriate treatment and the patient’s outlook.

Several tissue samples are taken and are assigned a score between 1 and 5. The lowest and highest scores are added together to give the Gleason’s score, which is a number between 1 and 10. A low Gleason’s score indicates that the cancer cells are very similar to normal prostate cells; a high score means that the cancer cells are very different. In general, the more the cancerous cells diverge from the normal prostate cells, the more serious the cancer.

The Gleason’s score is often used in conjunction with a measure called the TNM classification, which defines the extent to which a cancer has spread.

glenoid
A term meaning “resembling a pit or socket”. For example, the glenoid fossa (depression) is the cavity at the top of the scapula (shoulderblade) into which the head of the humerus (the bone of the upper arm) fits.

glioblastoma multiforme
A fast-growing and highly cancerous type of primary brain tumour. Glioblastoma multiforme is a type of glioma that often develops in the cerebrum (the main mass of the brain). The cause is unknown. Treatment of glioblastoma multiforme may include surgery, radiotherapy, and/or chemotherapy.

glioma
A type of brain tumour arising from connective tissue (glial cells) in the brain. Types of glioma include astrocytoma, glioblastoma multiforme, ependymoma, medulloblastoma, and oligodendrogloma. Symptoms, diagnosis, and treatment are as for other types of brain tumour.

Brain scan of a glioma
In this scan, taken from below, a glioma (a type of brain tumour) is visible as a dark area in the right hemisphere (on the left of the image).

glipizide
An oral hypoglycaemic drug (see hypoglycaemias, oral) used to treat type 2 diabetes mellitus. Glibizide acts by stimulating the pancreas into increasing its production of insulin. Side effects are usually mild and infrequent, but dizziness and drowsiness may occur. Rarely, glibizide can cause an abnormal reaction of the skin to sunlight and can reduce blood sodium levels. Low blood sugar (see hypoglycaemia) may occur if the drug is not taken with sufficient food.
**globular**

A term used of a disorder affecting an entire body function or system. For example, global aphasia (see aphasia) is the loss of all ability to speak, write, or understand language; global paralysis is extreme weakness of the muscles in every part of the body, which may result in a complete inability to move.

**globin**

The protein that combines with certain iron-containing compounds to form the oxygen-carrying pigments haemoglobin, which is found in red blood cells, and myoglobin, which is present in muscle.

**globulin**

Any of a group of proteins that are insoluble in water but soluble in dilute salt solutions. There are many globulins in the blood, including immunoglobulins (also called antibodies).

**globus hystericus**

A condition in which there is an uncomfortable feeling of a “lump in the throat”. This lump is felt to interfere with swallowing and breathing; however, there is no physical basis for the condition. In severe cases, hyperventilation (rapid breathing) and symptoms of a panic attack ensue.

Globus hystericus occurs most commonly in people who are anxious or depressed. Treatment is by reassurance, breath-control training, or psychotherapy.

**glomerulonephritis**

Inflammation of the filtering units (see glomerulus) in both kidneys. Damage to the glomeruli hampers the removal of waste products, salt, and water from the bloodstream, which may cause serious complications. This condition occurs worldwide; in the US and Europe, it is one of the most common causes of chronic kidney failure.

**CAUSES**

Some types of glomerulonephritis are caused by the immune system making antibodies to eliminate microorganisms (usually infectious bacteria, such as those that cause streptococcal infections of the throat). The antibodies combine with bacterial antigens to form particles called immune complexes. These particles circulate in the bloodstream and become trapped in the glomeruli, triggering an inflammatory process that may damage the glomeruli and prevent them from working normally.

Glomerulonephritis also occurs in certain autoimmune disorders, such as systemic lupus erythematosus. Infectious diseases such as malaria and schistosomiasis are causes in tropical countries.

**SYMPTOMS**

Mild glomerulonephritis may cause no symptoms, and it may only be discovered during routine urine testing; alternatively, the condition may remain undetected until the kidney damage has reached an advanced stage and accumulated waste products have started to produce symptoms.

Some people develop symptoms suddenly. They may experience a dull ache over the kidneys. The urine may become bloodstained because when damaged the glomeruli allow red blood cells to escape into the urine. Protein may also be lost into the urine, causing oedema (see nephrotic syndrome); this is a common condition in affected children. Hypertension (high blood pressure) is a potentially serious complication. Long-term glomerulonephritis is a common cause of chronic kidney failure.

**DIAGNOSIS AND TREATMENT**

Diagnosis involves kidney function tests, urinalysis (the microscopic and chemical analysis of urine), and, in most cases, kidney biopsy (removal of a small tissue sample for microscopic analysis).

Treatment for glomerulonephritis is usually given in hospital, and depends on the cause and the severity of the disease. Children with nephrotic syndrome usually respond to corticosteroid drugs.

Glomerulonephritis caused by a streptococcal infection usually clears up after the infection is successfully treated with antibiotic drugs.

Adults tend to respond less well to treatment, but kidney failure may sometimes be prevented or delayed. Drugs may be prescribed to control hypertension, and a special diet may be given to reduce the workload on the kidneys. Temporary dialysis may be necessary to help remove waste products from the blood, and diuretic drugs may be given to help treat any oedema.

A few people with severe glomerulonephritis respond to treatment with immunosuppressant drugs (which reduce the activity of the immune system); others may undergo plasmapheresis (a procedure that removes immune complexes and other harmful substances from the bloodstream).
glomerulosclerosis
Scarring caused by damage to the glomeruli (see glomerulus), the filtering units of the kidney.
Mild glomerulosclerosis occurs as a normal part of the aging process. The condition may also occur in some severe types of glomerulonephritis. In addition, it may be associated with diabetes mellitus, hypertension (high blood pressure), AIDS, or intravenous drug abuse.

glomerulus
A filtering unit in the kidney. Each glomerulus consists of a cluster of capillaries (tiny blood vessels) enclosed in a capsule and supplied with blood from the renal artery; it forms part of a larger filtering unit called a nephron. Filtered blood eventually leaves the kidney via the renal vein. (See also glomerulonephritis; glomerulosclerosis.)

glomus tumour
A small, bluish swelling in the skin, usually on a finger or toe near or under the nail. The swelling feels tender and is more painful if the limb is hot or cold. Glomus tumours are caused by an overgrowth of the nerve structures that normally control blood flow and temperature in the skin. They are harmless but can be surgically removed.

glossectomy
Removal of all or part of the tongue. Glossectomy may be performed to treat tongue cancer. If a large part of the tongue is removed, speech is impaired and eating is difficult.

glossitis
Inflammation of the tongue. The tongue feels sore and swollen and looks red and smooth; adjacent parts of the mouth may also be inflamed.
Glossitis occurs in various forms of anaemia and in vitamin B deficiency. Other causes include infection of the mouth (especially by herpes simplex), irritation by dentures, and excessive use of alcohol, tobacco, or spices.
Treatment is for the underlying cause. Rinsing of the mouth with a salt solution and good oral hygiene may help to relieve the soreness.

glossodynia
A painful, burning sensation in the tongue, often with no known cause. Glossodynia tends to disappear of its own accord over time.

glossolalia
Speaking in an imaginary language that has no actual meaning or syntax. (See also neologism.)

glossopharyngeal nerve
The ninth cranial nerve. This nerve supplies the tongue and the throat, and performs both sensory and motor functions. It conveys sensations, especially taste, from the back of the tongue, regulates the secretion of saliva by the parotid gland, and controls movement of the throat muscles.

glottis
The part of the larynx (voice-box) that consists of the vocal cords and the slit-like opening between them.

**glucagon**
A hormone that stimulates the breakdown of stored glycogen into glucose (a simple sugar). Glucagon is released by the pancreas when the blood level of glucose is low (see feedback). Glucagon is used as an injected drug in the emergency treatment of people with diabetes mellitus who are unconscious as a result of hypoglycaemia (low blood glucose). Nausea and vomiting are occasional adverse effects.

glucagonoma
A tumour of the pancreas that secretes glucagon (the hormone responsible for raising blood sugar levels). Glucagonomas, which can be cancerous or noncancerous, may lead to attacks of hyperglycaemia (high blood glucose) due to excess glucagon production.

glucocorticoids
A group of corticosteroid hormones, produced by the cortex (outer layer) of the adrenal glands, that affect the chemical breakdown of carbohydrates by increasing both the blood sugar level and the amount of glycogen stored in the liver. Glucocorticoids also enable the body to respond effectively to physical stress. Both natural and synthetic glucocorticoids are used to treat inflammatory conditions (see corticosteroid drugs). The main glucocorticoid is hydrocortisone, also called cortisol.

gluconeogenesis
A process in which glucose (a simple sugar) is synthesized from sources other than carbohydrates, such as amino acids and glycerol. The process, which occurs mainly in the liver and muscles, is an important source of energy when insufficient amounts of carbohydrate are available (for example, between meals or when a person is fasting).

glucosamine
A molecule that occurs naturally as a component of various substances in the body, including cartilage and collagen. Glucosamine is also sold as a food supplement and is recommended to relieve symptoms of arthritis.

**glucose**
A simple sugar (monosaccharide) that is naturally present in fruits and is also a product of the digestion of starch and sucrose. Glucose is the chief source of energy for the body and is carried to all tissues in the circulation. (The term “blood sugar” refers to levels of glucose in the bloodstream.)
The level of glucose in the blood is normally kept fairly constant by the actions of various hormones, notably insulin, glucagon, adrenaline, corticosteroid hormones, and growth hormone. An abnormally high level of glucose in the blood (known as hyperglycaemia) may cause glucose to be lost into the urine. An abnormally low blood glucose level is called hypoglycaemia.
**glue ear**
Accumulation of fluid in the cavity of the middle ear, causing impaired hearing. Persistent glue ear is most common in children. It is often accompanied by enlarged adenoids and frequently occurs with viral respiratory tract infections, such as the common cold. It is usual for both ears to be affected.

In glue ear, the lining of the middle ear becomes overactive, producing large amounts of a sticky fluid, and the eustachian tube (which links the middle ear to the back of the nose and throat) becomes blocked so that the fluid cannot drain away. The accumulated fluid interferes with the movement of the delicate bones of the middle ear.

Glue ear is sometimes first detected by hearing tests. Examination with an otoscope (viewing instrument) can confirm the diagnosis.

Mild cases of the condition often clear up without specific treatment. If symptoms persist, the insertion of grommets (small tubes) may be necessary, which allows air into the middle ear and encourages fluid to drain away. Adenoidectomy (removal of the adenoids) may also be required.

**glue-sniffing**
See solvent abuse.

**glutaraldehyde**
A topical (applied to the skin) preparation for the treatment of warts, especially plantar warts (verrucas). Glutaraldehyde may cause a rash or irritation and may stain the skin brown.

**gluteal**
A term meaning “relating to the buttocks”, as in the gluteal muscles.

**gluten**
A combination of gliadins and glutenins (types of proteins) present in wheat, rye, and barley. Mixed with water, flours containing gluten become sticky and trap air, thus forming dough. Sensitivity to gluten causes coeliac disease.

**gluten enteropathy**
See coeliac disease.

**gluten intolerance**
See coeliac disease.

**gluteus maximus**
The large, powerful muscle in each of the buttocks that gives them their rounded shape. The gluteus maximus is responsible for moving the thigh sideways and backwards.

**glycerol**
A colourless, syrupy liquid that has a sweet taste. Glycerol is an essential constituent of triglycerides (simple fats) in the body. It may also be prepared commercially from fats and oils. Glycerol is added to moisturizing creams to help prevent dryness and cracking of the skin. It is also used in eardrops to help soften earwax, and in cough remedies to help soothe a dry, irritating cough. Furthermore, glycerol is added to rectal suppositories; it relieves constipation by softening hard faeces.

**glyceryl trinitrate**
A vasodilator drug used for the treatment and prevention of symptoms of angina pectoris (chest pain due to inadequate blood supply to the heart). Sublingual or buccal sprays and tablets are available for rapid pain relief and slow-release tablets or skin patches for sustained pain relief. The drug is sometimes prescribed to treat anal fissures but is not licenced for this use. High doses may cause headaches, flushing, and dizziness.

**glycogen**
The main form of carbohydrate stored in the body. Glycogen is a polysaccharide, consisting of chains of glucose molecules, and is found mainly in the liver and in muscles.

When there is excess glucose in the blood, it is converted to glycogen by the action of insulin and glucocorticoids (a class of corticosteroid hormones). When the blood glucose level is low, glycogen is converted back to glucose (regulated by adrenaline and glucagon) and released into the bloodstream.

**glycogen storage diseases**
A group of rare genetic disorders characterized by an absence or deficiency of certain enzymes (proteins that act as catalysts) responsible for the metabolism of glycogen. These enzyme defects may lead to abnormal concentrations of glycogen in the tissues, insufficient glucose (a simple sugar) in the blood, or the inability of the body to use glucose as energy. Also known as glycogenoses or GSDs, these diseases may affect the liver, the muscles, or both.
GLYCOSEURIA

TYPES AND CAUSES
There are several types of GSD. One is glycogen storage disease type I. This condition is caused by a defect in glucose-6-phosphatase, an enzyme that aids gluconeogenesis in the liver. The majority of GSDs have an autosomal recessive pattern of inheritance: they occur when a child inherits the affected gene from parents who are carriers.

SYMPTOMS AND SIGNS
These features vary according to the particular type of GSD. Symptoms and signs may include failure to grow normally during childhood; muscle cramps and wasting; an enlarged liver; and low blood glucose levels.

DIAGNOSIS, TREATMENT, AND OUTLOOK
Diagnosis may involve biochemical tests (see biochemistry) on tissue samples from a muscle or a liver biopsy.

Some types of GSD can be controlled by management of symptoms, including diet control. In certain cases a liver transplant is an option, but in other cases no treatment is possible and death occurs in the first few years of life.

Glycosuria
The presence of glucose in the urine. Glycosuria results from failure of the kidneys to reabsorb glucose back into the bloodstream after the blood has been filtered to remove waste products.

Failure to reabsorb sufficient glucose may be due to hyperglycaemia (an abnormally high blood glucose level), as in diabetes mellitus. It may also occur if the kidney tubules have been damaged (for example, through drug poisoning) and thus cannot reabsorb even normal amounts. In addition, glycosuria may occur during pregnancy, but is usually not serious provided that the blood glucose level is normal and there are no other symptoms.

Glycosuria is diagnosed by testing the urine (see urinalysis). The treatment depends on the cause.

Glycosylated haemoglobin
A form of haemoglobin that is bound to the sugar glucose. In most people, between three and eight per cent of haemoglobin is glycosylated. In people with diabetes mellitus, the level of glycosylated haemoglobin may be raised if treatment has not kept the blood glucose level within the normal range.

Glycosylated haemoglobin levels indicate blood glucose levels over the preceding three months.

GM foods
See genetically modified foods.

gnathic
Pertaining to the jaw, as in gnathitis (inflammation of the jaw).

goitre
Enlargement of the thyroid gland, visible as a swelling at the base of the neck.

CAUSES
The thyroid gland may enlarge (without any disturbance of its function) at puberty, during pregnancy, or in women taking oral contraceptives. In many parts of the world the main cause of a goitre is a dietary deficiency of iodine, an element that the thyroid needs in order to produce thyroid hormone. This form of the condition is called endemic goitre.

A condition called toxic goitre develops as a result of thyrotoxicosis in Graves’ disease and in certain other forms of hyperthyroidism (overactivity of the thyroid gland). A goitre is also a feature of different types of thyroiditis (inflammation of the thyroid gland), including Hashimoto’s thyroiditis and De Quervain’s thyroiditis. Other causes include a tumour or nodule in the gland and, in rare cases, thyroid cancer.

There are also various types of familial goitre. This kind of goitre is caused by an inherited thyroid disorder; it appears during childhood and is often associated with signs of hypothyroidism, such as learning difficulties.

SYMPTOMS
A goitre can range in size from a barely noticeable lump to a large swelling, depending on the cause. Large goitres may press on the oesophagus or the trachea and therefore make swallowing or breathing difficult.

Appearance of goitre
The thyroid gland can become enlarged for a variety of reasons, including dietary deficiency of iodine, inflammation, or an autoimmune disorder affecting the gland.

DIAGNOSIS AND TREATMENT
Diagnosis may involve various thyroid-function tests, including blood tests and radionuclide scanning, to determine the activity of the thyroid gland.

A goitre that is not due to disease may eventually disappear of its own accord. Goitre due to iodine deficiency can be treated by iodine-rich foods. When a goitre is the result of disease, treatment is for the underlying disorder. Large goitres can be surgically removed (see thyroidectomy).

gold
A precious metal. Certain compounds containing gold are used to treat severe rheumatoid arthritis and, occasionally, arthritis arising as a complication of psoriasis (see disease-modifying antirheumatic drugs).

Gold is used in a form called sodium aurothiomalate, given as intramuscular injections, or is taken orally (see auranofin). A common adverse effect of gold treatment is dermatitis (skin inflammation). Gold may result in damage to the kidneys, liver, and bone marrow and may also cause loss of appetite, nausea, and diarrhoea.

Goldberg–Maxwell syndrome
A common form of male pseudohermaphroditism (a biological intersex condition in which the external genitalia of a genetic male resemble those of a female). Affected individuals have testes but have a small penis and a divided scrotum that resembles labia. (See also sex determination.)

Goldenhar’s syndrome
A rare, congenital type of dysplasia (growth abnormality) in which the head and face fail to develop normally before birth. Common features include missing or abnormally developed ears and malformations of the jaw, mouth, palate, eyes, and vertebrae.

golfer’s elbow
A condition caused by overuse of the forearm muscles that bend the wrist and fingers, usually due to activities such as using a screwdriver or playing golf with a faulty grip. The injury leads to inflammation of the epicondyle (bony prominence) on the inner part of the elbow, where the affected muscles are attached. Symptoms include pain and tenderness of the elbow and sometimes also the forearm.
Treatment consists of resting the elbow, applying ice-packs, and taking analgesic drugs (painkillers). Severe or persistent pain may be relieved by local injections of a corticosteroid drug.

**gonadal dysgenesis**
Defective development of the **gonads** (the testes and ovaries). Gonadal dysgenesis is a feature of **Turner's syndrome**.

**gonadorelin**
A medicinal version of gonadotrophin-releasing hormone (GnRH), which is naturally released by the hypothalamus. GnRH stimulates the nearby pituitary gland to secrete the two **gonadotrophin hormones** follicle-stimulating hormone (FSH) and luteinizing hormone (LH).

Gonadorelin can be given by injection. It is used to investigate suspected disease of the hypothalamus.

Gonadorelin analogues are synthesized forms of, and closely resemble, gonadorelin. They cause the hypothalamus to release less GnRH, and this effect leads to a reduction in the levels of FSH and LH. Gonadorelin analogues are used to counter the effects of natural hormones during gonadorelin treatment of infertility. The drugs are also used to treat **endometriosis** and hormone-dependent cancers including breast cancer and prostate cancer.

**gonadotrophin hormones**
Hormones that stimulate cell activity in the **ovaries** and **testes**. Gonadotrophins are essential for fertility. The most important are follicle-stimulating hormone (FSH) and luteinizing hormone (LH), secreted by the pituitary gland. Another gonadotrophin, HCG (see **gonadotrophin, human chorionic**), is produced by the placenta in pregnancy.

Certain gonadotrophins are used as drugs in the treatment of infertility.

**gonadotrophin, human chorionic**
A hormone produced by the **placenta** in early pregnancy. Human chorionic gonadotrophin (HCG) stimulates the ovaries to produce **oestrogen** and **progesterone**, which are necessary for a healthy pregnancy. HCG may also be produced in nonpregnant women by a **choriocarcinoma** (a cancerous tumour of the uterus), and by some testicular tumours (see **testis**, **cancer of**). in men.

HCG is excreted in the urine; the detection of HCG levels in urine forms the basis of pregnancy tests. HCG extracted from the urine of pregnant women is given by injection to treat certain types of infertility. It may help to induce ovulation in women who have not been ovulating, and, in men, it may increase sperm production. HCG is occasionally given to prevent miscarriage in women whose production of progesterone is deficient.

**gonads**
The sex glands: the testes (see **testis**) in men and the ovaries (see **ovary**) in women. The activities of the gonads, both male and female, are regulated by **gonadotrophin hormones**, which are released by the pituitary gland.

**gonorrhoea**
One of the most common sexually transmitted infections. Gonorrhoea is widespread throughout the world.

**CAUSES AND INCIDENCE**
Gonorrhoea, which is caused by the bacterium **Neisseria gonorrhoeae**, is most often transmitted during sexual activity, including oral and anal sex. An infected woman may also transmit the disease to her baby during childbirth.

**SYMPTOMS AND SIGNS**
Gonorrhoea has an incubation period of between two and ten days. In men, symptoms include a discharge from the urethra and pain on passing urine. Many infected women have no symptoms; if symptoms are present, they usually consist of a vaginal discharge or a burning sensation on passing urine.

Infection acquired through anal sex can cause gonococcal **proctitis** (inflammation of the rectum and anus). Oral sex with an infected person may lead to gonococcal **pharyngitis**, which sometimes causes a sore throat. A baby exposed to the infection during birth may acquire the eye infection gonococcal **ophthalmia**.

**COMPLICATIONS**
Untreated gonorrhoea may spread to other parts of the body. In men, it may cause **prostatitis** (inflammation of the prostate) or **epididymo-orchitis** (inflammation of a testis and the chamber where sperm mature), affecting fertility. In women, it causes pelvic inflammatory disease, which may damage the fallopian tubes. This problem increases the risk of later ectopic pregnancy and may lead to infertility. Gonococcal bacteria in the bloodstream may result in **septicaemia** or **septic arthritis**.

**DIAGNOSIS AND TREATMENT**
Tests are performed on a sample of discharge or on swabs taken from the urethra, cervix, or rectum in order to confirm the diagnosis.

Gonorrhoea is treated with **antibiotic drugs**. Treatment is effective but does not protect against reinfection; in addition, bacterial resistance to antibiotics is an increasing problem. The patient’s recent sexual contacts will need to be tested to establish whether or not they are also infected (see **contact tracing**).

**Goodpasture’s syndrome**
A rare autoimmune disorder (in which the body’s immune system attacks its own tissues) causing inflammation of the glomeruli (see **glomerulus**) in the kidneys and the alveoli (tiny air sacs) in the lungs, as well as **anaemia**. Goodpasture’s syndrome is a serious disease; unless treated early it may lead to life-threatening bleeding into the lungs and progressive **kidney failure**. It is most common in young men, but can develop at any age and in women.

Goodpasture’s syndrome may respond to treatment with **immunosuppressant drugs** and **plasmapheresis** (a procedure for removing unwanted antibodies from blood plasma). People who have severe or repeated attacks of the disorder require **dialysis** (a technique for removing waste products from the blood) and, ultimately, a **kidney transplant**.

**GORD**
The abbreviation for gastro-oesophageal reflux disease (see **acid reflux**).

**goserelein**
A synthetic drug chemically related to the hypothalamic hormone **gonadorelin**. Goserelein is used to treat **breast cancer**, **prostate cancer**, **fibroids**, infertility, and **endometriosis**. Adverse effects of goserelein include loss of bone density after prolonged application.

**gout**
A common metabolic disorder that causes attacks of **arthritis**, usually in a single joint (often the base of the big toe). Gout is due to high levels of uric acid in the blood (see **hyperuricaemia**); the arthritis is due to the deposition of uric acid crystals in joint tissue.

The affected joint is red, swollen, and extremely tender. Attacks last for a few days and often recur. They are sometimes accompanied by fever. With recurrent
attacks, more joints may be involved, and there may be constant pain due to joint damage from chronic inflammation. In addition, gout may be associated with kidney stones (see *calculus, urinary tract*) or, rarely, with kidney damage due to the deposition of crystals in the kidney tissue.

The diagnosis is confirmed by tests on blood or fluid from the affected joint to measure uric acid levels.

The pain and inflammation of acute (of sudden onset) attacks can be controlled by *nonsteroidal anti-inflammatory drugs* (NSAIDs) or by *colchicine*. If these drugs are ineffective, *a corticosteroid drug* may be injected into the joint. Many people require no further treatment.

Long-term treatment with drugs that help to lower urate levels, such as *allopurinol* or *sulfipyrazone*, can stop or reduce the frequency of recurrent attacks. These drugs, however, may trigger an attack at the start of treatment, so are initially prescribed with NSAIDs.

**Graefe’s sign**

Lagging of the upper eyelid (see *lid lag*) as it follows the downward rotation of the eyeball in *Graves’ disease*.

**grafting**

The process of transplanting healthy tissue from one part of the body to another (autografting) or from one person to another (allografting). Tissue transplantation from an animal to a person (xenografting) is also carried out.

Grafting is used to repair or replace diseased, damaged, or defective tissues or organs. Common operations of this type are *skin graft*, *bone graft*, *bone marrow transplant*, *corneal graft*, *kidney transplant*, *heart transplant*, *liver transplant*, *heart–lung transplant*, *heart-valve surgery*, and *microsurgery* on blood vessels and nerves.

**COMPLICATIONS**

With autografting, the grafted tissue is usually assimilated well into the surrounding tissue at the new site.

There is a risk of tissue rejection following other forms of grafting. The only exceptions are grafts between identical twins, because the tissue match exactly, and corneal grafting, because the cornea has no blood supply and therefore no white blood cells and antibodies to act as a defence system against the foreign cells.

To overcome rejection, as close a match as possible between the tissues of recipient and the tissues of donor is sought (see *tissue-typing*). The recipient is given *immunosuppressant drugs* to suppress the body’s natural defences. (See also *transplant surgery*.)

**graft-versus-host disease**

A complication of a *bone marrow transplant* in which certain *immune system* cells, called killer *T-lymphocytes*, in the transplanted marrow attack the tissues of the recipient.

Graft-versus-host (GVH) disease may occur soon after transplantation or may take some months to appear. The first sign is usually a skin rash. This may be followed by diarrhoea, abdominal pain, *jaundice*, *inflammation* of the eyes and mouth, and breathlessness. Most people with GVH recover within a year, but about one in five may eventually develop fatal complications.

GVH disease can usually be prevented by giving *immunosuppressant drugs* to all transplant patients. If, despite prophylactic treatment, the disease develops, it can be treated with *corticosteroid drugs* and immunosuppressant drugs such as *cyclosporin*. In some cases, however, it can be difficult to control.

**DIAGNOSIS**

Gout is suspected if an attack of arthritis affects a single joint. A blood test is usually performed; a high level of uric acid will suggest gout. Examination of fluid from the joint may confirm the diagnosis.

**GOUT**

Gout is a common joint disease, affecting 10 times more men than women. In men it may occur at any time after puberty; in women it usually occurs only after the menopause. There is often a family history of the disorder. Hyperuricaemia (excess uric acid in the blood) leads to the formation of uric acid crystals inside joints. Crystals may also be deposited in the soft tissues in the ears and around tendons.

**DIAGNOSIS**

Gout is suspected if an attack of arthritis affects a single joint. A blood test is usually performed; a high level of uric acid will suggest gout. Examination of fluid from the joint may confirm the diagnosis.

**GOUT**

Gout is a common joint disease, affecting 10 times more men than women. In men it may occur at any time after puberty; in women it usually occurs only after the menopause. There is often a family history of the disorder. Hyperuricaemia (excess uric acid in the blood) leads to the formation of uric acid crystals inside joints. Crystals may also be deposited in the soft tissues in the ears and around tendons.

**DIAGNOSIS**

Gout is suspected if an attack of arthritis affects a single joint. A blood test is usually performed; a high level of uric acid will suggest gout. Examination of fluid from the joint may confirm the diagnosis.
Gram’s stain
An iodine-based stain used to differentiate between types of bacterium.

A specimen of bacteria is stained with gentian violet and a solution of Gram’s stain. It is then treated with a decolorizing agent, such as acetone, before being counterstained with a red dye. Bacteria that retain the dark violet stain are known as Gram-positive; those that lose the violet stain after decolorization and take up the counterstain (so that they appear pink) are known as Gram-negative.

Examples of Gram-positive bacteria include Streptococcus and Clostridium. Gram-negative bacteria include Vibrio cholerae, which causes cholera, and various species of Salmonella.

grand mal
The former name for tonic–clonic seizures, which occur in epilepsy. The episode may start with warning sensations, such as unease or fear. This so-called aura lasts for a few seconds. The person then loses consciousness and collapses, and may briefly stop breathing. During the seizure there are generalized, jerky muscle contractions. As it finishes, the muscles relax and bowel and bladder control may briefly be lost. This type of seizure usually lasts for only a few minutes; the person may have no recall of it on awakening.

grand multipara
A term relating to a pregnant woman who has had five or more previous pregnancies that have resulted in delivery. During any subsequent pregnancy, a grand multipara woman is considered to be at increased risk of a variety of conditions including anaemia, hypertension (high blood pressure), diabetes mellitus, placenta praevia, malpresentation, prolonged labour, delivery by caesarean section, ruptured uterus, and postpartum haemorrhage.

granulation tissue
Red, moist, granular tissue that develops on the surface of an ulcer or an open wound during the process of healing.

granulocyte
A type of white blood cell.

granuloma
A growth comprising cells of a type associated with chronic inflammation. Granulomas usually occur as a reaction to certain infections, such as tuberculosis, or to a foreign body, such as a suture (stitch), but they may also develop for unknown reasons in conditions such as sarcoidosis.

A pyogenic granuloma is an excess of granulation tissue developing at the site of an injury to the skin or mucous membrane. (See also granuloma annulare; granuloma inguinale.)

granuloma annulare
A harmless skin condition characterized by circular, raised areas of skin that spread outwards, forming rings. It occurs mostly in children and young adults, usually on the backs of the hands and feet. The cause is unknown.

The diagnosis of granuloma annulare is often made simply from its appearance, or may be confirmed by a skin biopsy (removal of a tissue sample for analysis). No treatment is necessary. In most cases, the skin heals fully over several months or years.

granuloma inguinale
A sexually transmitted infection that causes ulceration of the genitals. The infection is caused by Calymmatobacterium granulomatis, also known as Donovan’s bodies. It is common in parts of the tropics but rare in temperate countries.

The first symptoms are painless, raised nodules on the penis or labia (external female genitals) or around the anal area. The nodules gradually ulcerate forming red, raised areas, which may contain pus. Left untreated, the affected areas may eventually heal but there will be extensive scarring.

A biopsy (removal of a tissue sample for microscopic analysis) is performed on a sore in order to confirm diagnosis. The antibiotics tetracycline or erythromycin are effective treatments.

granulomatosis
Any condition marked by the formation of multiple granulomas (collections of inflamed tissue), such as Hodgkin’s disease and Wegener’s granulomatosis.

granulomatous lung disease
A condition in which one or more granulomas (collections of inflamed tissue) develop within the lungs. In certain diseases, such as Churg–Strauss syndrome and Wegener’s granulomatosis, granulomas and vasculitis (an inflammation of the blood vessels) develop at the same time.

Other conditions result from an immune system response to a foreign substance or infectious organism. Causes include tuberculosis, fungal infections, and inhaled rock or mineral dusts. In some diseases, however, such as sarcoidosis, the cause is unknown.

grip reflex
A primitive reflex (see reflex, primitive) in which the fingers or toes curl when the palm or sole is touched or stroked. The grasp reflex is normal in babies, but if it continues into later life or appears in an adult, it may indicate a disorder of the frontal lobe of the brain.

Graves’ disease
An autoimmune disorder (in which the immune system attacks the body’s own tissues) that affects the thyroid gland. Graves’ disease is characterized by toxic goitre (an overactive and enlarged thyroid gland); excessive production of thyroid hormones (hyperthyroidism), leading to thyrotoxicosis; and exophthalmos (bulging eyelids).

gry
The medical term for a pregnant woman. The term “gry” is often combined with a prefix to indicate the number of pregnancies that a woman has had (including the current one); for example, a primigravida is a woman who is pregnant for the first time.

grymal
A form of skin ulcer that occurs in the lowermost parts of the body. The usual site is the lower leg (see leg ulcer), and a common cause is varicose veins.

grye
An SI unit (part of the International System of Units) of radiation dosage (see radiation unit).

grye
See abrasion.

greenstick fracture
A type of fracture that occurs when a long bone in the arm or leg bends and cracks on one side only. This type of fracture occurs only in children, whose bones are still growing and flexible.

grey baby syndrome
A rare but potentially fatal condition in newborn, and particularly premature, babies. Grey baby syndrome is caused
by the antibiotic drug chloramphenicol, which is not usually prescribed for newborns, but may be passed to a baby via the mother’s bloodstream. Newborn babies’ bodies cannot process or excrete the drug effectively, so very high levels build up. An affected infant is cold and has grey skin (see cyanosis) due to circulatory collapse (see shock).

If the condition is detected early, and the drug is discontinued, the infant may recover fully. Treatment with chloramphenicol should be avoided in late pregnancy and during breast-feeding.

grey matter

Regions of the central nervous system consisting mainly of closely packed and interconnected nerve cell bodies and their branching dendrites. (In contrast, the nerve cells’ axons, which conduct nerve impulses, make up the white matter of the central nervous system.)

Grey matter is found mostly in the outer layers of the cerebrum (the main mass of the brain that is responsible for advanced mental functions) and in deeper regions of the brain, such as the basal ganglia. Grey matter also makes up the core of the spinal cord.

grief

A painful emotion, usually caused by loss of a loved one. (See bereavement.)

grip

The ability of the hand to hold objects firmly. The hand has an opposable thumb (which can touch each of the fingers), specialized skin on the palm and fingers to give adhesion, and a complex system of muscles, tendons, joints, and nerves that enables precise movements of the digits. The hand is capable of performing two types of grip: grasping, in which the whole hand is used, and pinching, a precise hold using the thumb and one finger.

Gripping ability is greatly reduced by conditions that cause muscular weakness or impairment of sensation in the hands. Such conditions include stroke or nerve injury, and disorders that affect the bones or joints of the hand or wrist, such as arthritis or a fracture.

gripe

Severe abdominal pain (see colic).

gripe

An outdated term of French origin for any illness resembling influenza.

griseofulvin

An oral antifungal drug. Griseofulvin is particularly useful for infections affecting the scalp, beard, palms, soles of the feet, and nails. Common side effects are headache, dry mouth, abdominal pain, and photosensitivity (increased sensitivity of the skin to sunlight). Long-term treatment with the drug may cause liver or bone marrow damage.

Groenouw’s corneal dystrophy

An inherited disorder of the eye. There are two forms of the condition: type I (granular) and type II (macular).

Granular corneal dystrophy is an autosomal dominant disorder (see genetic disorders) characterized by small granular opacities in the top layers of the cornea. It develops in the first ten years of life. Macular corneal dystrophy is an autosomal recessive disorder typified by a diffuse haze with areas of dense corneal opacity. It develops in young people up to the age of 20.

Treatment for discomfort associated with the disorder may include antibiotic eye-drops. Severe cases may require laser surgery or a corneal transplant.

groin

The hollow between the lower abdomen and the top of the thigh.

groin, lump in the

A swelling in the groin. The most common cause is enlargement of a lymph node due to an infection (see glands, swelling). Another common cause is a hernia, in which the abdominal contents protrude through a weak area in the abdominal wall. Rarely, in males, an undescended testis may lead to a lump in the groin (see testis, undescended). Treatment depends on the cause.

groin strain

Pain and tenderness in the groin as a result of overstretching a muscle, typically while running or playing sport. The muscles commonly affected are the adductors (on the inside of the thigh) and the rectus femoris (at the front of the thigh). Groin strain is most often treated with physiotherapy, but recovery may be slow.

grommet

A small tube that may be inserted through an incision in the eardrum during surgery to treat glue ear, usually in children (see myringotomy). The grommet equalizes the pressure on both sides of the eardrum, permitting mucus to drain down the eustachian tube into the back of the throat.

Grommets are usually allowed to fall out as the hole in the eardrum closes; this generally occurs six to 12 months after insertion.

group therapy

Any treatment of psychological problems in which a group of patients is given therapy together. The group meets regularly, under the guidance of a therapist, in order to discuss their problems. Interaction between the members of the group is thought to be beneficial.

Group therapy may be useful for people with personality problems and for those who are suffering from alcohol dependence, drug dependence, anxiety disorders, and eating disorders.

growing pains

Vague aches and pains that occur in the limbs of children aged between six and 12 years old. Pains are usually felt at night, often in the calves. The cause is unknown, but the pains seem to be unrelated to the growing process itself.

Growing pains are of no medical significance and need no treatment. In contrast, pains that occur in the morning, cause a limp, or prevent normal use of a limb are not growing pains and should be assessed by a doctor.

growth

An abnormal proliferation of cells in a localized area (see tumour). Growth is also increase in size, usually as a result of increasing age (see growth, childhood).

growth, childhood

The increase in size that occurs as a child develops. Growth is usually monitored by measuring height, weight, and, in babies, head circumference.

The period of fastest growth occurs before birth. Growth is still rapid in the first few years of life, especially in the first year, but the rate decreases during childhood. Puberty marks another major period of growth, which continues until adult height and weight are reached, usually at age 16 to 17 in girls and between 19 and 21 in boys. See growth charts (p.352).

The body shape changes during childhood because different areas grow at different rates. For example, at birth, the head is already about three quarters
of its adult size; it grows to almost full size in the first year. Thereafter, it becomes proportionately smaller because the body grows at a much faster rate than that of the head.

Growth can be influenced by heredity and by environmental factors, such as nutrition and general health. Hormones also play an important role, particularly growth hormone, thyroid hormones, and, at puberty, the sex hormones.

A chronic illness, such as cystic fibrosis, may retard growth. Even a minor illness can slow the growth rate briefly, although the rate usually catches up when the child recovers. In some cases, slow growth is the only sign that a child is ill, malnourished, or emotionally distressed, when it is known as failure to thrive. However, short stature does not always indicate poor health.

Abnormally rapid growth is rare. Usually, it is a familial trait, but it may occasionally indicate an underlying disorder, such as a pituitary gland tumour causing gigantism. (See also age; child development.)

**growth, excessive**

See gigantism.

**growth factor**

Any of various chemicals that are involved in stimulating new cell growth and maintenance. Some growth factors, such as vascular endothelial growth factor, which stimulates the formation of new blood vessels, are significant in the growth and spread of cancers.

**growth hormone**

A substance produced by the pituitary gland that stimulates normal body growth. Growth hormone increases the production of protein in muscle cells and the release of energy from the breakdown of fats. Oversecretion of the hormone leads to gigantism if it occurs before puberty or acromegaly if it occurs afterwards. A deficiency of the hormone may result in short stature. Synthetic growth hormone may be given by injection to treat short stature caused by pituitary or genetic disorders.

**growth rate**

The increase in size of an individual over a given period of time. Growth rate may be expressed in absolute terms or relatively, as a percentage of the average growth rate. (See also growth, childhood; height velocity.)

**growth, restricted**

See short stature.

**G syndrome**

See Opitz syndrome.

**GTN**

The abbreviation for glyceryl trinitrate.

**guaiac**

A chemical used to detect haemoglobin (the oxygen-carrying pigment in red blood cells) in faeces. Tests using guaiac, known as faecal occult blood tests, are performed to detect hidden bleeding in the digestive tract (see occult blood, faecal).

**guar gum**

A gum extracted from the cluster bean (Cyanopsis tetragonoloba). Guar gum is not digested in the body. It is used to help control the blood glucose level in people with diabetes mellitus because it slows the absorption of glucose from the small intestine. The gum is taken as granules sprinkled on food or dissolved in water. It may cause flatulence, nausea, and abdominal discomfort.

**Guillain–Barré syndrome**

A rare condition affecting the peripheral nervous system that causes weakness, usually in the limbs.

**CAUSES**

The cause of Guillain–Barré syndrome is believed to be an allergic reaction to an infection, usually viral; the nerves are damaged by antibodies produced against the virus. Most cases develop two or three weeks after the infection.

**SYMPTOMS**

Weakness, often accompanied by numbness and tingling, usually starts in the legs and spreads to the arms. It may worsen, resulting in paralysis. The muscles of the face and those controlling speech, swallowing, and breathing may also be affected.

**DIAGNOSIS AND TREATMENT**

Diagnosis is confirmed by electrical tests to measure how fast nerve impulses are conducted, and by a lumbar puncture, in which a sample of cerebrospinal fluid is taken from the spinal canal for analysis.

Most people recover fully with only supportive treatment. Severe cases may...
GROWTH CHARTS

Growth charts are used to record the growth of children from the age of two to 18 years. Recording of a child’s weight and height are carried out as part of a routine health check. The doctor or health visitor measures the child’s weight and height and plots them against age on a chart. The growth curve is compared with the typical range, represented by the shaded area on the chart, for all children of the same age and gender.

The vertical axis on the charts show the weight, in kilograms and pounds, and the height in centimetres and inches; the horizontal axis shows the age range from two to 18 years. About 98 per cent of children fall below the line of the 98th percentile; the 50th percentile is the average, and 50 per cent fall below this line; only 2 per cent of children fall below the line of the 2nd percentile.

**BOYS’ WEIGHT (2–18 YEARS)**

Growth in boys

Normally, there is a steady increase in height and weight until the onset of puberty. A sudden spurt in growth occurs during puberty (between the ages of 13 and 16). This chart was constructed using the height and weight of thousands of children; it is used by doctors to check whether growth of a particular boy is significantly above or below average.

**GIRLS’ WEIGHT (2–18 YEARS)**

Growth in girls

Normally, there is a steady increase in height and weight until the onset of puberty. A sudden spurt in growth occurs during puberty (between the ages of 11 and 14). These charts were constructed using the height and weight of thousands of children; it is used by doctors to check whether growth of a particular girl is significantly above or below average.

**BOYS’ HEIGHT (2–18 YEARS)**

**GIRLS’ HEIGHT (2–18 YEARS)**
need treatment with \textit{plasmapheresis} (in which blood is treated to remove antibodies) or \textit{immunoglobulin}. Mechanical \textit{ventilation} may be used to aid breathing if the chest muscles and \textit{diaphragm} are severely affected. Some people are left with a permanent weakness, others may have further attacks of the disease, and a number may suffer both weakness and further attacks.

\textbf{guilt}
A painful emotion that arises from the awareness of having broken a moral code. Guilt (unlike shame, which depends on how other people view the transgression) is self-inflicted. Some psychoanalysts view it as a result of the prohibitions of the \textit{superego} (conscience) that are instilled in early life, while others see guilt as a conditioned response to actions that on previous occasions have led to punishment.

Feeling guilty for no reason, or for an imagined crime, is one of the main symptoms of \textit{depression}.

\textbf{Guinea worm disease}
A tropical disease caused by a parasitic worm about 1 m long. The disease occurs in Africa, South America, the Middle East, and India.

Infection results from drinking water containing the water flea \textit{Cyclops}, which harbours the worm larvae. Once consumed in a drink, the larvae pass through the intestine and mature in body tissues. After about a year, the adult female worm, now pregnant, reaches the skin surface and creates an inflamed blister that bursts, exposing the end of the worm. \textit{Urticaria} (nettle rash), nausea, vomiting, and diarrhoea often develop during the formation of the blister.

The traditional remedy for the disease is to wind the worm from the skin on to a small stick. The drugs \textit{tiabendazole} and niridazole are given to reduce inflammation, \textit{antibiotic drugs} are given to control secondary infection, and the patient is immunized against \textit{tetanus}.

\textbf{Gulf War syndrome}
A group of symptoms affecting armed forces personnel of various nationalities involved in the war in the Persian Gulf in 1991. A wide range of symptoms has been associated with the illness, including severe fatigue, fever, headaches, rashes, chronic \textit{bronchitis}, visual disturbances, impaired short-term memory, and \textit{depression}. The cause is unknown.

\textbf{gullet}
The common name for the \textit{oesophagus}.

\textbf{gum}
The soft tissue surrounding the \textit{teeth} that protects underlying structures and keeps the teeth in position in the \textit{jaw}.

Healthy gums are pink or brown and firm. Careful \textit{oral hygiene} helps to keep the gums clean and prevent disease. \textit{Gingivitis} (an early, reversible stage of gum disease characterized by inflammation of the gums) may occur if \textit{plaque} is allowed to collect around the base of the teeth. If untreated, it may lead to chronic \textit{periodontitis}, advanced gum disease in which infected pockets form between the gums and the teeth.

Bleeding gums are nearly always a symptom of gingivitis; rarely, they are due to \textit{leukaemia} or \textit{scurvy} (vitamin C deficiency). Gingival \textit{hyperplasia} (fleshy thickening of the gums) occurs most commonly as a side effect of treatment with \textit{phenytoin} (an anticonvulsant drug). (See also \textit{receding gums}.)

\textbf{gumboil}
See \textit{abscess}, \textit{dental}.

\textbf{gumma}
A soft tumour that may develop in the late stages of untreated \textit{syphilis}. Gummas are rare in developed countries.

\textbf{gustatory}
Related to the organs or sense of \textit{taste}.

\textbf{gut}
A common name for the \textit{intestine}.

\textbf{Guthrie test}
A blood test performed routinely on blood samples taken from the heels of babies between the eighth and the fourteenth days after birth. The test is used to check for the inherited disorder \textit{phenylketonuria}, which can lead to severe brain damage if left untreated.

\textbf{guttate psoriasis}
A form of \textit{psoriasis} (a skin disease characterized by patches of inflamed skin) that is found mainly in children and young adults, especially following \textit{streptococcal infections}. A particular feature of guttate psoriasis is the formation of multiple small, teardrop-shaped skin blemishes. When it occurs in children following a streptococcal infection, it usually clears up completely. However, affected children are at a higher risk of developing plaque psoriasis (the more common form of psoriasis) in later life.

\textbf{gynaecology}
The medical speciality concerned with the female \textit{reproductive tract}. Gynaecology deals with \textit{contraception}; the investigation and treatment of menstrual problems (see \textit{menstruation}, \textit{disorders of}); \textit{sexual problems}; \textit{infertility}; problems relating to the \textit{menopause}; and disorders such as \textit{uterine fibroids} and \textit{ovarian cysts}. Gynaecologists also deal with disorders in the early stages of pregnancy, such as recurrent \textit{miscarriage}.

\textbf{gynaecomastia}
Enlargement of one or both \textit{breasts} in men or boys. The condition is sometimes due to an excess of the female sex hormone \textit{oestrogen}.

\textbf{CAUSES AND INCIDENCE}
Mild, temporary gynaecomastia can occur in boys at birth due to maternal hormones, and the condition is also common at \textit{puberty}.

Gynaecomastia that develops in later life may be due to a chronic liver disease, such as \textit{cirrhosis}, in which the liver is unable to break down oestrogen. Hormone-secreting tumours, such as pituitary or testicular tumours, may also be responsible for the condition.

Adult gynaecomastia, which sometimes occurs in only one breast, can also occur when synthetic hormones and some drugs, such as \textit{digoxin}, \textit{spironolactone}, and \textit{cimetidine}, cause a change to the balance of sex hormones. Very rarely, a discrete lump that develops on one breast may be caused by a male breast cancer.

\textbf{DIAGNOSIS AND TREATMENT}
Investigation may involve \textit{blood tests}. If cancer is suspected, a \textit{biopsy} (removal of the lump or a piece of tissue for analysis) will be performed.

Treatment depends on the cause. If a drug is responsible, an alternative will be given if possible. If there is no underlying disease, the swelling usually subsides over a period of time. In severe cases, however, cosmetic surgery (see \textit{mammoplasty}) may be considered.
haemoglobin and its formation, as to (repetitive, involuntary, may also (lack of muscle coordination). Cryosurgery, antihistamine receptor antagonists, a type of ulcer-healing drug. (See also cimetidine; ranitidine; famotidine.)

habit tic A type of tic (repetitive, involuntary movement of a muscle) that has a psychological cause and does not result from damage to or disease of the nervous system.

habitual abortion An outdated term for the spontaneous abortion (see miscarriage) of a fetus in three or more consecutive pregnancies, after less than 24 weeks’ gestation. Habitual abortion is now more commonly known as recurrent pregnancy loss or recurrent miscarriage. Habitual abortions may be caused by defects or disorders of the uterus, such as fibroids, or of the cervix (see cervical incompetence). Certain conditions affecting the mother, such as systemic lupus erythematosus or Hughes’ syndrome, may also cause habitual abortion.

habituation The process of becoming accustomed to an experience. In general, the more a person is exposed to a stimulus, the less he or she is affected by it. People can become habituated to certain drugs and develop a reduced response to their effects (see tolerance).

haem A prefix that is placed before a variety of words (for example, haemoglobin) to indicate blood.

haemangioblastoma A rare type of brain tumour consisting of blood-vessel cells. Haemangioblastomas develop slowly as cysts, often in the cerebellum, and are mostly noncancerous. Symptoms include headache, vomiting, nystagmus (abnormal jerky eye movements) and, if the tumour is in the cerebellum, ataxia (lack of muscle coordination). Most haemangioblastomas can be removed surgically.

haemangioma A birthmark caused by an abnormal distribution of blood vessels. Haemangiomas may be flat or raised.

TYPES Port-wine stains are large, flat, purple-red marks, which are permanent and can be unsightly. In rare cases, port-wine stains are associated with abnormalities in the blood vessels of the brain (see Sturge-Weber syndrome).

Small, flat marks, often known as stork marks or stork bites, are common in newborn babies, particularly on the back of the neck. Most begin to fade about three weeks after birth.

Raised bright red haemangiomas, often called strawberry marks, usually enlarge rapidly during the first few weeks after birth. They generally disappear without leaving a scar by the time a child is five to seven years old.

COMPLICATIONS AND TREATMENT Haemangiomas do not usually require treatment. However, a haemangioma that bleeds persistently or that looks unsightly may need to be removed by laser treatment, cryosurgery (destruction of tissue by extreme cold), radiotherapy, embolization (obstruction of blood flow to tissue), or plastic surgery.

haemarthrosis Bleeding into a joint, causing the capsule that encloses the joint to swell, and resulting in pain and stiffness.

CAUSES Haemarthrosis is usually the result of severe injury to a joint, such as a torn capsule, torn ligaments, or fracture of a bone forming part of the joint. Often the cause is a sports injury to the knee.

Less common causes are bleeding disorders, such as haemophilia (in which failure of the blood-clotting mechanism causes abnormal bleeding). Any joint may be affected and bleeding into the joint may occur spontaneously or be caused by even a minor knock. Overuse of anticoagulant drugs can also cause haemarthrosis.

Repeated haemarthrosis may damage joint surfaces, causing osteoarthritis.

SYMPTOMS AND SIGNS Haemarthrosis causes a joint to swell immediately after injury. The joint may gradually stiffen into a fixed position as a result of spasm in surrounding muscles.

TREATMENT Ice-packs may reduce swelling and pain. Fluid may be withdrawn from the joint in order to relieve pain and for diagnosis. Haemophiliacs are given factor VIII to promote blood clotting. Resting the joint in an elevated position can prevent further bleeding.

haematemesis The medical term for vomiting blood.

haematocritos The accumulation of menstrual blood in the vagina due to blockage of the vaginal opening. This rare condition occurs either when the hymen (the membrane around the vaginal opening) lacks the perforation that would normally allow the blood to leave the body or as a result of developmental abnormalities of the vagina. Haematocolpos requires surgical treatment to drain the blood and, if necessary, to reconstruct the vagina.

haematology The study of blood and its formation, as well as the investigation and treatment of disorders that affect the blood and the bone marrow.

Microscopic examination and counting of blood and bone marrow cells are essential procedures in diagnosing types of blood disorder, such as anaemia or leukaemia. Analysis of blood is used in the diagnosis of a range of disorders as well as specific blood disorders.

haematoma A localized collection of blood (usually clotted) that is caused by bleeding from a ruptured blood vessel. Haematomas can occur almost anywhere in the body and vary from a minor to a potentially fatal condition.

Less serious types of haematoma include those that develop under the nails or in the tissues of the outer ear (cauli-
flower ear). Most haematomas disappear without treatment in a few days, but if they are painful they may need to be drained. More serious types include extradural and subdural haematomas, which press on the brain (see extradural haemorrhage; subdural haemorrhage).

**haematoma auris**
The medical term for cauliflower ear.

**haematospermia**
An alternative term for haemospermia, the medical term for blood in the semen (see semen, blood in the).

**haematuria**
Blood in the urine, which may or may not be visible to the naked eye. In small amounts, it may give the urine a smoky appearance.

Almost any urinary tract disorder can cause haematuria. Urinary tract infection is a common cause; prostatitis may be a cause in men. Cysts, kidney tumours, bladder tumours, stones (see calculus, urinary tract), and glomerulonephritis (inflammation of the filtering units of the kidney) may cause haematuria. Bleeding disorders may also cause the condition.

Blood that is not visible to the naked eye may be detected by a dipstick urine test or microscopic examination. CT scanning, ultrasound scanning, or intravenous urography can help to determine the cause. If bladder disease is suspected, cystoscopy is performed.

**haemochromatosis**
An inherited disease in which too much dietary iron is absorbed. Excess iron gradually accumulates in the liver, pancreas, heart, testes, and other organs. Men are more frequently affected than women because women regularly lose iron in menstrual blood.

**SYMPTOMS AND COMPLICATIONS**
Haemochromatosis rarely causes problems until middle age. Loss of sex drive and a reduction in the size of the testes are often the first signs. Excess iron over a period of time causes enlargement of the liver and cirrhosis (chronic liver damage) and can lead to diabetes mellitus, bronzed skin coloration (due to iron pigment deposition in the skin), cardiac arrhythmia, and, eventually, liver failure and liver cancer.

**DIAGNOSIS AND TREATMENT**
Diagnosis is based on blood tests and a liver biopsy (removal of a small sample of tissue for analysis). Treatment is by venesection (withdrawal of blood from a vein). Initially, the procedure is performed every week. After iron levels have returned to normal, however, the process of venesection is required less often. (See also haemosiderosis.)

**haemodialysis**
One of the two means of dialysis (artificial filtration of the blood) used to treat kidney failure.

**haemoglobin**
The oxygen–carrying pigment that is present in red blood cells. Haemoglobin molecules, which are produced by bone marrow, are made up of four protein chains (two alpha- and two beta-globin) and four haem (a red pigment that contains iron).

**haemoglobinopathy**
A term used to describe the genetic disorders in which there is a fault in the production of the globin chains of haemoglobin (the oxygen-carrying substance in the blood). Examples of haemoglobinopathies include sickle cell anaemia and the thalassaemias.

**haemoglobinuria**
The presence of haemoglobin in urine. Haemoglobin is an oxygen-carrying substance mainly contained in red blood cells, but a small amount is free in the blood plasma. Excessive breakdown of red blood cells, due to heavy exercise, cold weather, falciparum malaria, or haemolytic anaemia, increases the concentration of free haemoglobin in the plasma. The body excretes the excess haemoglobin in the urine.

**haemolysis**
The destruction of red blood cells. Haemolysis is the normal process by which old red blood cells are destroyed, mainly in the spleen. Bilirubin, a waste product of haemolysis, is excreted into the bile by the liver. Abnormal haemolysis, in which red blood cells are destroyed prematurely, may cause anaemia and jaundice (see anaemia, haemolytic).

**haemolytic anaemia**
See anaemia, haemolytic.

**haemolytic disease of the newborn**
Excessive haemolysis (destruction of red blood cells) in the fetus and newborn by antibodies produced by the mother. Haemolytic disease of the newborn is most often caused by Rhesus incompatibility. This occurs when a mother with Rh-negative type blood, who has previously been exposed to Rh-positive blood through birth, miscarriage, abortion, or amniocentesis, is pregnant with a baby that has Rh-positive blood. Haemolytic disease has become uncommon since the introduction of routine preventive treatment for Rh-negative women during pregnancy (see anti-D (Rh) immunoglobulin).

**SYMPTOMS AND SIGNS**
In mild cases of the disease, the newborn baby becomes slightly jaundiced during the first 24 hours of life (due to an excess of the bile pigment bilirubin in the blood) and slightly anaemic. In more severe cases, the level of bilirubin in the blood may increase to a dangerous level,
causing a risk of kernicterus (a type of brain damage). Severely affected babies have marked anaemia while still in the uterus. They become swollen (hydrops fetalis) and are often stillborn.

**TREATMENT**
In mild cases, no treatment is necessary. In other cases, the aim is to deliver the baby before the anaemia becomes too severe, usually by induction of labour at 35–39 weeks’ gestation. If the baby is too young to be delivered safely, fetal blood transfusions may be necessary.

After birth, phototherapy (light treatment that converts bilirubin in the skin into a water-soluble form that is more easily excreted from the body) can help to reduce jaundice. An exchange blood transfusion may be needed.

**haemolytic–uraemic syndrome**
A rare disease in which red blood cells are destroyed prematurely and the kidneys are damaged, causing acute kidney failure. Thrombocytopenia (reduction of platelets in the blood) can also occur. haemolytic–uraemic syndrome most commonly affects young children.

**CAUSES**
The precise cause of haemolytic–uraemic syndrome is uncertain, but the disorder may be triggered by a serious bacterial or viral infection. It is thought that the lining of small blood vessels in the kidneys becomes damaged, causing small clots to form. These clots cause haemolysis (breakdown of red cells) as blood flows past them.

**SYMPTOMS**
The onset of the disease is sudden; symptoms include weakness, lethargy, and a reduction in the volume of urine. Severe hypertension (high blood pressure) is common and may cause seizures.

**DIAGNOSIS AND TREATMENT**
Blood and urine tests can determine the degree of kidney damage. Dialysis (artificial filtration of the blood) may be needed until the kidneys have recovered. Most patients recover normal renal function.

**haemophilia**
An inherited bleeding disorder caused by deficiency of a blood protein, factor VIII, which is essential for blood clotting. Haemophiliacs (who are almost always male) suffer recurrent bleeding, usually into their joints, which may occur spontaneously or after injury.

**INCIDENCE AND CAUSES**
The lack of factor VIII is due to a defective gene, which shows a pattern of sex-linked inheritance. Affected males pass on the gene not to their sons but to their daughters, who are carriers of the condition. Some of the sons of carrier females may be affected, and some of the daughters of carriers may themselves be carriers. Many haemophiliacs have an uncle, brother, or grandfather also affected. However, in about one third of cases there is no family history of haemophilia.

**SYMPTOMS**
The severity of the disorder differs markedly among individuals. However, episodes of bleeding are painful and, unless treated promptly, can lead to deformity of the knees, ankles, and other joints. Injury, and even minor operations such as tooth extraction, may lead to profuse bleeding. Internal bleeding can lead to blood in the urine or extensive bruises.

**DIAGNOSIS AND TREATMENT**
Haemophilia is diagnosed by blood-clotting tests and by amniocentesis or chorionic villus sampling in a fetus. Bleeding can be controlled by infusions of factor VIII concentrates. People with a severe form of the disorder may need regular intravenous injections of factor VIII as a preventive measure.

**OUTLOOK**
Most people with haemophilia can lead an active life but should avoid the risk of injury. Contact sports, such as football, are not advisable but other forms of exercise, such as swimming and walking, can be beneficial. The female relatives of anyone with haemophilia should obtain genetic counselling before planning a pregnancy.

**Haemophilus influenzae**
A bacterium (see bacteria) responsible for numerous cases of the infectious diseases epiglottitis and meningitis.

**haemoptysis**
The medical term for coughing up blood.

**haemorrhage**
The medical term for bleeding. (See also haematoma.)

**haemorrhagic fever**
See viral haemorrhagic fever.

**haemorrhagic shock**
Physiological shock (a dangerous reduction of blood flow throughout the body tissues), which is caused by severe blood loss. (See also hypovolaemia.)

**haemorrhoidectomy**
Surgical removal of haemorrhoids. The procedure is used to treat large, prolapsing, or bleeding haemorrhoids, if other simpler methods such as banding have not been successful.

Complete healing after a haemorrhoidectomy takes three to six weeks. Laxative drugs are usually given during this period to soften faeces and make them easier to pass.

**haemorrhoids**
Swollen veins in the lining of the anus. Haemorrhoids may occur close to the anal opening, when they are called external haemorrhoids, or higher in the anal canal, in which case they are called internal haemorrhoids. Sometimes these veins protrude outside the anal canal, in which case they are called prolapsing haemorrhoids.

**CAUSES**
Haemorrhoids are caused by increased pressure in the veins of the anus, most commonly through straining repeatedly to pass hard faeces. Such faeces may result from a diet that is too high in refined foods and too low in fibre (see constipation). Haemorrhoids are also common during pregnancy, when the weight of the fetus exerts pressure on blood vessels.

**SYMPTOMS**
Rectal bleeding and discomfort on defaecation are the most common features. Prolapsing haemorrhoids often produce a mucous discharge and itching around the anus. A complication of prolapse is thrombosis and strangulation. This occurs when a blood clot forms in the vein, preventing it from returning to its position in the anus and restricting its blood supply. The condition can cause extreme pain.

**DIAGNOSIS AND TREATMENT**
Diagnosis is usually by proctoscopy (inspection of the rectum with a viewing instrument). Mild cases are controlled by drinking plenty of fluids, eating a high-fibre diet, and establishing regular bowel movements. Rectal suppositories and creams that contain corticosteroid drugs and local anaesthetics reduce pain and swelling. More troublesome haemorrhoids may be treated by sclerotherapy (injection of an irritant liquid), cryosurgery (application of extreme cold), or by banding, in which a band is tied around the haemorrhoid, causing it to wither and drop off. A haemorrhoidectomy (the surgical removal of haemorrhoids) is generally required for prolapsing haemorrhoids.
TREATING HAEMORRHOIDS

In the procedures shown below, the patient will usually have been given a laxative so that the lower bowel is clear of faeces. Banding requires no anaesthesia; either general or epidural anaesthesia is given before a haemorrhoidectomy is performed.

BANDING HAEMORRHOIDS

1 This common, simple, and effective procedure is usually painless (causing no more than a mild ache afterwards) and no anaesthesia is required. The patient lies on one side, the proctoscope (instrument for examining the rectum) is positioned, and the haemorrhoid is grasped with forceps.

2 The banding instrument is inserted and pressed into the anal wall. Gentle traction is applied to draw the mass into the drum of the instrument.

3 The trigger mechanism of the banding instrument is fired and the bands are squeezed on to the neck of the mass. The proctoscope is withdrawn, leaving the haemorrhoid with its base tightly constricted by the bands. The haemorrhoid then withers and drops off painlessly within a few days of the operation.

HAEMORRHOIDECTOMY

Stages of the procedure

Under general or epidural anaesthesia, the patient’s rectum is examined with a proctosigmoidoscope to exclude a diagnosis of tumour. The patient is then placed in the lithotomy position. The haemorrhoid is clamped, placed under traction (as shown above), secured with a suture, and then removed with a knife.

HAEMOSIDEROSIS

A general increase in iron stores in the body. Haemosiderosis may occur after repeated blood transfusions or, more rarely, as a result of excessive iron intake.

HAEMOSPERMA

The medical term for blood in the semen (see semen, blood in the).

HAEMOSTASIS

The arrest of bleeding. There are three main natural mechanisms by which bleeding is stopped after injury. First, small blood vessels constrict. Second, small blood cells called platelets aggregate and plug the bleeding points. Third, the blood plasma coagulates, forming filaments of a substance called fibrin, which help to seal the damaged blood vessel (see blood clotting). Defects in any of these mechanisms can cause a bleeding disorder.

HAEMOSTATIC DRUGS

A group of drugs to treat bleeding disorders and to control bleeding. Haemostatic preparations that help blood clotting are given to people with clotting factor deficiencies. For example, factor VIII is used for haemophilia. Drugs that prevent the breakdown of fibrin in clots, such as tranexamic acid, can also help stop bleeding.

HAEMOTHERAX

A collection of blood in the pleural cavity (the space between the chest wall and the lung). Haemothorax is most commonly caused by chest injury, but it may arise spontaneously in people with defects of blood coagulation or as a result of cancer.

Symptoms of haemothorax include pain in the affected side of the chest and upper abdomen, and breathlessness. If extensive, there may be partial lung collapse. Blood in the pleural cavity is withdrawn through a needle.

HAILEY–HAILEY DISEASE

Also known as benign familial pemphigus, a form of pemphigus (a blistering skin disease) that mainly affects the neck, armpits, and groin. Hailey–Hailey disease tends to run in families.

HAIR

A threadlike structure composed of dead cells containing keratin, a fibrous protein.

STRUCTURE AND FUNCTION

The root of each hair is embedded in a tiny pit in the dermis (inner) layer of the skin called a hair follicle. Each shaft of hair consists of a spongy semihollow core (the medulla), a surrounding layer of long, thin fibres (the cortex), and, on the outside, several layers of overlapping cells (the cuticle).

While a hair is growing, the root is enclosed by tissue called a bulb, which supplies the hair with keratin. The bulb is the pale swelling that sometimes can be seen when a hair is pulled out. The upgrowth of dead cells and keratin from the root forms the hair. Once the hair has stopped growing, the bulb retracts from the root and the hair eventually falls out.

Hair is involved in the regulation of body temperature (known as thermoregulation). If the body is too cold, the erector pili muscles in the skin contract, pulling the hairs upright to form goose pimples. Erect hairs trap an insulating layer of air next to the skin.

TYPES

There are three types of human hair. From the fourth month of gestation, the fetus is covered with downy hair called lanugo, which is shed during the ninth month. After birth and until puberty, vellus hair, which is fine, short, and colourless, covers most of the body. The third type, terminal hair, is thicker, longer, and often pigmented; it grows on the scalp, the eyebrows, and the eyelashes. At
puberty, terminal hair replaces vellus in the pubic area and the armpits. In most men and some women the process continues on the face, limbs, and trunk.

**COLOUR AND TEXTURE**
Hair colour is determined by the amount of pigment called melanin that is present in the hair shaft. Melanin is produced by cells called melanocytes at the base of the hair follicle. Red melanin is responsible for red and auburn hair, black melanin for all other colours. If cells receive no pigment, the cortex of each hair becomes transparent and the hair appears white. The degree of curliness of a hair depends on the cross-section shape of its follicle.

**DISORDERS**
Brittle hair may be due to excessive styling, hypothyroidism (underactivity of the thyroid gland), or severe vitamin or mineral deficiency. Very dry hair can be caused by malnutrition. Ingrown hairs occur when the free-growing end of the hair penetrates the skin near the follicle, which may cause inflammation. (See also hirsutism; hypertrichosis.)

**hairball**
A ball of hair in the stomach, found in people who nervously suck or chew their hair (see bezoar).

**hair cycle**
The alternating phases of activity in a hair follicle. There are two main phases: an active phase, when new hair forms in the follicle, and a resting phase, when cell activity slows down and stops. The active phase lasts for several years, until a hair has reached its maximum length. During the resting phase, that hair dies. During the next growth phase, a new hair is formed and pushes the dead one out of the follicle.

The growth cycles of hairs may be disrupted by various factors, including hormonal or immune system disorders; pregnancy; adverse reactions to drugs; and radiotherapy.

**hairiness, excessive**
See hirsutism; hypertrichosis.

**hair removal**
Hair is usually removed from the body purely for cosmetic reasons. It may also be shaved from around an incision site before surgery. Temporary methods of hair removal include shaving, waxing, depilatory creams, and waxing; electrolysis, however, is the only permanent method of removal.

**hair transplant**
A cosmetic operation in which hairy sections of scalp are removed and transplanted to hairless areas to treat alopecia (baldness). There are several different techniques available.

**HOW IT IS DONE**
In strip grafting, a strip of skin and hair is taken from a donor site, usually at the back of the scalp or behind the ears. The removed hairs and their follicles are then inserted into numerous incisions made in a bald area, known as the recipient site. The procedure usually takes 60–90 minutes. The patient is given a mild sedative and the donor and recipient sites are anesthetised. The donor site heals in about five days. Although transplanted hairs fall out shortly afterwards, new hair growth appears from the follicles between three weeks and three months later.

Other transplant techniques include punch grafting, in which a punch is used to remove small areas of bald scalp, which are replaced with areas of hairy scalp; flap grafting, in which flaps of hairy skin are lifted, rotated, and stitched to replace bald areas; and male pattern baldness reduction, which involves cutting out areas of bald skin and stretching surrounding areas of hair-bearing scalp to replace them.
hairy cell
A large, abnormal white blood cell with numerous hairlike projections. Hairy cells occur with a rare form of leukemia, known as hairy cell leukaemia, when they proliferate in the blood, bone marrow, liver, and spleen.

Haldol
A brand name for the antipsychotic drug haloperidol.

half-life
The time taken for the activity of a substance to reduce to half its original level. The term is usually used to refer to the time taken for the level of radiation emitted by a radioactive substance to decay to half its original level. The concept is useful in radiotherapy for assessing how long material will stay radioactive in the body. Half-life is also used to refer to the length of time taken by the body to eliminate half the quantity of a drug.

halitosis
The medical term for bad breath. Halitosis is usually the result of smoking, drinking alcohol, eating onions or garlic, or poor oral hygiene. Persistent bad breath not caused by any of these may be a symptom of mouth infection, sinusitis, or certain lung disorders, such as bronchiectasis.

Hallervorden–Spatz syndrome
A very rare disorder thought to be caused by a build-up of iron in certain areas of the brain. The symptoms, which are progressive, usually appear in early childhood and include abnormal muscle rigidity and spasms (see dystonia).

Hallgren’s syndrome
A congenital disorder (present at birth) that is characterized by deafness; congenital cataract (opacity of the lens of the eye); and ataxia (clumsiness and incoordination) due to brain damage.

hallucination
A perception that occurs when there is no external stimulus. Auditory hallucinations (the hearing of voices) are a major symptom of schizophrenia but may also be caused by manic–depressive illness and certain brain disorders. Visual hallucinations most often occur in states of delirium brought on by a physical illness (such as pneumonia) or alcohol withdrawal (delirium tremens). Hallucinogenic drugs are another common cause of visual hallucinations. Hallucinations of smell are associated with temporal lobe epilepsy. Those of touch and taste are rare, however, and occur mainly in people with schizophrenia. People subjected to sensory deprivation or overwhelming physical stress sometimes suffer from temporary hallucinations.

hallucinogenic drug
A drug that causes hallucination. Hallucinogens include certain drugs of abuse, such as LSD, marijuana, mescaline, and psilocybin. Some prescription drugs, such as anticholinergic drugs and levodopa, occasionally cause hallucinations.

hallux
The medical name for the big toe.

hallux rigidus
Loss of movement in the large joint at the base of the big toe as a result of osteoarthritis. The joint is usually tender and swollen. Treatment comprises resting the toe and wearing a support insert in the shoe. Surgery may be required.

hallux valgus
A deformity of the big toe in which the joint at the base projects out from the foot, and the top of the toe turns inwards. The condition is more common in women, because it is usually associated with wearing narrow, pointed, high-heeled shoes, but it may be caused by an inherited weakness in the joint. A hallux valgus often leads to formation of a bunion or to osteoarthritis in the joint, causing pain and limiting foot movement. Severe deformity may be corrected by osteotomy (removal of part of a bone) or arthrodesis (fusion of bones in a joint).

haloperidol
An antipsychotic drug used to treat mental illnesses such as schizophrenia and mania. Haloperidol is also given to control the symptoms of Gilles de la Tourette’s syndrome (a rare neurological disorder) and, in small doses, to sedate people who are aggressive due to dementia. Side effects include drowsiness, lethargy, weight gain, dizziness, and parkinsonism (symptoms such as abnormal movements and stiffness of the face and limbs).

halothane
A colourless liquid inhaled as a vapour to induce and maintain general anaesthesia (see anaesthesia, general). Repeated use of halothane may result in damage to the liver and, for this reason, it is now less widely used.

hamartoma
A noncancerous mass, resembling a tumour, which consists of an overgrowth of tissues that are normally found in the affected part of the body. Hamartomas are common in the skin (the most common is a haemangioma), but they also occur in the lungs, heart, or kidneys.

hammer-toe
A deformity of the toe (usually the second toe) in which one of the joints remains in a bent position due to a tendon abnormality. A painful corn often develops on this joint. A protective pad can ease pressure on the joint and relieve pain, but surgery may be needed if the pain is persistent.

Appearance of hammer-toe
This photograph shows the typical appearance of a hammer-toe, in which one of the joints of the second toe is fixed in a bent position.

hamstring muscles
A group of muscles at the back of the thigh. The upper ends of the hamstring muscles are attached by tendons to the pelvis; the lower ends are attached by tendons called hamstrings to the tibia and fibula. The hamstring muscles bend the knee and swing the leg backwards from the thigh.

Tearing of the hamstring muscles is common in sports. The injury happens suddenly and is very painful. Bruising over the area develops several days later. Repeated strenuous exercise may sprain the muscles (see overuse injury). Both types of injury can often be prevented by warming-up exercises.

Repeated spasms of the hamstring muscles can also sometimes occur as a protective response to a knee injury; by restricting movement of the damaged knee joint, the muscle spasms help to limit further injury.
**hand**

The hand, which is the most versatile part of the body, allows humans (and other primates) to hold and manipulate objects. This ability is primarily due to the fact that the fingers and thumb can move independently and can grip.

**STRUCTURE**

The hand is made up of the wrist, palm, and fingers. Movement of the hand is achieved mainly by tendons that attach the muscles of the forearm to the bones of the hand (the carpals, metacarpals, and phalanges). These tendons are surrounded by synovial sheaths containing a lubricating fluid that prevents friction. Other movements are controlled by short muscles in the palm of the hand; some of these muscles make up the prominent areas along the sides of the hand from the bases of the thumb and little fingers to the wrist.

Blood is supplied to the hand by two arteries (the radial on the thumb side of the wrist and the ulnar on the little finger side). Prominent veins on the back of the wrist and the ulnar on the little fingers to the wrist.

The hands are highly susceptible to injury, including cuts, burns, bites, fractures, and tendon injuries. Dermatitis is also common, since the hands are exposed to a considerable variety of irritating substances.

Other hand disorders include Dupuytren’s contracture, which causes shrinkage of tissues in the palm, and Volkmann’s contracture, in which damage to muscles in the forearm causes wrist and finger deformities. Degeneration of a tendon sheath on the upper side of the wrist may cause a harmless swelling called a ganglion. Osteoarthritis commonly affects the joint at the base of the thumb. Rheumatoid arthritis may cause deformity by attacking the joints at the base of the fingers and rupturing tendons.

**hand–arm vibration syndrome**

Pain and numbness in the hand and arm due to prolonged use of vibrating tools. Symptoms often also include blue or white coloration of the fingers and a tingling sensation in affected areas. Hand–arm vibration syndrome tends to develop slowly over years and is the result of repeated damage to blood vessels and nerves. Exposure to cold tends to aggravate the condition.

There is no specific treatment, but avoiding vibrating tools is essential to prevent the disease progressing. In some cases, calcium channel blockers may help to relieve some symptoms.

**handedness**

Preference for using the right or left hand. Some 90 per cent of adults use the right hand for writing; two thirds prefer the right hand for most activities requiring coordination and skill. The others are either left-handed or ambidextrous (able to use both hands equally well).

It is uncertain why all humans are not simply ambidextrous. Up to the age of about 12, it is possible to switch handedness if, for example, the dominant hemisphere of a person’s brain has been damaged.

Handedness is related to the division of the brain into two hemispheres, each of which controls movement and sensation on the opposite side of the body. In most right-handed people the speech centre is in the left brain hemisphere. Inheritance is probably the most important factor in determining an individual’s handedness.

**hand-foot-and-mouth disease**

An infectious disease, mainly affecting young children, that is caused by the coxsackievirus. Hand-foot-and-mouth disease may occur in small epidemics, usually in the summer.

The illness is usually mild and lasts for only a few days. Symptoms include blistering of the palms, soles of the feet, and inside of the mouth, and a slight fever. There is no treatment other than mild analgesic drugs. This infectious disease is not related to foot-and-mouth disease, which occurs in cattle.

**handicap**

The extent to which a physical or mental disability interferes with a person’s normal functioning and causes him or her to be disadvantaged.

**Hand–Schuller–Christian disease**

A form of histiocytosis X that affects children. Problems include patchy bone loss, loose teeth, exophthalmos (protruding eyeballs), and swollen lymph nodes. Involvement of the pituitary gland can result in diabetes insipidus and growth hormone deficiencies.

**hangnail**

A strip of skin torn away from the side or base of a fingernail, exposing a raw, painful area. Hangnails usually occur when frequent immersion in water has dried the skin on the fingers. Biting the nails is another common cause. Unless trimmed away and covered until it heals, a hangnail may develop into paronychia (infection of the skin fold around the nail).

**hangover**

The unpleasant effects that are commonly experienced after over-indulgence in alcohol, characterized by headache, nausea, vertigo, and depression. Alcohol increases production of urine, and some
of the symptoms of a hangover are a result of mild dehydration. (See also alcohol intoxication.)

**Hanhart’s syndrome**

A *birth defect* in which there are severe physical deformities, including under-development of the lower jaw (see *micrognathia*) and tongue, misshapen and missing teeth, and malformations of the limbs.

**Hansen’s disease**

A chronic bacterial infection, also called leprosy, that damages nerves, mainly in the limbs and facial area, and may cause skin damage.

**CAUSE**

The disease is caused by a bacterium, *Mycobacterium leprae*, which is spread in droplets of nasal mucus. Hansen’s disease is not highly contagious; a person is infectious only in the early stages. Prolonged close contact puts people at risk. The disease is most prevalent in Asia, Central and South America, and Africa.

**SYMPTOMS AND SIGNS**

Hansen’s disease has a long incubation period – about three to five years. There are two main types: the lepromatous type, in which damage is widespread, progressive, and severe; and the tuberculoid type, which is milder. Damage is initially confined to the skin or to peripheral nerves supplying the skin and muscles. Skin areas supplied by affected nerves become lighter or darker and sensation and sweating are reduced. As the disease progresses, the peripheral nerves swell and become tender. Hands, feet, and facial skin eventually become numb and muscles become paralysed, leading to deformity. Other possible features include blindness, destruction of bone, and sterility.

**DIAGNOSIS AND TREATMENT**

The presence of the causative bacteria is confirmed by a *skin biopsy*. Drug treatment may be with a combination of *dapsone*, rifampicin, and clofazimine, which kills most of the bacteria in a few days. Any damage that has occurred before treatment, however, is irreversible. Plastic surgery may be necessary to correct deformities; and nerve and tendon transplants may improve the function of damaged limbs.

**hantavirus**

A viral infection that is transmitted to humans through the urine or faeces of infected rodents, such as rats. Symptoms range from a minor flu-like illness with headache and a sore throat to high fever, nausea and vomiting, and abnormal bleeding. Some strains of hantavirus can cause severe infections that may lead to *kidney failure*, serious lung damage, and death.

**Harada’s syndrome**

A combination of certain eye and brain disorders that occurs in the Far East, particularly in Japan. The condition usually affects young adults.

The eye problems, which affect both eyes, include severe inflammation of the *iris*, the *ciliary body*, or the *choroid*; oedema (a build-up of fluid) in the *retina*; and *retinal detachment*. These problems are associated with *meningoencephalitis* (inflammation of the brain tissue and the membranes surrounding it). Other conditions that occur with Harada’s syndrome include deafness, alopecia (hair loss), and patchy loss of pigmentation in the skin, eyes, and ends of the hair.

**hardening of the arteries**

The popular term for *atherosclerosis*.

**harelip**

A common term for the *birth defect* in which there is a split in the upper lip due to failure of the two sides to fuse during fetal development. A harelip is often associated with a similar failure of the two halves of the palate to join. (See also *cleft lip and palate*.)

**Harrison’s sulcus**

A depression seen at the lower part of the ribcage of a child that is usually caused by exaggerated suction of the *diaphragm muscle* in respiratory conditions such as severe *asthma*. Harrison’s sulcus may also be the result of the normal pull of the diaphragm on ribs that have been weakened – for example, in conditions such as *ricket*. A deficiency in tryptophan may result in episodes of various symptoms, in particular *cerebellar ataxia* (a poorly coordinated, unsteady gait); symptoms similar to those of *pellagra*: a red, scaly rash on skin exposed to the sun; depression; and thought disorders. There may also be headaches and diarrhoea. Symptoms can be triggered by infections, stress, or exposure to sunlight and last for up to four weeks. flare-ups are often followed by long periods of remission.

The diagnosis can be confirmed by testing the urine for abnormally high levels of amino acids. Treatment with nicotinic acid and a high-protein diet often offers a good prognosis. The frequency of attacks usually decreases with increasing age.

**Hashimoto’s thyroiditis**

An autoimmune disorder in which the body’s immune system develops antibodies against its own thyroid gland cells. As a result, the thyroid gland cannot produce enough *thyroid hormones*, a condition known as *hypothyroidism*. Hashimoto’s thyroiditis is eight times more common in women than men. The principal symptoms of Hashimoto’s thyroiditis are tiredness, muscle weakness, and weight gain, and the thyroid gland becomes enlarged (see *goitre*).

A positive diagnosis is confirmed by blood tests indicating the presence of antithyroid antibodies and low levels of thyroid hormones. Treatment is by lifelong thyroid hormone replacement therapy. In some cases, other autoimmune disorders may also develop.

**hashish**

Sometimes shortened to “hash”, this is another name for *marijuana*.

**Haverhill fever**

A form of rat-bite fever (see *rats, diseases from*) caused by infection with the bacterium *Streptobacillus moniliformis*. Unlike other forms of the disease, Haverhill fever can not only be transmitted through the bite of a rodent but can also be passed on indirectly, in contaminated water or milk products.

**Havrix**

The brand name for one form of a *vaccine* given to provide protection against *hepatitis A*.

**hay fever**

The popular name for the seasonal form of *allergic rhinitis* (see *rhinitis, allergic*) that is often combined with another condition, *allergic conjunctivitis*. 361
Hb
The abbreviation for haemoglobin, an oxygen-carrying component of red blood cells.

HCG
The abbreviation for the hormone human chorionic gonadotrophin (see gonadotrophin, human chorionic).

HDL
The abbreviation for the lipoprotein known as high density lipoprotein.

head
The part of the body that contains the skull, the brain, and the organs of sight, hearing, smell, and taste. The term head is also used to refer to the uppermost part of any structure and to the rounded portion of a bone that slots into an area of another bone to form a joint.

headache
One of the most common types of pain. A headache is only rarely a symptom of a serious underlying disorder. The pain arises from tension in the meninges (the membranes around the brain), and in the blood vessels and muscles of the scalp. Headache may be felt all over the head or may occur on only one side, or in the forehead or the back of the neck. Sometimes the pain shifts from one area to another. The pain of headache may be superficial, throbbing, or sharp and may be accompanied by nausea, vomiting, and visual or other sensory disturbances.

TYPES
Many headaches are simply a response to some adverse stimulus, such as hunger. Headaches such as these usually clear up quickly. Tension headaches, due to tightening in the face, neck, and scalp muscles as a result of stress or poor posture, are also common, and may last for days or weeks. Migraine can be a severe, incapacitating headache that is preceded or accompanied by visual and/or stomach disturbances. Cluster headaches cause intense pain behind one eye.

CAUSES
Common causes of headache include hangover and noisy or stuffy environments. Some headaches are caused by the overuse of painkillers (see analgesic drugs). Other possible causes include sinusitis, toothache, cervical osteoarthritis, and head injury. Food additives may also be a cause. Among the rare causes of headache are a brain tumour, hypertension (high blood pressure), temporal arteritis (inflammation of arteries in the face, neck, and scalp), an aneurysm (ballooning of a blood vessel), and increased pressure within the skull.

TREATMENT
Most headaches can be relieved by painkillers and rest. If a neurological cause is suspected, CT scanning or MRI (magnetic resonance imaging) may be performed.

head-banging
The persistent, rhythmic banging of the head against a wall or hard object. Head-banging is seen in some people with severe learning difficulties, particularly those who lack stimulation. It also occurs in some normal toddlers, often when they are frustrated or angry; most children grow out of the behaviour.

head injury
Injury to the head may occur as a result of traffic accidents, sports injuries, falls, assault, accidents at work and at home, or bullet wounds. Most people suffer a minor head injury at least once in their lives, but very few of the injuries are severe enough to require treatment.

A head injury can damage the scalp, skull, or brain. Minor injuries usually cause no damage to the underlying brain. Even when there is a skull fracture, or the scalp is split, the brain may not be damaged. However, a blow to the head may severely shake the brain, and this can sometimes cause brain damage even when there are no external signs of injury.

A blow often bruises the brain tissue, causing death of some of the brain cells in the injured area. When an object actually penetrates the skull, foreign material and dirt may be implanted into the brain and lead to infection. A blow or a penetrating injury may also tear blood vessels causing brain haemorrhage (bleeding in or around the brain). Head injury may cause swelling of the brain; this is particularly evident after bullet wounds because their high velocity causes extensive damage. If the skull is fractured, bone may be driven into the underlying brain.

SYMPTOMS AND SIGNS
If the head injury is mild, there may be no symptoms other than a slight headache. In some cases there is concussion, which may cause confusion, dizziness, and blurred vision (sometimes persisting for several days). More severe head injuries, particularly blows to the head, may result in unconsciousness that lasts longer than a few minutes, or coma (a state of unconsciousness and unresponsiveness to stimuli), which may be fatal.

Post-concussive amnesia (loss of memory of events that occurred after an accident) may occur, especially if the skull has been fractured. This amnesia usually lasts more than an hour after consciousness is regained. There may also be pretraumatic amnesia (loss of memory of events that occurred before the accident). The more serious the injury to the brain, the longer unconsciousness and amnesia are likely to last.

After a severe brain injury, a person may suffer some muscular weakness or paralysis and loss of sensation.

Symptoms such as persistent vomiting, pupils of unequal size, double vision, or a deteriorating level of consciousness suggest progressive brain damage.

TREATMENT
Investigations may include skull X-rays and MRI or CT scanning (techniques that produce cross-sectional or three-dimensional images of body structures). A blood clot inside the skull may be life-threatening and requires surgical removal. Severe skull fractures may also require surgery.

OUTLOOK
Recovery from concussion may take several days. There may be permanent physical or mental disability if the brain has been damaged. Recovery from a major head injury can be a very slow process and there may be signs of progressive improvement for several years after the injury.

head lag
The backward flopping of the head that occurs when an infant is placed in a sitting position. Head lag is obvious in a newborn because the neck muscles are still weak, but by four months the baby can hold his or her head upright (see child development).

head lice
Tiny, wingless insects (Pediculus humanus capitis) that live on the human scalp and feed by sucking blood. Infestation with head lice is extremely common, especially among young school children, and is not caused by low standards of hygiene. An affected child may often pass head lice on to other family members.

The insects do not fly or jump but are spread through head-to-head-contact or shared combs, hairbrushes, and hats. Female lice stick their eggs (which are
known as nits) to hair shafts, close to the scalp. The nits may be seen as small, white specks; often, however, the first sign of infestation is intense itching due to an allergy to lice bites.

**TREATMENT**

Infestations can be treated with medicated lotions containing insecticides, which kill the lice. Because head lice can develop resistance to particular chemicals, a pharmacist should be consulted about local patterns of resistance. For children under two years of age or those with eczema or asthma, treatment should be discussed with a doctor or pharmacist. It is important to treat all family members at the same time.

Some people are reluctant to use insecticides repeatedly. An alternative method of ridding the scalp of head lice is to apply liberal amounts of hair conditioner and comb through the hair carefully with a fine tooth comb to remove the insects and nits. This procedure needs to be repeated every few days in order to be effective and to prevent recurrences. Whichever method is used, frequent inspection of a child’s head is the key to controlling head lice.

**Heaf test**

A type of **tubercul in test**.

**healing**

The process by which the body repairs bone, tissue, or organ damage caused by injury, infection, or disease.

The initial stages of healing are the same in all parts of the body. After injury, **blood clots** form in damaged tissues. White **blood cells**, **enzymes**, **histamine**, other chemicals, and **proteins** from which new cells can be made accumulate at the site of damage. Fibrous tissue is laid down within the blood clot to form a supportive structure, and any dead cells are broken down and absorbed by the white blood cells. Some tissues, such as bone and skin, are then able to regenerate by the proliferation of new cells around the damaged area. In skin injuries, the fibrous tissue shrinks as new skin forms underneath. The tissue hardens to form a scab, which falls off when new skin growth is complete. A scar may remain.

An inadequate blood supply or persistent infection prevents regeneration, and some tissues, such as nerve tissue, may be unable to regenerate. In these cases, the fibrous tissue may develop into tough scar tissue, which keeps the tissue structure intact but may impair its function.

**health**

At its simplest, a term that is used to describe the absence of physical and mental disease. A wider concept promoted by the World Health Organization is that all people should have the opportunity to fulfill their genetic potential. This includes their ability to develop without the impediments of poor nutrition, environmental contamination, or infectious diseases. (See diet and disease; health hazards.)

**health centre**

Premises in which healthcare professionals, such as health visitors, district nurses, and general practitioners, work together.

**health food**

A term applied to any food products thought to promote health.

**health hazards**

Environmental factors that are known to cause, or are suspected of causing, disease. The major types of health hazard are the numerous infectious diseases that are transmitted by contact or by insects or other animals (see bacteria; fungal infections; insects and disease; viruses; zoonosis); an insufficient supply, or the contamination, of food and water (see food additives; food-borne infection; food poisoning); work-related hazards (see occupational disease and injury); hazards associated with domestic and social life; smoking and alcohol consumption; and global environmental hazards (see pollution; radiation hazards; sunlight, adverse effects of).

**health promotion**

The work of healthcare professionals in encouraging people to adopt a healthier lifestyle and so reduce their risk of developing various diseases. The print and broadcast media, as well as patient self-help or campaigning groups, also have a role to play in health promotion at a national or community level.

Health promotion involves the recommendation of specific tests as appropriate. Examples include encouraging women to undergo regular **cervical smear tests** and mammograms (see mammography) to detect early signs of cervical or breast cancer, and advising people at increased risk of coronary heart disease to have their blood cholesterol levels checked.

In addition, health promotion may involve a formal individual consultation to review a person’s health and make appropriate recommendations for him or her, for example regarding diet and exercise. Healthy living advice may also be given opportunistically; for example, individuals may be advised to give up smoking when they see their doctor for blood pressure checks.

**hearing**

The sense that enables sound to be perceived. The **ear** transforms the sound waves it receives into nerve impulses that pass to the **brain**.

Each ear has three distinct regions: the outer, middle, and inner ear. Sound waves are channelled through the ear canal to the middle ear, from where a complex system of membranes and tiny bones conveys the vibrations to the inner ear. The vibrations are converted into nerve impulses in the **cochlea**. These impulses travel along the auditory nerve to the medulla of the brain. From there, they pass via the **thalamus** to the superior temporal gyrus, part of the cerebral cortex involved in perceiving sound. For further details, see Hearing box, overleaf. (See also deafness.)

**hearing aids**

Electronic devices that improve hearing in people with certain types of deafness. A hearing aid consists of a tiny microphone (to pick up sounds), an amplifier (to increase their volume), and a speaker (to transmit sounds). Newer devices are now small enough to be hidden completely within the ear canal. The particular device required depends on the type and cause of the hearing loss. (See also cochlear implant.)

**hearing loss**

A deterioration in the ability to perceive sound. (See also deafness.)

**hearing tests**

Tests carried out to assess hearing. In newborns and young babies, **otoacoustic emission** tests can be used to check for a normal response of the inner ear to sound. Hearing tests are also performed as part of a routine assessment of **child development** and whenever hearing impairment is suspected. They are sometimes included in a general medical examination. The tests may also be used in people with **tinnitus** or dizziness.

An audiometer (an electrical instrument) is used to test the ability of an individual to hear sounds at different frequencies and volumes. The lowest
Hearing

The ears are the organs of hearing. Each ear has three regions: the outer ear, middle ear, and inner ear. The outer ear channels sound vibrations through the eardrum to the middle ear. The eardrum has to have equal air pressure on each side so that it can vibrate freely; the pressure is equalized via the eustachian tube, which runs from the back of the throat to the middle ear. Inside the middle ear, a complex system of membranes and tiny bones conveys the vibrations to the inner ear via a membrane called the oval window. In the inner ear, the vibrations are converted to nerve impulses and sent to the brain via the vestibulocochlear nerve.

Structure and function of cochlea
Running the length of the cochlea is a fluid-filled tube called the cochlear duct. It contains several membranes and a structure called the organ of Corti. Tiny hairs on the organ of Corti brush against a membrane called the tectorial membrane, producing electrical signals. These signals are detected by nerve fibres.

Route to the brain

Electrical signals are picked up by nerve fibres in the cochlea and pass along the vestibulocochlear nerve to the medulla. From there, they pass via the thalamus to the superior temporal gyrus – the part of the cerebral cortex (see brain) involved in receiving and perceiving sound.

Comparison of frequency ranges

The frequency of a sound (how high or low it is) is measured in Hertz (Hz). Different animals can hear different ranges of sound frequencies. The diagram shows the normal ranges that can be heard by a human, a bat, a dolphin, and a dog. Humans can hear a range between about 20 and 20,000 Hz.
level at which a person can hear and repeat words (the speech reception threshold) is tested in each ear, as is the ability to hear words clearly (speech discrimination). Tuning fork tests (see Rinne’s test) can be used to determine whether hearing loss is conductive or sensorineural (see deafness).

heart
The muscular pump in the centre of the chest that beats continuously and rhythmically to send blood to the lungs and the rest of the body. During an average lifetime, the heart contracts more than 2,500 million times.

STRUCTURE
Much of the heart consists of myocardium, a type of muscle, which, when given oxygen and nutrients, contracts rhythmically and automatically without any other stimulus. The internal surface of the heart is lined with a smooth membrane called endocardium, and the entire heart is enclosed in a tough, membranous bag, the pericardium.

Inside the heart there are four chambers. A thick central muscular wall, the septum, divides the heart cavity into right and left halves. Each half consists of an upper chamber, called an atrium (plural: atria), and a larger lower chamber, called a ventricle. (See Structure of the heart box, overleaf.)

The body’s principal blood vessels emerge from the top and sides of the heart. The superior and inferior venae cavae (see vena cava), the largest veins, deliver deoxygenated blood from the body to the heart. The aorta, which is the main artery, carries oxygen-rich blood to be circulated around the body. The pulmonary vessels carry blood to and from the lungs, where the blood absorbs oxygen and releases the waste product carbon dioxide.

FUNCTION
The two sides of the heart have distinct, though interdependent, functions. The right atrium receives deoxygenated blood from the entire body via the two venae cavae. This blood is transferred to the right ventricle, then pumped to the lungs via the pulmonary artery to be oxygenated and lose carbon dioxide. The left atrium of the heart receives oxygenated blood from the lungs (via the pulmonary veins); this is transferred to the left ventricle and pumped to all body tissues. One-way valves at the chamber exits ensure that blood flows in one direction (see heart valves).

THE CARDIAC CYCLE
The pumping action of the heart consists of three phases, which together make up a cycle corresponding to one heartbeat (see Heart cycle box, overleaf). These phases are called diastole, atrial systole, and ventricular systole. In diastole, the heart muscle relaxes and the heart fills with blood. In atrial systole, the atria contract, sending blood into the ventricles. In ventricular systole, the ventricles contract, pumping blood into the blood vessels.

For the heart to function efficiently, the muscular contractions must occur in a precise sequence. This sequence is regulated by electrical impulses that emanate from the sinoatrial node (an area of specialized muscle at the top of the right atrium), the heart’s natural pacemaker. The electrical impulses are carried to the atria and ventricles partly by the heart muscle itself and partly by nerve fibres.

In order to prevent bottlenecks from developing in the blood circulation, the volume that is pumped at each beat by the two sides of the heart must be balanced exactly. Resistance to blood flow through the general circulation is much greater than resistance through the lungs. Therefore, the left side of the heart must contract more forcibly than the right; for this reason, the left side has greater muscular bulk.

heart, artificial
An implantable mechanical device that takes over the action of the heart. However, the term is also used to describe devices that assist the heart in maintaining the circulation.

HEARING TESTS

<table>
<thead>
<tr>
<th>Tests</th>
<th>Function</th>
</tr>
</thead>
<tbody>
<tr>
<td>Tuning fork tests</td>
<td>These basic tests are used to determine whether hearing loss is conductive or sensorineural. In Rinne’s test, the patient is asked whether the sound is louder with the vibrating tines held near the opening of the ear canal (air conduction) or with the base of the fork held against the mastoid bone (bone conduction). In a normal ear or one with sensorineural loss, air conduction is greater than bone conduction. In conductive hearing loss, bone conduction is greater than or equal to air conduction. Weber’s test, in which the base of the fork is placed on the forehead, is useful for diagnosing unilateral hearing loss. If the hearing loss is conductive, the patient hears the tuning fork better in the ear with the poorer hearing.</td>
</tr>
<tr>
<td>Pure-tone audiometry</td>
<td>This is a test in which an audiometer is used to generate sounds of different frequencies and intensities and a person’s ability to hear these sounds is measured. Hearing is first assessed by transmitting the sounds through one earphone while the other ear is prevented from hearing them. The sound frequencies range from 250 to 8,000 Hertz; for each frequency, the sound is increased in intensity until it can be heard. The patient gives a signal at the moment when he or she detects each sound and the results are recorded on a graph called an audiogram. Bone conduction is then assessed in the same way but the signal is transmitted through a rubber pad held against the bone behind the ear.</td>
</tr>
<tr>
<td>Auditory evoked response</td>
<td>This test may be used to evaluate the presence of hearing in someone who cannot cooperate with other tests (such as a very young baby). The brain’s response to sound stimulation produced by an audiometer is analysed by means of electrodes placed on the scalp. Auditory evoked response can also help to rule out acoustic neuroma (a benign tumour affecting the auditory nerve, part of the vestibulocochlear nerve).</td>
</tr>
<tr>
<td>Impedance audiometry</td>
<td>Also known as tympanometry, this test is used to assess middle-ear damage occurring in cases of conductive deafness or to detect the effects of fluid within the middle ear. A probe is fitted tightly into the entrance of the ear canal, thereby sealing off the outside air pressure and sound. The probe emits a continuous sound. Air is pumped through the probe at varying pressures and, at the same time, a microphone in the probe registers the differing reflections of sounds from the eardrum as pressure changes in the ear canal. The reflections are recorded on a graph known as a tympanogram. The pattern of differing reflections relates to the type of disease that is causing the deafness.</td>
</tr>
</tbody>
</table>
An intra-aortic balloon pump, comprising a balloon in the aorta that inflates with each heartbeat, increases the volume of blood entering the circulation. This is a commonly used means of mechanical circulatory support and may be used for the first few days after a myocardial infarction (heart attack) until the heart is able to maintain blood pressure unassisted. A left ventricular assist device takes blood from the left ventricle and pumps it electrically into the abdominal aorta. True artificial hearts are mechanical hearts, which are powered from outside the body by battery packs.

Problems with artificial hearts include the formation of blood clots within the device and infection. They are therefore used as a temporary measure until a heart transplant can be performed.

heart attack
See myocardial infarction.

heartbeat
A contraction of the heart that pumps blood to the lungs and the rest of the body. The different parts of the heart contract in a precise sequence that is regulated by electrical impulses emanating from the sinoatrial node, at the top of the right atrium. Each heartbeat consists of three phases, which occur in a cycle: the diastole (resting phase), the atrial systole (contraction of the heart's upper chambers), and the ventricular systole (contraction of the lower chambers). The rate at which contractions occur is called the heart rate.

The term pulse refers to the character and rate of the heartbeat when felt at a point on the body, such as the wrist.

heart block
A common disorder of the heartbeat that is caused by an interruption to the passage of electrical impulses through
the heart’s conducting system. Heart block may be congenital or may be due to heart disease, such as coronary artery disease. Other causes include overdose of a digitalis drug (used in the treatment of heart disease) and rheumatic fever.

**TYPES**

There are two main types of heart block: atrioventricular block, a blockage in the heart’s conducting system between an atrium (upper chamber of the heart) and a ventricle (lower chamber of the heart); and bundle branch block, in which the block is confined to conduction within the ventricles.

**Atrioventricular block** There are three degrees of atrioventricular heart block. In first degree block, there is an increased delay between contraction of the atria and that of the ventricles. In second degree heart block, some atrial beats fail to reach the ventricles. In complete heart block, there is a total blockage in the heart’s conducting system that prevents atrial beats from being conducted to the ventricles. The two chambers therefore beat at their own intrinsic rate, with the ventricles beating very slowly and completely independently of the atria.

**Bundle branch block** Each ventricle has its own conduction system, known as the right and left bundle branches. These work together. Blockage in one or other of the bundle branches (or, less commonly, both) leads to an abnormal pattern of conduction through the ventricles.

Right bundle branch block can sometimes be seen in a healthy heart. It may also be due to certain conditions, such as congenital heart disease (see heart disease, congenital). Left bundle branch block is more serious and is always a sign of an underlying cardiac disorder. It is usually caused by coronary artery disease but may also occur as a result of hypertension (high blood pressure) or aortic stenosis.

**SYMPTOMS**

First degree heart block and left or right bundle branch block alone usually cause no symptoms. However, in more severe atrioventricular heart block, the rate of ventricular contraction does not increase in response to exercise. This may cause breathlessness as a result of heart failure (reduced pumping efficiency) or chest pains due to angina pectoris (caused by reduced blood supply to the heart muscle). If the ventricular beat becomes very slow, or if it stops altogether for a few seconds, episodes of loss of consciousness may occur.

**DIAGNOSIS AND TREATMENT**

Both types are usually diagnosed on an ECG (electrocardiogram) trace. Heart block with no symptoms may not require any treatment. Heart block causing symptoms is usually treated by fitting a permanent artificial pacemaker. Drugs to increase the heart rate and the strength of the heart’s contractions may be given temporarily. Any underlying heart disease is treated as necessary.

**Heartburn**

A burning pain in the centre of the chest, which may travel from the tip of the breastbone to the throat. Heartburn is often brought on by lying down or bending forwards. It may be caused by eating rich or spicy food, or by drinking alcohol. Recurrent heartburn is a symptom of oesophagitis (inflammation of the oesophagus), which is usually caused by acid reflux.

**Heart disease, congenital**

A term that is used to describe any abnormality of the heart that is present from birth. Congenital defects (see Types of congenital heart disease box, overleaf) may affect different parts, including the chambers, valves, or main blood vessels of the heart.
Possible complications resulting from an untreated heart defect include underdevelopment of the limbs and muscles, and pneumonia after even mild respiratory infections. With prolonged cyanosis, clubbing (thickening and broadening) of the ends of fingers and toes may develop. If there is insufficient capacity in the heart to increase blood flow on effort, the child may rapidly tire during physical exercise. In some untreated cases, a serious complication called Eisenmenger complex (increased resistance of the lungs to blood flow) develops.

**DIAGNOSIS AND TREATMENT**

Antenatal diagnosis, using specialized ultrasound scanning, is possible for most defects. After birth, any suspected defect is investigated using chest X-rays, ECG, or echocardiography.

Oxygen and various drug treatments may improve the symptoms. Some conditions, such as small septal defects or patent ductus arteriosus, may become smaller or may disappear of their own accord. Other defects will require surgical correction. Narrowed heart valves can often be treated by balloon valvuloplasty. In other cases, open heart surgery or a heart transplant may be required.

**OUTLOOK**

Following successful surgery, the child's health often improves dramatically, with resumed growth, increased activity, and a near-normal life expectancy.

Children with heart defects (corrected or uncorrected) are at an increased risk of bacterial endocarditis, a potentially dangerous infection of the heart lining and heart valves. To prevent this, such children are given antibiotic drugs before all surgical procedures, including dental treatments.

**heart disease, ischaemic**

The most common form of heart disease. In ischaemic heart disease, there is narrowing or obstruction of the coro-

**DISORDERS OF THE HEART**

Heart disorders are by far the most common cause of death in developed countries. They also affect the quality of life of millions of people. A wide range of conditions can affect the heart’s structure and/or disrupt its action.

**Congenital defects**

Structural abnormalities in the heart are among the most common birth defects. They result from errors of development in the fetus and include septal defects (“holes in the heart”) and some types of heart valve abnormalities (see heart disease, congenital).

**Genetic disorders**

Genetic factors do not usually play a large part in causing heart disorders. They do, however, contribute to hyperlipidaemias, which predispose affected people to atherosclerosis and coronary artery disease.

**Infection**

Infection of the lining of the heart and of the heart valves (see endocarditis) can result in malfunction of the heart valves. Viral infections can lead to some types of cardiomyopathy (malfunctioning of the heart muscle) or myocarditis (inflammation of the heart muscle).

**Tumours**

Tumours arising in the heart tissues are rare. The main types are noncancerous myxomas, which develop inside the heart chambers, and cancerous sarcomas. Secondary tumours, spreading from elsewhere in the body, are more common than primary tumours.

**Arterial disorders**

The coronary arteries (supplying blood to the heart) may become narrowed due to atherosclerosis. Areas of heart muscle may be starved of oxygen, and angina pectoris or, eventually, myocardial infarction may result.

**Nutritional disorders**

Obesity is an important factor in heart disease, probably through its effect on other risk factors, such as hypertension, diabetes mellitus, and cholesterol. Malnutrition may cause the heart muscle to become thin and flabby from lack of protein and calories. Thiamine (vitamin B₁) deficiency, common in alcoholics, causes beriberi with congestive heart failure.

**Poisoning**

The most common toxin affecting the heart is alcohol. Excessive drinking over many years may cause a type of cardiomyopathy. Another common source of toxins is smoking; nicotine and carbon monoxide in tobacco smoke are thought to encourage the development of atherosclerosis, which can lead to coronary artery disease.

**Drugs**

Certain medications, such as the anticancer drug doxorubicin, tricyclic antidepressants, and even drugs used to treat heart disease, may disturb the heartbeat or damage the heart muscle.

**Other heart disorders**

Many disorders may be complications of an underlying condition, such as cardiomyopathy or a congenital defect. They include cardiac arrhythmia; some cases of heart block; heart failure; and cor pulmonale, which is a failure of the right side of the heart due to lung disease.

**INVESTIGATION**

Techniques used for investigating heart disorders include auscultation (listening to the heart); ECG (electrocardiography); imaging techniques such as chest X-ray, echocardiography, coronary angiography, CT scanning, and MRI; cardiac catheterization (see catheterization, cardiac); blood tests; and, rarely, by a biopsy of the heart muscle.
nary arteries, usually due to atherosclerosis, that results in a reduced blood supply (see coronary artery disease).

**Heart failure**

Inability of the heart to cope with its workload of pumping blood to the lungs and to the rest of the body. Heart failure can primarily affect either the right or the left side of the heart; however, it most commonly affects both sides. Heart failure can be acute or chronic (congestive).

**Types and Causes**

**Left-sided heart failure** Left-sided failure may be due to hypertension (high blood pressure), anaemia, hyperthyroidism (overactivity of the thyroid gland), a heart valve defect (such as aortic stenosis, aortic incompetence, or mitral incompetence), or a congenital heart defect (see heart disease, congenital). In all of these conditions, the left side of the heart must work harder than normal to pump the same amount of blood. Sometimes, the heart can compensate for the extra workload by an increase in the size of the left side and in the thickness of its muscular walls, or by an increase in the heart rate. This compensation is only temporary, however, and heart failure eventually follows.

Other causes of left-sided heart failure include coronary artery disease, myocardial infarction (heart attack), cardiac arrhythmias (irregularities of heart rhythm), and cardiomyopathy (disease of the heart muscle). In cardiomyopathy, the pumping power of the heart is reduced to a point where it can no longer deal with its normal workload.

Whatever the underlying cause, in left-sided heart failure the left side of the heart fails to empty completely with each contraction, or has difficulty in accepting blood that has been returned from the lungs. The retained blood creates a “back pressure” that causes the lungs to become congested with blood. This condition leads to pulmonary oedema (excess fluid in the lungs), of which the main symptom is shortness of breath, eventually even when at rest. The patient may awaken at night with attacks of breathlessness, wheezing, and sweating.

**Right-sided heart failure** Right-sided failure is most often caused by pulmonary hypertension (raised blood pressure in the arteries supplying the lungs). This is itself caused by left-sided heart failure, or a lung disease such as chronic obstructive pulmonary disease (see pulmonary disease, chronic obstructive). Right-sided failure can also be due to a heart valve defect, such as tricuspid incompetence, or to a congenital heart defect.

In all types of right-sided heart failure, there is back pressure in the circulation from the heart into the venous system, causing swollen neck veins, enlargement of the liver, and oedema (excess fluid in body tissues), especially swelling of the legs and ankles. In addition, the intestines may become congested, causing discomfort and indigestion.

**Investigation and Treatment**

Investigation of suspected heart failure may involve a physical examination, X-ray, ECG, and echocardiography.
Attacks of acute heart failure may subside of their own accord or may require urgent, life-saving treatment. Immediate treatment of heart failure consists of bed rest, with the patient sitting up. Diuretic drugs are given to increase the output of urine from the kidneys, thereby ridding the body of excess fluid and reducing blood volume. Morphine and oxygen may be given as emergency treatment in acute left-sided heart failure. Long-term drug treatment usually involves the use of ACE inhibitor drugs and diuretics. Angiotensin-II antagonists, other vasodilator drugs, and beta blocker drugs may also be required. If heart failure is associated with atrial fibrillation, digoxin will most likely be prescribed to control the heart rate.

Other possible treatments of heart failure include fitting a pacemaker, coronary artery bypass, and heart transplant.

**Heart imaging**
Any technique that provides images of heart structure. Imaging is used to detect disease or abnormalities.

**Types**
A chest X-ray, the simplest and most widely used method of heart imaging, shows heart size and shape, and the presence of abnormal calcification. Pulmonary oedema (excess fluid in the lungs) and engorgement of the vessels connecting the heart and lungs are also usually detectable with X-rays.

Echocardiography is useful for investigating congenital heart defects and abnormalities of the valves or heart wall. An ultrasound technique that uses the Doppler effect, known as Doppler echocardiography, allows measurement of blood flow through valves. Angiography may be used to assess the condition of the coronary arteries and valves.

Radionuclide scanning can be used to detect myocardial infarction (heart attack), to measure myocardial function and its blood supply, or to determine the viability of the heart muscle following disruption to the blood supply. The information that is obtained depends upon the radioisotope used; for example, thallium-201 may be used to investigate if heart muscle is still viable. Radionuclide scans can also be used to produce images of ventricular function. For example, a MUGA scan is used to determine how much blood the heart can pump with each beat and whether different parts of the heart wall are contracting properly.

High-speed CT scanning and MRI can both be used to produce detailed cross-sectional or three-dimensional images of cardiac structure.

**Heart–lung machine**
A machine that temporarily takes over the function of the heart and lungs in order to facilitate operations such as open heart surgery, heart transplant, and heart–lung transplant.

A heart–lung machine consists of a pump (to replace the heart’s function) and an oxygenator (to replace the lungs’ function). It bypasses the heart and lungs. Once the machine is in operation, the patient’s heart can be stopped while surgery is carried out.

The use of a heart–lung machine tends to damage red blood cells and to cause blood clotting. These problems can be minimized, however, by the administration of heparin, which is an anticoagulant drug.

**Heart–lung transplant**
A procedure in which the heart and lungs of a patient are removed, to be replaced by donor organs. This surgery is used to treat diseases in which lung damage has affected the heart, or vice versa. Such diseases include cystic fibrosis, fibrosing alveolitis, and some severe congenital heart defects (see heart disease, congenital). A heart–lung machine is used to take over the function of the patient’s heart and lungs during the operation. A heart–lung transplant is no more dangerous than a heart transplant and is technically more straightforward because blood vessels to the lungs need not be disturbed.

**Heart rate**
The rate at which the heart contracts to pump blood around the body. In most people, heart rate is between 60 and 100 beats per minute at rest. It tends to be faster in childhood and to slow slightly with age. Very fit people may have a rate below 60 beats per minute.

**Changes in heart rate and output**
The rate at which the heart beats, and the amount of blood pumped out with each contraction, can vary considerably according to the body’s demands for oxygenated blood. At rest, the heart contracts at 60 to 80 beats per minute and each ventricle puts out about 80 ml of blood at each beat (about six litres per minute). During vigorous exercise, the heart rate may increase to 200 contractions per minute; the output may increase to almost 250 ml per beat, producing a total output of 50 litres per minute. Such changes in heart rate and output are brought about by the action of heart muscle and by the involvement of the autonomic nervous system (the part of the nervous system concerned with automatic control of body functions).

First, the heart muscle responds automatically to any increase in activity by increasing its output. This increase occurs because active muscles squeeze the veins that pass through them, pushing the blood back towards the heart. The more the veins are filled with blood during diastole (the filling phase of the heart’s cycle), the more forcibly they contract during ventricular systole to expel the blood.

Second, the heart rate is under the control of the autonomic nervous system. The parts of the system concerned with heart action are a nucleus of nerve cells called the cardiac centre, in the brainstem, and two sets of nerves called parasympathetic and sympathetic nerves, whose activities, controlled by the cardiac centre, exert opposing effects on the heart.

When a person is at rest, the parasympathetic nerves (particularly the vagus nerve) are active. Signals carried along the vagus nerve act on the sinoatrial node to slow the heart rate from its inherent rate of about 140 impulses per minute to around 70 impulses per minute (a process called vagal inhibition). During or in anticipation of muscular activity, vagal inhibition lessens and the heart rate speeds up. The speed may increase even more when the sympathetic nerves come into action. These nerves release the hormone noradrenaline, which increases heart rate and the force of contractions. The release of adrenaline and noradrenaline by the adrenal glands also acts to increase the heart rate.

The switch from parasympathetic to sympathetic activity is triggered by any influence on the cardiac centre that signals a need for increased blood output from the heart. Such influences may include fear or anger, low blood pressure, or a reduction of oxygen in the blood.

**Measuring heart rate**
Doctors can measure the rate and rhythm of the heart by feeling the pulse or by listening to the heart with a stethoscope. A more accurate record can be obtained by ECG (a test in which the electrical activity of the heart is measured). A resting heart rate above...
**HEART–LUNG TRANSPLANT**

In this procedure, both the heart and the lungs of a patient have to be removed and are replaced with organs taken from a brain-dead donor. The donor organs are then inserted into the patient. The removed heart can sometimes be given to another patient. A heart–lung transplant is more straightforward than a heart transplant because blood vessels to the lungs need not be disturbed.

1. The donor heart and lungs must be healthy. The lungs must also match the size of the patient’s chest, as measured by means of chest X-rays.

2. In both donor and patient, the heart and lungs are reached via an incision in the sternum (breastbone), and the chest is opened up.

3. The patient is connected to a heart–lung machine. During the operation, this machine takes over the function of heart and lungs, oxygenating blood taken from the venae cavae and pumping it back to the body via the aorta.

4. In both patient and donor, the heart and lungs are removed through cuts in the aorta, trachea (windpipe), and the area where the venae cavae join the heart. The blood vessels linking the donor heart and lungs are left intact.

5. The donor heart and lungs are inserted into the patient. The trachea and aorta are joined to those of the patient, and the right atrium of the donor heart is joined to the patient’s venae cavae. (This procedure is simpler than attaching a donor heart in a heart transplant, because fewer connections have to be made.)

**WHY IT IS DONE**

Subject to the availability of a donor, a heart-lung transplant can offer hope to someone who is dying of a terminally chronic lung disease, whether or not he or she is also suffering from heart disease. The range of diseases that can be treated with this operation include emphysema, cystic fibrosis, sarcoidosis, and interstitial pulmonary fibrosis. The record of success for the heart–lung transplant operation is better than that for lung transplant alone.

Healthy and diseased lung
These images are of a healthy lung (left) and a lung damaged by emphysema (right), in which the alveoli (tiny air sacs) have become greatly enlarged and the walls surrounding them are damaged.
100 beats per minute is termed a tachycardia, and a rate below 60 beats per minute is known as a bradycardia. (See also arrhythmia, cardiac.)

**heart sounds**

The sounds made by the heart during each heartbeat. In each heart cycle, there are two main heart sounds that can clearly be heard through a stethoscope. The first is like a “lubb”. It results from closure of the tricuspid and mitral valves at the exits of the atria (upper heart chambers), which occurs when the ventricles (lower heart chambers) begin contracting to pump blood out of the heart. The second sound is a higher-pitched “dupp” caused by closure of the pulmonary and aortic valves at the exits of the ventricles when the ventricles finish contracting.

Abnormal heart sounds may be a sign of various disorders. For example, high-pitched sounds or “clicks” are due to the abrupt halting of valve opening, which can occur in people with certain heart valve defects. Heart murmurs are abnormal sounds caused by turbulent blood flow. Murmurs may be due to heart valve defects or to congenital heart disease.

**heart surgery**

Any operation that is performed on the heart. Open heart surgery allows the treatment of most types of heart defect that are present at birth (see heart disease, congenital) as well as various disorders of the heart valves. Coronary artery bypass is performed to redirect blood away from a blocked coronary artery. Angioplasty balloons (see angioplasty, balloon) can be used to open up narrowed heart valves in cases where the patient is unsuitable for open heart surgery (see valvuloplasty). Heart transplant surgery can offer hope to people with progressive, incurable heart disease.

**heart transplant**

Replacement of a patient’s damaged or diseased heart with a healthy heart taken from a donor who has just died. Typically, a transplant patient has advanced coronary artery disease or cardiomyopathy (disease of heart muscle). During the operation, the function of the heart is taken over by a heart–lung machine. Most of the diseased heart is removed, but the back walls of the atria (upper chambers) are left in place. The ventricles (lower chambers) are then attached to the remaining areas of the recipient’s heart. Because the transplant-ed heart has no nerve supply, patients tend to have a high resting heart rate and no variation in blood pressure from day to night.

After the immediate post-operative period, the outlook is good. Patients do, however, face the long-term problems associated with other forms of transplant surgery, including rejection and infection. (See heart–lung transplant.)

**heart valve**

A structure at the exit of a heart chamber, consisting of two or three cup-shaped flaps, that allows blood to flow out of the chamber but prevents it from washing back. There are four heart valves: aortic, pulmonary, mitral, and tricuspid. The opening and closing of the heart valves during each heart cycle produces heart sounds.
DISORDERS
Heart valves may be affected by stenosis (narrowing), in which the heart must work harder to force blood through, or by incompetence or insufficiency (leakiness), which makes the valve unable to prevent regurgitation (backwash) of blood. These defects cause heart murmurs.

Defects of the heart valves may be present from birth (see heart disease, congenital) or acquired later in life. The most common congenital valve defects are aortic stenosis and pulmonary stenosis. Acquired heart-valve disease is usually the result of degenerative changes or ischaemia (reduced blood supply) affecting part of the heart and leading to aortic stenosis or mitral incompetence. Rheumatic fever can cause mitral stenosis, mitral incompetence, defects of the aortic valve, tricuspid stenosis, and tricuspid incompetence. Heart valves may also be damaged by bacterial endocarditis.

Heart-valve disorders commonly lead to heart failure, arrhythmias, or symptoms that arise from reduced blood supply to the tissues.

Heart-valve defects may be diagnosed by auscultation, chest X-ray, ECG, or echocardiography and may be corrected by heart-valve surgery.

heart-valve surgery
An operation to correct a heart valve defect or to remove a diseased or damaged valve. A heart valve may have to be repaired, widened, or replaced because it is either incompetent (leaky), stenotic (narrowed), or both. Widening of a valve may involve valvotomy or valvuloplasty. A damaged valve can be replaced by a mechanical one (fashioned from metal and plastic), a valve constructed from human tissue, a pig valve, or a valve taken from a human donor after death. A heart–lung machine is used during valve replacement.

After heart-valve surgery, there may be symptoms of breathlessness for several weeks that require continued medication. Some people require long-term treatment with anticoagulant drugs to prevent the formation of blood clots around the new valve. Certain types of replacement valve, such as mechanical valves, are more likely to cause clots than other types.

heat cramps
Painful muscle contractions caused by salt loss through profuse sweating. Heat cramps are usually brought on by strenuous activity in extreme heat. They may develop independently or may occur as a symptom of heat exhaustion or heatstroke. Prevention and treatment consist of drinking plenty of fluids, although heat cramps often resolve themselves.

heat disorders
The body functions most efficiently at a temperature of about 37°C, and any major deviation from this temperature disrupts body processes. The body has special mechanisms for keeping its internal temperature constant; any malfunctioning or overloading of these mechanisms may cause a heat disorder.

The mechanisms by which the body loses excess heat are controlled by the part of the brain known as the hypothalamus.

HEART-VALVE REPLACEMENT TYPES

There are three main types of replacement heart valve: bioprostheses (such as the Carpentier–Edwards valve, right), mechanical valves (such as the tilting-disc valve, centre right), and homografts (valves taken from a human donor, far right). A valve is only replaced if it cannot be repaired. Heart-valve replacement (see previous page) is carried out by open surgery, which requires a cardiopulmonary bypass. The most frequently replaced valves are the aortic and mitral valves.

</table>
When blood temperature rises, the hypothalamus sends out nerve impulses to stimulate the sweat glands and dilate blood vessels in the skin. These changes in the skin cool the body down, but excessive sweating may result in an imbalance of salts and fluids in the body, leading to heat cramps or heat exhaustion. When the hypothalamus is disrupted (for example, by fever), the body may overheat, leading to heatstroke. Excessive external heat may cause prickly heat.

Most heat disorders can be prevented by gradual acclimatization to hot conditions and taking salt tablets or solution. A light diet and frequent cool baths or showers may also help. Alcohol and strenuous exercise should be avoided.

heat exhaustion

Fatigue, leading to collapse, that is caused by overexposure to heat. The principal causes of heat exhaustion are insufficient water intake, insufficient salt intake, and a deficiency in sweat production. In addition to fatigue, symptoms may include faintness, dizziness, nausea and vomiting, headache, and, when salt loss is heavy, heat cramps. The skin is usually pale and clammy, breathing is fast and shallow, and the pulse is rapid and weak. Unless it is treated, heat exhaustion may develop into heatstroke.

Treatment of heat exhaustion involves rest and replenishing lost water and salt. Prevention is usually by gradual acclimatization to hot conditions.

heat, prickly

See prickly heat.

heatstroke

A life-threatening condition in which overexposure to heat, coupled with a breakdown of the body’s mechanisms for regulating temperature, cause the body to become overheated. A common cause is prolonged, unaccustomed exposure to the sun in a hot climate. Unsuitable clothing, strenuous activity, overeating, and overconsumption of alcohol can also be contributory factors.

Heatstroke is often preceded by heat exhaustion, which consists of fatigue and profuse sweating. With the onset of heatstroke, the sweating diminishes and may stop entirely. The skin becomes hot and dry, breathing is shallow, and the pulse is rapid and weak. Body temperature rises dramatically and, without treatment, the victim may lose consciousness and even die.

Heatstroke can be prevented by gradual acclimatization to hot conditions (see heat disorders). If it does develop, emergency treatment is needed. This consists of cooling the victim by wrapping him or her in a cold, wet sheet, fanning the body, sponging with water, and giving the person a salt solution to drink.

heat treatment

The use of heat to treat disease, aid recovery from injury, or to relieve pain. Heat treatment is useful for certain conditions, such as ligament sprains, because it stimulates blood flow and promotes healing of tissues.

Moist heat may be administered by soaking the affected area in a warm bath, or by applying a hot compress or poultice. Dry heat may be administered by a heating pad, a hot-water bottle, or a heat lamp that produces infra-red rays. More precise methods of administering heat to tissues deeper in the body include ultrasound treatment and short-wave diathermy.

hebephrenia

A form of schizophrenia that usually becomes evident in adolescence. It is characterized by inappropriate and disorganized behaviour, withdrawal from social contact, and changes in mood.

Heberden’s node

A bony enlargement affecting the joint at the end of the finger, adjacent to the nail. The tendency to develop such nodes is a feature of osteoarthritis and is usually inherited.

heel

The part of the foot that is situated below the ankle and behind the arch. The heel consists of the calcaneus (heel bone), an underlying pad of fat that acts as a cushion, and a layer of skin, which is usually thickened and hardened due to pressure from walking.

heel, cracked

Painful cracks that develop in the thickened skin over the heels. Regular removal of any hard skin using a file or pumice stone, combined with the use of moisturizing cream, can reduce the frequency of such cracks and the severity of the pain. Cracked heels may also be caused by a bacterial infection of the skin on the soles of the feet, also known as pitted keratolysis. The disorder causes small, round pits to develop in the skin; these pits eventually join together to form cracks.

heel, painful

Discomfort resulting from disorders of the calcaneus (heel bone) or the soft tissues around it. Pain in the heel may result from a fracture of the calcaneus; a spur (a bony growth on the calcaneus); inflammation of the fluid-filled pad cushioning the back of the heel (see calcaneal bursitis); or inflammation of the tissues at the bottom of the heel (called plantar fasciitis), which, in some cases, is a feature of ankylosing spondylitis. In addition, the skin overlying the heel may become blistered and painful as a result of walking long distances and/or wearing ill-fitting shoes.

heel prick blood test

See Guthrie test.

height chart

A chart used by a doctor or health visitor to record a child’s growth and to compare his or her height with the typical range in a particular age group. (See also growth, childhood.)

height velocity

The rate of children’s increase in height at a particular age. The measurement is given in centimetres per year.

Heimlich manoeuvre

A first-aid treatment for choking. The aim of the Heimlich manoeuvre is to dislodge the material that is causing the blockage. The first aider stands behind the victim and places one fist, covered by the other, centrally just below the victim’s rib cage and pulls sharply inwards and upwards to give an abdominal thrust. This action, like coughing, forces air out of the airways and should help to dislodge any blockage.

Helicobacter pylori

A bacterium (see bacteria) now known to be the cause of most peptic ulcers as well as a factor in stomach cancer. The infection is probably acquired during childhood through person-to-person spread. There is an extremely high worldwide incidence of Helicobacter pylori infection, with higher rates in developing countries. Of those infected, only about 15 per cent develop peptic ulcer disease, although 95 per cent of people with duodenal ulcers are found to be infected with Helicobacter pylori. The bacterium is thought to damage the mucus-producing layer of the stomach and duodenum, bringing gastric acid into contact with the linings of these structures and cause ulceration.
INVESTIGATION AND TREATMENT

There are several different ways of diagnosing *Heliobacter pylori* infection. A breath test relies on the ability of the bacterium to split molecules of radio-tagged urea, releasing labelled carbon dioxide, which can then be detected in the breath. Tests to check for the presence of antibodies (proteins produced by the immune system) to the bacterium may be useful, but they cannot confirm that infection has been eradicated. A biopsy sample taken from the stomach or duodenal lining can be used to conduct chemical tests, for microscopic analysis, or cultured for the organism.

Treatment to eradicate the infection with a combined course of acid-suppressing ulcer-healing drugs and antibiotic drugs has proved successful in achieving long-term recovery from peptic ulcers. Reinfection is rare. (See also gastritis.)

**heliotherapy**

A form of phototherapy involving exposure to sunlight.

**helminth infestation**

Infection by any parasitic worm. (See [worm infestation](#)).

**helper T-cell**

A type of white blood cell, also known as a helper T-lymphocyte (see [lymphocyte]), that has an important role in the immune system. Helper T-cells assist in the destruction of abnormal cells (such as cancer cells) in the body by recognizing foreign antigens on the surface of the abnormal cells and subsequently stimulating the production of killer T-cells.

**Helweg–Larsen’s syndrome**

An autosomal dominant genetic disorder, affecting both sexes, that is chiefly characterized by a reduced ability to lose body heat through sweating. Affected individuals have anhidrosis (inability to sweat) from birth; they have a very small number of sweat glands, and those that do exist are abnormally enlarged. This defect leads to disturbances in body temperature. There are also malformations in the skin and nail tissues. In addition, affected people develop deafness due to inner ear problems in their 30s or 40s.

**hemianopia**

Loss of half of the visual field in each eye. Hemianopia may be “homonymous” (in which the same side of both eyes is affected) or “heteronymous” (in which the loss occurs in opposite sides of the eyes). The visual loss can be either temporary or permanent.

Hemianopia results from damage to the optic nerves or the brain. Transient homonymous hemianopia in young people is usually caused by migraine. In older people, it occurs in transient ischaemic attacks (brief interruptions of blood supply to the brain). Permanent homonymous hemianopia is usually caused by a stroke, but it may result from brain damage by a tumour, infection, or injury. Hemianopia may also be caused by pressure on the optic nerve from a pituitary tumour.

**hemiballismus**

Irregular and uncontrollable flinging movements of the arm and leg on one side of the body, caused by disease of the basal ganglia (nerve cell clusters in the brain concerned with muscular coordination). (See also athetosis; chorea.)

**hemicolecotomy**

The surgical removal of half, or a major portion, of the colon. (See also colectomy.)

**hemiparesis**

Muscular weakness or partial paralysis in one side of the body (see hemiplegia).

**hemiplegia**

Paralysis or weakness on one side of the body, caused by damage or disease affecting the motor nerve tracts in the opposite side of the brain. A common cause is a stroke. Others include head injury, brain tumour, brain haemorrhage, encephalitis (brain inflammation), multiple sclerosis, complications of meningitis, or a conversion disorder (a type of psychological disorder). Treatment is for the underlying cause, and is carried out in conjunction with physiotherapy.

**hemivertebral**

A birth defect in which half of a vertebra (spinal bone) fails to develop fully.

Hemoccult

A brand name for a type of faecal occult blood test that uses guaiac to screen for gastrointestinal bleeding, a possible sign of colorectal cancer (see colon, cancer of; rectum, cancer of).

**Henoch–Schönlein purpura**

Inflammation of small blood vessels, causing leakage of blood into the skin, joints, kidneys, and intestine. The disease is most common in young children, and may occur after an infection such as a sore throat. Henoch–Schönlein purpura may also be due to an abnormal allergic reaction.

The main symptom is a raised purplish rash on the buttocks and backs of the limbs. The joints are swollen and often painful, and colicky abdominal pain may occur. In some cases, there is intestinal bleeding, leading to blood in the faeces. The kidneys may become inflamed, resulting in blood and protein in the urine.

The only treatment usually required is bed rest and analgesic drugs (painkillers). Complications may arise if kidney inflammation persists. In severe cases, corticosteroid drugs may be given.

**heparin**

An anticoagulant drug used to prevent and treat abnormal blood clotting. Heparin is given by injection and is used as an immediate treatment for deep vein thrombosis or for pulmonary embolism; it may also be given as a preventative measure to people immobilized as a result of illness or surgery. Low molecular weight heparins, such as tinzaparin, which only need to be injected once a day, are now widely used and can be self-administered at home.

Adverse effects of heparin include rash, aching bones, and abnormal bleeding in different parts of the body. Long-term use may cause osteoporosis.

**hepatectomy, partial**

Surgical removal of part of the liver. This procedure may be needed to remove a damaged area of liver following injury, or to treat noncancerous liver tumours and hydatid disease. Rarely, liver cancer is treated in this way.

**hepatectomy, total**

Surgical removal of the liver. Hepatectomy is the first stage in a liver transplant operation.

**hepatic**

Relating to the liver.

**hepatic encephalopathy**

A brain disorder caused by a build-up of toxins in the body as a result of liver failure. (See also encephalopathy.)

**hepatic failure**

This is the medical term for liver failure, in which the function of the liver is severely impaired.
HEPATITIS

hepatitis
Inflammation of the liver, with accompanying damage to liver cells. The condition may be acute (see hepatitis, acute) or chronic (see hepatitis, chronic) and may have various causes. (See also hepatitis A; hepatitis B; hepatitis C; hepatitis D; hepatitis E; hepatitis, viral.)

hepatitis A
Also known as epidemic hepatitis, this disorder is caused by the hepatitis A virus, which exists in the urine and faeces of infected people and is transmitted in contaminated food or drink. The incubation period lasts for 15–40 days, after which nausea, fever, and jaundice develop. Recovery usually occurs within three weeks. Serious complications are rare. Active immunization gives the best protection against hepatitis A, and may be advised for people travelling to Mediterranean or developing countries. An attack of the disease can confer immunity against subsequent infection.

hepatitis, acute
Short-term inflammation of the liver. Acute hepatitis usually clears up in one to two months. In some cases, the disorder may progress to chronic hepatitis (see hepatitis, chronic), but it rarely leads to acute liver failure.

Acute hepatitis is fairly common. The most frequent cause is infection with one of the hepatitis viruses (see hepatitis, viral), but it can arise as a result of other infections such as cytomegalovirus infection. It may also occur as a result of overdose of halothane or paracetamol, or because of exposure to toxic chemicals including alcohol (see liver disease, alcoholic). Symptoms range from mild to severe. They include tiredness; fever; nausea and vomiting; pain in the upper right side of the abdomen; and jaundice.

Blood tests, including liver function tests, may be used for diagnosis. In most cases of acute viral hepatitis, natural recovery occurs within a few weeks. If the disorder is caused by exposure to a chemical or drug, detoxification using an antidote may be possible. Intensive care may be required if the liver is badly damaged. Rarely, a liver transplant is the only way of saving life. In all cases, alcohol should be avoided after the illness.

hepatitis B
A disorder caused by the hepatitis B virus. The infection is transmitted in blood, blood products, or other body fluids (often through contact with used needles and syringes); blood transfusions; or sexual contact. After an incubation period of one to six months, the onset of symptoms, such as headache, fever, and jaundice, may be sudden or gradual; sometimes, there are no symptoms. Most affected people recover, but hepatitis B can be fatal. A vaccine is available; it is usually given to people at high risk of coming into contact with the virus, such as health-care workers or people visiting areas where the disease is common.

In a few cases, the virus continues to cause inflammation and can still be detected in the blood for longer than six months after infection. People who suffer from persistent infection are at long-term risk of liver cancer and cirrhosis and may need to be treated with interferon.

hepatitis C
Caused by the hepatitis C virus and formerly known as non-A non-B hepatitis, this infection is often transmitted through sharing needles. Blood transfusions no longer pose a significant risk in the UK because all blood used for transfusions is now routinely screened for the virus.

Hepatitis C has an incubation period of six to 12 months. It begins as a mild illness, which may go undetected. In about three in four patients, chronic hepatitis develops (see hepatitis, chronic), which can progress to cirrhosis of the liver and an increased risk of hepatoma (a type of liver cancer).

hepatitis, chronic
Inflammation of the liver that persists for a prolonged period. Eventually, chronic hepatitis causes scar tissue to form and may lead to the development of cirrhosis.

The disorder may develop following an attack of acute hepatitis (see hepatitis, acute) or hepatitis C. It may also occur as the result of an autoimmune disorder, a viral infection (see hepatitis, viral), a reaction to certain types of prescribed drugs or, more rarely, to a metabolic disorder, such as haemochromatosis or Wilson’s disease. In some cases, no obvious cause can be found.

Symptoms of chronic hepatitis, such as jaundice and slight fatigue, may alternate with periods in which there are no symptoms at all. If left untreated, the condition may progress to liver failure.

Chronic hepatitis is diagnosed by liver biopsy. Autoimmune hepatitis is treated with corticosteroid drugs and immunosuppressants. Viral infections often respond to interferon. In the drug-induced type of chronic hepatitis, withdrawal of the medication can lead to recovery. For metabolic disturbances, treatment is for the underlying disorder.

hepatitis D
An infection of the liver caused by the hepatitis D virus, which occurs only in people who already have hepatitis B infection. People who develop hepatitis D will usually suffer from severe chronic liver disease. Hepatitis D is also known as delta hepatitis.

hepatitis, serum
The former name for hepatitis B.

hepatitis, viral
Any type of hepatitis caused by a viral infection. Five viruses that attack the liver as their primary target have been identified. They cause hepatitis A, hepatitis B, hepatitis C, hepatitis D, and hepatitis E.

hepatocele
The medical term used to describe the protrusion of part of the liver through the wall of the abdomen.

hepatocellular carcinoma
The most common type of primary liver cancer that arises from within mature liver cells. Hepatocellular carcinoma may develop in people who are suffering from cirrhosis of the liver, especially following infection with hepatitis B or hepatitis C. Incidence of hepatocellular carcinoma is far greater in tropical areas of the world. Symptoms of the condition include hepatomegaly (enlargement of the liver), jaundice, and weight loss.

hepatoma
A tumour of the liver. A cancerous hepatoma is also known as a hepatocellular carcinoma.

hepatomegaly
Enlargement of the liver, occurring as a result of any liver disorder (see liver, disorders of).

hepatotoxic
A term for substances, such as certain drugs, that cause damage to liver cells.

---

**Herald Patch**

A single pink patch with a scaly edge that appears on the skin of the trunk. A herald patch develops about a week before the full rash of the skin disorder *pityriasis rosea* breaks out.

**Herbal Medicine**

Systems of medical treatment in which various parts of different plants are used to promote health and to treat symptoms of illness. Herbal medicine is a form of *complementary medicine*. Herbal remedies are also used in treatments such as *homeopathy* and *Chinese medicine*.

Although herbal medicine is thought by some to be harmless because it is natural, some herbal remedies contain significant amounts of pharmacologically active substances that may interact with other drugs or affect other medical conditions. Herbal remedies should only be used on the advice of an approved practitioner; a patient should always inform his or her doctor of any herbal medicine he or she is using.

**Herd Immunity**

Protection of a whole community from an infectious disease as a result of immunity in a majority, but not all, of that community. Such immunity may be naturally acquired or may be induced by *immunization*. For example, vaccination of more than 85 per cent of a population against diphtheria will prevent the spread of the disease, should it occur, due to an insufficient number of susceptible people who could catch it and pass it on to others. As a result, even those people without immunity receive a degree of protection from being part of an immune population.

**Hereditary Haemorrhagic Telangiectasia**

An inherited condition in which capillaries (tiny blood vessels) in the skin and in the mucous membranes of areas such as the nose, mouth, and gastrointestinal tract are distended and prone to recurrent bleeding. The condition can result in iron deficiency anaemia (see *anaemia, iron deficiency*). Hereditary haemorrhagic telangiectasia shows an autosomal dominant pattern of inheritance (see *genetic disorders*). (See also *telangiectasia*.)

**Hereditary Spherocytosis**

See *spherocytosis, hereditary*.

**Heritability**

A measure of the extent to which a disease or disorder is the result of inherited factors, as opposed to environmental influences such as diet and climate. Certain disorders (such as *haemophilia* or *cystic fibrosis*) are known to be caused entirely by hereditary factors. In contrast, others are caused wholly by environmental factors. However, existing between these extremes are many disorders (such as schizophrenia) in which both inheritance and environment probably play a part.

A rough estimate of heritability can be obtained from the known incidence of a disorder in the first-degree relatives (parents or siblings) of affected people compared with the incidence of the disorder in a population exposed to similar environmental influences. Estimates of heritability are useful in *genetic counselling*. (See also *genetic disorders*.)

**Hermaphroditism**

A congenital disorder in which *gonads* (testes or ovaries) of both sexes are present within one individual, and in
which the external genitalia are not clearly male or female. True hermaphroditism is extremely rare and its cause is unknown. A more common condition is pseudohermaphroditism, in which the gonads of only one sex are present, but the external genitalia are not clearly either male or female, or are those of the opposite sex.

**hernia**

Protrusion of an organ or tissue through a weak area in the muscle or tissue that normally contains it. The term is usually applied to a protrusion of the intestine through the abdominal wall. In a *hiatus hernia*, the stomach protrudes through the diaphragm, into the chest.

**CAUSES**

Abdominal hernias may be caused by a congenital weakness in the wall of the abdomen. Hernias may also be the result of damage caused by lifting heavy objects, persistent coughing, or straining to defaecate, or they may develop following an operation.

**TYPES**

There are several types of abdominal hernia, which are classified according to their location in the body. The most important are inguinal hernias, which mainly affect men; femoral hernias, which are more common in overweight women; and umbilical hernias, which occur in babies.

**SYMPTOMS AND TREATMENT**

The first symptom of an abdominal hernia is usually a bulge in the abdominal wall. There may also be some abdominal discomfort.

Sometimes the protruding intestine can be pushed back into place (known as a reducible hernia). In other cases, however, the hernia bulges out and cannot be put back (an irreducible hernia). This condition is painful, and surgery is usually necessary to repair the weakened area (see hernia repair).

If the trapped portion of intestine becomes twisted, the blood supply to the area will be impaired. This problem, known as a strangulated hernia, needs urgent treatment, otherwise gangrene of the bowel may develop.

Umbilical hernias in babies can usually be left untreated as they tend to disappear naturally by age five.

**hernia repair**

Surgical correction of a *hernia*. Surgery is usually performed to treat a hernia of the abdominal wall that is painful or cannot be pushed back into place. A strangulated hernia (in which the blood supply to a trapped portion of intestine is cut off) requires an emergency operation.

During surgery, the protruding intestine is pushed back into the abdomen and the weakened muscle wall strengthened. Either open or minimally invasive surgery, using an endoscope to repair the hernia from within the abdominal cavity, may be used.

**herniated disc**

See disc prolapse.

**herniorrhaphy**

See hernia repair.

**heroin**

A narcotic drug similar to morphine. When used for medical purposes, it is generally known as diamorphine. Heroin may also be abused for its mood-altering effects (see heroin abuse).

**heroin abuse**

Nonmedical, illicit use of heroin. The heroin taken by drug abusers is a white or brownish powder that can be smoked, sniffed, or dissolved in water and injected.

---

### MAIN TYPES OF ABDOMINAL HERNIA

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Inguinal hernia</strong></td>
<td>At least 2 per cent of adult males in the UK suffer at some time from this kind of hernia, in which part of the intestine bulges through the inguinal canal (the passage through which the testes descend into the scrotum). The hernia is detected as a bulge in the groin or scrotum; untreated, the hernia may become stuck, so early surgery is generally recommended.</td>
</tr>
<tr>
<td><strong>Femoral hernia</strong></td>
<td>This type of hernia occurs most commonly in obese women; part of the intestine emerges where the femoral vein and artery pass from the abdomen to the thigh. A femoral hernia is noticed as a swelling of the top front of the thigh. Although the hernia itself may be large, its neck is narrow, and the condition can only be corrected by surgery.</td>
</tr>
<tr>
<td><strong>Epigastric hernia</strong></td>
<td>Also called a ventral hernia, an epigastric hernia is caused by a weakness in the muscles of the central upper abdomen; the intestine bulges out at a point between the navel and the breastbone. This form of hernia is three times more common in men than in women and is most likely to occur in people between 20 and 50 years old.</td>
</tr>
<tr>
<td><strong>Umbilical hernia</strong></td>
<td>This occurs when part of the intestine protrudes through the abdominal wall at the navel. Babies are the most common sufferers; the hernia can be repaired surgically or it may disappear naturally by about the age of five. A similar problem, a parumbilical hernia, occurs mostly in obese, middle-aged women who have had several children.</td>
</tr>
<tr>
<td><strong>Incisional hernia</strong></td>
<td>An area of weakness may occasionally develop following a surgical incision in the wall of the abdomen. This area may then develop into an incisional hernia. The defect may become so severe that a large amount of intestine bulges through the abdominal wall; if this happens, a repair using a piece of mesh may be necessary.</td>
</tr>
</tbody>
</table>
Heroin has an analgesic effect and produces sensations of warmth, calmness, drowsiness, and a loss of concern for outside events. Long-term drug use causes tolerance and psychological and physical dependence (see drug dependence; heroin abuse). Sudden withdrawal produces shivering, abdominal cramps, diarrhoea, vomiting, and restlessness.

Heroin addiction has many adverse effects on the user, including injection scars, skin abscesses, weight loss, immunity suppression, and the risk of infection with hepatitis B, hepatitis C, and HIV through sharing needles. Death commonly occurs from accidental overdose.

**herpangina**
A throat infection caused by coxsackievirus. Herpangina most commonly affects young children. The virus is usually transmitted via infected droplets coughed or sneezed into the air. Many people harbour the virus but do not have symptoms.

**SYMPTOMS**
After an incubation period of two to seven days, there is a sudden onset of fever, accompanied by a sore throat and sometimes also headache, abdominal discomfort, and muscular pains. The throat becomes red and a few small blisters appear, which enlarge and burst, forming shallow ulcers. These symptoms usually clear up within a week, without specific treatment.

**HERNIA REPAIR**
During surgery the hernia is removed or repositioned and the weakened abdominal wall is reinforced with stitching or mesh.

1. The protruding sac of intestine is pushed back into the abdomen or, in some cases (such as strangulation), the sac is removed surgically.

2. The muscular wall of the abdomen may then be repaired by overlapping the edges of the weakened area and securing them with rows of stitching.

**LARGE HERNIAS**

Alternative method
For repair of some large or recurrent hernias, two mesh leaves are secured by rows of stitching, then joined at the centre.

**herpes**
Any of a variety of conditions that are characterized by an eruption of small, usually painful, blisters on the skin. The term “herpes” usually refers to an infection with the herpes simplex virus. Two forms of this virus, called HSV1 and HSV2, are generally responsible for cold sores and genital herpes (see herpes, genital), respectively.

A closely related organism, the varicella–zoster virus, is responsible for two other conditions in which skin blisters are a feature: chickenpox and herpes zoster (shingles).

**herpes, genital**
A sexually transmitted infection caused mainly by HSV2, one form of the herpes simplex virus. Rarely, genital infections can be due to HSV1 that has been transmitted by oral contact with the genitals. After an incubation period of about a week, the virus produces soreness, burning, itching, and small blisters in the genital area. The blisters burst to leave small, painful ulcers, which heal in 10 to 21 days. The lymph nodes in the groin may become enlarged and painful, and the person may develop other symptoms such as a headache, fever, and aching muscles.

**TREATMENT**
Genital herpes cannot be cured, but early treatment can reduce the severity of symptoms. Antiviral drugs, such as aciclovir make the ulcers less painful and also encourage healing. Other measures that may be taken include taking analgesic drugs and bathing the genital area in a salt solution.

**OUTLOOK**
Once the virus has entered the body, it stays there for the rest of the person’s life. Recurrent attacks may occur, usually during periods when the person is feeling run down, anxious, or depressed, or, in some cases, a few days before menstruation. The virus may be shed continuously and can be transmitted to others through sexual intercourse, even when the infected person has no symptoms. Recurrent attacks tend to become less frequent and less severe over time.

Genital herpes may be passed from a pregnant woman to her baby during delivery. If the genital herpes develop in late pregnancy, delivery by caesarean section is usually recommended.

**herpes gestationis**
A rare skin disorder of pregnant women that produces crops of tense, itchy blisters on the legs and abdomen. Herpes gestationis is an autoimmune disorder that is essentially a type of pemphigoid triggered by pregnancy.

Severe herpes gestationis is treated with corticosteroid drugs in tablet form. An affected woman may need to be monitored closely as there is an increased risk of fetal prematurity and low birthweight.

The disorder may initially worsen after delivery but then clears up. It tends to recur in subsequent pregnancies.

**herpes simplex**
A common viral infection that is characterized by small, fluid-filled blisters. Herpes simplex infections are contagious and are usually spread by direct contact. Most infections are quite mild.

**TYPES**
There are two forms of the virus: HSV1 (herpes simplex virus, type 1) and HSV2 (herpes simplex virus, type 2). Most people are infected with HSV1 at some time in their lives, usually during childhood. HSV1 is usually associated with infections of the lips, mouth, and face; HSV2 is often associated with infections of the genitals and infections acquired by babies at birth. There is considerable overlap between the two types; sometimes, conditions usually due to HSV1 are caused by HSV2, and vice versa.

**Type 1 virus** The initial infection may be symptomless; alternatively, it may cause a flu-like illness with mouth ulcers. Thereafter, the virus remains dormant in nerve
cells in the facial area. In many people, the virus is periodically reactivated, causing cold sores that invariably erupt in the same site (usually around the lips).

Sometimes the virus can infect a finger after touching a cold sore, causing a painful eruption called a herpetic whitlow. HSV1 may also produce eczema herpeticum (an extensive rash of skin blisters) in a person with a pre-existing skin disorder, such as eczema. Eczema herpeticum may require hospital admission. If the virus gets into an eye it may cause conjunctivitis, which usually lasts only a few days; more seriously, it may cause a corneal ulcer.

Rarely, HSV1 spreads to the brain, leading to encephalitis. The virus may cause a potentially fatal generalized infection in a person with an immunodeficiency disorder or in someone taking immunosuppressant drugs.

**Type 2 virus** HSV2 is the usual cause of sexually transmitted genital herpes (see herpes, genital), in which painful blisters erupt in the genital area. In some people, the blisters tend to recur.

**TREATMENT**

Treatment of herpes simplex depends on its type, site, and severity of symptoms. Antiviral drugs, such as aciclovir, may be helpful, particularly if used early in an infection.

**herpes zoster**

An infection of the nerves supplying certain skin areas that is characterized by a painful rash of small crusting blisters. Also called shingles, herpes zoster is especially common among older people.

**TYPES**

Herpes zoster usually affects only one side of the body, and follows the path of a nerve. It commonly develops on a strip of skin over the ribs, although the rash may also appear on the neck, arm, or lower part of the body. Sometimes the infection involves the face and eye; this form of the disorder is called herpes zoster ophthalmicus.

**CAUSES**

Herpes zoster is caused by the varicella–zoster virus, which also causes chickenpox. After an attack of chickenpox, some of the viruses survive and lie dormant for many years in the nerve cells near the spinal cord. In some people, a decline in the efficiency of the immune system – especially in old age – because of disease or severe stress, allows the viruses to re-emerge and cause herpes zoster. The disorder is also common in people whose immune system is weakened by stress or by certain drugs, such as corticosteroid drugs or anticancer drugs.

**SYMPTOMS**

The first indication of herpes zoster is excessive sensitivity in the skin, followed by pain, which is often severe. The infection can be difficult to diagnose at this stage and may be mistaken for a different condition; for example, pain in the chest wall may be mistaken for angina pectoris. After about five days, the rash appears as small, raised, red spots that soon turn into blisters. Within a few days, the blisters dry, flatten, and develop crusts. Over the next two weeks, the crusts drop off, sometimes leaving small pitted scars.

The most serious feature of herpes zoster is pain after the attack, known as postherpetic neuralgia, which affects about a third of all infected people. This pain is caused by nerve damage, and may last for months or years. Herpes zoster ophthalmicus may cause a corneal ulcer or uveitis (inflammation of the part of the eye known as the uvea).

**TREATMENT**

If treatment is begun soon after the rash appears, antiviral drugs, such as aciclovir, will reduce the severity of the symptoms and minimize nerve damage. Analgesic drugs (painkillers) may also be helpful in relieving pain. If postherpetic neuralgia is a problem, anticonvulsant drugs, such as gabapentin, may be helpful.

**herpetic whitlow**

A painful swelling on the finger caused by infection with the herpes simplex virus. (See also whitlow.)

**heterosexuality**

Sexual attraction of an individual to members of the opposite sex. (See also bisexuality; homosexuality.)
tighten the oesophageal sphincter. This can now be carried out by minimally invasive surgery through an endoscope.

**Hib vaccine**
A vaccine administered routinely at two, three, and four months of age to provide immunity to the bacterium *Haemophilus influenzae* type b (Hib). Before the vaccine was generally available, Hib infection was a common cause of bacterial meningitis and epiglottitis in children.

**hiccup**
A sudden, involuntary contraction of the diaphragm followed by rapid closure of the vocal cords. Most attacks of hiccups last only a few minutes, and are not medically significant. Rarely, they may be due to a condition, such as pneumonia or pancreatitis, that causes irritation of the diaphragm or phrenic nerves. Chlorpromazine, haloperidol, or diazepam may be prescribed for frequent, prolonged attacks.

**Hickman catheter**
A flexible plastic tube, also known as a skin-tunnelled catheter, that is passed through the chest and inserted into the subclavian vein, which leads to the heart. It is often used in people who have leukaemia or other cancers and need regular chemotherapy and blood tests. The catheter allows drugs to be injected directly into the bloodstream and blood samples to be obtained easily. It is inserted under local anaesthesia. A Hickman catheter can remain in position for months; the external end is plugged when not in use.

**hidradenitis suppurativa**
Inflammation of the sweat glands in the armpits and groin due to a bacterial infection. Abscesses develop beneath the skin; the affected area becomes reddened and painful and may ooze pus. The condition tends to be recurrent and can eventually cause scarring. Antibiotic drugs may help to reduce the severity of an outbreak.

**hidrosis**
The medical term for sweating. (See also hyperhidrosis; hypohidrosis.)

**high density lipoprotein**
A type of lipoprotein, made up of protein and lipid (fat), that transport lipids in the blood. High levels of high density lipoprotein (HDL) can help to protect against atherosclerosis (fatty deposits on artery walls) because it removes cholesterol from the circulation and takes it to the liver for processing. (See also fats and oils; low density lipoprotein.)

**high-dependency unit**
A level of hospital inpatient care intermediate between that of a general ward and that of an intensive care unit. Also known as a “step-down” facility, staff in a high-dependency unit provide monitoring and support for acutely ill patients. It also has facilities for short-term ventilation (use of a machine to assist breathing) and emergency resuscitation.

**hilum**
The term that is used to describe a small indentation on the surface of an internal organ where blood vessels, nerve fibres, or other similar structures enter or leave the organ. For example, the hilum of the lung is its junction with the main bronchus and the major vessels. A commonly used alternative term is “hilus”.

**hindmilk**
The breast milk that is produced at the end of a feed. Hindmilk contains more fat than foremilk and therefore provides the baby’s main source of energy. (See also breast-feeding.)

**hindwaters**
A term for the amniotic fluid that is discharged behind the presenting part of the baby (usually the head) during pregnancy and delivery. In contrast, the forewaters (the “waters”) precede the presenting part of the baby and may rupture (or “break”) before or after the onset of labour.

**hinge joint**
A type of mobile joint that allows movement in one plane only (forwards and backwards). Examples of hinge joint are the knee joint and the elbow joint.

**hip**
The joint between the pelvis and the upper end of the femur (thigh bone). The hip is a ball-and-socket joint; the smooth, rounded head of the femur fits securely into the acetabulum, a cup-like cavity in the pelvis. Tough ligaments attach the femur to the pelvis, further stabilizing the joint and giving it the necessary strength to support the weight of the body and take the strain of leg movements. The structure of the hip allows a considerable range of leg movement.

**ducking, gulping**
A fairly common condition in adults in which a characteristic dull clicking can be heard and felt during certain movements of the hip joint. Clicking hip is caused by a tendon slipping over the acetabulum of the hip.
bony prominence on the outside of the femur (thigh bone), and does not indicate disease.

Clicking of the hip may sometimes be heard during examination of newborn babies; in this instance, it indicates possible dislocation of the hip (see developmental hip dysplasia).

**hip, congenital dislocation of**
See developmental hip dysplasia.

**hip dysplasia, developmental**
See developmental hip dysplasia.

**hippocampus**
A structure in the limbic system of the brain. The hippocampus, consisting of a band of grey matter, is involved with some learning processes and long-term memory storage.

**Hippocratic oath**
A set of ethical principles that are derived from the writings of the Greek physician Hippocrates that is concerned with a doctor’s duty to work for the good of the patient.

**hip replacement**
A surgical procedure to replace all or part of a diseased hip joint with an artificial substitute. The replacement is most often carried out in older people whose joints are stiff and painful as a result of osteoarthritis. It may also be needed if rheumatoid arthritis has spread to the hip joint or if the top end of the femur (thigh bone) is badly fractured (see femur, fracture of).

**Hirschsprung’s disease**
A congenital disorder in which the rectum, and sometimes the lower part of the colon, lack the ganglion cells that control the intestine’s rhythmic contractions. The affected part of the colon becomes narrowed and blocks the movement of faecal material.

The disease is rare and tends to run in families. It occurs about four times more often in boys. Symptoms, which include constipation and bloating, usually develop in the first few weeks of life. The child usually has a poor appetite and may fail to grow properly.

A barium X-ray examination can show the narrowed segment of the intestine. A biopsy may also be taken. Treatment of Hirschsprung’s disease involves removing the narrowed segment and rejoining the normal part of the intestine to the anus.

**hirsutism**
Excessive hairiness, which particularly appears in women. The additional hair is coarse in texture and grows in a male pattern on the face, trunk, and limbs. Hirsutism can be a symptom of certain conditions, such as polycystic ovary syndrome and congenital adrenal hyperplasia, in which the level of naturally occurring male hormones in the blood is abnormally high. Hirsutism can also be a result of taking anabolic steroids (see steroids, anabolic). More commonly, however, hirsutism is not a sign of any disorder at all; it occurs mildly in many normal women, especially after the menopause, in which hormone balance is upset (See also hypertrichosis.)

**hirudin**
An anticoagulant contained in the saliva of leeches (see leech) that prevents blood from clotting.

**histamine**
A chemical present in cells (mainly mast cells) throughout the body that is released during an allergic reaction (see allergy). Histamine activates two main types of receptors: H₁ and H₂. H₁ activation is responsible for the swelling and redness that occur in inflammation. It also narrows the airways in the lungs and causes itching. H₂ activation stimulates acid production by the stomach, but in large amounts it can irritate the stomach lining, causing gastritis or peptic ulcers.

**PERFORMING A HIP REPLACEMENT**
In this operation, the surgeon pushes aside or cuts through the surrounding muscles to expose the hip joint. The femur (thigh bone) is cut and the pelvis is drilled to make room for the two components of the artificial joint. These parts are secured in place, the femur is repaired, and the muscles and tendons are replaced and repaired.

**Components**
An artificial hip joint has two parts. The ball and shaft are metal; the socket may be metal or plastic.
Allergic reactions caused by H₁ can be controlled by antihistamine drugs. Overproduction of stomach acid due to H₂ can be counteracted by H₂-receptor antagonists (see ulcer-healing drugs).

**histamine-ᵢ-receptor antagonists**
See H₂-receptor antagonists.

**histamine-ᵢ-receptor antagonists**
See H₂-receptor antagonists.

**histiocytosis X**
A rare childhood disease, now more commonly known as Langerhans cell histiocytosis, in which there is an overgrowth of a type of tissue cell called a histiocyte. The cause is unknown, but the condition probably results from a disturbance of the immune system. In the mildest form, rapid cell growth occurs in one bone only, usually the skull, a clavicle, a rib, or a vertebra, causing swelling and pain. In the most severe, and least common, form, there is a rash and enlargement of the liver, spleen, and lymph nodes, as well as lung involvement. In these cases, treatment is with anticancer drugs, but the outlook is poor.

**histocompatibility antigens**
A group of proteins that have a role in the immune system. Certain types of histocompatibility antigen are present on every cell in the body; they are essential for the immunological function of killer T cells, which help to defend the body against disease. The antigens act as a guide enabling the killer T cells to distinguish between self and nonself and to kill abnormal or foreign cells.

The main group of histocompatibility antigens is the human leukocyte antigen (HLA) system, which consists of several series of antigens. There are six different genes known as HLA-A, HLA-B, HLA-C, HLA-DR, HLA-DQ, and HLA-DR. Each of these has many different forms, or alleles; for example, HLA-B has over 40 different numbered alleles. A person's tissue type (the particular set of HLAs in the body tissues) is unique, except in the case of identical twins, who have identical sets of HLAs.

HLA analysis has some useful applications. Comparison of HLA types may show that two people are related, and it has been used in paternity testing. The HLA system is also used in tissue-typing to help match recipient and donor tissues before transplant surgery. Certain HLA types occur more frequently in people with particular diseases. For example, HLA-B27 is associated with several forms of arthritis, particularly ankylosing spondylitis, and HLA-DR2 and an HLA-DQ type with narcolepsy. HLA testing can help to confirm the diagnosis in someone who may have one of these conditions.

**histology**
The study of tissues, including their cellular structure and function. The main application of histology in medicine is in the diagnosis of disease. This process often involves obtaining a sample of tissue (see biopsy) and examining it under a microscope to detect any abnormalities, such as cancerous cells or areas of scar tissue. Examination of tissue samples may also be performed to determine the extent of a disease, such as cancer, once it has been detected. If a cancerous tumour is found, for example, it may be removed, together with an area of surrounding tissue; by examining this material, doctors can tell whether the whole of the diseased area has been removed or whether cancerous cells have spread beyond the edges of the tumour.

**histopathology**
A branch of histology concerned with the effects of disease on the microscopic structure of tissues.

**histoplasmosis**
An infection caused by inhaling spores of the fungus Histoplasma capsulatum, which is found in soil contaminated with bird or bat droppings. Histoplasmosis occurs in parts of the Americas, the Far East, and Africa. Treatment is by intravenous infusion of antifungal drugs.

**history-taking**
The process by which a doctor gathers information from patients regarding the symptoms of their illnesses and details of any previous disorders. (See also diagnosis.)

**histrionic personality disorder**
A psychiatric disorder characterized by exaggerated emotional reactions and attention-seeking behaviour. Affected people also constantly demand praise or reassurance, and require immediate satisfaction of their demands. The disorder usually first appears in early adulthood, and is more common in women.

**HIV**
The abbreviation for human immunodeficiency virus. HIV is a retrovirus that infects and gradually destroys cells in the immune system and may eventually lead to AIDS (acquired immunodeficiency syndrome). There are two closely related viruses: HIV-1, which is the most common cause of AIDS throughout the world; and HIV-2, which is largely confined to West Africa.

**METHODS OF TRANSMISSION**
HIV is transmitted in body fluids, such as blood, semen, and vaginal secretions. It most commonly gains access to the body during sexual activity (either vaginal, anal, or oral), particularly when contaminated body fluids come into contact with broken skin. Other sources of infection are nonsterile needles (for example, among people who abuse intravenous drugs and share needles and syringes) and, in some parts of the world, contaminated blood transfusions. In addition, if a pregnant woman is infected, the virus can pass to the fetus via the placenta. It is not transmitted by everyday physical contact such as shaking hands or hugging.

**EFFECTS OF THE VIRUS**
HIV infects cells that have a special structure, called a CD4 receptor, on their surface. This includes immune system cells called CD4 lymphocytes, which defend the body against cancerous and infected cells, as well as certain cells in other tissues, such as the brain. The virus multiplies within the cells, killing them in the process; the dead cells then release many virus particles into the blood. If the virus is untreated, the number of CD4 lymphocytes falls. This results in a reduced ability to fight off infections and certain types of cancer.

HIV is extremely successful at withstanding any attempt by the body to destroy it. Every time HIV replicates, it changes its antigen makeup, thereby ensuring that it is extremely difficult for the body to mount an effective immune response to it.

**SYMPTOMS**
Initially, some people who are infected with HIV may have no symptoms. However, between six and eight weeks after exposure, some people develop a flu-like illness similar to glandular fever (see mononucleosis, infectious), with fever, fatigue, sore throat, aching muscles, and swollen lymph nodes. These symptoms usually clear up after a few weeks. Some people may then develop...
HIV (human immunodeficiency virus), like any virus, consists of some nucleic acid inside a capsule made of protein. The virus invades a lymphocyte (a type of white blood cell).

1. The strand of nucleic acid escapes from the capsule and uses the host cell's resources to make copies of itself.

2. Each copy forms a capsule and leaves the host cell, which eventually ceases to function efficiently in fighting disease.

3. The host cell is then destroyed, and copies of virus are released into the blood stream, where they can infect other cells.

HIV may also affect the brain, causing a variety of neurological disorders, including dementia.

If HIV infection is untreated, the infected person may eventually develop full-blown AIDS. In this condition, the immune system is severely weakened, resulting in severe infections caused by organisms that are usually harmless as well as in certain types of cancer.

DIAGNOSIS, TREATMENT, AND OUTLOOK
HIV is diagnosed through an HIV test, a blood test that detects the presence of antibodies (proteins manufactured by the immune system) to HIV in the blood.

People infected with HIV should have regular monitoring in order to determine when specific treatments, such as antiretroviral drugs, are necessary. The main types of antiretroviral used are protease inhibitors, such as indinavir and lopinavir, and reverse transcriptase inhibitors, such as zidovudine. These drugs can slow the course of the disease and may prevent the development of full-blown AIDS.

In wealthier countries, HIV infection is no longer necessarily a fatal disease. It remains life-threatening, however, and the most effective strategy for defeating it is prevention of infection.

PREVENTION
The risk of infection with HIV can most easily be reduced by practising safer sex. Intravenous drug users should take care not to share needles. Others who may be at risk, such as healthcare workers who may come into contact with infected body fluids or needles, should observe recommended safety regulations.

hives
An alternative name for urticaria.

HIV test
A blood test that is used to detect the presence in the blood of antibodies to HIV, the virus that can lead to AIDS. Antibodies are proteins manufactured by the immune system in response to a foreign protein (antigen) in the body, although they may not develop for three months after initial infection with HIV. A positive result, in which these antibodies are detected, indicates the presence of HIV.

HLA
The abbreviation for human leukocyte antigen.

HLA types
See histocompatibility antigens.

hoarseness
A rough, husky, or croaking voice. Hoarseness is usually due to irritation of, or strain on, the larynx (voicebox).

CAUSES
Short-lived hoarseness is often due to overuse of the voice, which strains the muscles in the larynx. It is also commonly caused by inflammation of the vocal cords in acute laryngitis.

Persistent hoarseness may be due to chronic irritation of the larynx, which can be caused by smoking, excessive alcohol consumption, chronic bronchitis, or constant dripping of mucus from the nasal passages. Polyps (harmless growths) on the vocal cords may also cause hoarseness. In people with hypothyroidism (underactivity of the thyroid gland), hoarseness can result from formation of tissue on the vocal cords. In young children, it may be a symptom of croup.

Occasionally, persistent hoarseness in adults has a more serious cause, such as cancer of the larynx (see larynx, cancer of), thyroid cancer, or lung cancer.

TREATMENT
In cases where voice strain or laryngitis is the cause, resting the voice often helps recovery. If hoarseness persists for more than two weeks, a doctor should be consulted. A laryngoscopy (examination of the larynx with a mirror or with a more specialized viewing instrument) may be performed to exclude any serious underlying causes.

Hodgkin’s disease
An uncommon cancerous disorder in which there is a proliferation of cells in lymphoid tissue (which is found mainly in the lymph nodes and spleen). This is also known as a lymphoma. Men are affected more commonly than women. The cause is unknown.

SYMPTOMS AND SIGNS
The most common sign is the painless enlargement of lymph nodes, typically in the neck or armpits. There may be a general feeling of illness, with fever, weight loss, and night sweats. There may also be generalized itching and, rarely, pain in the swollen lymph nodes after drinking alcohol. As the disease progresses, the immune system becomes increasingly impaired.

DIAGNOSIS AND TREATMENT
A diagnosis of Hodgkin’s disease is usually made by performing a biopsy (removal of a small sample of tissue for microscopic analysis) of an enlarged lymph node. The identification of characteristic cells, called Reed-Sternberg cells, in the biopsy confirm the diagnosis. The extent of the disease (its stage) can be assessed by chest X-ray, CT scanning, or MRI of the abdomen and a bone marrow biopsy. The disease can usually be cured with radiotherapy, chemotherapy, or a combination of the two treatments. (See also lymphoma, non-Hodgkin’s.)

hole in the heart
The common term for a septal defect.

holistic medicine
A form of therapy that treats the whole person rather than the specific disease symptoms. A holistic approach is emphasized by many practitioners of complementary medicine.
Holmes–Adie pupil
Also known as Adie’s syndrome, a dilated pupil (the circular opening in the centre of the iris), usually only in one eye, that may be irregular in shape. The pupil does not respond, or may respond only very slowly, to bright light; in addition, it responds only partially when focusing on different distances. The condition, which is most common in young women, is of unknown cause and has no detrimental effects.

Holmes–Rahe questionnaire
A survey, devised in the 1960s, that is used to determine the comparative stress levels caused by certain common life events, such as the death of a partner, changes in financial or social circumstances, and serious illness.

Each potentially stressful event on the scale is allotted a specific score, with the death of a partner given the maximum (100) and the other stressors ranked in order of their scores. People undergoing the test select all of the stressful events that apply to them from the scale, then add together the scores for these stressors to determine their overall stress level.

Holter monitor
A wearable device used in ambulatory electrocardiography (ECG) to record the heart’s electrical activity continuously for 24 hours or longer. The monitor records this activity by means of electrodes attached to the chest and allows the detection of intermittent arrhythmias (irregularities in the heartbeat). (See also telecardiography.)

Holt–Oram syndrome
A genetic disorder in which there is an atrial septal defect (a hole in the wall dividing the upper chambers of the heart) together with various malformations of the upper limbs, particularly of the hands and forearms.

Homeopathy
A holistic system of complementary medicine that aims to treat the whole person rather than only the symptoms of a condition. Homeopathy works on the principle that the mind and body are so closely linked that physical conditions cannot be successfully treated without an understanding of a person’s constitution and character. The particular remedy chosen to give to a patient with a condition may depend on a variety of factors, such as the patient’s temperament, state of mind, and lifestyle.

Homeostasis
The automatic processes by which the body maintains a constant internal environment despite changes within or outside it. Homeostasis is vital for the body, because tissues and organs can only function efficiently within a narrow range of physical conditions. The body regulates conditions such as temperature and acidity by means of negative feedback; for example, when the body overheats, sweating is stimulated until the temperature returns to normal. Homeostasis also involves the regulation of blood pressure and the levels of natural chemicals such as glucose.

Homeostatic mechanisms sometimes malfunction. In diabetes mellitus, for example, blood glucose levels can no longer be regulated properly because of a malfunction in insulin production.

Homocystinuria
A rare, inherited condition caused by an enzyme deficiency. Homocystinuria is a type of inborn error of metabolism (see metabolism, inborn errors of) in which there is an abnormal presence of homocysteine (an amino acid) in the blood and urine. Affected people may be very tall, with long limbs and fingers. Some have skeletal deformities and abnormalities of the eye lens. The condition is incurable, but it may be improved by a special diet.

Homosexuality
Sexual attraction to people of the same sex. (See also bisexuality; heterosexuality.)

Homoygote
A term used to describe a person whose cells contain two identical alleles (forms of a gene) controlling a specified inherited trait. The cells of a heterozygote contain two different alleles controlling that trait. (See also inheritance; genetic disorders.)

Hookworm infestation
An infestation of the small intestine by small, round, bloodsucking worms of the Necator americanus or Ancylostoma duodenale species. Infestation with

Hookworm Life-Cycle
Infestation begins with larvae that penetrate the skin or are ingested and enter the bloodstream. They migrate throughout the body, particularly to the small intestine. Adult worms develop and lay eggs, which leave the body in faeces and eventually hatch into larvae.

Head of hookworm
The hookworm uses its sharp, curved, tooth-like structures to cling to the bowel wall.
hookworm occurs mainly in the tropics, particularly in areas where sanitation is poor or where human faeces is used as fertilizer for agriculture.

The larvae enter the body by penetrating the skin of the feet or by ingestion. They migrate throughout the body and grow to maturity in the small intestine. Adult worms are about 12 mm long and have mouths with hooked teeth; they feed by attaching themselves to the intestinal wall and sucking blood. The female worms lay eggs, which then pass out in the faeces.

When larvae penetrate the skin, a red, itchy rash may develop on the feet. In light infestations, there may be no further symptoms. However, in heavier infestations, migration of the larvae through the lungs may produce coughing and, in some cases, pneumonia; adult worms in the intestines may cause abdominal discomfort. The most important problem is iron-deficiency anaemia due to loss of blood.

Diagnosis is made by microscopic examination of the faeces for worm eggs. Anthelmintic drugs kill the worms. (See also larva migrans.)

hordeolum
The medical name for a sty.

hormonal contraception
See: contraception, hormonal methods of.

hormonal disorders
Conditions caused by malfunction of an endocrine gland.

hormone
A hormone is a chemical messenger that is released into the bloodstream by a gland or tissue in order to have a specific effect on tissues elsewhere in the body, altering their activity. Hormones control a wide variety of body functions, including metabolism of cells, growth, sexual development, and the body’s response to stress or illness.

Many hormones are produced by endocrine glands. The primary function of the major endocrine glands (the pituitary, thyroid, parathyroid, and adrenal glands and the pancreas, ovaries and testes) is the production of various hormones. Hormones are also secreted by other organs (see Sources and effects of particular hormones table, opposite), including the brain, kidneys, intestines, and, in pregnant women, the placenta.

hormone antagonist
A drug that is used to block the action of a hormone.

hormone replacement therapy (HRT)

The use of a synthetic or natural hormone to treat a hormone deficiency.

Most commonly, the term HRT refers to the use of female hormones to replace those lost after the menopause. This loss may occur naturally or as a result of treatment such as radiotherapy or the removal of the ovaries.

**BENEFITS AND RISKS**

The benefits of HRT have to be weighed against the risks. In the short term, HRT relieves symptoms of oestrogen withdrawal, particularly night sweats, hot flushes, and vaginal dryness. The minimum effective dose should be used for the shortest duration, however.

In the long term, HRT may give protection against osteoporosis (the loss of bone density that can lead to fractures). However, HRT is now only used for this purpose in women who are unable to take other treatments, such as bisphosphonate drugs; when other treatments have been unsuccessful; or in women who have gone through a premature menopause (before the age of 40).

Minor adverse effects of HRT include nausea, breast tenderness, fluid retention, and leg cramps. HRT may increase the risk of abnormal blood clotting; the likelihood of deep vein thrombosis (see thrombosis, deep vein) and pulmonary embolism developing may also increase. Women taking HRT have an increased risk of developing breast cancer compared to women who are not taking it, and the risk increases the longer it is continued.

Whether or not HRT is appropriate depends on the individual woman concerned. Women who are considering HRT should consult their doctor, who will discuss their specific circumstances. Once it has been started, the therapy should be reviewed regularly by a doctor.

**TYPES OF HRT**

In women with a uterus, HRT involves taking a continuous dose of an oestrogen drug, which is combined with an additional progestogen drug for ten to 13 days of the 28-day cycle. The progestogen drug provokes bleeding which is similar to that of menstruation. This is necessary to prevent excessive thickening of the lining of the uterus and the risk of it becoming cancerous.

Alternatively, in cases in which more than one year has passed since the woman’s last menstrual period, continuous bleed-free HRT, or a single drug with both oestrogenic and progestogenic effects (such as tibolone), can be used. Women who have had a hysterectomy need only take oestrogen drugs.

Oestrogen drugs can be given in the form of tablets, skin patches, gels, or implants; progestogen drugs are given as tablets, skin patches, or vaginal gel.

horn, cutaneous
A hard, noncancerous protrusion occasionally found on the skin of the elderly. Caused by overgrowth of keratin, they vary in colour from yellow to brown or black. They may develop where there was previously a wart and may grow slowly. Left untreated, they can grow considerably; surgical removal may be advised.

Appearance of cutaneous horn
The horny protuberance that has developed on this woman’s face results from an overgrowth of keratin (a skin protein).

Hormer’s syndrome
A group of physical signs (such as narrowing of the eye pupil, drooping of the eyelid, and absence of sweating) affecting one side of the face that indicates damage to part of the sympathetic nervous system (see autonomic nervous system).

horseshoe kidney
A congenital abnormality in which the two kidneys are fused at the base, forming a so-called horseshoe shape. The joined kidneys usually function normally, but this condition may be associated with other kidney problems, such as urinary tract infection.
The various glands of the hormonal system constitute a control and communications network that is complementary to the nervous system. However, instead of using nerve impulses, the glands secrete chemical messages (in the form of hormones) to affect other glands and tissues in various parts of the body. Hormones are carried in the bloodstream to their targets, where they exert their specific effects. The table below lists the hormones that are secreted by different parts of the body and gives a description of their wide-ranging actions.

</table>
hospice
A hospital or part of a hospital devoted to the care of patients who are terminally ill (see dying, care of the).

hospitals, types of
Most of the hospitals in the UK are part of the National Health Service. Each NHS district has a general hospital providing services that include medicine, surgery, gynaecology, obstetrics, and pediatrics. Some more specialist services are concentrated in fewer centres. Many of the UK’s private hospitals cater for nonemergency surgery, obstetric care, or inpatient care for the mentally ill.

host
In medical terminology, an organism, either animal (including human) or plant, in which a parasite lives for part or all of its life cycle.

hot abscess
An abscess (a collection of pus) that is of relatively brief duration, but which causes severe, painful inflammation that is red, swollen, and hot to the touch. (See also cold abscess.)

hot flushes
Temporary reddening of the face, neck, and upper trunk that is accompanied by a sensation of heat and is often followed by sweating. Hot flushes are usually the result of decreased oestrogen production during or following the menopause, and they sometimes occur following the removal of the ovaries (see oophorectomy). If they are severe, hot flushes can often be alleviated by hormone replacement therapy (HRT), but this is not advised in the long term. Alternatively, they can be treated with clonidine, an antihypertensive drug.

hot spot
An area of increased radionuclide uptake as seen on a radionuclide scan. A hot spot usually indicates an abnormal area in which there is increased activity in the tissue. The term may be used in relation to any radionuclide scan, but it is commonly applied to a bone scan in which the hot spot may indicate an abnormality such as an infection or a tumour.

house dust mite
A microscopic organism commonly found in homes that may cause a variety of allergic reactions. Inhalation of dust containing the faeces of the house-dust mite is a common cause of asthma, eczema, and allergic rhinitis (see rhinitis, allergic) in susceptible people.

housemaid’s knee
Also known as prepatellar bursitis, inflammation of the fluid-filled sac that acts as a cushion over the kneecap.

HPV
The abbreviation for human papillomavirus.

HRT
See hormone replacement therapy.

5HT₁ agonists
Another name for serotonin agonists.

5HT₃ antagonists
Another name for serotonin antagonists.

HTLV
The abbreviation for human T-lymphotropic virus.

Hughes’ syndrome
A potentially serious condition, also called antiphospholipid syndrome, that is characterized by an increased tendency for the blood to clot inside the blood vessels (see thrombosis). The syndrome is sometimes referred to as “sticky blood”.

CAUSE
Hughes’ syndrome is thought to be an autoimmune disorder, in which the immune system attacks fatty molecules called phospholipids, which are found throughout the body (particularly in cell membranes). The condition may occur alone or with another autoimmune disease, such as systemic lupus erythematosus. It is most common in women.

SYMPTOMS AND COMPLICATIONS
Thrombi (clots) may form in both arteries and veins anywhere in the body. The legs are most commonly affected (see deep vein thrombosis). In the brain, a clot can cause areas of tissue to be starved of blood, leading to headaches, migraines, and memory loss. In the lungs, they can cause shortness of breath, chest pain, or coughing up blood. Other possible symptoms include dizziness or disturbances in balance; visual disturbances; and “pins and needles”. The blood vessels under the skin may also be affected, particularly on the wrists and knees, causing a red, lacy rash called livedo reticularis.

Clotting within an artery may lead to life-threatening complications such as myocardial infarction (heart attack), pulmonary embolism, transient ischaemic attack, or stroke. These disorders may occur at an unusually young age (under age 45). In pregnant women, clots may
develop in the placenta, disrupting the blood supply to the fetus and causing miscarriage; affected women may have several consecutive miscarriages.

**TREATMENT AND OUTLOOK**
Hughes’ syndrome is treated with drugs that reduce the tendency of the blood to clot: aspirin, heparin, or warfarin. Treatment is long-term or even lifelong, but greatly improves the outlook. It enables people to lead a completely normal life and, in women of childbearing age, drastically reduces the risk of miscarriage.

**human chorionic gonadotrophin**
See gonadotrophin, human chorionic.

**human gamma-globulin**
See gamma-globulin.

**human genome**
See genome, human.

**human leukocyte antigen (HLA)**
A protein that belongs to the group of proteins called histocompatibility antigens, which play a role in the immune system.

**human papillomavirus**
A type of virus that is responsible for warts and genital warts. There are over 70 subtypes of human papillomavirus. At least two of these subtypes are thought to be a causative factor in cervical cancer and anal cancer.

**human T-cell lymphotropic virus**
A type of retrovirus, also called human T-cell leukaemia virus or HTLV. There are several types of HTLV, the most common of which is HTLV-1, which is endemic in tropical regions, including southern Japan, the Caribbean, South America, and West Africa. The virus can be transmitted by sexual contact, breast-feeding, a transfusion of contaminated blood, or by intravenous drug users who share contaminated needles.

**SYMPTOMS AND TREATMENT**
Most people who become infected with HTLV-1 have no symptoms, but a small percentage (less than one in 20) may develop serious disorders. One such disorder is the cancerous condition adult T-cell leukaemia, which may appear up to 20 years after infection. In this disease, there is a rapid and abnormal turnover of white blood cells in the bone marrow and of cells in lymphoid tissue. Typically, lymph nodes, the liver, and the spleen are enlarged. Anticancer drugs may halt the condition temporarily, by killing abnormal cells, but people tend to survive for only a few months to a few years.

Another condition associated with HTLV-1 is myelopathy (spinal cord disease). This condition causes pain in the lower back and legs, together with progressively worsening weakness of the legs and difficulty in walking.

**humerus, fracture of**
The bone of the upper arm. The dome-shaped head of the bone lies at an angle to the shaft and fits into a socket in the scapula (shoulderblade) to form the shoulder joint. Below its head, the bone narrows to form a cylindrical shaft, which has a spiral groove housing the radial nerve (one of the main nerves in the arm, running from the shoulder to the hand). It flattens and widens at its lower end, forming a prominence on each side called an epicondyle. At its base, it articulates with the ulna and the radius (the bones of the forearm) to form the elbow.

**humoral immunity**
A state of protection against disease that is brought about by the production of antibodies by the immune system to combat infection. In contrast, cellular immunity is the direct response of lymphocytes (a type of white blood cell) to infection and abnormal cells in the body.

**humours**
A term that describes any liquid or jelly-like substance in the body. Humours usually refers to the aqueous humour and vitreous humour that occur in the eye.

**hunchback**
See kyphosis.

**hunger**
A disagreeable feeling caused by the need for food; it is different from appetite, which is a pleasurable sensation caused by the presence of food. Hunger occurs when the stomach is empty and the blood glucose level is low, which may occur several hours after the last meal or following strenuous exercise. In response to these stimuli, messages from the hypothalamus in the brain cause the muscular stomach wall to contract rhythmically; these contractions, if they are pronounced enough, can produce hunger pains.
Hunger can also occur in thyrotoxicosis (a disorder of the thyroid gland), and in diabetes mellitus when there is an incorrect balance between insulin and carbohydrate intake that causes abnormally low blood glucose levels (see hypoglycaemia).

Huntington’s disease
An uncommon disease that causes degeneration of the basal ganglia (paired nerve cell clusters in the brain). The disease is due to a defective gene and is inherited in an autosomal dominant manner (see genetic disorders).

Symptoms of Huntington’s disease do not usually appear until age 35 to 50, although they can develop in childhood. The main symptoms are chorea (rapid, jerky, involuntary movements) and dementia (progressive mental impairment). The chorea usually affects the face, arms, and trunk, resulting in random grimaces and twitches, and clumsiness. Dementia takes the form of irritability, personality and behavioural changes (including outbursts of aggressive, antisocial behaviour), memory loss (especially short-term memory), and apathy. The disease progresses slowly; affected people live for about ten to 20 years after the onset of symptoms.

At present, there is no cure for Huntington’s disease. Treatment is aimed at reducing symptoms with drugs; for example, antipsychotic drugs may help to control the abnormal muscle movements. Speech therapy and occupational therapy may also be of benefit. Genetic testing is available for people with family members affected by the condition. However, because there is no effective treatment for Huntington’s disease, this may raise difficult ethical questions.

Hurler’s syndrome
A rare, inherited condition caused by an enzyme defect. The syndrome is a type of inborn error of metabolism (see metabolism, inborn errors of) in which there is an abnormal accumulation of substances called mucopolysaccharides in the body tissues (see mucopolysaccharidosis).

Affected children may appear normal at birth; however, at six to 12 months of age, they develop cardiac abnormalities, umbilical hernia, skeletal deformities, and enlargement of the tongue, liver, and spleen. Growth is limited and mental development slows. If the condition is diagnosed in early infancy, a bone marrow transplant may be curative.

hyaline cartilage
The most common type of cartilage. Hyaline cartilage is also known as intra-articular cartilage. This type of cartilage is a smooth, tough, connective tissue that covers and protects the bone surfaces that are in contact with each other within a joint.

hyaline casts
Cylinders of semi-transparent matter that may be seen in urine viewed under a microscope. Hyaline casts are moulded in the same shape as the kidney tubules and are composed of protein derived from the breakdown of cells. Although they may be present in people with kidney disease, hyaline casts may also be a normal finding, particularly if an individual has exercised prior to giving the urine sample.

hyaline membrane disease
A lung condition affecting premature babies that is more commonly known as respiratory distress syndrome.

hyaluronic acid
A component of connective tissue and the fluid surrounding most joints (see synovium). Synthetic hyaluronic acid can be injected into joints affected by osteoarthritis and may help to relieve pain for up to six months.

hyaluronidase
A type of enzyme (a protein that regulates a chemical reaction in the body) that occurs naturally in the testes, the spleen, and certain other body tissues. Hyaluronidase increases tissue permeability and is used in pharmaceutical preparations to enhance the body’s absorption of injected fluids.

HyCoSy
See hysterocontrast sonography.

hydatid disease
A rare infestation that is caused by the larval stage of the small tapeworm Echinococcus granulosus (see tapeworm infestation). Larvae usually settle in the
liver, lungs, or muscle, causing the development of cysts. In rare cases, the brain is affected.

The infestation is generally confined to dogs and sheep, but may be passed on to humans through accidental ingestion of worm eggs from materials contaminated with dog faeces.

**SYMPTOMS, DIAGNOSIS, AND TREATMENT**

The cysts grow slowly, and symptoms may not appear for some years. In many cases, there are no symptoms.

Cysts in the liver may cause a tender lump or lead to **bile duct obstruction** and **jaundice**. Cysts in the lungs may press on an airway and cause inflammation; rupture of a lung cyst may cause chest pain, the coughing up of blood, and wheezing. Cysts in the brain may cause **seizures**. Ruptured cysts may, rarely, cause **anaphylactic shock**, a severe allergic reaction that can be fatal.

Diagnosis of hydatid disease is by **CT scanning** or **MRI** (magnetic resonance imaging). The cysts are usually drained or removed surgically.

**Hydatidiform mole**

An uncommon noncancerous tumour that develops from placental tissue early in a pregnancy in which the **embryo** has failed to develop normally. A hydatiform mole is thought to be the result of a chromosomal abnormality that occurs at conception. A pregnancy in which a hydatiform mole occurs is known as a **molar pregnancy**.

The mole, which resembles a bunch of grapes within the uterus, is caused by degeneration of the **chorionic villi** – minute, finger-like projections in the **placenta**. The cause of the degeneration is unknown. In a small number of affected pregnancies, the mole develops into a **choriocarcinoma**, a cancerous tumour that can invade the walls of the uterus if left untreated.

**SYMPTOMS, DIAGNOSIS, AND TREATMENT**

Vaginal bleeding and severe morning sickness generally occur in early pregnancy and the uterus may be larger than expected for the duration of the pregnancy. There is no viable fetus.

Diagnosis of a hydatiform mole is by **ultrasound scanning**, which will reveal the tumour, and urine and by blood tests to detect excessive amounts of human chorionic gonadotrophin, or **HCG** (see **gonadotrophin, human chorionic**), a hormone that is produced by the tumour. The mole is removed by emptying the uterus using suction. This procedure is carried out under general anaesthetic (see **anaesthesia, general**).

There is a small risk that the condition may occur in a subsequent pregnancy. Women who have had a hydatidiform mole should have their levels of **HCG** monitored for at least two years, and should not conceive again until their **HCG** levels have been normal for at least one year.

**Hydralazine**

An **antihypertensive drug** that is used principally as an emergency treatment for **hypertension** (high blood pressure). Hydralazine may cause nausea, headache, dizziness, irregular heartbeat, loss of appetite, rash, and joint pain. Taken for the long term and in high doses, it may cause the connective tissue disorder **lupus erythematosus**.

**Hydramnios**

See **polyhydramnios**.

**Hydration**

In medical terms, either the ingestion of water or the amount of water present in an individual or a tissue. (See also **dehydration, rehydration therapy**.)

**Hydrocele**

A soft, painless swelling in the **scrotum** caused by the space around a **testis** filling with fluid. A hydrocele may be caused by inflammation, infection, or injury to the testis; occasionally, the cause is a tumour. More often, there is no apparent cause. Hydroceles commonly occur in middle-aged men, and treatment is rarely necessary. If the swelling is uncomfortable or painful, however, the fluid may be withdrawn through a needle. Recurrent swelling may be treated by surgery.

**Hydrocephalus**

An excessive build-up of **cerebrospinal fluid** within the skull. The condition occurs either because too much cerebrospinal fluid is produced or because the fluid does not drain away normally. The excess fluid causes an increase in pressure within the skull, which may lead to brain damage.

Hydrocephalus may be **congenital** (present at birth), when it is often associated with other abnormalities, such as **spina bifida**. Or it may be a result of **brain injury**, brain **haemorrhage**, infection (such as meningitis), or tumour.

With congenital hydrocephalus, the main feature is an enlarged head that continues to grow rapidly. Other features include rigidity of the legs, vomiting, **epilepsy**, irritability, lethargy, and the absence of normal reflex actions. If it is not treated, hydrocephalus progresses to severe brain damage, which may result in death within weeks.

If hydrocephalus occurs later in life, when the skull bones have fused, the skull is unable to expand to accommodate the extra fluid. In this situation, the raised pressure within the skull causes symptoms including headache, vomiting, loss of coordination, and the deterioration of mental function.

In most cases, treatment of hydrocephalus involves a surgical procedure in which a tube called a shunt is inserted into the skull. This tube enables the fluid from the brain to drain into another part of the body, for example, the abdominal cavity, where it can be absorbed. In older children and adults, treatment is given for any underlying cause of the condition, such as a brain tumour.

**Hydrochloric acid**

A strong acid released by the stomach lining. This acid forms part of the stomach juices and helps in the digestion of proteins. Excessive production of hydrochloric acid, which may be triggered by smoking or stress, can lead to irritation of the stomach lining, and is an important factor in the development of **peptic ulcers**. If the acid escapes from the stomach into the oesophagus (see **acid reflux**), it can irritate the tissues, causing **oesophagitis** and **heartburn**.

**Hydrochlorothiazide**

A thiazide **diuretic drug** that is used to reduce **oedema** (fluid retention) in people with **heart failure, nephrotic syndrome**.
(a kidney disorder), and cirrhosis. It is also given for hypertension (high blood pressure). Adverse effects include leg cramps, dizziness, rash, and impotence. The drug may, rarely, cause gout and may aggravate diabetes mellitus.

Hydrocortisone
Also called cortisol, a hormone produced naturally by the adrenal glands. Synthetic hydrocortisone is used as a corticosteroid drug to treat severe allergic conditions; for example, it is given by injection to treat anaphylactic shock. It is also used as a replacement treatment when the adrenal glands fail to function (see Addison’s disease). Hydrocortisone is widely given in the form of a cream or ointment, to treat inflammatory skin conditions, such as heat rash, and is effective at reducing itching; however, used to excess, hydrocortisone creams may cause thinning of the skin, wrinkles or loss pigmentation.

Hydrogen peroxide
A substance used as mild antiseptic solution or cream to treat infections of the skin or mouth, or used to bleach hair. Hydrogen peroxide combines with catalase, an enzyme present in the skin and mouth, to release oxygen. This reaction kills bacteria. Solutions used to treat the skin and mouth usually contain 3% per cent hydrogen peroxide; those used for bleaching hair are stronger. Occasionally, solutions containing hydrogen peroxide may irritate the skin.

Hydronephrosis
A condition in which a kidney becomes swollen with urine due to an obstruction in the urinary tract. The excess urine causes pressure to build up inside the kidney and prevents it from functioning normally. Hydronephrosis may affect one or both kidneys. In some cases, hydronephrosis may be due to a congenital narrowing of the ureter. In other cases, the obstruction of a ureter may be caused by a stone (see calculus, urinary tract), a kidney tumour, or a blood clot. Occasionally, hydronephrosis is caused by obstruction to the outflow of urine from the bladder by an enlarged prostate gland (see prostate, enlarged) in men, or by enlargement of the uterus in pregnant women. In such cases, both kidneys are affected. Acute hydronephrosis, in which there is a sudden blockage of the ureter, causes severe pain in the abdomen and the small of the back. Chronic hydronephrosis, in which the obstruction develops slowly, may cause no symptoms until total blockage results in kidney failure. Hydronephrosis also increases the risk of kidney infection because bacteria can multiply more easily in stagnant urine. Hydronephrosis can be diagnosed using X-rays (see intravenous urography), CT scanning or MRI (techniques that produce cross-sectional or three-dimensional images of body structures). Following diagnosis, it is usually possible to relieve pressure by draining urine through a tube either directly onto the surface of the skin or by bypassing the blockage. Further treatment will then be needed to treat the cause of the blockage.

If the blockage can be removed surgically, the kidney is likely to function normally again. Occasionally, however, a kidney is so badly damaged that it requires removal (see nephrectomy).

Hydrophobia
A popular term, now almost obsolete, for rabies.

Hydrops
An abnormal accumulation of fluid in a body tissue (see oedema), cavity, or sac (a baglike body structure).

Hydrops fetalis
Serious oedema (swelling of the body tissues) that occurs in a fetus before birth. Hydrops fetalis is often the result of Rhesus incompatibility (see haemolytic disease of the newborn). In pregnant women who are affected by Rhesus incompatibility, additional ultrasound scanning may be carried out to detect any swelling and help doctors to determine whether any treatment will be necessary for the fetus.

Hydrotherapy
A form of physiotherapy in which exercises are performed in water to aid recovery from injury or to improve mobility. Hydrotherapy includes the use of exercise pools, whirlpool baths, and showers. People who cannot bear their full body weight on a limb (such as people with arthritis or those who have fractured a limb) may undergo exercises in a hydrotherapy pool. The buoyancy of the water supports the person’s body; in addition, the water provides gentle resistance that helps to improve muscle strength. Warm whirlpool baths can also provide a gentle massage to stimulate areas of the body and relieve stiffness.

Hydrous ointment
An oil-and-water based greasy skin preparation that is used to treat dry or scaling skin conditions such as eczema and psoriasis. Such ointment hydrates the affected area and can provide relief from itching.

Hydroxocobalamin
A long-acting synthetic preparation of vitamin B12. Hydroxocobalamin is given by injection to treat disorders involving vitamin B12 deficiency, particularly pernicious anaemia (see anaemia, megaloblastic), in which vitamin B12 cannot be absorbed from the intestines.

Hydroxyapatite
A complex crystalline form of calcium phosphate that occurs naturally in the body as a major component of bones and teeth. A synthetic form of hydroxyapatite is used as a calcium supplement to reduce bone loss when the intake of dietary calcium is inadequate.

5-Hydroxytryptamine
Another name for serotonin.

Hydroxyzine
A sedating antihistamine drug used to relieve itching and, occasionally, in the treatment of anxiety.

Hygiene
The science and practice of preserving health. The word “hygiene” is commonly used of personal cleanliness. It can also refer to public health – the scientific study of various environmental influences on health, such as safe sanitation and good housing. The terms “industrial hygiene” and “occupational hygiene” refer to the scientific discipline of assessing and regulating the work environment in order to prevent occupational disease and injury.

Hygiene, oral
See oral hygiene.

Hygroma, cystic
A lymphangioma (a type of noncancerous tumour) that occurs around the head and neck, the armpits, or the groin and contains clear fluid. Cystic hygromas are usually present from birth, reach their maximum size by the time the child is about two years old, then gradually disappear. The tumour may be surgically removed if it is obstructing the airway, but the final appearance is usually better if surgery can be avoided.
**hymen**
The thin membrane around the vaginal opening. The hymen has a central perforation which is usually stretched or torn by the use of tampons or during first sexual intercourse.

Imperforate hymen is a rare condition in which the hymen has no perforation; as a result, at the onset of menstruation, menstrual blood collects in the vagina, causing lower abdominal pain. The condition is easily corrected by a minor operation.

**hyoid**
A small, U-shaped bone that is situated centrally in the upper part of the neck. The hyoid bone is not joined to any other bone but is suspended by ligaments from the base of the skull. It provides an anchor point for the muscles of the tongue and for the muscles of the upper front part of the neck. The hyoid bone may be fractured as a result of deliberate strangulation.

**hyoscine**
An anticholinergic drug prescribed in two distinct forms: hyoscine butylbromide which is used to relieve the symptoms of irritable bowel syndrome, and hyoscine hydrobromide, which is used to control motion sickness. Hyoscine hydrobromide eye-drops may be given to dilate the pupil before an eye examination or surgery. An injection of hyoscine hydrobromide may be given as part of a premedication because it dries secretions in the mouth and lungs.

Possible adverse effects of both forms of the drug include a dry mouth, blurred vision, drowsiness, and constipation.
be undetectable except by a blood test, but if the blood bilirubin rises to twice the normal level, jaundice develops.

**hypercalcaemia**

An abnormally high level of calcium in the blood. Hypercalcaemia may be a result of hyperparathyroidism (overproduction of parathyroid hormone, a substance that normally helps to control the level of calcium in the blood). Cancer may also cause hypercalcaemia, either by spreading to the bones or by producing abnormal hormones that cause the bones to release calcium. Less commonly, the condition occurs as a result of intaking excessive amounts of vitamin D or of certain inflammatory disorders, such as sarcoidosis.

**SYMPTOMS**

Hypercalcaemia causes nausea, vomiting, lethargy, depression, thirst, and excessive urination. Higher blood levels of calcium produce confusion, extreme fatigue, and muscle weakness. If the disorder is left untreated and the calcium levels continue to rise, hypercalcaemia can be extremely serious, causing cardiac arrhythmias (irregularities of the heartbeat), kidney failure, coma, and may even lead to death.

Long-standing hypercalcaemia may cause nephrocalcinosis (calcification of the kidney) or kidney stones (see calculus, urinary tract).

**DIAGNOSIS, AND TREATMENT**

Diagnosis is by blood tests to measure the blood level of calcium and further tests to help reveal the cause. Treatment involves rehydration and, if necessary, reduction of dangerously high calcium levels with drugs such as bisphosphonate drugs or corticosteroid drugs. At the same time, the underlying cause is treated if possible.

**hypercapnia**

An excess of carbon dioxide in the blood. The condition is caused by failure of internal mechanisms, such as breathing rate, that normally control blood carbon dioxide levels. Hypercapnia leads to respiratory acidosi.

**hypercholesterolaemia**

A condition in which there is an increased concentration of cholesterol in the blood. Hypercholesterolaemia is thought to be associated with high levels of low density lipoprotein (LDL) in the blood; the condition may be caused by a genetic defect in which there is a lack of LDL receptors, which remove cholesterol from the bloodstream. (See also hyperlipidaemias.)

**hyperemesis**

The medical term for excessive vomiting. Hyperemesis may cause dehydration and weight loss.

The condition may occur during pregnancy, when it is known as hyperemesis gravidarum. Unlike morning sickness, the vomiting is so severe that the affected woman cannot keep down any food or fluid. The cause is not known, but a contributing factor is thought to be an excess of the hormone human chorionic gonadotrophin (HCG), which is due to the existence of more than one fetus or to a hydatidiform mole. Psychological stress may aggravate the symptoms. If left untreated, hyperemesis gravidarum may be life-threatening for the mother and fetus. (See also vomiting in pregnancy.)

**hyperglycaemia**

An abnormally high level of glucose in the blood that occurs in people with untreated or inadequately controlled diabetes mellitus. Hyperglycaemia may also occur in people with diabetes as a result of an infection, stress, or surgery.

Features of hyperglycaemia include the passing of large amounts of urine, thirst, glycosuria (glucose in the urine), and ketosis (accumulation in the body of organic substances called ketones). If it is severe, hyperglycaemia can lead to confusion and coma, which requires emergency treatment with insulin and intravenous infusion of fluids.

**hypergonadism**

Overactivity of the gonads (testes or ovaries) that results in overproduction of androgen hormones or oestrogen hormones. Hypergonadism may be caused by disorders of the gonads or a disorder of the pituitary gland that results in overproduction of gonadotrophin hormones. If hypergonadism develops during childhood, it results in premature sexual development (see precocious puberty) and excessive growth.

**hyperkalaemia**

Abnormally high blood levels of potassium, often due to failure of the kidneys to excrete it. Hyperkalaemia can lead to a fatal heart irregularity if severe.

**hyperkeratosis**

Thickening of the skin’s outer layer due to an increased amount of keratin, a tough protein that is the major component of the outer skin layer. The most common forms of hyperkeratosis affect small, localized areas of skin and include corns, calluses, and warts. A rare, inherited form affects the whole of the soles and palms. The term “hyperkeratosis” may also be used to describe thickening of the nails.

**hyperlipidaemias**

A group of metabolic disorders that are characterized by high levels of lipids (fats) in the blood.

**CAUSES**

Some hyperlipidaemias are inherited, resulting from inheritance of an abnormal gene (unit of hereditary material). Hyperlipidaemias may also be associated with another disorder, such as hypothyroidism (underactivity of the thyroid gland), diabetes mellitus, kidney failure, or Cushing’s syndrome (high levels of corticosteroid hormones in the blood). Sometimes they may result from the use of corticosteroid drugs.

Hyperlipidaemias are classified according to which forms of lipids have elevated levels in the blood. Lipids are carried in the blood in several forms, principally cholesterol and triglycerides in the form of lipoproteins (lipid molecules linked to protein molecules). Lipoproteins are classified according to their density, which depends on their relative proportions of cholesterol and protein: the higher the proportion of cholesterol, the lower the density of the lipoprotein. Elevated levels of low density lipoproteins (LDLs) and very low density lipoproteins (VLDLs) are associated with an increased risk of heart disease. The “good cholesterol” is high-density lipoproteins (HDLs), which help remove cholesterol from the bloodstream.
lipoapatins (VLDLs) contribute to hyperlipidaemias. High density lipoproteins (HDLs) are not involved.

**RISKS AND SYMPTOMS**

Hyperlipidaemias are associated with an increased risk of atherosclerosis (narrowing of the arteries as a result of fatty deposits) and coronary artery disease.

The symptoms depend on the particular type of hyperlipidaemia; they may include fatty yellow nodules in the skin on the back of the hands, on the tendons around the ankles and on the wrist joints; a white line around the rim of the cornea; and abdominal pain.

**DIAGNOSIS AND TREATMENT**

A diagnosis is made using blood tests. Treatment is designed to reduce blood lipid levels, usually by means of weight loss, a low-fat diet, and lipid-lowering drugs. Early treatment can reduce the risk of a heart attack. There is no known cure for inherited hyperlipidaemias. (See also hypercholesterolaemia.)

---

**HYPERPARATHYROIDISM**

In this disorder, the parathyroid glands produce too much parathyroid hormone. Symptoms, signs, and complications of the disorder occur as a result of an increased calcium level in the blood and urine, the loss of calcium from bones, and calcinosis (the formation of calcium deposits in different tissues). Surgical removal of abnormal parathyroid tissue is carried out to prevent complications.

**hypermagnesaemia**

An abnormally high level of magnesium in the blood. The most common cause of hypermagnesaemia is kidney failure, although the condition may also be caused by excessive magnesium intake; hypothyroidism (underactivity of the thyroid gland); Addison’s disease; and it may be associated with hypercalcaemia. Hypermagnesaemia may lead to lethargy, weakness, and irregularities with the electrical activity of the heart. As levels of magnesium increase, the condition may result in coma. Treatment of hypermagnesaemia is of the underlying cause.

**hypermetropia**

Commonly known as longsightedness, hypermetropia is an error of refraction (the focusing of light rays within the eye) that initially causes difficulty in seeing near objects and goes on to affect distance vision. The condition tends to run in families.

Hypermetropia is caused by the eye being too short from front to back, which results in images not being clearly focused on the retina. The error is present from birth, but symptoms do not generally appear until later life because the focusing power of accommodation, which compensates for hypermetropia, declines with age.

Glasses or contact lenses with convex lenses reinforce focusing power.

**hypernephroma**

A type of kidney cancer, also known as renal cell carcinoma.

**hyperparathyroidism**

Overproduction of parathyroid hormone (PTH) by the parathyroid glands. Normally, PTH, together with vitamin D and another hormone called calcitonin, controls the level of calcium in the body. An excess of PTH raises the level of calcium in the body. (See also hypercalcaemia.)
by removing calcium from bones. This activity can lead to bone disorders, such as osteoporosis. In an attempt to bring the high calcium level back to normal, the kidneys excrete large amounts of calcium in the urine, which can lead to the formation of kidney stones (see calculus, urinary tract).

**CAUSES**

Hyperparathyroidism is most often caused by a small noncancerous tumour of one or more of the parathyroid glands, in which case is known as primary hyperparathyroidism. This usually develops after the age of 40 and is twice as common in women as in men. Hyperparathyroidism may also occur when all the glands become enlarged for no known reason. It may also develop in response to a condition that causes abnormally low levels of calcium, such as chronic kidney failure, in which case it is known as secondary hyperparathyroidism.

**SYMPTOMS**

Hyperparathyroidism may cause muscular aches and pains, depression, and abdominal pain. Often however, the only symptoms are those that are caused by kidney stones. If hypercalcaemia is severe, there may be nausea, tiredness, excessive urination, confusion, and muscle weakness.

**DIAGNOSIS AND TREATMENT**

The condition is diagnosed by X-rays of the hands and skull and by blood tests to measure levels of calcium and PTH.

If the hyperparathyroidism is only mild, no treatment may be needed; instead, the affected person’s blood calcium levels and kidney function will be monitored annually. More serious cases may need treatment with drugs to lower the blood calcium levels. If a parathyroid tumour is found, the affected gland will be surgically removed; this usually cures the condition. If the remaining tissue is unable to produce enough PTH, treatment for hypoparathyroidism (underactivity of the parathyroid glands) is required.

**hyperphosphataemia**

An abnormally high level of phosphates in the blood. Hyperphosphataemia is usually caused by decreased phosphate excretion as a result of impaired kidney function or kidney failure. It may also be associated with hypoparathyroidism (underactivity of the parathyroid gland) or hypocalcaemia (low blood calcium levels). A side effect of hyperphosphat-

**HYPERPHOSPHATAEMIA**

aemia is the formation of calcium phosphate crystals in the blood and soft tissue. This can cause arteriosclerosis, which may lead to myocardial infarction (heart attack) or stroke. Treatment is of the underlying cause.

**hyperpigmentation**

Abnormally dark coloration of the skin. Hyperpigmentation is usually seen in scar tissue and damaged areas of skin, such as in areas affected by acne. The condition results in permanent changes in skin colour and is more obvious in darker skin. Hyperpigmentation is also a feature of Addison’s disease.

**hyperplasia**

Enlargement of an organ or tissue due to an increase in the number of its cells. However, unlike the cells of a tumour, the new cells are normal. Hyperplasia is usually the result of hormonal stimulation. It may occur normally (such as in the enlargement of breast tissue in pregnancy) or it may indicate a disorder. (See also hypertrophy.)

**hyperplasia, gingival**

Abnormal enlargement of the gums. Causes include gingivitis (inflammation of the gums), ill-fitting dentures, persistent breathing through the mouth, and taking the anticonvulsant drug phenytoin. Surgical treatment may be needed.

**hyperpyrexia**

A term used to refer to extremely high body temperature (see hyperthermia).

**hypsersensitivity**

Overreaction of the immune system (defence against infection) to an antigen (a protein that is recognized as foreign). Hypersensitivity reactions occur only on second or subsequent exposures to particular antigens, after the first exposure has sensitized the immune system. Such reactions have the same mechanisms as those of protective immunity; however, while the latter may protect against disease, hypersensitivity reactions lead to tissue damage and disease.

There are four main types of hypersensitivity reaction.

**TYPE I**

Type I is associated with allergy. After first exposure to an antigen (which may be a harmless substance such as grass pollen), antibodies (substances that can recognize and bind to the antigen) are formed. These antibodies coat mast cells in various tissues. On second exposure, the antigen and antibodies combine, causing the mast cells to disintegrate and release chemicals that cause the symptoms of asthma, allergic rhinitis (hay fever), urticaria (nettle rash), anaphylactic shock (a severe allergic reaction), or other allergic illnesses.

**TYPE II**

In type II reactions, antibodies bind to antigens on the surfaces of cells in particular tissues, leading to possible destruction of those cells. Type II reactions may lead to certain autoimmune disorders (in which antibodies attack the body’s own tissues). They may also be responsible for some cases of haemolysis (destruction of red blood cells) triggered by certain drugs.

**TYPE III**

In type III reactions, antibodies combine with antigens to form particles known as immune complexes. These particles lodge in various tissues and activate further responses form the immune system, leading to tissue damage. This type of reaction is responsible for serum sickness, allergic alveolitis (a lung disease caused by exposure to the spores of certain fungi), and the large swellings that sometimes form after a person has a booster vaccination.

**TYPE IV**

In type IV reactions, sensitized T-lymphocytes (a class of white blood cell) bind to antigens and release chemicals known as lymphokines, which promote an inflammatory reaction. Type IV reactions are responsible for contact dermatitis and the rash that occurs in measles; they may also play a part in some “allergic” reactions to drugs.

**TREATMENT**

Treatment of hypersensitivity depends on the type, cause, and severity. When possible, exposure to the offending antigen should be avoided.

**hypersplenism**

Overactivity of the spleen that results in, and which is associated with, blood disease. One of the functions of the spleen is to break down blood cells as they age and wear out. An overactive spleen may begin to destroy cells regardless of their age and condition, causing a deficiency of any of the types of blood cell. In most cases, the spleen will also be enlarged.

If the condition occurs for no reason it is called primary hypersplenism. More commonly, however, it is secondary to
another disorder, such as *Hodgkin’s disease* or *malaria*, in which the spleen has become enlarged.

Signs of hypersplenism include *anaemia* and *thrombocytopenia* (deficiency of platelets). There may also be decreased resistance to infection. Primary hypersplenism is treated with *splenectomy* (removal of the spleen). Treatment of secondary hypersplenism is aimed at control of the cause.

**Hypertension**

Persistently raised *blood pressure* (the pressure of blood in the main arteries). Blood pressure goes up temporarily as a normal response to stress and physical activity, and it rises naturally with increasing age and weight. A person with hypertension, however, has persistently high blood pressure even when at rest. Because the condition itself causes no symptoms, a large number of people have hypertension without realizing it; however, because hypertension causes the risk of developing serious cardiovascular disorders to increase, regular medical checks are advised in order to detect the condition at an early stage. Hypertension is very common, particularly in men, and its incidence is highest in the middle-aged and elderly.

Blood pressure is measured as two values, each expressed as millimetres of mercury (mmHg) or mmHg. The systolic value (the higher value) is the pressure when the ventricles (lower chambers of the heart) relax between beats. A person with hypertension may have hypertension without realizing it; however, because hypertension causes the risk of developing serious cardiovascular disorders to increase, regular medical checks are advised in order to detect the condition at an early stage. Hypertension is very common, particularly in men, and its incidence is highest in the middle-aged and elderly.

Blood pressure is expressed by two values – the systolic and diastolic pressures – and measured in millimetres of mercury.

Although hypertension rarely causes symptoms, it is a serious condition. It may cause excessive strain on the arteries. Left untreated, it increases the risk of stroke and other disorders. In many cases there is no obvious cause for hypertension, but in some people there is a specific cause, such as a kidney disorder, pregnancy, or the use of oral contraceptives. Hypertension is linked to obesity and, in some people, to a high salt intake. Smoking compounds the risks of the condition.

**COMMON FACTORS AND PREVENTIVE MEASURES**

| Factors associated with essential hypertension | Age (incidence higher in the elderly) |
| Factors that may aggravate hypertension | Family history of the condition |
| Self-help and treatment | Gender (incidence higher in men than in women) |
| | Smoking |
| | Obesity |
| | Excess alcohol intake |
| | Diabetes mellitus |
| | High salt intake |
| | Regular screening of blood pressure is important for early diagnosis and can help to prevent complications. |
| | Sufferers from essential hypertension should: Reduce weight; Not smoke; Reduce or stop alcohol intake Reduce salt intake; Take regular exercise; Learn relaxation. |
| | Antihypertensive drugs, prescribed by a doctor, can usually keep high blood pressure under control. |
HYPERTENSION, MALIGNANT

called essential hypertension. Genetic factors are important, although hypertension is not attributed to a specific gene. Other factors that are associated with hypertension include high alcohol intake, a high-salt diet, obesity, diabetes mellitus, a sedentary lifestyle, and smoking. There is also evidence that low birth weight increases the risk of developing hypertension in later life.

If hypertension results from a specific disorder, the condition is known as secondary hypertension. Causes include various kidney disorders; certain disorders of the adrenal glands; pre-eclampsia (a complication of pregnancy); coarctation of the aorta (a congenital heart defect); and the use of certain drugs. Taking the combined contraceptive pill (see oral contraceptives) can lead to hypertension in susceptible women.

**DIAGNOSIS**

The patient’s blood pressure is measured at rest on several occasions in order to make a diagnosis. If there is any doubt, an ambulatory blood pressure device is fitted to monitor blood pressure over a 24 hour period. This may detect a condition known as white coat hypertension, in which blood pressure is raised during a test by a doctor, but it is otherwise normal and does not require treatment. The eyes may also be examined for evidence of longstanding hypertension. If secondary hypertension is suspected, blood tests, X-rays, and other appropriate tests are carried out to exclude any potential causes.

**TREATMENT**

With mild to moderate hypertension, if no underlying cause is found, lifestyle changes are recommended as the first line of treatment. For example, smokers should give up their habit and drinkers should reduce their consumption of alcohol. Any overweight person with hypertension should try to lose weight by modifying the diet and introducing gradually increasing amounts of exercise into the daily routine. Biofeedback training and relaxation techniques can also help to reduce blood pressure.

If self-help measures have no effect, or if hypertension is severe, antihypertensive drugs may be given. There is a large range of drug treatments available and the treatment chosen depends on the presence of other disorders, such as diabetes mellitus. The response of the condition to treatment, as well as any side effects it has provoked, may prompt a change of treatment. Usually, the patient is monitored by having regular blood pressure checks, so that adjustments to drug type or dosage can be made if necessary. It may be possible for the patient to monitor his or her own blood pressure at home, but the individual’s machine should be checked regularly and calibrated against the doctor’s machine.

In many cases, drug treatment must continue for life, but this may help to extend life expectancy significantly. (See also intracranial hypertension, benign; portal hypertension; pulmonary hypertension.)

**hypertension, malignant**

See Malignant hypertension.

**hypertensive arteriosclerosis**

Thickening and loss of flexibility in the walls of arteries (see arteriosclerosis) as a result of persistent hypertension (high blood pressure).

**hypertensive encephalopathy**

A variety of symptoms, including headache, seizures, and loss of consciousness, caused by malignant, or accelerated, hypertension (high blood pressure). (See also encephalopathy.)

**hypertensive retinopathy**

Damage to the retina (the light-sensitive layer at the back of the eye) caused by persistent hypertension (high blood pressure) affecting the blood vessels in the eyes. Any changes visible in the retina reflect those occurring in small blood vessels throughout the body. Examination of the retina is therefore important in the assessment of hypertension. (See also retinopathy.)

**hyperthermia**

A medical term for very high body temperature.

**hyperthermia, malignant**

Also known as malignant hyperpyrexia, a sudden rise in body temperature to a dangerously high level, which is brought on by general anaesthesia (see anaesthesia, general). The condition is caused by exposure to inhaled anaesthetics such as halothane and enflurane, or to the muscle-relaxant drug succinylcholine. In most cases, susceptibility to malignant hyperthermia is inherited, with an autosomal dominant pattern of inheritance (see genetic disorders). People with certain muscle disorders may also be at risk. The condition is rare.

The patient’s body temperature rises soon after the anaesthetic is given, sometimes as high as 42° C (107.6° F). At the same time, large amounts of lactic acid pass from the muscles into the blood, causing acidosis and possibly leading to kidney damage. There are signs of greatly increased metabolism, such as an increase in heart rate and breathing rate. The muscles stiffen and the patient turns blue (see cyanosis). Without emergency treatment, seizures and death may follow rapidly.

Malignant hyperthermia may be suspected if a patient does not relax normally in the early stages of anaesthesia. If it occurs, the anaesthetic is stopped immediately and the patient’s body is cooled with ice packs. Oxygen and repeated intravenous injections of dantrolene sodium are given until the body temperature returns to normal. The patient will also receive care in an intensive care unit.

If a person is known to be susceptible to malignant hyperthermia, or has a family history of the condition, the anaesthetist must be informed before any surgical procedure, even if the patient has previously undergone general anaesthesia with no problems. The patient may be given dantrolene sodium before surgery to prevent hyperthermia.

**hyperthyroidism**

Production of excess thyroid hormones by an overactive thyroid gland (speeding up body functions). The most common form of hyperthyroidism is Graves’ disease, which is an autoimmune disorder (in which the immune system attacks the thyroid tissue). Less commonly, the condition is associated with enlarged nodules in the thyroid gland.

**SYMPTOMS AND SIGNS**

The characteristic signs of hyperthyroidism include increased appetite, weight loss, increased sweating, heat intolerance, rapid heart rate, and protruding eyes (in people with Graves’ disease). In severe cases, the thyroid gland often becomes enlarged (see goitre) and there is physical and mental hyperactivity and muscle wasting (see Symptoms and signs of hyperthyroidism box, overleaf).

**DIAGNOSIS, TREATMENT, AND OUTLOOK**

The diagnosis of hyperthyroidism is confirmed by measuring the level of thyroid hormones present in the blood. The condition can be treated with drugs that inhibit the production of thyroid hormones (see antithyroid drugs) or by...
SYMPTOMS AND SIGNS OF HYPERTHYROIDISM

Hyperthyroidism (oversecretion of thyroid hormones) produces a range of symptoms associated with overactivity of the body’s metabolism. Early signs of the condition include weight loss, increased appetite, intolerance to heat, and increased sweating; there may also be tremors and a rapid heart rate.

One form of the condition, called Graves’ disease, may cause bulging eyes. In severe cases of hyperthyroidism, the thyroid gland is often enlarged, causing a visible swelling (goitre) in the neck, and there tends to be physical and mental hyperactivity and muscle wasting.

Hypothyroidism (undersecretion of thyroid hormones) produces a range of symptoms associated with underactivity of the body’s metabolism. Early signs of the condition include weight gain, decreased appetite, intolerance to cold, and decreased sweating; there may also be fatigue and a slow heart rate.

the removal of part of the thyroid gland. People suffering from hyperthyroidism may be given radioactive iodine to destroy part of the thyroid tissue.

Many people recover fully after treatment, but their hormone levels need to be monitored regularly so that any further abnormal changes can easily be detected and treated. Treatment with radioactive iodine may result in development of hypothyroidism (underactivity of the thyroid gland).

hypertonia
Increased rigidity in a muscle. Hypertonia may be caused by damage to the nerves supplying the muscle or by changes within the muscle itself. The condition causes episodes of continuous muscle spasm. Persistent hypertonia in limb muscles following a stroke or head injury leads to spasticity.

hypertonic solution
A fluid that is more concentrated than blood plasma or the fluid within cells. If a hypertonic solution is introduced into the body, water will pass from the cells into the solution (see osmosis). If the solution is too concentrated, the body’s cells may lose too much water. Fluids used for intravenous infusion are usually isotonic (having the same concentration as the fluids in cells); if they are being used to treat dehydration, infused fluids are mildly hypotonic.

hypertrichosis
Growth of excessive hair, all over the body, even in places that are not normally hairy. Hypertrichosis often occurs as a result of taking certain drugs (including ciclosporin and minoxidil). It may also be associated with anorexia nervosa. In addition, the term “hypertrichosis” is used to describe hair growth in a mole (see naevus).

Hypertrichosis is not the same as hirsutism, which is excessive hair growth (particularly in women) due to abnormal levels of male hormones.

hypertrophic cardiomyopathy
A disease of the heart muscle (see cardiomyopathy) in which the walls of the left ventricle (the heart’s lower chamber) become abnormally thickened, preventing the heart from pumping efficiently. This may lead to breathlessness, chest pain, and palpitations.

Hypertrophic cardiomyopathy is most commonly inherited, and it shows an autosomal dominant pattern of inheritance (see genetic disorders). Family members can be screened (see familial screening) by means of echocardiography, although the condition may not become apparent until after puberty. Hypertrophic cardiomyopathy is sometimes a cause of sudden death (see death, sudden) in young people.

Treatment is with antiarrhythmic drugs and, in some cases, an implantable defibrillator (see defibrillation).

hypertrophic pulmonary osteoarthropathy
A condition in which severe pain and swelling of the wrists and ankles is associated with clubbing of the ends of the fingers and toes. The most common cause of the condition is lung cancer. X-rays of the affected bones show new bone formation in the long bones near...
HYPERTROPHY

the painful joints. Hypertrophic pulmonary osteoarthropathy may sometimes improve with treatment of the underlying lung cancer.

hypertrophy

Enlargement of an organ or tissue due to an increase in the size, rather than number, of its constituent cells. For example, skeletal muscles enlarge in response to increased physical demands. (See also hyperplasia.)

hyperuricaemia

An abnormally high level of *uric acid* in the blood. Hyperuricaemia may lead to *gout* due to the deposition of uric acid crystals in the joints; it may also cause kidney stones (see *calculus, urinary tract*) and collections of crystals in other body tissues (see *tophus*).

CAUSES

Hyperuricaemia may be caused by an inborn error of metabolism (see *metabolism, inborn errors of*), by the rapid destruction of cells in a disease such as *leukaemia*, or by any medication that reduces the excretion of uric acid by the kidneys, such as *diuretic drugs*. Large amounts of *purine* (a nitrogen-containing substance) in the diet may also cause hyperuricaemia.

TREATMENT

Drugs such as *allopurinol* or *sulfinpyrazone* may be prescribed for the duration of the patient’s life. Purine-rich foods, such as liver, poultry, and dried pulses, should be avoided.

hyperventilation

The term used to describe abnormally deep or rapid breathing. Hyperventilation is usually caused by *anxiety*. It may also develop as a result of uncontrolled *diabetes mellitus* or *kidney failure*; oxygen deficiency; some lung disorders; or abuse of *stimulant drugs*.

Hyperventilation causes an abnormal loss of carbon dioxide from the blood, which can lead to an increase in blood alkalinity (see *alkalosis*). Symptoms of hyperventilation include numbness of the extremities, faintness, *tetany* (painful muscle cramps and twitches, especially in the hands and feet), and a sensation of not being able to take a full breath.

If the hyperventilation is due to anxiety, the affected person may find it helpful to breathe in and out of a paper bag. This action reduces the loss of carbon dioxide and may help to relieve the symptoms of alkalosis.

Controlled hyperventilation of patients, using mechanical *ventilators*, is often part of the treatment for *cerebral oedema* (swelling of the brain) after injury or surgery to the brain.

hypervigilance

A feature of *post-traumatic stress disorder* involving a continuously heightened state of arousal and an exaggerated startle reaction.

hypervitaminosis

Any condition caused by an excess intake of one or more *vitamins* (usually from unnecessary use of vitamin supplements). Hypervitaminosis is most likely to arise with *vitamin A* and *vitamin D* because excess amounts of these vitamins are stored in the body rather than excreted.

hypoxaemia

Blood in the front chamber of the eye, usually caused by an injury that ruptures a small blood vessel in the *iris* or *ciliary body*. Initially, there may be blurred vision, but the blood usually disappears completely within a few days and vision is restored.

Appearance of hyphaema

Blood that has collected in the front chamber of the eye is clearly visible in front of the iris. This case, like most instances, was caused by injury.

hypoaaldosteronism

A rare condition that is characterized by a deficiency of the hormone *aldosterone*, which is produced by the *adrenal glands*. The condition may be caused by damage or disease affecting the adrenal glands. It may occur in *Addison’s disease*, in which the adrenal glands are damaged, often as a result of an autoimmune process. Hypoaldosteronism may produce muscle weakness. It is treated by the drug fludrocortisone.

hypocapnia

Abnormally low *carbon dioxide* levels in the blood. Hypocapnia may be caused by hyperventilation (abnormally deep or rapid breathing); it can result in a pins-and-needles sensation and painful muscle cramps and spasms.

hypochoondriasis

A disorder that is characterized by a person’s unrealistic belief that he or she is suffering from a serious illness, despite medical reassurance to the contrary. In its mildest form, hypochondriasis causes people to worry constantly about their health and interpret any symptom, however trivial, as evidence of disease. In its most severe form, hypochondriasis may dominate the person’s life; he or she may constantly seek medical advice and may undergo numerous tests and treatments for disease.
The likelihood of hypochondriasis occurring is increased in people who have had past experience of a serious disorder (particularly during childhood) or have seen such disorders in relatives. Other predisposing factors include social stresses and personality type. The condition may also be a complication of other psychological disorders such as phobia, obsessive–compulsive disorder, generalized anxiety disorder, and brain diseases such as dementia.

Where possible, treatment is designed to relieve the underlying mental disorder. Hypochondriasis without an underlying cause is difficult to treat.

**hypochondrium**

The area on each side of the upper abdomen, below the lower ribs.

**hypodermic**

A term that means “under the skin”. The word is usually used to describe injections that are delivered into the layer of fat beneath the skin, as well as for the needles and syringes used to administer these injections.

**hypogammaglobulinaemia**

An abnormally low blood level of immunoglobulins (proteins produced by immune system cells to fight infection; also called antibodies) that belong to a group called gamma-globulins. Hypogammaglobulinaemia is associated with an increased susceptibility to infections. The condition may be either inherited or acquired.

Inherited hypogammaglobulinaemia is an X-linked disorder (see genetic disorders) that results in susceptibility to infections from approximately three to six months of age. This condition requires repeated treatment with intravenous immunoglobulin.

There are several types of acquired hypogammaglobulinaemia. Common variable hypogammaglobulinaemia may appear during childhood or may occur later in adult life and requires regular replacement of immunoglobulin. Immunoglobulin A (IgA) deficiency is a very common form of hypogammaglobulinaemia that may have no symptoms and may carry no heightened risk of infection. Secondary hypogammaglobulinemia occurs in connection with a number of other diseases, including multiple myeloma and chronic lymphocytic leukaemia (see leukaemia, chronic lymphocytic).

**hypoglossal nerve**

The 12th cranial nerve, which controls movement of the tongue.

**hypoglycaemia**

An abnormally low level of glucose in the blood. Almost all cases of hypoglycaemia occur in people with Type 1 diabetes mellitus, in whom the pancreas fails to produce enough insulin, resulting in an abnormally high glucose level. To lower the level, insulin is given. Too high a dose of insulin can reduce the blood glucose to an excessively low level. Hypoglycaemia can also occur if a diabetic person misses a meal or takes strenuous exercise.

Less commonly, the condition may occur in people with Type 2 diabetes mellitus (in which body cells are resistant to the effects of insulin). Rarely, the condition can result from drinking too much alcohol or from an insulin-producing pancreatic tumour.

Symptoms include sweating, hunger, dizziness, trembling, headache, palpitations, confusion, and sometimes double vision. The person’s behaviour is often irritable and aggressive. Coma may occur in severe cases. Hypoglycaemia may also be the cause of seizures and jittery behaviour in newborn babies (see neonatal hypoglycaemia).

At the first sign of a hypoglycaemic attack, an affected person should consume a sugary food or drink. If the person has lost consciousness, emergency medical help is required; the patient must receive an injection of glucose solution or the hormone glucagon. (See also reactive hypoglycaemia.)

**hypoglycaemics, oral**

**COMMON DRUGS**

**SULPHONYLUREA DRUGS**

* Chlorpropamide
* Glibenclamide
* Glipizide
* Gliquidone
* Tolbutamide

**OTHERS**

* Acarbose
* Glucagon
* Insulin
* Insulin lispro
* Metformin
* Pioglitazone
* Repaglinide
* Rosiglitazone

A group of antidiabetic drugs that are used to reduce the blood glucose levels of people with type 2 diabetes mellitus.

Oral hypoglycaemics have many different modes of action. Sulphonylurea drugs act by increasing the body’s insulin production. Metformin increases the uptake of glucose into body tissues and increases its use by the body, thereby helping to reduce blood glucose levels. Other oral hypoglycaemics work in a variety of ways. For example, acarbose and guar gum reduce or slow absorption of carbohydrate from the intestines after meals; repaglinide stimulates the release of insulin from the pancreas; and rosiglitazone and pioglitazone reduce resistance to the effects of insulin in the tissues.

Too high a dose of hypoglycaemic drugs may provoke the onset of hypoglycaemia (abnormally low blood sugar levels), causing symptoms such as dizziness, nausea, and sweating. The use of metformin, acarbose, or guar gum does not usually result in this condition.

**hypogonadism**

Underactivity of the gonads (testes or ovaries). Hypogonadism may be caused by disorders of the gonads or a disorder of the pituitary gland that causes deficient production of gonadotrophin hormones. In men, hypogonadism causes the symptoms and signs of androgen hormone deficiency; in women, it causes those of oestrogen deficiency.

**hypohidrosis**

Reduced activity of the sweat glands. Hypohidrosis is a feature of hypohidrotic ectodermal dysplasia, a rare, inherited, incurable condition that is characterized by reduced sweating and is accompanied
HYPOKALAEMIA

by dry, wrinkled skin, sparse hair, small, brittle nails, and conical teeth. Other causes of hypohidrosis include exfoliative dermatitis and some anticholinergic drugs.

hypokalaemia
A deficiency of potassium in the blood. Hypokalaemia is usually caused by excess fluid loss due, for example, to severe diarrhoea, but may be the result of treatment with diuretic drugs.

hypomagnesaemia
An abnormally low level of magnesium in the blood. Hypomagnesaemia may result from malabsorption, malnutrition, alcohol abuse (see alcohol-related disorders), severe diarrhoea, or some kidney diseases. Magnesium deficiency causes impaired nerve and muscle function and may lead to seizures. Treatment of hypomagnesaemia is by injection of magnesium salts.

hypomania
A mild degree of mania.

hypoparathyroidism
Insufficient production of parathyroid hormone by the parathyroid glands. A deficiency of this hormone results in low levels of calcium in the blood (see hypocalcaemia).

The most common cause of hypoparathyroidism is damage to the parathyroid glands during surgery. Occasionally, the glands are absent from birth or may cease to function for no apparent reason.

A low level of calcium in the blood may lead to tetany (increased excitability of the nerves, causing uncontrollable, painful, cramplike spasms, especially in the hands and feet). Occasionally, seizures similar to those of an epileptic attack may occur.

The condition is diagnosed by blood tests. To relieve an attack of tetany, calcium may be injected slowly into a vein. To maintain the blood calcium at a normal level, a lifelong course of calcium and vitamin D tablets is necessary.

hypophosphataemia
An abnormally low level of phosphates in the blood. Hypophosphataemia may be associated with hyperparathyroidism, osteomalacia, rickets, and certain kidney abnormalities, such as Fanconi’s syndrome. It may cause symptoms such as fatigue, muscle weakness, haemolysis (premature breakdown of red blood cells), confusion, and seizures. Treatment of hypophosphataemia involves replacement of phosphates and, if possible, treatment of the underlying cause.

hypophysectomy
The surgical removal or destruction (by radiotherapy) of the pituitary gland. Hypophysectomy may be performed to treat a pituitary tumour. Life-long hormone treatment is necessary following hypophysectomy because hypopituitarism is an inevitable result.

hypopigmentation
A lack or absence of normal colour in the skin. The condition is due to underproduction of melanin, the brown pigment in skin, hair, and eyes. It may be the result of inflammation, scarring, or the skin condition vitiligo.

hypopituitarism
Underactivity of the pituitary gland, resulting in inadequate production of one or more pituitary hormones. The effects depend on which hormones are affected. Possible causes are a pituitary tumour, an abnormality affecting the hypothalamus (part of the brain), or injury to the pituitary gland. Hypopituitarism may also follow surgery or radiotherapy of the pituitary gland (see hypophysectomy). Treatment involves replacing the deficient hormones.

hypospadias
A congenital defect of the penis, in which the opening of the urethra is on the underside of the glans (head of the penis) or shaft. In some cases, the penis curves downwards, a condition that is known as chordee. Hypospadias can usually be corrected by surgery.

hyposplenia
A condition characterized by diminished functioning of the spleen. If the spleen suffers a loss of function, there is a resultant reduction in production of the antibodies, lymphocytes, and phagocytes that act to destroy invading microorganisms. Hyposplenia therefore results in increased susceptibility to certain severe infections. Those people whose spleen has been removed (see splenectomy) or is failing to function normally are advised to have pneumococcal immunization and long-term antibiotic drugs.

hypostasis
The pooling of blood in the lowest areas of limbs or organs, due to gravity. Hypostasis usually occurs as a result of poor circulation. The condition also occurs after death, when blood settles in the parts of the body that were lowest at the time of death.

hypotension
The medical term for low blood pressure. In its most common form, known as postural hypotension, symptoms occur when a person abruptly stands or sits up. Normally, blood pressure is maintained with changes in posture; in people with postural hypotension, it falls. Postural hypotension may be a side effect of anti-depressant drugs or antihypertensive drugs. It may also occur in people with diabetes.
**HYPOPLASTIC LEFT-HEART SYNDROME**

The heart defects associated with this syndrome are shown on the right and compared with those of the normal heart, on the left. Neither the left ventricle (pumping chamber) nor the aorta is properly formed.

---

**HYPOGLYCEMIA**

Acute hypotension is a feature of shock, and may be caused by serious injury or a disease such as myocardial infarction (heart attack) or adrenal failure.

Treatment depends on the cause. In the absence of serious disease, low blood pressure is associated with a decreased risk from cardiovascular disorders and stroke. Symptomless hypotension does not require treatment.

**Hypothalamus**

A region of the brain, roughly the size of a cherry, situated behind the eyes and under another area of the brain called the thalamus. The hypothalamus has nerve connections to most other regions of the nervous system.

**FUNCTION**

The hypothalamus controls the sympathetic nervous system (part of the autonomic nervous system). In response to sudden alarm or excitement, signals are sent from higher regions of the brain to the hypothalamus, initiating sympathetic nervous system activity. This causes a faster heartbeat, widening of the pupils, an increase in breathing rate and blood flow to muscles (together called the “fight or flight” response).

Other groups of nerve cells in the hypothalamus are concerned with the control of body temperature. When blood flowing to the brain is hotter or cooler than normal, the hypothalamus switches on mechanisms that regulate body temperature (including sweating and shivering). It receives information from internal sense organs regarding the body’s water content and the level of glucose in the blood; if these are too low the hypothalamus stimulates thirst and appetite for food. (See feedback mechanism.) The hypothalamus is also involved in regulating sleep, motivating sexual behaviour, and determining mood and emotions.

A further role of the hypothalamus is to coordinate the functions of the nervous and endocrine (hormonal) systems.

**LOCATION OF THE HYPOTHALAMUS**

This small area of the forebrain, shown in blue, lies under the thalamus and above the pituitary gland.

**Hypothalamic**

A fall in body temperature to below 35°C. Hypothermia most often occurs in sick, elderly people who are exposed to low temperatures. The body loses its sensitivity to cold as it ages, becoming less able to reverse a fall in temperature. Hypothyroidism (underactivity of the thyroid gland) also predisposes an individual to hypothermia. Babies may also have an increased risk of hypothermia because they lose heat rapidly and cannot easily reverse a fall in temperature. The condition is also common in climbers and walkers who are inadequately dressed for cold weather.

**SYMPTOMS AND SIGNS**

A person suffering from hypothermia is usually pale and listless. The heart rate is slow, the body is cold, and the victim is often drowsy and confused. In severe hypothermia, breathing becomes slow and shallow, the muscles are stiff, the victim may become unconscious, and may actually appear dead. Eventually, the heart may stop beating.

**TREATMENT**

Hypothermia is a medical emergency. Treatment varies according to the age of the victim. A baby or child can be warmed by direct skin-to-skin contact; for example, by being held inside an adult’s clothing. A young person may be placed in a warm bath. An elderly victim is usually warmed gradually by being covered with layers of heat-reflecting material in a room temperature of 25°C. If the person is fully conscious,
they may be given a warm non-alcoholic drink. Alcohol should not be given as it can exacerbate the condition. In cases where hypothermia is life-threatening, victims may be admitted to an intensive care unit for controlled warming in which warmed fluids are administered intravenously.

Most people suffering from hypothermia make a full recovery – the outlook is best in the case of young, otherwise healthy individuals.

**hypothermia, surgical**

The deliberate reduction of body temperature to prolong the period for which the vital organs can safely be deprived of their normal blood supply during open heart surgery. Cold reduces the rate of metabolism in tissues and thus increases their tolerance to lack of oxygen. Cooling may be achieved by continuously instilling cold saline at about 4°C into the open chest cavity.

**hypothyroidism**

The underproduction of thyroid hormones by an underactive thyroid gland. These hormones are important in metabolism and a deficiency therefore causes many of the body’s functions to slow down. Most cases are caused by an autoimmune disorder such as Hashimoto’s thyroiditis. More rarely, however, hypothyroidism results from the removal of part of the thyroid gland to treat hyperthyroidism (overactivity of the thyroid).

**SYMPTOMS AND SIGNS**

Symptoms of hypothyroidism include tiredness, lethargy, and cold intolerance. There may also be muscle weakness, cramps, a slow heart rate, dry skin, hair loss, constipation, a husky voice, and weight gain. Women may experience heavy menstrual periods. A syndrome called myxoedema, in which the skin and other tissues thicken, may develop. Enlargement of the thyroid gland may also occur (see goitre). If the condition occurs in childhood, it may retard growth and normal development.

**DIAGNOSIS AND TREATMENT**

The disorder is diagnosed by measuring the level of thyroid hormones in the blood. Treatment consists of replacement therapy with the thyroid hormone thyroxine, usually for life. In adults, the symptoms usually improve about three weeks after the start of treatment. Hormone treatment is monitored regularly so that the correct dosage is maintained.

**hypotonia**

Abnormal muscle slackness. Normally, a muscle that is not being used has a certain inbuilt tension, but in a number of disorders affecting the nervous system this natural tension is reduced.

**hypotonia in infants**

Also known as floppy infant syndrome, excessive limpness in infants. Hypotonic babies cannot hold their limbs up against gravity and tend, therefore, to lie flat with their arms and legs splayed. Hypotonia may be caused by Down’s syndrome or hypothyroidism (underproduction of thyroid hormones) and may be an early feature of cerebral palsy. It occurs in disorders of the spinal cord, such as Werdnig–Hoffman disease, and in some children with muscular dystrophy.

**hypotonic solution**

A fluid that is less concentrated than blood plasma or the fluid within cells. If a hypotonic solution is introduced into the body, the water in the fluid will pass through cell walls and into the cells (see osmosis). If the solution is too weak (for example, if it is pure water), the body’s cells will become over-filled and will rupture. Fluids used for intravenous infusion are isotonic (having the same concentration as the fluids in cells), except when they are being used to treat dehydration, in which case they are mildly hypotonic.

**hypoventilation**

A condition in which too little air enters the alveoli (tiny air sacs) in the lungs. Hypoventilation is due to breathing that is too shallow or slow, or to a reduction in lung function (for example, from a disorder such as emphysema). The inadequate air supply leads to insufficient oxygen passing from the alveoli into the bloodstream (see respiration), and as a result too little oxygen reaches the body tissues (see hypoxia) and carbon dioxide builds up.

**hypovitaminosis**

Any condition that results from the deficiency of one or more vitamins. Hypovitaminosis may be due to an inadequate dietary intake or a digestive disorder that causes malabsorption.

**hypovolaemia**

An abnormally low volume of blood in the circulation, usually following blood loss due to injury, internal bleeding, or surgery. Hypovolaemia may also be due to loss of fluid from diarrhoea and vomiting. Untreated, it can lead to shock.

**hypoxaemia**

An abnormally low level of oxygen in the arterial blood (the blood that carries oxygen to the body tissues). This condition may lead to hypoxia.

**hypoxia**

An inadequate supply of oxygen to the tissues. Temporary hypoxia may result from strenuous exercise. More serious causes include impaired breathing (see respiratory failure), ischaemia (reduced blood flow to part of the body), and severe anaemia. A rare cause is carbon monoxide poisoning. Severe, prolonged hypoxia may lead to tissue death.

Hypoxia in muscles forces the muscle cells to produce energy by anaerobic processes, which can lead to cramps. In heart muscle, it may cause angina pectoris. In the brain, it causes confusion, dizziness, and loss of coordination; and may lead to unconsciousness and death if it is persistent.

Hypoxia can be assessed by using an oximeter to measure the oxygen concentration of blood in the tissues. Severe hypoxia may require oxygen therapy or artificial ventilation.

**hypromellose**

A substance that is included in artificial tears (see tears, artificial). Hypromellose is applied as eye-drops.

**hysterectomy**

Surgical removal of the uterus. Hysterectomy may be performed to treat fibroids (noncancerous tumours of the uterus), and cancer of the uterus (see uterus, cancer of) or cervix (see cervix, cancer of). It may also be performed to treat endometriosis (displaced fragments of the uterine lining) and to remove a prolapsed uterus (see uterus, prolapse of). Hysterectomy used to be performed frequently to relieve heavy menstrual bleeding, but alternative treatments, such as endometrial ablation or insertion of a progesterogen IUD, are now increasingly used in these instances.

**TYPES**

The most common type of hysterectomy is a total hysterectomy, in which both the uterus and the cervix are removed. Occasionally, the fallopian tubes and ovaries are removed as well. For the treatment of cervical cancer, a rad-
hysterectomy (in which the uterus, cervix, and pelvic lymph nodes are removed) is performed. Hysterectomy may be performed through the abdomen or through the vagina. A procedure known as laparoscopically assisted vaginal hysterectomy is carried out partly through the vagina and partly using minimally invasive surgery. Vaginal hysterectomy has the advantage of needing no external incision, and, as a result, the patient usually recovers more rapidly. However, a vaginal hysterectomy cannot be performed if the uterus is significantly enlarged or if the hysterectomy is a treatment for cancer.

**RECOVERY AND OUTLOOK**

After the operation, a drainage tube may be inserted at the site of the incision to aid healing. For a few days there may be some vaginal bleeding and discharge, as well as tenderness and pain. A vaginal hysterectomy requires a short hospital stay; any further stay depends on the age and health of the woman and whether there are any postoperative problems. Full recovery usually takes between three and six weeks; sexual intercourse can be resumed about a month after surgery. The recovery period after an abdominal hysterectomy may be longer and may also require a longer stay in hospital. Following a hysterectomy, a woman is unable to bear children; she does not have menstrual periods and does not need to use contraception. If a woman’s ovaries have also been removed before or around the woman’s menopause, hormone replacement therapy (HRT) may be given. It is not uncommon for a woman to suffer from depression after a hysterectomy if she has not been adequately counselled beforehand.

**hysterocontrast sonography (HyCoSy)**

Ultrasound examination of the uterine cavity and the fallopian tubes. A contrast medium visible on ultrasound is introduced into the uterine cavity through the vagina and the cervix. Hysterocontrast sonography is a technique that is used to investigate infertility; the advantage that this method has over hysterosalpingography is that it does not involve X-rays.

**hysterosalpingography**

An X-ray procedure in which a dye (radiopaque contrast medium) is introduced into the cavity of the uterus through the cervix to make the uterus and fallopian tubes visible on X-rays. Hysterosalpingography is used to investigate infertility.

**hysteroscopy**

A technique that uses a hysteroscope (a type of endoscope) to view the inside of the uterus and fallopian tubes for the purposes of diagnosing disorders. Hysteroscopy can be performed under local anaesthesia. Minor surgery, such as the removal of fibroids (noncancerous tumours of the uterus), may also be performed using a hysteroscope.
iatrogenic
A term meaning “physician-produced”. It may be applied to any medical condition, disease, or adverse event resulting from medical treatment.

IBS
See irritable bowel syndrome.

Ibugel
A brand name for a topical gel containing ibuprofen that is used for relieving muscle pain.

Ibuleve
A brand name for a topical gel containing ibuprofen that is used to relieve muscle pain.

ibuprofen
A nonsteroidal anti-inflammatory drug (NSAID) used as a painkiller to treat conditions such as headache, menstrual pain, and injury to soft tissues. The drug’s anti-inflammatory effect also helps to reduce the joint pain and stiffness that occurs in types of arthritis. Side effects may include abdominal pain due to inflammation of the stomach lining; nausea; heartburn; and diarrhoea.

ICD
The commonly used abbreviation for International Classification of Diseases, a list of all known diseases that is published by the World Health Organization. An updated version is produced approximately every ten years. ICD enables countries and organizations to gather statistical information on the frequency of a disease and causes of death.

Icelandic disease
A previously used term for chronic fatigue syndrome.

ice-packs
A means of applying ice (wrapped in a towel or other material) to the skin in order to reduce inflammation or swelling, relieve pain, or stem bleeding.

The low temperature causes the blood vessels to constrict (narrow), thus reducing the blood flow.

Ice-packs are used to relieve pain in a variety of disorders, including severe headache. They are used on sports injuries to minimize swelling and bruising, and they can also be used to help stop bleeding from small vessels, as in a nosebleed.

ichthammol
A drug used in skin preparations for the treatment of eczema, to reduce itching.

Ichthropaste
A brand name for a medicated bandage that is impregnated with the drug ichthammol and zinc paste. Ichthropaste is used in the treatment of chronic eczema, to reduce itching.

ichthyosis
A rare, inherited condition in which the skin is dry, thickened, scaly, and darker than normal due to abnormal production of keratin. Ichthyosis usually appears at, or shortly after, birth and usually improves during childhood. Commonly affected areas are the thighs, arms, and backs of the hands. There is no particular treatment, but lubricants and emulsifying ointments may be applied to help relieve the dryness, and bath oils may also be used to moisten the skin.

ICP
The abbreviation for intracranial pressure.

ICSI
See intracytoplasmic sperm injection.

icterus
A term for jaundice.

ICU
The abbreviation for intensive care unit.

id
One of the three constituents of the personality (together with the ego and superego) described by Sigmund Freud. The id is defined as the primitive, unconscious energy store from which come the instincts for food, love, sex, and other basic needs. It thus guides behaviour and also fuels the turmoil leading to the conflict and guilt of neurosis. The id seeks simply to gain pleasure and avoid pain. (See also psychoanalytic theory.)

IDDM
The abbreviation for insulin-dependent diabetes mellitus (type 1 diabetes).

ideas of reference
An individual affected by ideas of reference finds personal significance in casual remarks made or action taken by other people. The individual may feel that people in public places are talking about, or laughing at, him or her. The condition falls short of a delusion because affected individuals are aware that they are not actually noticed more than others; however, they may be unable to discuss these feelings.

identical twins
Two offspring, also known as monozygotic twins, who develop from a single fertilized ovum (egg) and share identical genes. (See also twins.)

identification
A term used in psychology to refer to the process of unconsciously taking on another person’s traits or behaviour. In children, identification with an older person, usually a parent, is considered a normal part of development.

identity crisis
A colloquial term used to describe feelings of uncertainty about one’s own personality and characteristics. Experiencing an “identity crisis” is common in periods of emotional turmoil, such as adolescence.

idiopathic
A term that is used to refer to a medical condition that has no known cause. As science advances, causes may be found for conditions previously considered to be idiopathic.

idiopathic epilepsy
A term used to describe epilepsy that has no known physical cause (such as brain injury, for example).

idiopathic hypertension
See essential hypertension.

idiopathic thrombocytopenic purpura (ITP)
An autoimmune disorder in which platelets are destroyed, leading to bleeding beneath the skin (see purpura). ITP may be acute or chronic. Acute ITP mainly affects children, is usually mild, and disappears without treatment.
Chronic ITP generally affects adults and is much more serious. Initial treatment is with corticosteroid drugs; if this fails, a splenectomy (surgical removal of the spleen) may be required. Immunosuppressant drugs may be given if all other treatment fails.

**idoxuridine**
An antiviral drug used in skin preparations to treat the blistering rashes caused by herpes simplex and herpes zoster (shingles) infections. Recently developed antiviral drugs, such as aciclovir, are more effective and idoxuridine is now used less often.

**Ig**
The abbreviation for immunoglobulin.

**IgA nephropathy**
A kidney disease that causes haematuria (passage of blood in the urine) and in which deposits of IgA immunoglobulins (certain proteins produced by the immune system to combat infection) are found within the kidneys. Excessive amounts of IgA are sometimes produced in response to a throat infection. In such cases, IgA complex collects in the filtering units of the kidneys. IgA nephropathy is the most common form of glomerulonephritis.

The condition mainly affects children and young men. It may cause either microscopic haematuria (in which blood is passed in the urine but cannot be seen by the naked eye) or episodes of macroscopic haematuria (in which blood can be seen in the urine). In some cases, nephrotic syndrome develops; in this condition, large amounts of protein are passed in the urine, leading to raised blood pressure and oedema (swelling of the tissues).

Treatment of IgA nephropathy may involve corticosteroid drugs and immunosuppressant drugs, in addition to treatment to relieve any symptoms. Overall, the prognosis for IgA nephropathy is good. In some cases, however, kidney function deteriorates and, in up to one in five people, kidney failure develops after many years.

**ileal conduit**
A section of the ileum (the final part of the small intestine) used by a surgeon to provide a substitute channel for urine outflow when the bladder has been removed. (See urinary diversion; see also cystectomy.)

**ileal pouch**
A reservoir constructed from loops of the ileum (lower part of the small intestine) to replace a rectum that has been surgically removed. If an ileal pouch cannot be created, a permanent ileostomy will be required.

**ileitis, regional**
An outdated name for Crohn’s disease.

**ileostomy**
An operation in which the ileum (lower part of the small intestine) is cut and the end brought through the abdominal wall and formed into an artificial opening called a stoma. Waste is discharged from the remaining ileum into a disposable bag (stoma bag) or drained into a pouch made from the end of the ileum and situated beneath the skin (a procedure called a continent ileostomy). In the latter situation, faeces draining into the pouch are emptied regularly through a soft catheter. An ileostomy may be either permanent or temporary.

**WHY IT IS DONE**
Permanent ileostomy is usually performed on people who have severe,
uncontrolled ulcerative colitis. The operation is done after a total colectomy (removal of the colon and rectum).

Temporary ileostomy is sometimes performed at the same time as partial colectomy to allow the colon to heal before waste material passes through it. It may also be done as an emergency treatment for an obstruction in the intestine. The stoma is created from a loop of the intestine that is brought to the skin surface. Once the intestine has healed, a second operation is carried out to close the temporary ileostomy.

RECOVERY PERIOD
During convalescence, patients are given counselling and are taught the practical aspects of stoma care or drainage of continent ileostomies. Full recovery from the operation takes about six weeks.

ileum
The final, longest, and narrowest section of the small intestine. It is joined at its upper end to the jejunum and at its lower end to the large intestine (caecum, colon, and rectum). The ileum’s function is to absorb nutrients from food that has been digested in the stomach and the first two sections of small intestine (the duodenum and jejunum).

LOCATION OF THE ILEUM
The ileum is situated between the jejunum (the middle part of the small intestine) and the caecum (the first part of the large intestine).

DISORDERS
Occasionally, the ileum becomes obstructed – for example, by pushing through a weakness in the abdominal wall (see hernia) or by becoming caught up with scar tissue following abdominal surgery (see adhesion). Other disorders of the ileum include Meckel’s diverticulum (a pouch in the ileum wall that may become ulcerated) and diseases in which the absorption of nutrients is impaired, such as Crohn’s disease, coeliac disease, tropical sprue, and lymphoma.

ileus, gallstone
The blockage of the small intestine by a gallstone that has travelled from the biliary tract. Gallstone ileus is sometimes a complication of cholecystitis (inflammation of the gallbladder). Symptoms may include severe abdominal pain and bloating, vomiting, and lack of bowel movements. Surgery is usually needed to remove the stone. The gallbladder is generally removed at the same time.

ileus, paralytic
A disorder in which the muscles of the intestines are unable to contract normally, and as a result the intestinal contents cannot pass out of the body. Paralytic ileus is usually a temporary condition. It commonly follows abdominal surgery and may also be induced by severe abdominal injury, peritonitis (inflammation of the membrane lining the abdomen), acute pancreatitis (inflammation of the pancreas), major disturbances in blood chemistry (such as diabetic ketoacidosis), or interference with the blood or nerve supply to the intestine. Symptoms include a swollen abdomen, vomiting, and failure to pass faeces.

The condition is treated by resting the intestine. A tube passed through the nose or mouth into the stomach or intestine removes accumulated fluids and keeps the stomach empty. Body fluid levels are maintained by intravenous infusion (drip).

ilium
The largest of the hip bones that form part of the pelvis.

illness
Perception by a person that he or she is not well. Illness is a subjective sensation; it may have both physical and psychological causes. The term “illness” is also used to mean disease or disorder.

illusion
A distorted sensation that is based on the misinterpretation of a real stimulus (for example, a pen is seen as a dagger). Illusion differs from a hallucination, in which a perception occurs without any stimulus. Usually, illusions are brief and can be understood when they are explained. They may be caused by tiredness or anxiety, to drugs, or to forms of brain damage. Delirium tremens (a condition usually arising from alcohol withdrawal in alcoholics) often brings on illusions.

image, body
See body image.

imaging techniques
Techniques that produce images of structures within the body (see Imaging the body box).

X-RAY TECHNIQUES
The most commonly used and simplest techniques are the X-rays (sometimes called plain X-rays) used to view dense structures such as bone. Simple X-ray examinations include those of the chest, skull, and limbs following injury.

Contrast X-rays involve the introduction into the body of a medium that is opaque to X-rays. The techniques include barium X-ray examinations (used to examine the oesophagus, the stomach, and the intestine); cholecystography (used to visualize the gallbladder and common bile duct); bronchography (to view the airways connecting the windpipe to the lungs); angiography and venography (to provide images of the blood vessels); intravenous urography (to visualize the kidneys and urinary tract); and ERCP (in which the pancreatic duct and biliary system are examined after introducing a contrast medium through an endoscope).

Many X-ray techniques have now been superseded by newer procedures that are simpler to perform and safer and more comfortable for the patient.

ULTRASOUND TECHNIQUES
Ultrasound scanning involves the passing of high-frequency sound waves through the body using a transducer placed against the skin. The waves are reflected to varying degrees by structures of different density; the pattern of echoes is recorded electronically on a screen. Ultrasound scanning can now be used to produce three-dimensional images as well as moving images to show, for example, the opening and closing of a valve or blood flow within a vessel.
Over the past two decades many methods of imaging the body have been developed and are now widely used. These techniques have made it possible to visualize internal structures in a variety of ways. Today, in addition to conventional X-rays (which primarily show bones), techniques such as CT scanning, radionuclide scanning, ultrasound scanning, MRI, and PET scanning are used to provide detailed diagnostic pictures of soft tissues and organs. The examples given here show some of the different ways in which the kidneys can be imaged.

**X-RAYS**
Radiopaque contrast media may be utilized to give distinct X-ray images of soft tissues, as in intravenous urography, which is used to give clear images of the kidneys and urinary tract.

**Intravenous urogram**
This intravenous urogram shows the renal pelvises (urine-collecting areas of the kidneys) and the ureters, which have been filled with contrast medium. In the right-hand renal pelvis and ureter (on the left of the urogram), the medium has been retained due to a kidney stone blocking the ureter; the stone appears as a small gap in the ureter.

**SCANNING TECHNIQUES**
The body, particularly the soft tissues, can be imaged using a variety of modern techniques. Some of these techniques, such as CT scanning and MRI, rely on computers to process the raw imaging data and produce the actual image. Others, such as ultrasound scanning and radionuclide scanning, can produce images without the need of a computer for image processing, although one may be used for image enhancement.

**Radionuclide scanning**
A radioactive substance is introduced into the body, and the radiation emitted is detected by a gamma camera, which then converts it into an image. Active or overactive cells will take up more of the substance, and will appear brighter, than underactive cells. This scan (taken from the back) shows healthy kidneys. In each kidney, the medulla (central part) has absorbed more of the radioactive substance than the cortex (outer part).

**Ultrasound scanning**
Ultra-high-frequency sound waves reflected from tissues in the body are converted into an image by special electronic equipment. This scan shows a fluid-filled cyst inside a kidney; the cyst appears as a dark area on the image.

**CT scanning and MRI**
These techniques produce cross-sectional images (slices) or three-dimensional images of body structures. This CT scan shows a cross-section through the body, as seen from below; the front of the body is at the top of the image. The right kidney (shown on the left of the image) is enlarged and distorted by a tumour. The left kidney has a cyst.
COMPUTER-ASSISTED SCANNING
Many scanning techniques use computers to process the raw imaging data and produce the actual image. In CT scanning (computed tomography scanning), X-rays are passed through the body at different angles. The computer analyses the data to produce cross-sectional images (“slices”) of the tissues that are being examined. Newer CT scanners can use a spiral technique to produce three-dimensional images of structures.

In MRI (magnetic resonance imaging), the patient is placed in a strong magnetic field within the scanner and radiofrequency waves are passed through the body. A computer analyses changes in the magnetic alignment of the nuclei in the hydrogen cells to give either a cross-sectional or a three-dimensional image of the tissues. This technique provides greater contrast between normal and abnormal tissues than that given by CT scanning.

PET scanning (positron emission tomography scanning) involves the introduction of very short-lived radioisotopes into the tissues of the brain. A computer analyses the paths of the gamma rays emitted by these radioisotopes, thereby providing information about both the structure and function of the brain.

In radionuclide scanning, a gamma camera records radiation emitted from tissues into which a radioactive substance has been introduced. A computer transforms the recordings into images and may be used to obtain more information from the results. Certain radioactive substances are taken up, to varying degrees, by different tissues, allowing specific organs to be studied in isolation.

Imdur
A brand name for a slow-release preparation of isosorbide mononitrate, a drug used in the treatment of angina pectoris (chest pain caused by an inadequate blood supply to the heart).

Imidazole drugs
A specific group of antifungal drugs used for the treatment of fungal infections such as candidiasis (vaginal thrush) and tinea (ringworm).

Imigran
A brand name for sumatriptan, a serotonin agonist drug that is used to treat migraine or cluster headaches. Imigran is available in different forms, including tablets, injection, and nasal spray.

Imipramine
A tricyclic antidepressant drug that is most commonly used in the long-term treatment of depression. Possible adverse effects of imipramine include excessive sweating, blurred vision, dizziness, dry mouth, constipation, nausea, and, in older men, difficulty passing urine.

Immersion foot
A type of cold injury, also called trench foot, occurring when the feet are wet and cold for a long time. Initially, the feet turn pale and have no detectable pulse; later, they become red, swollen, and painful. If the condition is ignored, muscle weakness, skin ulcers, or gangrene may develop.

Immobility
Reduced physical activity, for example through disease, injury, or following major surgery. Immobility is particularly harmful in elderly people because it causes muscle wasting and progressive loss of function.

Immobilization
An orthopaedic term that describes techniques that are used to prevent movement of joints or displacement of fractured bones. Immobilization is performed so that fractured bones can reunite properly (see fracture).

Immune complex
A combination of an antigen (any substance that the body identifies as foreign and that provokes an immune response) and an antibody (a protein produced by the immune system for the purpose of attacking foreign substances). Immune complexes are normally removed from the circulation by the liver and spleen. However, they may sometimes continue to circulate and eventually become trapped in organs or other tissues, causing inflammation, tissue damage, and specific immune complex diseases (which are also known as type III hypersensitivity reactions).

One example of an immune complex disease is extrinsic allergic alveolitis – farmer’s lung, for example. In this disorder, immune complexes form after exposure to allergens such as fungal spores; they then collect in the lungs, causing inflammation of the alveoli (tiny air sacs). Other conditions caused by immune complexes include some forms of glomerulonephritis (inflammation of the tiny structures in the kidneys that help to filter blood); certain connective tissue diseases, including systemic lupus erythematosus and rheumatoid arthritis; and adverse reactions to streptokinase, a thrombolytic drug used in the treatment of myocardial infarction (heart attack).

Immune response
The body’s defensive reaction to microorganisms, cancer cells, transplanted tissue, and other substances or materials that are recognized as antigenic or “foreign”. The immune response consists of the production of cells called lymphocytes; substances called antibodies or immunoglobulins; and other substances and cells that act to destroy the antigenic material. (See also immune system).

Immune system
A collection of cells and proteins that works to protect the body from harmful microorganisms, such as bacteria, viruses, and fungi. The immune system also plays a role in the control of cancer and is responsible for the phenomena of allergy, hypersensitivity, and rejection after transplant surgery.

Natural immunity
The term “natural (or innate) immunity” is given to the protection every individual is born with, such as the skin and mucous membranes that line the mouth, nose, throat, intestines, and vagina. Natural immunity also includes antibodies, or immunoglobulins (protective proteins), that are passed to the child from the mother via the placenta. If microorganisms penetrate these defences, they encounter “cell-devouring” white blood cells called phagocytes, and other types of white cells, such as cell-killing (cytotoxic) cells.

Microorganisms may also encounter substances that are naturally produced within the body (such as interferon) or
Each of us has many inborn defences against infection. These defences include external barriers such as the skin and eye surfaces (below), the inflammatory response (right), and the action of white blood cells called phagocytes (below right). Others include a substance called complement (which is activated by and attacks bacteria) and another called interferon (which has antiviral effects). All of these defences are nonspecific and quick-acting. By contrast, the adaptive immune system (see overleaf) mounts specific attacks against particular microbes. These cells are most effective on second exposure to the organisms.

The two parts of the immune system work together; antibodies produced by the adaptive immune system assist phagocyte action.

**Physical and chemical barriers**
These barriers, briefly described below, provide the first line of defence against harmful microbes (bacteria, viruses, and fungi).

- **Eyes**
  - Tears produced by the lacrimal apparatus help to wash away microorganisms;
  - tears contain an enzyme called lysozyme, which can destroy bacteria.

- **Mouth**
  - Lysozyme present in saliva destroys bacteria.

- **Breast-feeding**
  - Antibodies (proteins with a protective role) formed by the mother against particular microbes are transferred to the baby in breast milk. Breast-feeding provides some extra immunity until the baby can form his or her own specific antibodies.

**THE INFLAMMATORY RESPONSE**
If microbes break through the body’s outermost barriers, inflammation is the second line of defence. Chemicals such as histamine are released, prompting the effects shown below, including the attraction of phagocytes to the microorganisms and the release of substances such as complement.

The symptoms of inflammation are redness, pain, swelling, and heat.

**ACTION OF PHAGOCYTES**
These white blood cells are attracted to sites of infection, where they adhere to, engulf, and digest microorganisms and debris.

1. **Adherence**
   - The phagocyte comes into contact with a microbe and recognizes it as foreign. This process is assisted by chemicals released during inflammation.

2. **Ingestion**
   - The phagocyte engulfs the microbe in a pouch formed in its membrane. Fluid-filled particles, lysosomes, move towards the microbe.

3. **Digestion**
   - Enzymes within the lysosomes are released into the pouch to help digest the microbe. Debris from this process is later ejected.
ACQUIRED IMMUNITY

The second part of the immune system, which is known as “acquired (or “adaptive”) immunity”, comes into play when the body encounters certain organisms that overcome the innate defences. The acquired, or adaptive, immune system responds specifically to each type of invading organism, and retains a memory of the invader so that defences can be rallied instantly in any future invasion.

The acquired immune system first must recognize part of an invading organism or tumour cell as an antigen (a protein that is foreign to the body). One of two types of response (humoral or cellular) is then mounted against the invading antigen.

HUMORAL IMMUNITY

Humoral immunity is important in the defence against bacteria. Following a complex recognition process, certain B-lymphocytes multiply and produce vast numbers of antibodies that bind to the antigens on the invading organism; the bacterium is then engulfed by phagocytes and destroyed. The binding of antibody and antigen may activate the complement system, which increases the efficiency of the phagocytes.

CELLULAR IMMUNITY

Cellular immunity is particularly important in the defence against viruses, some types of parasities that hide within cells, and, possibly, against cancer cells. Cellular immunity involves two a group of blood proteins called the complement system, which act to destroy the invading organisms.

IMMUNE SYSTEM

This system is based on white blood cells called lymphocytes. It has two parts. Humoral immunity relies on the action of B-lymphocytes; these cells produce antibodies, which circulate and attack specific microbes. In cellular immunity, cells called T-lymphocytes are activated and attack specific microbes or abnormal cells (such as virally infected cells or tumour cells).

HUMORAL IMMUNITY

A humoral response is started when an antigen (foreign protein), here on the surface of a bacterium, is recognized by one type of B-lymphocyte and activates it.

This particular type of B-lymphocyte multiplies, forming cells called plasma cells, which make antibodies designed specifically to attack the bacterium.

After a few days, the antibodies are released. They attach themselves to the antigen. This triggers more reactions, which ultimately destroy the bacterium.

Some B-lymphocytes remain in the body as memory cells; if the bacterium enters the body again, they rapidly produce large amounts of antibodies to halt the infection.

Cellular immunity particularly important against:

- Many viruses (e.g. herpes simplex)
- Some bacteria (e.g. tuberculosis)
- Some fungi (e.g. candidiasis)

Lymphocytes

These types of white blood cells are found in the blood and the lymphoid organs (the lymph nodes, spleen, and thymus). The two main types (B- and T-lymphocytes) have different functions but look similar under the microscope.
Two main types of immunization exist. In passive immunization, antibodies (protective proteins) are injected into the body and provide immediate, but short-lived, protection against specific disease-causing bacteria, viruses, or toxins. Active immunization primes the body to make its own antibodies against such microorganisms and confers longer-lasting immunity.

PASSIVE IMMUNIZATION
1 Blood is taken from a person or, rarely, an animal previously exposed to a particular microorganism. The blood will contain antibodies against that microorganism.

2 An extract from the blood containing the antibodies (known as immune serum or antiserum) is injected into the person to be protected.

3 The antibodies help to destroy the microorganism if it is present in the blood or enters it over the following few weeks.

ACTIVE IMMUNIZATION
1 The person to be protected is inoculated with a killed or modified microorganism (vaccine) that does not cause disease.

2 The immune system is provoked to make antibodies against the modified microorganism; it also retains a “memory” of the organism.

3 If the real microorganism then enters the blood, antibodies can be produced quickly and in large numbers.

immunization
The process of artificially inducing immunity as a preventive measure against infectious diseases.

TYPES AND BENEFITS
Immunization may be active or passive. In the passive form, antibodies are injected into the blood to provide immediate but short-lived protection against specific bacteria, viruses, or toxins. Active immunization, also called vaccination, primes the body to make its own antibodies and confers longer-lasting immunity. It also protects the more vulnerable members of a community, such as the very old or the very young (see herd immunity).

WHO SHOULD BE IMMUNIZED
Routine childhood immunization programmes exist for diseases such as diphtheria, tetanus, pertussis, poliomyelitis, and haemophilus influenzae (Hib); measles, mumps, and rubella; meningitis C; and tuberculosis (see BCG vaccination). For injections and timings, see Typical childhood immunization schedule, overleaf.

Additional immunizations may also be necessary before foreign travel (see travel immunization).

POSSIBLE RISKS
Immunizations are usually given by injection, and most of them have no after-effects. Some vaccines, however, cause pain and swelling at the site of injection and may produce a slight fever or flu-like symptoms. Others may produce a mild form of the disease. Very rarely, severe reactions occur as a result of, for example, an allergy to one of the vaccine’s components. Not all immunization provides complete protection against disease; typhoid fever vaccinations, in particular, give only partial protection.

People with immunodeficiency disorders or who have widespread cancer, or those taking oral corticosteroid drugs should not receive vaccines containing live organisms. Those who have previously had a severe reaction to a vaccine should not be immunized. Some vaccines should not be given to young children, during pregnancy, or to HIV positive individuals.

imunoassay
A group of laboratory techniques, which include radioimmunoassay and ELISA (enzyme-linked immunosorbent assay), that are used in the diagnosis of infectious diseases, to confirm immunity, and also to investigate allergies. The
tests are performed to determine the presence or absence of particular antigens (proteins that are present on the surface of microorganisms or allergens) or antibodies (proteins that are formed by the immune system to combat a particular microorganism or allergen). Immunoassay procedures may also be used to measure blood levels of hormones (which are also proteins).

**immunocompromised**

A term used to describe a person whose immune system activity has been reduced by disease (such as AIDS or cancer) or by certain medical treatments (such as treatment with immunosuppressant drugs). An immunocompromised person is at a greater than normal risk of contracting infections, particularly so-called opportunistic infections (diseases caused by organisms that rarely pose a threat to healthy people).

**immunodeficiency disorders**

Disorders in which the defences of the immune system fail to fight infection and tumours. Immunodeficiency disorders may be due to an inherited or a congenital defect or may be the result of acquired disease. The result is persistent or recurrent infection, including infections with organisms that would not ordinarily cause disease (see opportunistic infections), and an undue susceptibility to certain forms of cancer. Opportunistic infections include pneumocystis pneumonia, fungal infections, and widespread herpes simplex infections.

**INHERITED IMMUNODEFICIENCY**

Congenital or inherited deficiencies can occur in either of the two prongs of the adaptive immune system – humoral or cellular immunity – or in both.

Deficiencies of the humoral system include hypogammaglobulinaemia and agammaglobulinaemia. The former may cause few or no symptoms, depending on the severity of the deficiency, but agammaglobulinaemia can be fatal if not treated with immunoglobulin.

Congenital deficiencies of T-lymphocytes may lead to problems such as persistent and widespread candidiasis (thrush). A combined deficiency of both humoral and cellular components of the immune system, called severe combined immunodeficiency (SCID), is usually fatal in the first year of life unless treatment can be given by bone marrow transplant.

**ACQUIRED IMMUNODEFICIENCY**

Acquired immunodeficiency may be due to disease processes (such as infection with HIV, which leads to AIDS). It may also be caused by damage to the immune system as a result of its suppression by drugs, either intentionally due to autoimmune diseases or after organ transplantation, or as a side effect of treatment for another condition. Severe malnutrition and many cancers can also cause immunodeficiency. Mild immunodeficiency arises through a natural decline in immune defences with age.

**immunoglobulin**

Also known as an antibody, a type of protein found in blood and tissue fluids. Such proteins are produced by B-lymphocytes (a type of white blood cell). Their function is to bind to substances in the body that are recognized as foreign antigens, such as proteins on the surfaces of bacteria and viruses. This binding is crucial for the destruction of antigen-bearing microorganisms. Immunoglobulins also play a key role in allergies and hypersensitivity reactions.

There are five main classes of immunoglobulin in the blood (IgA, IgD, IgE, IgG, and IgM). IgA is mainly found in secretions of the respiratory tract, intestine, and urinary tract. Only low levels of IgD are present in the body and its function is not known. IgE is involved in the immune response to worm infections; high levels are also produced to fight atopic (allergic) conditions. IgG is the major class of immunoglobulin, with four subclasses; its molecule consists of two parts, one of which binds to an antigen and the other to other cells of the immune system, which then engulf the microorganisms bearing the antigen. The most important function of IgG is to mount a response to bacterial infections. IgM is produced promptly in response to infection and then levels fall; IgM present in an infant at birth is an indicator of intrauterine infection.

Immunoglobulins can be extracted from the blood of people who have recovered from certain infectious diseases and used for passive immunization.

**immunoglobulin injection**

The administration of immunoglobulin preparations (antibodies) to prevent or treat infectious diseases. Such preparations, also known as immune globulin or gamma-globulin injections, work by passing on antibodies obtained from the blood of people who have previously been exposed to these diseases.

The main use of these injections is to prevent infectious diseases, such as chickenpox, in those people exposed to infection who are not already immune, or in those who are at special

*Combined injection †Booster
risk (during cancer treatment, for example). They are also given intravenously on a regular basis for immunodeficiency disorders. Side effects of such injections include rash and fever, and pain and tenderness at the injection site if injected into a muscle.

immunology
The discipline that is concerned with the immune system. Immunologists study the immune system’s functioning and investigate and treat immune system disorders, including autoimmune disorders, allergies, and immunodeficiency disorders such as AIDS.

Immunologists are also concerned with finding ways in which the immune system can be stimulated to provide immunity. In addition, they play a role in transplant surgery. Before operations, they look for a good match between recipient and donor organ; after transplantation they use drugs to suppress the recipient’s immune system, in order to minimize the chances of organ rejection.

immunostimulant drugs
COMMON DRUGS
- Aldesleukin
- BCG
- Interferon alfa
- Interferon beta
- Peginterferon alfa

A group of drugs that increase the efficiency of the body’s immune system. Immunostimulant drugs include vaccines, interferon, and aldesleukin (interleukin–2). Interferon alfa is used to treat persistent viral infections, such as hepatitis C. Interferon beta is used to treat some types of multiple sclerosis. Aldesleukin is used in the treatment of kidney cancer.

immunosuppressant drugs
COMMON DRUGS
- ANTICANCER DRUGS: Azathioprine
- Chlorambucil
- Cyclophosphamide
- Methotrexate
- Mycophenolate mofetil
- CORTICOSTEROID DRUGS: Prednisolone
- ANTIBODIES: Anti-lymphocyte globulin
- Basiliximab
- Daclizumab
- OTHER DRUGS: Ciclosporin
- Tacrolimus

A group of drugs that are used to reduce the activity of the immune system. Immunosuppressants are given to prevent rejection of donor tissue after transplant surgery. They are also given to slow the progress of autoimmune disorders such as rheumatoid arthritis and systemic lupus erythematosus.

The drugs work by suppressing the production and activity of white blood cells called lymphocytes. Side effects vary, but all of these drugs increase the risk of infection and of the development of certain cancers.

immunotherapy
Stimulation of the immune system as a treatment for cancer. The term is also used to describe hyposensitization treatment for allergy.

One type of immunotherapy that is employed in the treatment of cancer uses immunostimulant drugs. For example, treatment of bladder cancer may involve the introduction of BCG into the bladder. More recently, genetic engineering has been used to manufacture monoclonal antibodies (see antibody, monoclonal) to be directed against tumours. Interferon or chemical poisons can be linked to these antibodies in order to increase their ability to destroy tumour cells without damaging normal cells.

Imodium
A brand name for loperamide, an antidiarrhoeal drug.

impaction, dental
Failure of a tooth to emerge completely from the gum. It may occur because of overcrowding or when a tooth grows in the wrong direction.

Impacted wisdom teeth are common when the teeth come through in early adulthood. If they cause no symptoms, they do not need to be removed. In some cases, however, impacted wisdom teeth partially penetrate the gum, leaving a flap of tissue over most of the crown. Plaque, bacteria, and food debris may then collect between the tooth and the gum, causing pain and inflammation in the gum tissues (see gingivitis). If the problem persists, the affected teeth need to be removed.

impaction, faecal
See faecal impaction.

impedance audiometry
A hearing test used to investigate the performance of the middle ear in cases of conductive deafness.

imperforate
A term meaning “without an opening”. The term is used to describe a body structure, such as the hymen or the anus (see anus, imperforate), which should have an opening but does not.

impetigo
A highly contagious skin infection, common in children, that most commonly occurs around the nose and mouth, but can affect the skin anywhere on the body.

CAUSE AND SYMPTOMS
Impetigo is caused by bacteria (usually staphylococci) entering areas of broken skin. The skin reddens and small, fluid-filled blisters appear. The blisters tend to burst, leaving moist, weeping areas that dry to leave honey-coloured or golden crusts. In severe cases, there may be swelling of the lymph nodes in the face or neck and fever.

TREATMENT AND PREVENTION
Treatment is with topical (locally administered) antibiotic drugs unless the condition is widespread, in which case oral antibiotics are usually given.

As the condition is highly contagious, to prevent the spread of the infection, towels, flannels, and pillowcases should...
not be shared. Children should not go to school or mix with others until they have been treated and the condition has cleared up.

**implant**

Any material, either natural or artificial, that is inserted into the body for medical or cosmetic purposes.

**implantation, egg**

Attachment of a fertilized ovum (egg) to the wall of the uterus. Implantation occurs about six days after fertilization, when the blastocyst (early embryo) comes into contact with the uterus wall.

As the cells of the developing embryo continue to divide, the outer cell layer penetrates the lining of the uterus to obtain oxygen and nutrients from the mother's blood; later, this layer develops into the placenta. The embryo usually implants in the upper part of the uterus; if it implants low down near the cervix, placenta praevia may develop. Rarely, implantation occurs outside the embryo, possibly in a fallopian tube, resulting in an ectopic pregnancy.

**implant, dental**

A post that is surgically embedded in the jaw for the attachment of a dental prosthesis (an artificial tooth). Titanium or synthetic materials may be used. A dental implant is fitted under either a local or general anaesthetic (see anaesthesia, dental). A hole is drilled in the jaw and the post inserted. Several months later, an attachment that protrudes from the gum is screwed into the post; a few weeks after that, the prosthesis is fitted.

**implosive therapy**

A form of behaviour therapy, also known as flooding, used for desensitizing a person to the cause of a phobia.

**impotence**

The inability to achieve or maintain an erection. Impotence, known medically as erectile dysfunction, is the most common male sexual disorder, affecting most men at some time in their lives.

**CAUSES**

Impotence is usually caused by psychological factors, be they temporary (for example, due to stress) or longstanding (such as due to anxiety and guilt originating in childhood). Impotence may be a symptom of depression.

Some cases of impotence are caused by a physical disorder, such as diabetes mellitus, damage to the spinal cord, or an alcohol-related disorder. Impotence may be caused by taking various drugs, such as antidepressant drugs and antihypertensive drugs. Impotence is found to be more common in older men, which is possibly due to altered circulation or reduced levels of the male sex hormone testosterone.

**TREATMENT**

Tests may be performed to eliminate the possibility of a physical disorder. A change in current medication may also be advised to see if the condition of impotence is affected.

If the cause of impotence is psychological, counselling or sex therapy may be recommended and is often found to be a successful treatment.

Treatment of a physical cause may be possible, for example, with the drug sildenafil (Viagra). However, due to the drug's effects on the vascular system, it should be used with caution in men with certain disorders, such as angina pectoris; it should not be used after a recent stroke or myocardial infarction (heart attack). Sildenafil should never be taken without medical advice. Other treatments include self-administered injections into the penis and a surgical implant, which can produce a sustained erection.

**impression, dental**

A mould taken of the teeth, gums, and palate. A quick-setting material, such as alginate, is placed in a mould over the teeth. The mould is then removed, and plaster of Paris poured into it to obtain a model of the area. This model is then used as a base on which to build a denture, bridge, or dental inlay.

Dental impressions are also used in orthodontics to study the position of the teeth, and to make orthodontic appliances to correct irregularities.

**impulse**

A sudden, spontaneous force or action. In biology and medicine, the term “impulse” is usually used to refer to the electrical activity that travels along a nerve which may result, for example, in a muscle contraction.

**inattention, sensory**

In neurology (the study of diseases of the nervous system), a term meaning the inability to recognize a tactile stimulus (such as a pinprick) on one side of the body, while reacting normally to a simultaneous stimulus on the other side. Visual inattention (failure to respond to local visual stimuli) may also be present. The condition is most commonly the result of a stroke.

**inborn errors of metabolism**

See metabolism, inborn errors of.

**incest**

Sexual intercourse between close relatives, such as with a parent, a son or daughter, a brother or sister, an uncle or aunt, a nephew or niece, or a grandparent or grandchild. Incest is illegal or taboo in most societies and is against the teaching of many religions.

**incidence**

One of the two principal measures (the other is prevalence) of how common a disease is in a defined population. The incidence of a disease is the number of new cases that occur during a given period (for example, 17 new cases per 100,000 people per year).

**incision**

A cut made into the tissues of the body by a scalpel (surgical knife). Most incisions are made to gain access to tissue inside the body, usually to repair or remove a diseased organ. An incision may also be made to allow pus to drain from an abscess or boil.

**incisional hernia**

A type of hernia in which the intestine bulges through a scarred area of the abdominal wall because the surrounding muscle has been weakened by a previous surgical incision.

**incisor**

One of the eight front teeth (four in the upper jaw and four in the lower) used for cutting through solid food (see teeth).

**incompatible blood transfusion**

A blood transfusion in which the patient’s immune system reacts against the donor blood as a foreign invader (see blood transfusion, incompatible).

**incompetence**

A medical term applied to a structure that should close tightly but does not. For example, valve incompetence (see aortic incompetence; mitral incompetence) causes leakage of blood; cervical incompetence may result in a miscarriage.
incomplete abortion
The retention in the uterus of placental or fetal tissue after a miscarriage or a medical abortion (see abortion, induced). If this tissue is not promptly removed, it may become infected, resulting in a dangerous condition called septic abortion and haemorrhage (bleeding).

incontinence, faecal
Inability to retain faeces in the rectum, leading to involuntary defaecation.

CAUSES
A common cause of faecal incontinence is faecal impaction, which often results from long-standing constipation. In this condition the rectum becomes overfull, causing faecal fluid and small pieces of faeces to be passed involuntarily around the impacted mass of faeces. Temporary loss of continence may also occur in severe diarrhoea. Other causes include injury to the anal muscles (as may occur during childbirth), paraplegia (damage to the nerves in the lower trunk, including those supplying the intestines), and dementia (loss of normal brain functions, such as control of the bowels).

TREATMENT
Faecal incontinence can usually be successfully treated. If the underlying cause of faecal impaction is constipation, recurrence may be prevented by eating a high-fibre diet. Suppositories containing glycerol or laxative drugs may be recommended. Pelvic floor and anal sphincter damage can often be surgically repaired. Faecal incontinence in people with dementia or a nerve disorder may be avoided by regular use of enemas or suppositories to empty the rectum.

incontinence, urinary
Involuntary passing of urine, often due to injury or disease of the urinary tract. There are several types.

TYPES AND SYMPTOMS
Stress incontinence refers to the involuntary escape of urine when a person coughs, laughs, picks up a heavy object, runs, or jumps. It develops when the urethral sphincter muscles (which normally keep the bladder outlet closed) have been stretched and weakened. Stress incontinence is common in women, particularly after childbirth or in patients with prolapse of the uterus or vagina. This condition results in the loss of small amounts of urine.

In urge incontinence, also known as irritable bladder, an urgent desire to pass urine (even though the bladder is not full) is accompanied by inability to control the bladder as it contracts. Once urination starts, it cannot be stopped, leading to the loss of large volumes of urine. Urge incontinence is often caused by irritability of the bladder lining. The problem may be caused by infection or inflammation (see cystitis). It may also result from the presence of stones (see calculus, urinary tract) or bladder tumours; disorders affecting the nerves that supply the bladder (such as stroke or multiple sclerosis); or anxiety. In some cases the bladder muscles are too sensitive to increasing pressure within the bladder, inappropriately triggering emptying.

Total incontinence is a complete lack of bladder control due to loss of function in the urethral sphincter. It may be associated with spinal cord damage, due to disease or injury, that affects the nerves supplying the bladder.

Overflow incontinence occurs in long-term urinary retention, often because of an obstruction such as an enlarged prostate gland. The bladder is always full, leading to constant dribbling of urine.

Incontinence due to lack of control by the brain commonly occurs in young children (see enuresis) or elderly people, and in those with learning difficulties.

TREATMENT
A wide range of treatments for urinary incontinence are available, and most affected people achieve significant improvement. If weak pelvic muscles are causing stress incontinence, pelvic floor exercises may be helpful. Sometimes, surgery may be needed to tighten the pelvic muscles or correct a prolapse. Anticholinergic drugs may be used to relax the bladder muscle if irritable bladder is the cause. Collagen injections into the urethral wall, performed under anaesthetic, may also be effective.

If normal bladder function cannot be restored, incontinence pants can be worn; men, alternatively, can wear a penile sheath leading into a tube connected to a urine bag. Some people can avoid incontinence by means of self-catheterization (see catheterization, urinary). Permanent catheterization is necessary in some cases.

incoordination
Loss of the ability to produce smooth, muscular movements, leading to clumsiness and unsteady balance. The term “incoordination” can also mean the failure of a group of organs to work together successfully. (See also ataxia.)

incubation period
The time during which an infectious disease develops, from the point when the infectious organism enters the body until symptoms appear. Different infections have characteristic incubation periods; for example, 14–21 days for chickenpox and 7–14 days for measles. The incubation period for cholera may be as short as several hours.

incubator
A transparent plastic cot that provides premature or sick infants with ideal conditions for survival. In an incubator, oxygen, temperature, and humidity levels are controlled. Incubators have portholes to allow handling of the baby, and smaller ones through which monitoring cables and intravenous and respiratory tubing can pass.

inderal
A brand name for propranolol, a beta-blocker drug used to treat heart and circulatory disorders as well as some mental problems.
Indian medicine
A system of medicine originally based largely on herbal treatment, although simple surgical techniques were also used. Indian medicine, also known as ayurvedism, later developed into a scientifically based system with a wide range of surgical techniques (such as operations for cataracts and kidney stones) alongside emphasis on purifying techniques, diet, yoga, breathing exercises, and the herbal tradition. Indian medicine has been used effectively to treat a variety of conditions, including digestive problems, rheumatoid arthritis, allergies, viral infections, and anxiety-related disorders such as insomnia.

indigenous
Native to a particular place or country. In medicine, this concept is important when investigating the effect of environmental factors on disease patterns.

indigestion
A common term (known medically as dyspepsia) covering a variety of symptoms brought on by eating, including heartburn, abdominal pain, nausea, and flatulence (excessive wind in the stomach or intestine, that causes belching and discomfort).

Discomfort in the upper abdomen is often caused by eating too much, too quickly, or by eating very rich, spicy, or fatty foods. Persistent or recurrent indigestion may be due to a peptic ulcer, gallstones, oesophagitis (inflammation of the oesophagus), or, rarely, stomach cancer.

Antacid drugs help to relieve the symptoms, but they may mask an underlying cause that needs medical attention. They should not be taken for longer than two weeks without medical advice.

indole
A substance produced by the breakdown of the amino acid tryptophan in the intestine. Indole is excreted in urine. An indole compound (5-hydroxyindole acetic acid) is measured in the urine in the investigation of possible carcinoid tumours.

indolent ulcer
A term describing an ulcer that is slow to heal but usually causes little pain.

indometacin
A nonsteroidal anti-inflammatory drug (NSAID) used to relieve pain, stiffness, and inflammation caused by disorders such as rheumatoid arthritis, osteoarthritis, and tendinitis. It is also prescribed to relieve the pain that is caused by injury to soft tissues, such as muscles and ligaments. Side effects of indometacin include abdominal pain, nausea, heartburn, headache, dizziness, and an increased risk of peptic ulcer.

indoramin
An alpha-blocker drug used to treat hypertension (high blood pressure). It acts by relaxing the muscles in the blood vessel walls, thus allowing the vessels to widen and easing the flow of blood. In lower doses, indoramin is also prescribed to relieve the symptoms of an enlarged prostate gland (see prostate, enlarged); it relaxes the muscle of the prostate and thereby enables urine to be passed more easily.

When first taken, indoramin can cause a rapid fall in blood pressure. For this reason, the first dose is usually small and is taken lying down. Indoramin may also cause drowsiness at the start of treatment and whenever the dosage is increased.

induction of labour
Use of artificial means to begin labour if the health of the mother or baby would be at risk if the pregnancy was allowed to continue for longer.

WHY IT IS DONE
The most common reason for inducing labour is that the pregnancy has continued past the estimated delivery date, which increases the chance of complications during childbirth. Other reasons for induction are pre-eclampsia (a serious condition involving high blood pressure and fluid accumulation), Rh incompatibility (a difference between the blood groups of mother and fetus), or intrauterine growth retardation (poor growth of the developing fetus).

HOW IT IS DONE
Different methods of induction are used, depending on the stage of labour and cervical condition. A prostaglandin pessary may be inserted high into the vagina to encourage the cervix to soften and open. The hormone oxytocin may also be given as a continuous intravenous infusion in order to stimulate uterine contractions.

induration
A specific medical term meaning the hardening or thickening of areas of soft tissue (for example, the skin or blood vessel walls) or an organ (such as the lung or liver) due to inflammation or disease. (See also sclerosis.)

industrial diseases
See occupational disease and injury.

industrial psychology
A field of psychology in which human behaviour is studied in relation to the effects and influences of the workplace. The principles of industrial psychology are applied to such issues as leadership, communications, motivation, job analysis, and selection of employees.

indwelling catheter
A catheter (flexible tube) that remains in place for a prolonged period. The term usually refers to a urinary catheter that is used to drain the contents of the bladder via the urethra; it is held in place with a balloon (see balloon catheter).

in extremis
The Latin term for “at the point of death”.

Infacol
A brand name for dimeticone (an anti-foaming agent used to relieve colic).

infant
A term usually applied to a baby up to the age of 12 months.

infantile autism
An alternative term for autism, a disorder that usually develops in early childhood and causes severe impairment of language and communication skills.

infantile cataract
A congenital disorder (one present from birth) in which a baby’s sight is seriously impaired by opacity of the lens of the eye (see cataract). Causes include infections, such as rubella (German measles) and toxoplasmosis, passed from mother to baby before birth. Surgical removal of the cataract may be beneficial.

infantile colic
See colic, infantile.

infantile eczema
An alternative term for atopic eczema that first develops in early childhood.

infantile spasms
A rare type of recurrent seizure, also called progressive myoclonic encephalopathy or salaam attacks, that affects
babies. The condition is a form of epilepsy and first occurs around four to nine months of age. Spasms may occur hundreds of times a day, each lasting a few seconds. During a seizure, the baby’s head suddenly falls forwards, the body stiffens, and the limbs bend, then the arms and hands extend and move outwards. These seizures are usually a sign of brain damage; affected babies usually have severe developmental delay.

**infant mortality**
The number of infants who die during the first year of life per 1,000 live births (usually expressed as per year). The majority of infant deaths occur during the neonatal period (the first month of life). Most of those who die are very premature and of low birth weight, or have severe congenital abnormalities.

**infarction**
Death of an area of tissue due to ischaemia (lack of blood supply). One common example is myocardial infarction, commonly called a heart attack. Another is pulmonary infarction, which is lung damage caused by a pulmonary embolism – a blood clot that has moved into a vessel in the lung and is obstructing the flow of blood. (See also necrosis).

**infection**
The establishment in the body of disease-causing microorganisms (such as bacteria, viruses, or fungi). The organisms reproduce and cause disease by direct damage to cells or by releasing toxins. This activity normally provokes the immune system into responding, which accounts for many common symptoms. Infection can be localized within a particular area or tissue, as in a boil, or be systemic (spread throughout the body), as in influenza. Localized infection may result from the spread of organisms through wounds, or during surgery. This form of infection is generally associated with pain, redness, swelling, and formation of a pus-filled abscess at the site of infection, and a rise in temperature. Weakness, aching joints, and fever are expressions of systemic infectious disease.

Many minor infections are dealt with by the immune system and need no specific treatment. A localized infection that has produced pus may be drained surgically. Severe systemic infections may need treatment with drugs such as antibacterials or antivirals. For further information about different infectious diseases, see the accompanying tables.

**infection, congenital**
Infection that is acquired by a baby in the uterus or during birth.

**INFECTIONS ACQUIRED IN THE UTERUS**
Many microorganisms can pass from the mother, by way of the placenta, into the circulation of the growing fetus. Particularly serious infections that may be acquired in the uterus are rubella, syphilis, toxoplasmosis, and cytomegalovirus. All these infections may cause intrauterine growth retardation. Rubella that occurs in early pregnancy may cause deafness, congenital heart disease, and eye disorders.

Some diseases in later pregnancy may also damage the fetus severely. One such condition is infection with a herpes virus. A woman infected with HIV risks passing it on to her baby during pregnancy, but the risk can be reduced by use of antiretroviral drugs during the pregnancy.

**INFECTIONS ACQUIRED DURING BIRTH**
Infections acquired during birth are almost always the result of microorganisms in the mother’s vaginal secretions or uterine fluid. Premature rupture of the membranes is associated with increased risk of disease, particularly streptococcal infections. Conditions that may be acquired during delivery include herpes, chlamydial infections, and gonorrhoea.

**TREATMENT**
Treatment of the baby depends on the type of infection. Some birth defects caused by infection (such as certain types of heart defect) can be treated; others (such as congenital deafness) are usually not treatable.

**infectious disease**
Any illness that is caused by a specific microorganism. The most important disease-causing organisms are viruses, bacteria, including rickettsiae, chlamydiae, mycoplasmas, and fungi. Others are protozoa and worms.

**INCIDENCE**
In affluent countries, infectious diseases are generally less of a threat than in the past because of better methods to control the spread of disease organisms (such as improved sanitation and water purification); effective drugs; immunization; and better general health and nutrition. In poorer countries, such diseases still pose a threat, both to people who live in these countries and to travellers who visit them.

**INCUBATION PERIOD**
For most infectious diseases, there is a time gap between the entry of the microorganism into the body and the first appearance of symptoms.
appearance of symptoms. This incubation period, during which an infected person is likely to pass the microorganism to others, may vary from a few hours or days to, in some cases, several months.

**TREATMENT**

Antibiotic drugs and other antimicrobial drugs are the mainstay of treatment for bacterial infection. For viral infection, however, drug treatment is restricted to severe infections and often relies on supportive measures alone.

**OUTLOOK**

Progress has been made in the fight against infectious diseases, but many problems remain. The spread of diseases such as *sexually transmitted infections* is difficult to control and, for many infections, no effective vaccine exists.

Some bacteria have developed resistance to the drugs available; this could lead to a rise in potentially fatal bacterial infections similar to those common before the development of

antibiotics. The majority of viral infections cannot be combated with drugs.

The widespread incidence of HIV, particularly in developing countries, poses a great threat to world health; HIV infection also increases the risk of a surge in less common infections in those people whose immune systems are compromised.

**infectious mononucleosis**
See mononucleosis, infectious.

**infective arthritis**
An alternative term for septic arthritis.

**infective endocarditis**
See endocarditis.

**inferior**
An anatomical term that is used to describe the lower of two body structures, surfaces, or organs.

**inferiority complex**
A neurotic state of mind that develops because of repeated hurts or failures in the past. Inferiority complex arises from a conflict between the positive wish to be recognized as someone worthwhile and the haunting fear of frustration and failure.

Attempts to compensate for the sense of worthlessness may take the form of aggression and violence, or an overzealous involvement in activities. (See also superiority complex.)

**infertility**
The inability to produce offspring, which may result from a problem in either the male or the female reproductive system, or, in many cases, from a combination of problems in both.

**MALE INFERTILITY**
The main cause of male infertility is a lack of healthy sperm. In azoospermia, no sperm are produced; in oligospermia only a few sperm are produced. In some cases, sperm are produced but are malformed or short-lived.

The underlying cause of these problems may be blockage of the spermatic tubes or damage to the spermatic ducts, usually due to a sexually transmitted infection. Abnormal development of the testes due to an endocrine disorder (see hypogonadism) or damage to the testes by orchitis may also cause defective sperm. Smoking, toxins, or various drugs can lower the sperm count (the number of sperm cells in a sample of semen). Other causes are disorders affecting ejaculation (see ejaculation, disorders of). Rarely, male infertility is due to a chromosomal abnormality, such as Klinefelter's syndrome, or a genetic disease, such as cystic fibrosis.

**FEMALE INFERTILITY**
The most common cause of female infertility is failure to ovulate. Other causes are blocked, damaged or absent fallopian tubes; disorders of the uterus, such as fibroids and endometriosis; problems with fertilization; or difficulties with implantation in the uterus (see implantation, egg). Infertility also occurs if the woman’s cervical mucus contains antibodies that kill or immobilize her partner’s sperm. Rarely, a chromosomal abnormality, such as Turner's syndrome, is the cause of a woman’s infertility.

**INVESTIGATION**
The initial investigation performed for male infertility is semen analysis, which
INVESTIGATING INFERTILITY

First, a general check-up and/or a personal interview regarding sexual behaviour are carried out. If no cause for infertility is found at this stage, more specialized tests may be performed. It is important that both partners are tested for infertility, because infertility can be attributed to one person, to both people, or to mutual incompatibility.

CAUSES OF INFERTILITY

Conception is a complicated process; the reproductive organs can be affected in numerous ways, resulting in infertility. Some of the principal underlying causes of infertility in men and in women are illustrated on the right.

FEMALE INFERTILITY

Investigations to discover the cause of a woman’s infertility may include taking a menstrual history and a study of the woman’s body temperature during her menstrual cycle (below). There may also be blood and urine tests to discover whether ovulation is normal, hysterosalpingography (right), and/or laparoscopy (below right).

MALE INFERTILITY

The first test for investigating male infertility is semen analysis (below). If it reveals a low sperm count, more tests may be needed to investigate the underlying cause.

Body temperature and ovulation

Charting the changes in a woman’s body temperature during her menstrual cycle can reveal abnormalities of ovulation. The chart above shows typical daily temperature fluctuations during a normal menstrual cycle (blue line) and temperature changes associated with failure to ovulate (grey line).

Semen analysis

Semen produced by masturbation is examined as soon as possible, and the number, shape, and degree of motility (movement) of the sperm are determined. A postcoital semen test may also be performed.

Abnormal sperm

If a man’s semen contains large numbers of abnormally shaped sperm, such as the two-headed one at the top of this image, his fertility may be reduced.
includes a sperm count. Investigations to discover the cause of a woman’s infertility may include blood and urine tests to check that ovulation is occurring, ultrasound scanning or X-ray examinations to assess whether the fallopian tubes are blocked, and laparoscopy to determine if a condition, such as endometriosis, is present.

**TREATMENT**

Treatment of male infertility is limited. The only option for men with azoospermia is adoption of children or artificial insemination by a donor. If the sperm count is low, artificial insemination by the male partner or, alternatively, in vitro fertilization (IVF) with intracytoplasmic sperm injection may be tried. In some cases of male infertility, gonadotrophin hormone therapy may prove useful.

Failure of the woman to ovulate requires ovarian stimulation with a drug such as clomifene, given either with or without a gonadotrophin hormone. Microsurgery can sometimes repair damage to the fallopian tubes. If surgery is unsuccessful, IVF is an option. Uterine abnormalities or disorders, such as fibroids, may require treatment. In some cases, provided the woman has normal fallopian tubes, either gamete intrafallopian transfer (GIFT) or zygote intrafallopian transfer (ZIFT) may be carried out.

**Infestation**

The presence of animal parasites (such as mites, ticks, or lice) in the skin or hair, or of worms (such as tapeworms) inside the body.

**Infibulation**

A form of female circumcision in which the labia majora (the outer lips surrounding the vagina) are removed and the entrance to the vagina narrowed (see circumcision, female).

**Infiltrate**

The term used for a build-up of substances or cells within a tissue that are either not normally found in it or are usually present only in smaller amounts.

The word “infiltrate” may also refer to a drug (such as a local anaesthetic) that has been injected into a tissue, or to the build-up of a substance within an organ (for example, fat in the liver caused by excessive alcohol consumption). In addition, radiologists use the term to refer to the presence of abnormalities, most commonly on a chest X-ray, due to conditions such as infection.

**Infirmitiy**

A term meaning frailty, weakness or lack of strength. It is most commonly used in relation to illness or old age.

**Inflammation**

Redness, swelling, heat, and pain in a tissue due to injury or infection. When body tissues are damaged, mast cells release the chemical histamine and other substances. Histamine increases the flow of blood to the damaged tissue and also makes the blood capillaries more leaky; fluid then oozes out and into the tissues, causing localized swelling. The inflammatory chemicals stimulate the nerve endings, causing pain. Inflammation is usually accompanied by a local increase in the number of white blood cells. These cells help to destroy invading microorganisms and are involved in repairing the damaged tissue.

Inflammation may be suppressed by corticosteroid drugs or by nonsteroidal anti-inflammatory drugs.

**Inflammatory bowel disease**

A collective term for chronic disorders that affect the small and/or the large intestine and cause abdominal pain, bleeding, and diarrhoea. Crohn’s disease and ulcerative colitis are the most common types of inflammatory bowel disease.

**Inflammatory oedema**

A term sometimes used to describe the swelling associated with inflammation, such as the swelling that develops around a cut as it heals.

**Infliximab**

A drug that inhibits the activity of tumour necrosis factor (TNF), a chemical released by lymphocytes causing tissue damage and pain. Such drugs are known as TNF blockers or anti-TNF drugs. Infliximab is used to treat severe rheumatoid arthritis and Crohn’s disease that have not responded to other drug treatment.

**Influenza**

Popularly known as “flu”, a viral infection of the respiratory tract (air passages). Influenza is spread by infected droplets from coughs or sneezes. It usually occurs in small outbreaks or every few years in epidemics.

**CAUSES**

There are three main types of influenza virus: A, B, and C. A person who has had an attack caused by the type C virus acquires antibodies that provide immunity against type C for life. Infection with a strain of type A or B virus produces immunity only to that particular strain. Type A and B viruses, however, are capable of altering to produce new strains; type A has been the cause of pandemics (disease outbreaks affecting millions of people) in the last century.

**SYMPTOMS AND COMPLICATIONS**

Types A and B produce classic flu symptoms: fever, headache, muscle aches, and weakness. Type C causes a mild illness indistinguishable from a common cold.

Flu usually clears up completely within 7–10 days. Rarely, however, it takes a severe form, causing acute pneumonia that may be fatal within a day or two, even in healthy young adults.

Type B infections in children sometimes mimic appendicitis, and they have been implicated in Reye’s syndrome. In elderly people and those with lung or heart disease, influenza may be followed by a bacterial infection such as bronchitis or pneumonia.

**TREATMENT**

Analgesics (painkillers) help to relieve aches and pains and reduce fever. Antiviral drugs such as zanamivir may be used to treat at-risk people who develop flu; to be effective, treatment must be started within 48 hours of symptoms appearing. Amantadine may be used in specific cases for prevention during an outbreak of flu. Antibiotics may be used to combat secondary bacterial infection.

**PREVENTION**

Flu vaccines, containing killed strains of the types A and B virus in circulation, are available, but have only a 60–70 per cent success rate. The immunity that they provide is only short-lived and vaccination is recommended for older people, anyone suffering from respiratory or circulatory problems, chronic renal failure or diabetes mellitus as well as key health workers) must be repeated annually.

**Informed consent**

See consent.

**Infra-**

A prefix meaning “below”, commonly used in medical terminology.

**Infrapatellar bursitis**

Inflammation of the bursa (fluid-filled sac) that lies below the patella (kneecap) and over the top of the tibia (shinbone) acting as a cushion against friction. The condition is usually the result of prolonged kneeling in an upright position.
(which it is why it is sometimes called “clergyman’s knee”). Infrapatellar bursitis is similar to prepatellar bursitis, or housemaid’s knee; however, this second condition often results from prolonged kneeling while leaning forwards, which puts excessive pressure on the bursa that lies in front of the kneecap.

Infrapatellar bursitis causes swelling and pain. Knee movement may also be restricted. The swelling usually reduces with rest; nonsteroidal anti-inflammatory drugs may help to relieve the discomfort. For persistent symptoms, a doctor may drain the fluid from the bursa and inject a corticosteroid drug into the sac. Frequent changes in position and use of foam padding is recommended.

infra-red
A term denoting the part of the electromagnetic spectrum that is immediately beyond the red end of the visible light spectrum (see colour vision).

Infra-red radiation is directed on to the skin and heats the skin and the tissues immediately below it. An infra-red lamp is one means of giving heat treatment to promote healing from injuries and inflammatory conditions.

infundibulum
The medical term for a funnel-shaped passage or structure. Specifically, infundibulum refers to the short stalk carrying nerve fibres connecting the hypothalamus in the brain to the pituitary gland.

infusion, intravenous
See intravenous infusion.

ingestion
The act of taking any substance (for example, food, drink, or medications) into the body through the mouth. The term “ingestion” also refers to the process by which certain cells (for example, some white blood cells) surround and then engulf small particles.

ingrowing toenail
See toenail, ingrowing.

inguinal
A word relating to the groin (the area between the abdomen and thigh), as in inguinal hernia.

inguinal hernia
A type of hernia in which part of the intestine protrudes through the abdominal wall in the groin. It can be either direct or indirect. In a direct inguinal hernia, there is a localized weakness in the abdominal wall through which the intestine pushes. In an indirect inguinal hernia the intestine protrudes through the inguinal canal (in males the passage through which the testes descend into the scrotum). An indirect inguinal hernia may also occur in females.

inhalation
The act of taking in breath (see breathing). An inhalation is also a medication designed to be breathed in and prepared in the form of a gas, vapour, powder, or aerosol.

inhaler
A device used for administering a drug in powder or vapour form. Inhalers are used mainly in the treatment of various respiratory disorders, including asthma and chronic bronchitis. Metered-dose inhalers deliver a precise dose when the inhaler is pressed. Drugs taken by inhalation include bronchodilators and corticosteroids. See the illustrated box for information on using an inhaler.

inheritance
The transmission of characteristics and disorders from parents to their children through the influence of genes. Genes are the units of DNA (deoxyribonucleic acid) that are contained in a person’s cells; DNA controls all aspects of the body’s growth and functioning. Half of a person’s genes come from the mother and half from the father.

GENES AND CHROMOSOMES
Genes are organized into chromosomes (long, thread-like structures) in the cell nucleus. Genes controlling most characteristics come in pairs, one from each parent. Every individual has 22 pairs of chromosomes (called autosomes), with each chromosome in a pair bearing one of the paired genes. In addition, there are two sex chromosomes: females have two X chromosomes, and males have an X and a Y chromosome.

MECHANISMS OF INHERITANCE
Most physical characteristics, many disorders, and some mental abilities and aspects of personality are inherited. The inheritance of normal traits and disorders can be divided into three groups: those that are controlled by a single pair of genes on the autosomal chromosomes (unifactorial inheritance); those that are controlled by genes on the sex chromosomes (sex-linked inheritance, such as haemophilia); and those that are controlled by the combination of many genes (multifactorial inheritance, such as height).

<table>
<thead>
<tr>
<th>HOW TO USE A METERED-DOSE INHALER</th>
</tr>
</thead>
</table>

The user puts the mouthpiece of the inhaler in the mouth, presses the end, and simultaneously breathes in through the mouth. If the device is used correctly, the drug is dispersed to the bronchi. Young children, or people who find it difficult to use an inhaler, can use a spacer. A nebulizer is a device that delivers the drug directly as a fine mist, through a face-mask or mouthpiece, over several minutes.

Spacer
The inhaler fits on to the spacer and the drug dose is released into it. The user inhales normally from the spacer’s mouthpiece.

Aerosol inhaler
This type of inhaler delivers a dose of the drug as an aerosol spray when the user presses the top of the inhaler.

Top of inhaler is pressed
Canister of liquid drug

Inhaler fits on to end of spacer
UNIFACTORIAL INHERITANCE

Either of the pair of genes controlling a trait may take any of several forms, known as alleles.

For example, the genes controlling eye colour exist as two main alleles, coding for blue and brown eye colour. The brown allele is dominant over blue in that it “masks” the blue allele, which is described as “recessive” to the brown allele. Only one of the pair of genes controlling a trait is passed to a child from each parent. For example, someone with the brown/blue combination for eye colour has a 50 per cent chance of passing on the blue gene, and a 50 per cent chance of passing on the brown gene, to any child. This factor is combined with the gene coming from the other parent, according to dominant or recessive relationships, to determine the child’s eye colour. Certain genetic disorders are also inherited in a unifactorial manner (for example, cystic fibrosis and achondroplasia).

SEX-LINKED INHERITANCE

Sex-linked inheritance depends on the two sex chromosomes, X and Y. The most obvious example of this type of inheritance is gender of an individual. Male gender is determined by genes on the Y chromosome, which is present only in males. Any faults in a male’s genes on the X chromosome tend to be evident because there is no second, normal X chromosome that would mask the faults (as there is in females). Faults in the genes of the X chromosome include those responsible for colour vision deficiency, haemophilia, and other sex-linked inherited disorders, which almost exclusively affect males.

MULTIFACTORIAL INHERITANCE

Multifactorial inheritance, along with the effects of environment (such as diet and exposure to diseases or toxins), may play a part in causing certain disorders, such as diabetes mellitus and neural tube defects.

inhibition

The process of preventing any mental or physical activity. Inhibition in the brain and spinal cord is carried out by certain neurons (nerve cells), which damp down the action of other nerve cells in order to keep the brain’s activity in balance.

In psychoanalysis, the term “inhibition” refers to the unconscious restraint of instinctual impulses.

injection

Introduction of a substance into the body from a syringe via a needle. Injections may be intravenous (where they are given into a vein); intramuscular (into a muscle); intradermal (into the skin); subcutaneous (into the tissue layer under the skin); or intra-articular (into a joint).

injury

Physical harm to any part of the body. Injury may have many possible causes, including environmental influences (for example, force, heat, cold, electricity, vibration, and radiation), chemical causes (such as poisons), bites, or oxygen deprivation.

ink-blot test

An outdated psychological test in which the subject was asked to interpret the appearance of a number of ink blots; the person’s responses were thought to reveal aspects of mental function such as emotions and psychological conflicts. The most widely used example was the Rorschach test.

inlay, dental

A filling of porcelain or gold used to restore a badly decayed tooth where the cavity is too big to receive amalgam. An inlay may be needed for the back teeth or to protect a weakened tooth.

innate

A term to describe a condition or trait that is present from birth (see congenital).

inner ear

The deepest part of the ear, lying closest to the brain, that contains the organs of hearing and balance. The inner ear registers air vibrations and other sensory stimuli, such as head movement; cells convert the information into electrical impulses, which pass along nerves to the brain. The other parts of the ear are the outer and middle ear.

innervation

A term meaning the supply of nerves to an organ or other part of the body.

innocent murmur

A murmur (a sound made by blood flow through the heart, as heard through a stethoscope) that is not due to any disease of the heart or its valves. Innocent heart murmurs are commonly found in children and may be more noticeable after exercise or during a fever. If there is any doubt about the significance of a murmur, tests such as echocardiography or ECG may be requested.
inoculation
The act of introducing a small quantity of a foreign substance into the body, usually by injection, for the purpose of stimulating the immune system to produce antibodies (protective proteins) against the substance, a process known as active immunity. Inoculation is usually done to protect individuals against future infection by particular bacteria or viruses (see immunization).

inoperable
A term applied to any condition that cannot be alleviated or cured by surgery, particularly cancers.

inorganic
A term used to refer to any of the large group of substances that do not contain carbon. Some examples of inorganic substances include table salt (sodium chloride) and bicarbonate of soda (sodium bicarbonate). The term “inorganic” is also applied to a few of the most simple carbon compounds, such as carbon dioxide and carbon monoxide.

inotropic
A term used to refer to anything that affects the force or energy of muscular contractions, either positively (strengthening the contractions) or negatively (weakening the contractions).

Inotropic drugs are drugs that stimulate, and increase the force of, heart muscle contractions. Inotropic drugs are sometimes needed immediately after a myocardial infarction (heart attack) to maintain blood pressure and tissue circulation. In such cases, drugs such as dopamine and dobutamine are given by intravenous infusion. In cases of chronic heart failure, digitalis drugs, and especially digoxin, may be used for the same purpose.

inpatient treatment
Care or therapy in hospital following patient admission.

inquest
An official inquiry by a coroner into a death that is of unknown cause or is suspected of being unnatural.

INR
The abbreviation for International Normalized Ratio, a measure used in the management of anticoagulant drugs. It allows for uniform measurement of the anticoagulation status of patients.

insanity
A term commonly used for serious mental disorder. Although used legally, the term has no real technical meaning.

insect bites
Puncture wounds inflicted by bloodsucking insects such as gnats, mosquitoes, fleas, and lice. Most bites cause only temporary pain or itching, but some people have severe skin reactions. In the tropics and sub tropics, insect bites are potentially more serious because certain biting species are capable of transmitting disease (see insects and disease).

All insect bites provoke a skin reaction to substances in the insect’s saliva or faeces, which may be deposited at or near the site of the bite. Reactions vary from red pimples to painful swellings or an intensely itching rash. Some insects, such as bees and wasps, have stings (see insect stings) that can produce fatal allergic reactions. (See also lice; spider bites; mites and disease; ticks and disease.)

insecticides
See pesticides.

insects and disease
Relatively few insect species cause disease directly in humans. Some parasitize humans, living under the skin or on the body surface (see lice; chigoe; myiasis). The most troublesome insects are flies and biting insects. Flies can carry infectious microorganisms from human or animal excrement via their feet or legs and contaminate food or wounds. A number of serious diseases are spread by biting insects. These disorders include malaria and filariasis (transmitted by mosquitoes), sleeping sickness (from tsetse flies), leishmaniasis (sandflies), epidemic typhus (lice), and plague (rat fleas). Mosquitoes, sandflies, and ticks can also spread illnesses such as yellow fever, dengue, Lyme disease, and some types of viral encephalitis. Organisms picked up when an insect ingests blood from an infected animal or person are able to survive or multiply in the insect. Later, the organisms are either injected into a new human host via the insect’s saliva or deposited in the faeces at or near the site of the bite. Most insect-borne diseases are confined to the tropics and sub tropics, although tick-borne Lyme disease occurs in some parts of the UK.

PREVENTION
The avoidance of insect-borne disease is largely a matter of keeping flies off food, discouraging insect bites by the use of suitable clothing and insect repellents, and, in parts of the world where malaria is present, the use of mosquito nets and screens, pesticides, and antimalarial tablets.

insect stings
Reactions that are produced by the stings of insects such as bees and wasps. Venom injected by the insect contains inflammatory substances that cause local pain, redness, and swelling for about 48 hours. A sting in the mouth or throat is dangerous because the swelling may obstruct breathing. A severe allergic reaction can occur in response to insect venom, leading to anaphylactic shock. A procedure known as hyposensitization is sometimes recommended for such individuals.

If the symptoms of anaphylactic shock develop, it is essential to seek emergency medical treatment. Anyone

Malaria is by far the most prevalent of the insect-borne diseases, causing about 300 million acute illnesses and 1 million deaths each year.

Transmission of malaria
When an infected Anopheles mosquito feeds on a person’s blood, it injects saliva through its mouthparts to stop the blood from clotting; the protozoa that cause malaria enter the blood via the insect’s saliva.
who is known to be hypersensitive to bee or wasp venom should obtain and carry an emergency kit for the self-injection of adrenaline (epinephrine).

**insecurity**
Lack of self-confidence and uncertainty about one’s abilities, aims, and relationships with others. A feeling of insecurity may be a feature of anxiety and other neurotic mental disorders.

**insemination**
The term used for the introduction of a man’s semen into a woman’s uterus. Insemination may occur through sexual intercourse or by the use of instruments as part of infertility treatment (see artificial insemination).

**insight**
Being aware of one’s own mental state. In a general sense, “insight” means knowing one’s own strengths, weaknesses, and abilities.

The term also has the specific psychiatric meaning of knowing that one’s symptoms are an illness. Loss of insight may be a feature of psychotic disorders (see psychosis).

**in situ**
A Latin term meaning “in place”. The phrase “carcinoma in situ” is used to describe tissue (particularly of the skin or cervix) that is cancerous only in its surface cells.

**insomnia**
A regular inability to fall asleep or stay asleep, leading to excessive tiredness.

**CAUSES**
The most common cause of insomnia is stress, but other causes include physical symptoms such as a cough, itching, or conditions such as restless legs. Environmental and lifestyle factors or misuse of sleeping drugs are also common causes. Insomnia can be a symptom of a psychiatric illness, such as anxiety and/or depression. Withdrawal symptoms from antidepressants, antianxiety drugs, sleeping drugs, and some illicit drugs (see drug abuse) may also cause insomnia.

**PREVENTION AND TREATMENT**
People with insomnia should ensure that they get sufficient exercise during the day and moderate their alcohol and caffeine intake. They should also avoid eating late at night and should establish regular routines and times for going to bed and waking.

Sleeping drugs should be used only on medical advice. Possible complementary therapies for insomnia include acupuncture and aromatherapy using lavender oil. (See also nightmares; night terrors; sleepwalking.)

**inspiratory capacity**
The volume of air that can be drawn into the lungs in a maximum inhalation following a normal expiration.

**inspiratory reserve volume**
The volume of air that can be drawn into the lungs beyond the end of a normal inhalation.

**inspiratory stridor**
A harsh, high-pitched sound heard on inhaling. Inspiratory stridor is associated with damage to or a disorder of the respiratory tract, particularly in the area of the larynx (voice-box). (See also expiratory stridor; stridor.)

**inspissation**
Thickening or drying up of secretions as a result of dehydration or evaporation. Inspissated secretions in the airways, for example, can lead to blockage and collapse of areas of lung tissue.

**instep**
The arched area of the foot between the heel and ball of the foot.

**instinct**
An innate primitive urge. The need for warmth, food, love, and sex are all forms of instinct, but the instinct for survival is probably the most powerful. An instinct is different from a reflex, which is an involuntary response to a stimulus (such as withdrawing quickly from a source of pain).

**institutionalization**
Loss of personal independence that stems from living for long periods under a rigid regime, such as in a prison or other large institution. Apathy, obeying orders unquestioningly, accepting a standard routine, and loss of interests are the main features.

**insufficiency**
The inability of an organ or body part to perform its intended function. In hepatic insufficiency, for example, the liver cannot carry out its normal work (see liver failure). In another example, venous insufficiency, which usually affects the legs, the blood does not drain adequately through the veins; this condition can sometimes lead to swelling and leg ulcers.

**insufflation**
A technique in which air, another type of gas, or powder is blown into a body cavity. Insufflation may be used during medical investigations in order to make the viewing of organs easier or to identify blockages. In laparoscopy, for example, the abdomen is insufflated using carbon dioxide.

**insulin**
A hormone produced by clusters of cells in the pancreas, known as the islets of Langerhans, that regulates the level of glucose in the blood. It is produced continuously, but the amount increases in response to a raised glucose level after a meal. Insulin is essential if glucose is to be absorbed into cells where it is converted into energy. Insulin thus prevents a buildup of glucose in the blood and ensures that tissues have sufficient amounts of glucose.

Failure of insulin production results in diabetes mellitus. An insulinoma is a rare tumour that causes excessive production of insulin and consequent attacks of hypoglycaemia (an abnormally low blood glucose level).

**INSULIN THERAPY**
Insulin replacement, self-administered by injection or through an infusion pump (see pump, insulin), is used in the treatment of diabetes mellitus. Insulin cannot be taken orally because it is destroyed by stomach acid. This treatment prevents hyperglycaemia (high blood glucose) and ketosis (a buildup of acids in the blood), which, in severe cases, may cause coma. Human insulin preparations are produced by genetic engineering, although older beef or pork insulins are still available.

Too high a dose of insulin will cause hypoglycaemia, which can be reversed by consuming food or a sugary drink. Severe hypoglycaemia may cause coma, for which emergency treatment with an intravenous injection of glucose, or glucagon (a hormone that opposes the effects of insulin) given into a muscle, vein, or subcutaneously is necessary.

**insulinoma**
A rare noncancerous tumour of the insulin-producing cells of the pancreas. The tumour causes abnormal quantities
of insulin to be produced, with the result that the amount of glucose in the blood can fall to dangerously low levels (hypoglycaemia). Unless sugar is given immediately, this situation can cause coma and death. Once the condition has been diagnosed, a drug (diazoxide) is given to prevent hypoglycaemia from occurring until the tumour is removed.

insulin resistance
An impaired response of body cells to the effects of insulin, a hormone produced by the pancreas to regulate blood sugar levels. The most common cause of mild insulin resistance is obesity; and sensitivity is regained with weight loss. In type 2 diabetes mellitus, raised blood glucose levels are partly due to insulin resistance, but also to a reduced capacity to produce insulin.

Insulin resistance is also a feature of other conditions, such as polycystic ovary syndrome and acanthosis nigricans. People with unstable diabetes occasionally require massive doses of insulin to achieve a reduction in blood sugar. In such cases, the cause of the insulin resistance is often not known.

insulin shock
An uncommon term for hypoglycaemia (abnormally low blood glucose levels).

Intal
A brand name for inhaled sodium cromoglicate, an antiallergy drug commonly used to prevent asthma.

intelligence
The ability to understand concepts and to reason them out. Intelligence can also be considered as having three separate forms: abstract (understanding ideas and symbols); practical (aptitude in dealing with practical problems such as repairing machinery); and social (coping reasonably and wisely with human relationships).

Intelligence has been shown to be partly inherited, although the environment (including early nutrition) also plays a major part, as does physical health and personality. Intelligence increases up to the age of about six years and then stabilizes. Intelligence quotient (IQ), as measured by intelligence tests, continues to increase to about the age of 26, stays the same until about the age of 40, and then gradually declines.

Examples of extremes of intelligence occur in people with learning difficulties (as defined by a low IQ) and gifted people (as defined by IQ scores over 130).

intelligence quotient (IQ)
See intelligence tests; IQ.

intelligence tests
Tests designed to provide an estimate of a person’s mental abilities. The most widely used are Wechsler tests. There are two basic types: the Wechsler Adult Intelligence Scale (WAIS) and the Wechsler Intelligence Scale for Children (WISC). Each is divided into verbal (language skills) and performance sections including measures of visual–spatial and perceptual ability (interpretation of shapes) and constructional ability. Other tests include the Stanford–Binet test, used mainly as a measure of scholastic ability.

In most intelligence tests, scoring is based on mental age (MA) in relation to chronological age (CA). The intelligence quotient (IQ) is MA divided by CA, multiplied by 100. The tests are devised to ensure that 3 in 4 people have an IQ between 80 and 120. They are standardized so that the score indicates the same relative ability at different age levels.

Intelligence tests may be used to assess school or job aptitude. They have, however, been criticized for their alleged bias regarding gender and race.

intensive care unit
An intensive care unit has sophisticated equipment for constant monitoring of a seriously ill patient. He or she is usually sedated and connected to a ventilator to maintain breathing.

An ICU contains a high ratio of specially trained nursing and medical staff to patients, enabling treatment to be tailored to a patient’s condition as it changes. (See also coronary care unit.)

intention tremor
A form of tremor (involuntary, rhythmic shaking of the muscles) occurring only when a person tries to carry out a conscious movement, such as touching or picking up an object. The tremor worsens as the object is approached. The condition is usually due to disease or damage affecting the cerebellum (the area at the back of the brain responsible for coordinating movement).

inter-
A prefix that means between, as in intercostal (between the ribs). (See also intra-.)

intercostal
A term meaning “between the ribs”, as in the intercostal muscles, thin sheets of muscle between each rib.

intercourse, painful
Pain during sexual intercourse, known medically as dyspareunia, which can affect both men and women. Pain may be superficial (around the external genitals) or deep (within the pelvis).

CAUSES
In men, superficial pain may be due to anatomical abnormalities such as chordee (bowed erection) or phimosis (tight
Prostatitis (inflammation of the prostate gland) may cause a widespread pelvic ache, a burning sensation in the penis, or pain on ejaculation.

In women, one possible cause of pain is scarring (after childbirth, for example) and lack of vaginal lubrication, especially after the menopause. Psychosexual dysfunction may also cause pain during intercourse. Vaginismus, a condition in which the muscles of the vagina go into spasm, is usually psychological in origin. Deep pain is frequently caused by pelvic disorders (such as fibroids, endometriosis, ectopic pregnancy, or pelvic inflammatory disease due to sexually transmitted infections), disorders of the ovary (such as ovarian cysts), and disorders of the cervix. Other causes of deep and superficial dyspareunia are cystitis and urinary tract infections.

**TREATMENT**

Treatment of painful intercourse is directed at the underlying cause of the pain. If the discomfort is psychological in origin, special counselling may be needed (see sex therapy).

**intercurrent**

A term used to describe a condition, usually an infection, that develops in a person who is already suffering from another disorder.

**interdigital**

A term meaning between two fingers or toes. Interdigital is used to refer to the skin in such an area.

**interferon**

One of a group of proteins produced naturally by body cells in response to viral infections and other stimuli. Interferon inhibits viral multiplication and increases the activity of natural killer cells (a type of lymphocyte that is part of the immune system). The substance may also be produced artificially for use as a drug in the treatment of various disorders. Interferon has to be given by injection.

There are three main types: interferon alfa, beta, and gamma. Interferon alfa is used in the treatment of certain lymphomas, a type of leukaemia, and chronic hepatitis B and C. Peginterferon, a modified form of interferon alfa, remains in the circulation longer and is used particularly in the treatment of hepatitis C. interferon beta is used to treat some patients with relapsing multiple sclerosis. interferon gamma is used in the treatment of a rare condition called chronic granulomatous disease. Adverse reactions to interferons are common including fever, headaches, lethargy, depression, and dizziness.

**interleukin**

One of a group of proteins that occur naturally in the body. Interleukins are involved in the production of different types of blood cells and also help to regulate the immune system. At least 18 different interleukins have been identified. One form of interleukin, known as interleukin-2 or aldesleukin, is believed to slow the progress of kidney cancer. However, it often has very severe side effects, including damage to the brain and bone marrow and leakage of fluid into the lungs.

**intermenstrual bleeding**

Bleeding from the vagina between menstrual periods (see menstrual cycle). The condition may be due to a disorder of the uterus, but is also a common side effect of oral contraception (see breakthrough bleeding).

**intermenstrual pain**

Pelvic pain occurring between menstrual periods, which may be due to a variety of causes. In one type, pain occurs in the middle of the menstrual cycle, around the time of ovulation (see mittelschmerz).

**intermittent claudication**

Cramping pain in the legs due to inadequate blood supply (see claudication).

**intermittent positive pressure ventilation (IPPV)**

A form of mechanical ventilation in which air is delivered into a person’s lungs under pressure and in short bursts, to simulate intakes of breath. IPPV can be administered through a tube into a lung, which may be carried out in an intensive care unit. A similar procedure of continuous positive airway pressure (CPAP) can be delivered by mask to treat sleep apnoea.

**internal cardiac massage**

A procedure carried out during surgery on the chest to maintain circulation if the heart has stopped beating (see cardiac massage). In internal cardiac massage, the surgeon reaches into the open rib cage and squeezes the heart directly with his or her hands.

**internal fixation**

A procedure for treating fractured bones (see fracture) by surgically inserting metal plates, pins, rods, or wires to hold the broken bone ends together. The procedure is used to treat severe fractures that cannot be stabilized by other means. Once the bone has healed, the devices used for internal fixation are often left in place if they are not causing any problems. In some cases, however, it is necessary to remove them in another operation.

**internal haemorrhoids**

Swollen veins that develop within the rectum (see haemorrhoids).

**International Normalized Ratio (INR)**

A measure introduced by the World Health Organization to standardize the control of anticoagulant drug therapy internationally. The ratio is based on comparing the prothrombin time (see blood-clotting tests) of a patient’s blood with a control time.

**intersex**

A group of abnormalities in which the affected person has ambiguous genitalia (abnormal external sex organs) or external genitalia that have the opposite appearance to the chromosomal sex of the individual (see sex determination).

**interstitial**

A word used medically to refer to gaps (interstices) between cells, tissues, or other body structures. For example, tissue fluid between the body cells is called interstitial fluid. (See also interstitial radiotherapy.)

**interstitial cystitis**

A chronic inflammation of the bladder lining that causes pain and a frequent urge to pass urine. An ulcer usually develops in the bladder wall and, eventually, the bladder muscles thicken and contract (shorten).

Interstitial cystitis is most likely to occur in women. Unlike most other bladder inflammation (see cystitis) the disorder is not due to bacterial infection and the cause is unknown.

The disorder is difficult to treat. In a procedure carried out under general anaesthesia, the bladder may be stretched by being filled with water or other liquids. Anti-inflammatory drugs may also be given as a treatment.
interstitial pulmonary fibrosis

Scarring of lung tissue mainly affecting the alveoli (the tiny air sacs in the lungs; see alveolus, pulmonary). Interstitial pulmonary fibrosis (IPF) may have various causes, including occupational exposure to mineral dusts; fibrosing alveolitis (an autoimmune disorder in which the immune system attacks the lung tissue); and an allergic reaction (see allergy) that causes inflammation of the alveoli.

SYMPTOMS AND DIAGNOSIS

Symptoms of interstitial pulmonary fibrosis include progressive shortness of breath, coughing, chest pain, and clubbing (abnormal thickening and broadening) of the fingertips. There may also be additional symptoms caused by any underlying disease.

The diagnosis of IPF is based on the symptoms and a physical examination; it is confirmed by chest X-ray and a biopsy (removal of a sample of lung tissue for microscopic examination).

TREATMENT AND OUTLOOK

Treatment for interstitial pulmonary fibrosis depends on the cause. Treatment for fibrosing alveolitis often includes use of immunosuppressant drugs and corticosteroid drugs, which suppress the activity of the immune system. However, there is no known treatment for localized fibrosis due to radiotherapy. In other cases, treatment is directed at the underlying cause.

For people with fibrosing alveolitis, the outlook is poor: the lungs become progressively stiffer and heart failure and bronchopneumonia may develop.

Transplantation of a single lung (see transplant surgery) may be considered. The outlook of occupational dust disease depends on the type of dust involved and the level of exposure. If IPF is due to an allergy, however, the condition can more easily be treated and the outlook is better.

interstitial radiotherapy

Treatment of a cancerous tumour by inserting radioactive material into the cancerous growth or into neighbouring tissue. Using this method, which is a type of brachytherapy, radiation can be targeted at the diseased area.

Radioactive material (usually artificial radioisotopes) contained in wires, small tubes, or seeds is implanted into or near to the diseased tissue under general anaesthesia (see anaesthesia, general). The material is left in place for variable amounts of time depending on the radioactive substance and the tumour that is being treated. In some cases, such as in prostate cancer, the material is left in place permanently as the radiation decays after a relatively short period of time. (See also radiotherapy.)

intertrigo

Inflammation of the skin due to two surfaces rubbing together. Intertrigo is most common in obese people. The affected skin is red and moist and may have an unpleasant odour, and is often accompanied by a fungal infection such as candidiasis; there may also be scales or blisters. The condition worsens with sweating.

Treatment consists of weight reduction and keeping the affected areas clean and dry. A cream containing antifungal drugs, with or without a corticosteroid, is used if candidiasis is found to be present.

intervertebral cartilage

The strong tissue, also called fibrocartilage, that makes up the platelike, shock-absorbing discs between the bones of the spine (see cartilage; disc, intervertebral).

intervertebral disc

See disc, intervertebral.

intervertebral foramen

A natural opening between adjacent vertebrae (the spinal bones) in the spine formed by the space between...
small notches in each side of the verte-brae. Such gaps are the exit points for the peripheral nerves branching from the spinal cord.

intestinal imaging
See barium X-ray examinations.

intestinal lipodystrophy
See Whipple’s disease.

intestine
The major part of the digestive tract (see digestive system), extending from the exit of the stomach to the anus. It forms a long tube divided into two main sections: the small and large intestines.

SMALL INTESTINE
The small intestine is about 6.5 m in length and has three sections: the duode-num, the jejunum and the ileum. Partially digested food from the stomach is forced along the intestine by peristalsis.

The small intestine is concerned with the digestion and absorption of food. Digestive enzymes and bile, which break down food to release nutrients, are added to the partly digested food in the duodenum via the bile and pancreatic ducts (see biliary system). Glands within the walls of each section of the small intestine produce mucus and other enzymes, which also help to break down the food. Blood vessels in the intestinal walls absorb nutrients and carry them to the liver for distribution to the rest of the body.

LARGE INTESTINE
The large intestine is approximately 1.5 m long. The main section, the colon, is divided into an ascending, a transverse, a descending, and a pelvic portion (the sigmoid colon). The appendix hangs from a pouch (the caecum) between the small intestine and the colon. The final section before the anus is the rectum.

Unabsorbed material leaves the small intestine as liquid and fibre. As this material passes through the large intestine, water and mineral salts are absorbed into the bloodstream, leaving faeces that are made up of undigested food residue, fat, various secretions, and bacteria. The faeces are compressed and pass into the rectum for evacuation.

intestine, cancer of
A malignant tumour occurring in the small or the large intestine. Cancer of the small intestine is rare; cancer of the large intestine is one of the most common cancers (see colon, cancer of; rectum, cancer of). Both the small and large intestine may develop carcinoid tumours (causing carcinoid syndrome) and lymphomas.

intestine, obstruction of
A partial or complete blockage of the small or large intestine.

CAUSES
Possible causes include a strangulated hernia (protrusion of the intestines through the abdominal wall); stenosis (narrowing) of the intestine, often due to cancer in the intestine; intestinal atresia (congenital closure); adhesions (scar tissue); volvulus (twisting of loops of bowel); and intussusception (in which the intestine telescopes inside itself). Intestinal obstruction can also occur in diseases that affect the intestinal wall, such as Crohn’s disease or paralysis of the muscles in the intestinal wall (see ileus, paralytic).

Less commonly, an internal blockage of the intestine is caused by impacted food, faecal impaction, gallstones, or by an object of some kind that has been accidentally swallowed.

DISORDERS OF THE INTESTINE

The intestine is subject to the effects of many infective organisms and parasites. It may also be affected by tumours, structural defects, and other disorders.

Infection and inflammation
Generalized inflammation of the intestine may be caused by viral or bacterial infections such as food poisoning, traveller’s diarrhoea, cholera, typhoid fever, amoebiasis, or giardiasis, or to infestation with roundworms or tapeworms. It may also have noninfectious causes, as in ulcerative colitis and Crohn’s disease. Gastroenteritis is the condition commonly applied to inflammation of the stomach and intestines. Sometimes, inflammation is localized, as in appendicitis and diverticular disease.

Tumours
Tumours of the small intestine are rare, but noncancerous growths, lymphomas, and carcinoid tumours (causing carcinoid syndrome) may occur. Tumours of the large intestine are common (see colon, cancer of; rectum, cancer of). Some forms of familial polyposis, a condition causing the development of noncancerous growths, may progress to cancer.

Structural abnormalities
Structural defects may be congenital (present from birth) or may develop later. They include atresia (congenital closure), stenosis (narrowing), and volvulus (twisting of loops of bowel). These abnormalities can cause blockage of the intestine (see intestine, blockage of). In newborn babies with cystic fibrosis, meconium (fetal intestinal contents) is much thicker than normal and may block the intestine.

Obstruction
Impaired blood supply (ischaemia) to the intestine may result from partial or complete obstruction of the arteries in the abdominal wall (from diseases such as atherosclerosis) or from the blood vessels being compressed or trapped, as in intussusception or hernias. Loss of blood supply may cause gangrene.

Other disorders
Other disorders that affect the intestine include peptic ulcers, diverticulosis, malabsorption, coeliac disease, and irritable bowel syndrome.
and adenomas, leiomyomas, lipomas, and angiomas in the small intestine.

intoxication
A general term for a condition resulting from poisoning. It customarily refers to the effects of excessive drinking (see alcohol intoxication). The term may also be used of drug poisoning; poisoning from the accumulation of the by-products of metabolism in the body; or the effects of industrial poisons.

intra-
A prefix that means “within”, as in the term “intramuscular” (within a muscle). (See also inter-.)

intra-articular cartilage
See hyaline cartilage.

intracavitary therapy
Treatment of a cancerous tumour in a hollow organ by placing a radioactive implant or anticancer drugs within the cavity of the organ. Intracavitary radiotherapy is a type of brachytherapy (the practice of implanting radioactive wires or grains close to the tumour) that is mainly used to treat cancers of the uterus and cervix (see uterus, cancer of; cervix, cancer of). Implants of radioactive material (usually in the form of artificial radioisotopes in small tubes) are placed near the tumour and left there for a period of time. This varies from hours to days depending on the type of radioactive substance used and the type of tumour being treated.

Intracavitary chemotherapy may be used to treat a malignant effusion (a collection of fluid that contains cancerous cells) that has developed in the chest or abdomen. Treatment slows the rate at which the fluid returns after it has been drained. Intracavitary chemotherapy is also used to treat cancers of the bladder. The drugs are introduced into the cavity through a catheter (flexible tube) and may either be left in place or drained off after a certain period of time.

intracerebral haemorrhage
Blending into the tissue of the brain from a ruptured blood vessel. Intracerebral haemorrhage is one of the three principal mechanisms by which a stroke can occur.

CAUSES
This disorder mainly affects middle-aged or elderly people and is usually due to atherosclerosis (accumulation of fatty deposits in the walls of the arteries). Untreated hypertension (high blood pressure) increases the risk of intracerebral haemorrhage.

SYMPTOMS
The ruptured artery is usually in the cerebrum (the main mass of the brain). The escaped blood seeps out, damaging brain tissue. The symptoms are sudden headache, weakness, and confusion, and often loss of consciousness. Speech loss, facial paralysis, or one-sided muscle weakness may develop, depending on the area affected.

TREATMENT AND OUTLOOK
Surgery is usually impossible; treatment is aimed at life-support and the reduction of blood pressure. Large haemorrhages are usually fatal. For the survivor of an intracerebral haemorrhage, rehabilitation and outlook are the same as for any type of stroke.

intracranial aneurysm
The abnormal dilation of an artery occurring anywhere inside the area enclosed by the cranium (skull bones). Intracranial aneurysms may cause no symptoms. However, they can suddenly enlarge or rupture, causing subarachnoid haemorrhage or stroke, which are potentially fatal. (See also aneurysm; berry aneurysm.)

intracranial hypertension, benign
A condition in which intracranial pressure is substantially raised. The cause of the condition is unknown, but it often occurs in obese young women with menstrual irregularities. Rarely it is caused by drugs, including corticosteroid drugs. Symptoms may include headache, vomiting, and visual disturbance. The condition is not fatal but can damage the optic nerves, leading to permanent visual loss. Treatment is with diuretic drugs; occasionally, excess cerebrospinal fluid may be diverted by way of a surgically inserted shunt (artificial passage).

intracranial pressure (ICP)
Pressure exerted by cerebrospinal fluid (fluid that cushions and nourishes the brain and spinal cord) around the brain. ICP can be assessed during a lumbar puncture. Following serious head injury or some types of neurosurgery, ICP may be monitored continuously using a transducer that is inserted through the skull.

Raised ICP may be due to a brain tumour, head injury, meningitis, or benign intracranial hypertension. Untreated, it can result in permanent neurological damage and may be serious and, in some cases, life-threatening.

intracranial tumour
Any tumour that develops within the skull.

intratable
A term used to describe any condition that does not respond to treatment.

intracytoplasmic sperm injection (ICSI)
A treatment for male infertility in which a single sperm is collected from a sample of semen and injected into an ovum (egg). The ovum is then placed in the woman’s uterus (see in vitro fertilization).

intradermal
A medical term meaning “into or within the skin”. For example, an intradermal injection is made into the skin, whereas a subcutaneous injection is made into the layer of fat under the skin.
intradermal naevus
A type of pigmented naevus (skin blemish) formed by groups of melanocytes (pigment-producing cells) within the dermis (the thick inner layer of the skin). An intradermal naevus is usually raised and may range in colour from dark brown to pink. They are noncancerous and may disappear spontaneously. (See also junctional naevus.)

intramuscular
A medical term meaning “within a muscle”, as in an intramuscular injection, in which a drug is injected deep within a muscle.

intraocular pressure
The pressure within the eye that helps to maintain the shape of the eyeball. Normal intraocular pressure is produced by a balance between the rate of production and removal of aqueous humour, the watery fluid that fills the front of the eyeball. Aqueous humour is continually produced from the ciliary body and exits from the drainage angle (a network of tissue between the iris and cornea). If drainage is impeded, intraocular pressure builds up; this condition is called glaucoma. If the ciliary body is damaged (as a result of prolonged inflammation), insufficient aqueous fluid may be produced and the eyeball may become soft.

intrauterine contraceptive device
See IUD.

intrauterine growth retardation
Poor growth in a fetus (an unborn baby within the uterus). Intrauterine growth retardation usually results from a failure of the placenta to provide adequate nutrients (which is often related to pre-eclampsia) or sometimes from a fetal defect. Severe maternal disease, such as chronic kidney failure, can reduce fetal growth. If the mother smokes during pregnancy, this may also reduce the growth and birth weight. Problems in the fetus, such as an intrauterine infection or genetic disorder, can also impair growth.

Intrauterine growth retardation may be suspected on antenatal examination; ultrasound scanning may be performed to assess the problem.

The underlying cause is treated, if possible. If the baby’s growth is slowing, induction of labour or a caesarean section may be necessary. Most babies whose growth was retarded in the uterus gain weight rapidly after delivery. If an intrauterine infection or genetic disorder was the cause, however, poor growth may continue after birth.

intravenous
A term meaning “within a vein”, as in intravenous infusion (slow introduction of a substance into a vein) and intravenous injection (rapid introduction of a substance into a vein).

intravenous infusion
The slow introduction of fluid into the bloodstream through a cannula (thin plastic tube) inserted into a vein. An intravenous injection is given over several hours or days and is commonly known as a drip. The procedure is used to give blood (see blood transfusion) or, more commonly, fluids or essential salts. Other uses of intravenous infusion include providing nutrients to people who are unable to digest food (see feeding, artificial) as well as the administration of certain drugs. A machine known as an infusion pump may be used to control the amount of the drug or fluid being infused.

intravenous urography
An X-ray procedure, commonly abbreviated to IVU, that is used to give a clear image of the urinary tract.

The procedure involves intravenous injection of a contrast medium (a substance that is opaque to X-rays) into the arm. The medium is carried in the blood to the urinary system, where it passes through the kidneys, ureters, and bladder to be excreted in the urine. X-rays taken at intervals show outlines of the urinary system.

IVU reveals abnormalities such as tumours and obstructions, and signs of kidney disease.

intraventricular haemorrhage
Bleeding into the ventricles (the fluid-filled cavities of the brain). Premature babies are at greater risk because the nearby blood vessels are underdeveloped and fragile, but the bleeding may occur in babies carried to full term.

There may be no obvious signs that a haemorrhage has occurred; alternatively, the baby may be pale and limp. Seizures may also occur.

Ultrasound scanning of the baby’s brain through the fontanelle (a gap in the baby’s skull) is used to check for bleeding. Intraventricular haemorrhage may cause no long-term problems. In some cases, however, it may lead to disability or hydrocephalus (a buildup of fluid around the brain). In the most severe cases, it may be life-threatening.

intrinsic asthma
The name sometimes given to a type of asthma that is not associated with an identifiable allergic trigger, such as pollen. (See also allergy; hypersensitivity.)

intrinsic factor
A chemical produced by the stomach lining that is necessary for the absorption of vitamin B12. A lack of intrinsic factor leads to a deficiency in vitamin B12; this problem, in turn, results in pernicious anaemia.

introitus
A general term for the entrance to a body cavity or space. The word is most commonly used for the vagina.

introspection
The contemplation or analysis of one’s own thoughts, feelings, and other mental processes. (See also insight.)

introvert
A person who is more concerned with his or her inner world than the external or social environment. Introverts prefer to work alone, are shy and quiet, and become withdrawn when under stress. (See also extrovert; personality.)

intubation
A term most commonly used to refer to the process of passing an endotracheal (breathing) tube into the trachea (wind-
Endotracheal intubation is carried out if mechanical ventilation is needed to deliver oxygen into the lungs. The anaesthetist looks down the patient’s throat with a laryngoscope (viewing instrument) to identify the vocal cords. The tube is then passed through the mouth or nose and down the throat between the vocal cords and trachea. The term “intubation” is also used to refer to the placement of a gastric or intestinal tube in the stomach for purposes of suction or the giving of nutrients (see feeding, artificial).

intussusception
A condition in which part of the intestine telescopes in on itself, forming a tube within a tube, usually resulting in intestinal obstruction (see intestine, obstruction of). The condition usually affects the last part of the small intestine, where it joins the large intestine.

CAUSES
In some cases there is an association with a recent infection. In other cases, it may start at the site of a polyp or Meckel's diverticulum (a pouch-like projection from the ileum).

SYMPTOMS AND COMPLICATIONS
Intussusception occurs most commonly in children under the age of two. An affected child usually develops severe abdominal colic; vomiting is common, and blood and mucus are often found in the faeces.

In severe cases of intussusception, the blood supply to the intestine becomes blocked. Gangrene (tissue death), followed by peritonitis (inflammation of the abdominal lining) or perforation (rupture), may result.

inverted nipple
An indrawing of the nipple. The condition can be longstanding or may develop in later life as a result of changes in the breast tissue. Possible causes include normal changes associated with aging or, in some cases, an underlying cancer.

in vitro
The performance of biological processes in a laboratory rather than within the body. The term literally means “in glass”.

in vitro fertilization (IVF)
A technique used to treat infertility when its cause cannot be determined or treated or if there is a blockage in a fallopian tube. IVF is also used to treat couples affected by a genetic disorder because the

PROCEEDURE FOR IN VITRO FERTILIZATION
Fertilization of eggs outside a woman’s body can be performed to treat some types of infertility. One such technique used is in vitro fertilization; the main stages involved in this procedure are illustrated below.

Days 1 to 8
During the first eight days of a woman’s menstrual cycle, she is given fertility drugs to stimulate the ripening of several eggs.

Days 9 to 13
During these five days, the woman undergoes a series of ultrasound scans to monitor the ripening of the eggs in her ovaries.

Days 14 to 15
Immediately before ovulation (which may be induced with drugs), ripe eggs are removed by laparoscopy (above) or by ultrasound-guided needle aspiration through the vagina or the abdomen. The eggs are mixed with the man’s sperm in a dish (above, centre), which is then put in an incubator.

Days 16 to 17
About two days later, the eggs are examined to see if they have been fertilized and have started to develop into embryos. If they have, two or three of the best embryos are introduced into the woman’s uterus through the vagina. Further embryos may be frozen and stored.
embryo can be tested for abnormalities before implantation. IVF involves the surgical removal of an *ovum* (egg) from the ovary and its fertilization outside the body.

**HOW IT IS DONE**

The woman is given a course of fertility drugs to stimulate the release of mature ova, followed by ultrasound scanning to check the ova. The ova are collected immediately before ovulation using the guidance of ultrasound, either by laparoscopy or via the vagina under sedation. They are then mixed with sperm – usually from the partner, but sometimes from a donor – in the laboratory and are incubated at body temperature for about 48 hours to allow fertilization to take place. Two, or sometimes more, fertilized ova are introduced into the woman’s uterus through a thin tube fed through the cervix. If they become safely implanted in the uterine wall, the pregnancy usually continues normally.

Many attempts at IVF may be needed before a successful pregnancy is achieved. Modifications of the technique, such as gamete intrafallopian transfer (GIFT), are technically simpler than the original method. (See also intracytoplasmic sperm injection.)

**in vivo**

Literally “in the living organism”; biological processes occurring within the body. (See also *in vitro*.)

**involuntary movements**

Uncontrolled movements of the body. These movements occur spontaneously and may be slow and writhing (see athetosis); rapid, jerky, and random (see chorea); or predictable, stereotyped, and affecting one part of the body, usually the face (see tic). They may be a feature of a disease (for example, Huntington’s disease) or a side effect of certain drugs used to treat psychiatric conditions.

**involuntary muscle**

An alternative name for smooth muscle, which lines the walls of internal body structures such as the blood vessels, airways, and digestive tract.

**involution**

A term meaning a return to normal size; it is most commonly used to refer to the shrinkage of the enlarged uterus following childbirth.

---

**iodine**

*A trace element* essential for formation of the thyroid hormones, triiodothyronine (T3) and thyroxine (T4), which control the rate of metabolism (internal chemistry) as well as growth and development of the body.

Iodine must be obtained from the diet; it is found in seafood and dairy products, as well as in vegetables grown in soil containing iodides. Dietary shortage may lead to enlargement of the thyroid gland known as goitre or hypothyroidism. A deficiency in newborn babies can, if left untreated, lead to mental deficiency and incomplete physical development known as cretinism. Shortages are very rare in developed countries due to bread and table salt being fortified with iodide or iodate.

Radioactive iodine is sometimes used to reduce thyroid gland activity in cases of thyrotoxicosis and in the treatment of thyroid cancer. Iodine compounds are used as antiseptics, in radiopaque contrast media in some X-ray procedures (see *imaging techniques*), and in some cough remedies.

**ion**

A particle that carries an electrical charge; positive ions are called cations and negative ions anions. Many vital body processes, such as the transmission of nerve impulses, depend on the movement of ions across cell membranes. Sodium is the principal cation in the fluid that bathes all cells (extracellular fluid), affecting the flow of water into and out of cells (see *osmosis*), thereby influencing the concentration of body fluids.

The acidity of the blood and other body fluids is dependent on the level of hydrogen cations, which are produced by metabolic processes. To prevent the fluids from becoming too acidic, hydrogen cations are neutralized by bicarbonate anions in the extracellular fluid and the blood, and by phosphate anions inside cells (see *acid–base balance*).

**ionizer**

A device that produces ions. Some people believe that use of an ionizer, which produces negative ions, reduces...
symptoms, such as headaches and fatigue that may result from a buildup of the positive ions generated by electrical machines.

ionizing radiation
A type of radiation.

ipecauanha
A drug (also called ipecac) previously used to induce vomiting in the treatment of types of poisoning.

ipratropium bromide
A bronchodilator drug used in the treatment of breathing difficulties.

IQ
The abbreviation for intelligence quotient, which is an age-related measure of intelligence (see intelligence tests).

iridectomy
A procedure performed on the eye to remove part of the iris. The most common type of iridectomy, known as a “peripheral iridectomy”, is usually performed to treat acute glaucoma. A small opening is made, surgically or with a laser, near the outer edge of the iris to form a channel through which aqueous humour can drain.

iridocyclitis
Inflammation of the iris and ciliary body. Iridocyclitis is more usually known as “anterior uveitis”. (See eye, disorders of).

iridotomy
A surgical procedure performed on the eye, in which an incision is made in the iris using a knife or a laser. (See also iridectomy).

iris
The coloured part of the eye. The iris is made up of a loose framework of transparent collagen and two sets of muscle fibres (one radial and one circular) that lies behind the cornea and in front of the lens. It is connected at its outer edge to the ciliary body and has a central aperture, the pupil, through which light enters the eye and falls on the retina. The iris constantly contracts and dilates to alter the size of the pupil, in order to control the amount of light that passes through it and so falls on the retina.

The colour of the iris is inherited from the parents (see inheritance) and is determined principally by the amount of melanin (dark pigment) in its tissues. Brown eyes contain a high level of melanin. Blue and grey eyes contain very little melanin, their colour comes instead from the collagen tissues themselves. Hazel and green eyes contain moderate levels of melanin; their colour comes partly from the pigment and partly from the collagen tissues. Flecks of colour in the iris are due to scattered light reflected off blood vessels and muscle tissue. It is possible for people to have eyes of different colours (a fairly rare condition called heterochromia iridium). People with albinism have no melanin in their bodies and therefore the colour is governed by the tissues. Such people have light blue or even pink eyes.

iritis
An inflammation of the iris, now often termed an “anterior uveitis”.

iron
A mineral that is essential for the formation of certain enzymes, haemoglobin (the oxygen-carrying pigment in red blood cells), and myoglobin (the oxygen-carrying pigment in muscle cells). Iron is found in foods such as liver, cereals, fish, green leafy vegetables, nuts, and beans. During pregnancy, iron supplements may be required. Iron deficiency leading to anaemia (see anaemia, iron deficiency) is usually caused by abnormal blood loss, such as from a peptic ulcer or particularly heavy periods but may also be due to diet.

Iron supplements may cause nausea, abdominal pain, constipation, or diarrhoea and may colour the faeces black. Excessive iron in the tissues is a feature of haemochromatosis, which commonly results in cirrhosis, or other forms of organ damage.

iron-deficiency anaemia
See anaemia, iron-deficiency.

iron lung
A large machine formerly used to maintain breathing, especially in people paralysed by poliomyelitis. An iron lung consisted of a chamber that enclosed the patient’s chest. The air pressure in the chamber could then be controlled in order to force air into and out of the lungs. The iron lung has been replaced by more efficient means of maintaining breathing (see ventilation).

irradiation
See radiation hazards; radiotherapy.

irradiation of food
Treatment of food with ionizing radiation in order to kill bacteria, moulds, insects, and other parasites. Irradiation improves the keeping qualities of food and is a means of controlling some types of food poisoning. It does not, however, destroy bacterial toxins and may destroy vitamins. Irradiation does not render food radioactive, and there is no evidence that it poses a risk to human health.

irrigation, antral
See antral irrigation.

irrigation, wound
Cleansing of a dirty or contaminated wound by washing it out repeatedly with a medicated solution or sterile saline solution.

irritable bladder
Intermittent, uncontrolled contractions of the muscles in the bladder wall that may cause urge incontinence (see incontinence, urinary).

Irritable bladder can occur if there is a urinary tract infection (see cystitis); a catheter present within the bladder; a bladder stone (see calculus, urinary tract); or an obstruction to the outflow of urine by an enlarged prostate gland, however often the cause of discomfort.
is not known. In some cases, symptoms may be relieved by antispasmodic drugs; other treatment is directed at any underlying cause. Bladder training may also be used.

**Irritable bowel syndrome (IBS)**

A combination of intermittent abdominal pain and constipation, diarrhoea, or bouts of each, that occurs in the absence of other diagnosed disease.

**Cause and Incidence**

The precise cause of IBS is unknown, but anxiety and stress tend to exacerbate the condition. IBS affects about one in five people at some time in life and accounts for more referrals to gastroenterologists than any other disorder. It is twice as common in women as in men, and the disorder is generally found to begin in early or middle adulthood.

**Symptoms and Signs**

Symptoms of IBS include intermittent, cramplike pain in the abdomen; abdominal distension, often on the left side; transient relief of pain by bowel movement or passing wind; a sense of incomplete evacuation of the bowels; excessive wind; passage of mucus; diarrhoea; constipation; and nausea. Some people also have symptoms unrelated to the digestive tract, such as headache, back pain, and tiredness.

Symptoms are typically intermittent, and usually recur throughout life, though they may become less frequent and severe with time. The condition is unlikely to lead to complications.

**Diagnosis and Treatment**

There is no single test to diagnose IBS as opposed to another disorder of the digestive tract. In order for a diagnosis of IBS to be made, a patient must have had continuous or recurrent abdominal pain or discomfort for at least 12 weeks accompanied by at least two of the following features: relief of pain on defaecation; onset of pain associated with a change in stool frequency; and onset of pain associated with a change in stool consistency.

IBS can sometimes be controlled through a change in diet and use of relaxation techniques. An individual may need to experiment to find the approach that works best.

If constipation is the main problem, a high-fibre diet or bulk-forming agents (see laxative drugs), such as bran or methylcellulose, may be helpful. Short courses of antidiarrhoeal drugs may be given for persistent diarrhoea. Antispasmodic drugs may be prescribed to relax the contractions of the digestive tract and relieve abdominal pain. Hypnosis, psychotherapy, and counselling have proved effective in some cases.

**Ischaemia**

Insufficient blood supply to a specific organ or tissue. It is usually caused by a disease of the blood vessels, such as atherosclerosis, but may also result from injury, constriction of a blood vessel due to spasm of the muscles in the vessel wall, or an inadequate blood flow due to inefficient pumping of the heart. Symptoms displayed depend on the area affected.

Treatment may include vasodilator drugs to widen the blood vessels or, in more severe cases, an angioplasty or bypass operation.

**Ischaemic attack**

See transient ischaemic attack.

**Ischaemic colitis**

A form of colitis (inflammation of the colon, the main part of the large intestine) caused by an interruption of the blood supply to the colon. Ischaemic colitis most commonly affects people over 50 years old. People with diseases affecting blood vessels elsewhere in the body, such as stroke or peripheral vascular disease, are more likely to be affected. Other risk factors include a history of congestive heart failure or diabetes mellitus; surgery that has resulted in damage to the colon’s blood supply; and treatment of the abdomen with radiotherapy.

**Symptoms and Complications**

Like other forms of colitis, ischaemic colitis may cause abdominal pain, diarrhoea (which may contain blood), fever, and vomiting. A longstanding reduction in the blood supply may lead to the formation of a stricture (narrowed area) in the affected part of the colon. Sudden total loss of blood supply, due to thrombosis or to an embolism, can cause gangrene (tissue death) of the colon.

**Diagnosis and Treatment**

The condition may be diagnosed by viewing the colon (see colonoscopy; sigmoidoscopy) and by taking a biopsy (sample of colon tissue). Angiography may also be performed to locate any blocked blood vessels.

In mild ischaemia, treatment with drugs used to treat heart failure and hypertension in combination with lipid-lowering drugs and, in some cases, antiplatelet or anticoagulant drugs is often sufficient, but acute ischaemia may require surgery in order to remove any blockages in the blood vessels. Areas of colon that have been irreparably damaged must be removed before peritonitis and gangrene (tissue death) develop (see colectomy).

**Ischaemic necrosis**

The death of tissue as a result of an inadequate blood supply (see necrosis).

**Ischaemic optic atrophy**

See optic atrophy.

**ischium**

One of the bones that form the lower part of the pelvis.

**Islets of Langerhans**

Clusters of endocrine (hormone-producing) cells within the pancreas. The islets of Langerhans contain at least four different types of cells, which secrete hormones that control the level of glucose in the body. One type of cell secretes insulin, which lowers the blood glucose level; another secretes glucagon, which raises the blood glu-
cose level; a third secretes a hormone called somatostatin, which inhibits the secretion of insulin; and a fourth, about which relatively little is known, secretes a pancreatic polypeptide (a protein molecule).

One common disorder affecting the islets of Langerhans is type 1 diabetes mellitus, in which the insulin-secreting cells are destroyed. Other, less common disorders include the growth of tumours in particular groups of cells, leading to an excess of the hormone produced by those cells (see glucagonoma; insulinoma).

**Isogel**
A brand name for ispaghula husk, a bulk-forming agent used as a laxative drug. Isogel is also used to control some types of diarrhoea.

**Isoimmunization, Rhesus**
See Rhesus isoimmunization.

**Isolation**
Nursing procedures (also called barrier nursing) designed to prevent a patient from infecting others or from being infected. The patient is usually isolated in a single room.

Complete isolation is used if a patient has a contagious disease, such as lassa fever, that can be transmitted to others by direct contact and airborne germs. In this case, all bedding, equipment, and clothing are either sterilized or incinerated after use. Partial isolation is carried out if the disease is transmitted in a more limited way (by droplet spread, as in tuberculosis, for example).

Reverse isolation, also called reverse barrier nursing, is used to protect a patient whose resistance to infection is severely lowered by a disease or treatment such as chemotherapy. The air supply to the room is filtered and all staff and visitors must wear caps, gowns, masks, and gloves. Occasionally, long-term reverse isolation may be required for patients who have severe combined immunodeficiency (see immunodeficiency disorders).

**Isometric**
A term used for a system of exercise that involves no body movement, and in which muscles build up strength by working against resistance. The resistance is provided by either a fixed object or an opposing set of muscles. (See also isotonic.)

**Isoniazid**
An antibacterial drug that is used in the treatment of tuberculosis. Isoniazid is given in combination with other anti-tuberculous drugs, usually for a minimum of six months.

**Isoprenaline**
A drug that is used on rare occasions as an emergency treatment of heart block or severe bradycardia (an abnormally slow heart rate). Isoprenaline was previously used to treat asthma, but it has now been replaced by drugs with fewer side effects.

**Isosorbide**
A long-acting nitrate drug that acts as a vasodilator drug (by widening blood vessels). Isosorbide is used to reduce the severity and frequency of angina pectoris (chest pain caused by an impaired blood supply to the heart muscle). Isosorbide is also given to treat severe heart failure. There are two forms of isosorbide: mononitrate and dinitrate. Isosorbide dinitrate is converted by the body into isosorbide mononitrate, which is the active form of the drug.

Side effects of isosorbide include headache, hot flushes, and dizziness. In addition, tolerance to the drug may develop especially in patients who are using long-acting preparations or patches; a change in the dosage, frequency, or timing, or changing to a different drug, may be required.

**Isotonic**
Having the same tension. It is used to define a system of exercise, such as weight lifting, in which muscle tension is kept constant as the body works against its own, or an external, weight. The term “isotonic” also describes fluids, such as intravenous fluids or drinks, with the same osmotic pressure (see osmosis) as the blood. (See also isometric; hypotonic solutions.)

**Isotope**
Any one of the different atoms of a chemical element. Different isotopes of an element have the same number of protons (positively charged particles) but different numbers of neutrons (neutral particles) in their nucleus, and therefore a different atomic weight.

Radioactive isotopes are unstable and break down into more stable forms, with the release of electromagnetic radiation. This radiation release means that such isotopes may be used in some medical procedures, such as radiotherapy for cancer and imaging tests such as radionuclide scanning.

**Isotope scanning**
See radionuclide scanning.

**Isotretinoin**
A drug derived from vitamin A used in the treatment of acne. Isotretinoin works by reducing the formation of sebum (natural skin oils) and keratin (a tough protein that is the major component of the outer layer of skin).

Isotretinoin can be used as a topical gel to treat mild to moderate cases of acne, or it may be taken orally in the treatment of severe, scarring acne that is unresponsive to other treatments. Side effects of topical treatment include inflammation and peeling of the skin; sunlight should be avoided. Isotretinoin should only be taken orally under medical supervision. In this form, it may cause drying of the skin and the mucous membranes, nosebleeds, sore eyes, and disorders of the blood.

Isotretinoin may damage a developing fetus; pregnancy must be avoided during treatment and for at least one month after taking the drug. Regular blood tests are recommended to check for complications.

**Ispaghula**
A bulk-forming laxative drug that is used to treat constipation, diverticular disease, and irritable bowel syndrome. As ispaghula travels through the intestine, it absorbs water, thereby softening and increasing the volume of the faeces. Ispaghula is also used in people who have chronic, watery diarrhoea and in those patients who have had a colostomy or an ileostomy to control the consistency of faeces. Adverse effects include flatulence, abdominal distension, and discomfort.

**Isthmus**
A narrow connecting structure or tissue between two larger body parts, such as the portion of tissue connecting the two lobes of the thyroid gland.

**Istin**
A brand name for amlodipine, a calcium channel blocker drug used in the treatment of disorders such as angina pectoris (chest pain due to insufficient blood
ITCHING

THE IUD (INTRAUTERINE CONTRACEPTIVE DEVICE)

The IUD, also known as the IUCD, is a small plastic contraceptive device inserted into the uterus through the cervix. IUDs are thought to work by preventing the implantation of fertilized eggs in the uterus. All types of IUD can be fitted, by specially trained healthcare personnel, in family planning clinics, hospitals, or general practitioners’ surgeries.

![Site of an IUD](image)

An IUD is inserted into the uterus. Most types have two arms that hold them in position. The base of the IUD has one or two plastic threads that extend through the cervix to the vagina. The threads enable the user to check that the device is in place.

supply to the heart muscle) and hypertension (high blood pressure).

itching

Known medically as pruritus, an intense irritation or tickling feeling in the skin.

TYPES AND CAUSES

Generalized itching may result from excessive bathing, which removes the natural oils from the skin and may leave the skin excessively dry. Some people experience general itching after taking certain drugs. Many elderly people suffer from dry, itchy skin, especially on their backs. Itching commonly occurs during pregnancy.

Conditions, including chickenpox, urticaria (nettle rash), and eczema, produce itching. Generalized skin itchiness can be a result of diabetes mellitus, kidney failure, jaundice, and thyroid disorders.

Pruritus ani (itching around the anal region) occurs with haemorrhoids and anal fissure. Threadworm infestation is the most likely cause of anal itching in children. Pruritus vulvae (itching of the external genitalia in women) may be due to the condition candidiasis, hormonal changes, or to use of spermicides or vaginal ointments and deodorants. Insect bites, lice, and scabies infestations cause intense itching.

TREATMENT

Specific treatment for itching depends on the underlying cause. Cooling and soothing lotions, such as calamine, may help to relieve irritation; emollients (substances that moisten and soften the skin) may reduce dryness.

-itis

A suffix meaning “inflammation of”. Virtually every organ or tissue in the body can suffer inflammation, so “itis” is a very common word ending in medicine. Examples of its use are bronchitis (inflammation of the bronchi) and hepatitis (inflammation of the liver).

ITP

An abbreviation for idiopathic thrombocytopenic purpura.

itraconazole

A type of antifungal drug.

IUCD

An abbreviation for intrauterine contraceptive device (see IUD).

IUD

An abbreviation for intrauterine contraceptive device. An IUD, also known as an IUCD or coil, is a device inserted into the uterus for contraception. Most IUDs are plastic devices that have copper incorporated to improve their effectiveness. One type of IUD releases small amounts of progestogen hormone and is sometimes known as an IUS.

IUDs are believed to inhibit the implantation of a fertilized egg in the wall of the uterus (see implantation, egg).

HOW IUDS ARE USED

An IUD is inserted through the vagina and cervix into the uterine cavity. Once in position, it provides immediate protection. Most IUDs have one or two plastic strings attached to make removal easier and to indicate their presence. IUDs usually need to be replaced every three to eight years depending on the type.

WHO SHOULD USE IUDS

Women who have been pregnant are less likely to have complications than women who have never been pregnant. For example, they may feel less pain on insertion and have lighter menstrual flow and lower expulsion rates. IUDs are usually not recommended for women with fibroids or an irregular uterine cavity. If menstrual flow is heavy, an IUS may be recommended instead of an IUD.

RISKS AND COMPLICATIONS

A rare complication of the use of IUDs is perforation of the uterus, which most commonly occurs at the time of insertion. Rarely, pregnancy can occur with an IUD in place; however, an IUD seldom causes problems and it can be removed early in pregnancy. IUDs increase the risk of PID, which can lead to permanent infertility.

IUS

An abbreviation for intrauterine system. The IUS is a contraceptive device that fits inside the uterus, like an IUD. It contains the progestogen hormone levonorgestrel, which is released continuously over three to five years. The IUS acts by thinning the uterine lining and thickening cervical mucus. It also makes menstrual periods lighter, so may be used for women with heavy periods (see menorrhagia). One widely used brand of IUS is the Mirena.

IVF

See in vitro fertilization.

IVU

The abbreviation for intravenous urography (an X-ray imaging technique for visualizing the urinary tract).
J

**Jaccoud’s arthropathy**
Also called Jaccoud’s arthritis or Jaccoud’s syndrome, a rare form of chronic arthritis associated with systemic lupus erythematosus. The disorder causes fibrous changes in the joint capsules and tendons at the base of the fingers, leading to pain and swelling.

**Jacksonian seizures**
A temporary brain disturbance in which seizures begin in one part of the body, such as a limb or the face, and then spread to other areas or even the whole body (a progression called the march of the seizure). The person usually retains consciousness but may have amnesia (memory loss). (See also epilepsy.)

**Jahneke’s syndrome**
A form of Sturge–Weber syndrome in which there is malformation of blood vessels in the face and brain but without the glaucoma (increased fluid pressure in the eye) that is usually associated with the syndrome.

**Jakob–Creutzfeldt disease**
See Creutzfeldt–Jakob disease.

**Japanese B encephalitis**
An epidemic, mosquito-borne form of encephalitis (brain inflammation) occurring in Japan, India, and parts of southeast Asia. In most cases the infection causes no symptoms; however, some people develop severe encephalitis leading to paralysis, seizures, coma, and death. Immunization is available for those travelling to high-risk areas.

**Jargon aphasia**
A form of aphasia (loss of language skills) in which the affected person cannot form grammatical sentences but utters meaningless phrases composed of jumbled words or neologisms (made-up words). Jargon aphasia may be due to a lesion in the dominant temporal lobe of the brain, or, rarely, may be a sign of schizophrenia.

**jaundice**
Yellowing of the skin and whites of the eyes, caused by an accumulation of the yellow-brown pigment bilirubin in blood and tissues. Jaundice is the chief sign of many disorders of the liver and biliary system. Many otherwise healthy babies are affected briefly by jaundice soon after birth (see jaundice, neonatal).

**TYPES AND CAUSES**
Bilirubin is formed from haemoglobin (the oxygen-carrying pigment in red blood cells) when old red cells are broken down, mainly by the spleen. It is absorbed by the liver, where it is made soluble in water and excreted in bile.

There are three main types of jaundice: haemolytic, hepatocellular, and obstructive. In haemolytic jaundice, too much bilirubin is produced for the liver to process. This condition results from excessive haemolysis (breakdown of red blood cells), which can have many causes (see anaemia, haemolytic).

In hepatocellular jaundice, bilirubin accumulates because it is prevented from passing from liver cells into the bile. This form of jaundice is usually due to acute hepatitis (inflammation of the liver) caused by taking certain drugs or by liver failure.

In obstructive jaundice, also called cholestatic jaundice, bile cannot leave the liver because of bile duct obstruction, which may be caused by gallstones or due to a tumour anywhere in the duct. Obstructive jaundice can also occur if the bile ducts are underdeveloped (as in biliary atresia) or have been destroyed by disease. Cholestasis (stagnation of bile in the liver) then occurs and bilirubin overflows into the blood.

**DIAGNOSIS AND TREATMENT**
Blood tests, and possibly also a liver biopsy (removal of a sample of tissue for analysis), may be performed to identify the cause of the jaundice. Investigation of the bile duct may be carried out using such imaging techniques as ERCP and MRI. Treatment is for the underlying cause.

**jaundice, neonatal**
Yellowing of the skin and whites of the eyes in newborn babies, due to accumulation of the yellow-brown bile pigment bilirubin in the blood. Neonatal jaundice usually results from the liver being too immature to excrete bilirubin efficiently. The condition, which tends to be more common in breast-fed babies, is usually harmless and disappears within a week.

In rare cases, severe or persistent neonatal jaundice can be caused by the blood disorder haemolytic disease of the newborn; the genetic condition G6PD deficiency; hepatitis (inflammation of the liver); hypothyroidism (underactivity of the thyroid gland); biliary atresia (abnormal formation or absence of the bile ducts); or infection.

Jaundiced babies usually require extra fluids and may be treated with phototherapy (light therapy) or, in severe cases, exchange transfusion (see blood transfusion). If severe neonatal jaundice is not treated promptly, kernicterus (a form of brain damage) may occur.

**jaw**
The mobile bone of the face, also called the mandible (or lower jaw). The term sometimes includes the maxilla (upper jaw), the bone that extends from the inner rims of the eyes to the mouth.

The mandible bears the lower teeth on its upper surface, and is connected to the base of the skull at the temporomandibular joints. Muscles attached to the jaw move the bone to enable chewing, biting, and side-to-side and downward motions.

**ANATOMY OF THE JAW**

The U-shaped jaw bone (mandible) joins the skull in front of the ears, at the temporomandibular joint. The jaw can move in several directions to enable biting and chewing.

**jaw, dislocated**
Displacement of the lower jaw from one or both temporomandibular joints (which connect the jaw to the base of the skull), usually due either to a blow or yawning. There is usually pain in front
of the ear on the affected side, and the jaw projects forwards. The mouth cannot be fully closed, which makes eating and speaking difficult. Surgery may be performed to stabilize the joint, but dislocation tends to recur.

**jaw, fractured**
A fracture of the jaw bone, most often caused by a direct blow. A minor fracture may cause tenderness and pain on biting. In severe injuries, jaw movement may be limited, and there may be loss of feeling in the lower lip.

Minor fractures are normally left to heal on their own. Severe fractures with bone displacement, however, require surgery and immobilization of the jaw (see wiring of the jaws).

**JC virus**
A type of virus called a polyomavirus. JC virus does not usually cause symptoms in healthy adults but can be dangerous in people with a depressed immune system due to diseases such as leukaemia, lymphoma, or AIDS. In such cases, JC virus causes a brain disease called progressive multifocal leuкоencephalopathy, which leads to dementia.

**jealousy, morbid**
Preoccupation with the potential sexual infidelity of one’s partner. The sufferer, most often a man, becomes convinced that his partner is having an affair. Morbid jealousy is usually caused by a personality disorder, depression, or paranoia, but may also result from alcohol dependence or organic brain syndrome (see brain syndrome, organic).

**jejunal biopsy**
A diagnostic test in which a small piece of tissue is removed from the lining of the jejunum (middle section of the small intestine) for microscopic examination. It is especially useful in the diagnosis of coeliac disease, intestinal lymphoma, and other causes of malabsorption. The biopsy is taken through an endoscope introduced via the mouth, or with a device called a Crosby capsule, which is attached to a thread and swallowed.

**jejenum**
The middle, coiled section of the small intestine, joining the duodenum to the ileum. The main functions of the jejunum are to digest food and absorb nutrients. It may be affected by coeliac disease, Crohn’s disease, and lymphoma.

**jellyfish stings**
Injections of venom from the stinging cells of jellyfish, which belong to a group of marine animals called cnidarians. In most instances of jellyfish stings, there is only mild pain or itching, but some jellyfish venom causes vomiting, breathing difficulties, and collapse. Dangerous species live mainly in tropical waters. Antivenoms may be used to treat severe cases.

**jerky nystagmus**
A form of nystagmus (involuntary eye movement) in which the eyes move slowly in one direction, then dart back.

**jet-lag**
Fatigue and disruption of the sleep–wake cycle, caused by disturbance of normal body biorhythms as a result of flying across different time zones.

**jigger**
An alternative name for a chigoe, which is also sometimes known as a sand flea.

**jigger’s nipple**
Soreness of the nipple caused by friction from clothing, usually during such sports as jogging or long-distance running. Covering the nipple with a bandage or a layer of petroleum jelly reduces rubbing.

**joint**
The junction between two or more bones. Many joints are highly mobile, while others are fixed or allow only a small amount of movement (see Types of joint box opposite).

**structure**
In all types of joint, the bones are held together by soft tissues. In fixed joints, such as those in the skull, the bones are firmly secured by fibrous tissue. In semi-mobile joints (such as those in the spine), the bones are connected by cartilage, which allows limited movement. Mobile joints (such as those in the limbs) are supported by strong ligaments. They are moved by muscles, which are attached to the bones by tendons. Each mobile joint is also sealed within a tough, fibrous capsule.

**types**
There are several types of mobile joint, each allowing a specific form of movement. Hinge joints, such as those in the fingers, knees, and elbows, principally allow bending and straightening. Pivot joints, such as the joint between the first and second vertebrae (see vertebra), allow rotation only. Ellipsoidal joints, such as the wrist, allow all types of movement except pivotal. Ball-and-socket joints, such as the shoulder and hip, allow movement in all directions.

**disorders**
Common joint injuries include sprains (minor tears) or rupture of ligaments; damage to cartilage; and tearing of joint capsules. Such injuries may be caused by sudden twisting or wrenching movements, often during sport or vigorous exercise, or in a fall. Separation of the bone ends (see dislocation, joint), and partial displacement (see subluxation), are also usually caused by injury, but are occasionally present from birth. Rarely, the bone ends are fractured, which may cause bleeding into a joint (haemarthrosis). Joint effusion (build-up of fluid in a joint) is usually due to synovitis (inflammation of the joint lining).

One of the main diseases of the joints is arthritis, which causes pain, stiffness, inflammation, and degeneration of the joints. Other joint disorders include bursitis (inflammation of a fluid-filled cushion around a joint); distortion or rupture of an intervertebral disc (see disc, slipped); gout; and bunions.
### Types of Joint

There are several types of joint. Some are fixed (such as the skull joints), some allow only a little movement (the vertebral joints, for example), and some are mobile. Of the mobile joints, ball-and-socket have the widest range of movement. Pivot joints allow rotation only. Ellipsoidal joints allow movement in most directions. Hinge joints mainly allow bending.

#### Ball-and-socket joint

A ball-and-socket joint is formed by the ball-shaped end of one bone fitting into a hollow in another. It allows movement backwards or forwards, movement sideways, and rotation. Examples are the hip and shoulder joints.

#### Ellipsoidal joint

In an ellipsoidal joint, the oval-shaped end of one bone fits into an elliptical cavity in another, allowing all types of movement except pivoting. An example is the wrist joint.

#### Hinge joint

This is the simplest joint; the cylindrical end of one bone fits into a groove in another to allow bending and straightening, as in the fingers. The knee and elbow are modified hinge joints that allow some rotation as well.

#### Pivot joint

In a pivot joint, movement is limited to rotation, either by means of a bony projection pivoting within a ring or by a ring pivoting around an axis. An example of a moving ring is the joint between the first and second vertebrae, in the neck.

### Structure of a Fixed Joint

Fixed joints are firmly secured by fibrous tissue. The joints between the bones of the skull (known as sutures) are an example.

### Structure of a Mobile Joint

The surfaces of the bone ends are coated with very smooth cartilage to reduce friction as they move against each other. The ends are sealed within a tough fibrous capsule; this is lined with synovial membrane, which produces a sticky lubricating fluid. The joint is surrounded by strong ligaments that support it and prevent excessive movement. Its movement is controlled by muscles that are attached to bone by tendons on either side of the joint. Most mobile joints have at least one bursa (fluid-filled sac) nearby, which cushions a pressure point.
joint replacement
See arthroplasty.

Joubert’s syndrome
An autosomal recessive genetic disorder, present from birth, in which part of the cerebellum, an area located at the back of the brain, fails to develop properly. Affected children have impaired balance and coordination; abnormal breathing patterns; hypotonia (decreased muscle tone); and, sometimes, seizures.

joule
The international unit of energy, work, and heat. Approximately 4,200 joules (symbol J) or 4.2 kilojoules (kJ) equal 1 kilocalorie (kcal); 1 kJ is equal to about 0.24 kcal. (See also calorie.)

jugular vein
One of three veins on each side of the neck (the internal, external, and anterior jugular veins) that return deoxygenated blood from the head to the heart. The internal jugular vein, the largest of the three, arises at the base of the skull and travels down the neck alongside the carotid arteries, before passing behind the clavicle (collarbore), where it joins the subclavian vein (the large vein that drains blood from the arms).

jugular venous pressure
An assessment of the pressure within the internal jugular vein, one of the three major veins on each side of the neck that carry deoxygenated blood to the right atrium of the heart. Heart failure can cause raised jugular venous pressure.

junctional naevus
A pigmented naevus formed by a cluster of melanocytes (pigment-producing cells) in the skin, at the junction between the epidermis (outer layer) and the dermis (inner layer). The naevus looks like a flat, non-hairy, brown mole. (See also intradermal naevus.)

Jungian theory
The Swiss psychiatrist Carl Gustav Jung (1875–1961) theorized that certain ideas called archetypes, inherited from experiences in humanity’s distant past, existed in the unconscious and controlled the way a person viewed the world. Jung called these shared ideas the “collective unconscious”. Jungian therapy was aimed at putting people in touch with this source of ideas, particularly through the interpretation of dreams. Jung also postulated two basic types of personality: the extrovert and the introvert.

juvenile arthritis
See juvenile chronic arthritis.

juvenile chronic arthritis
A rare form of arthritis (joint inflammation) affecting children. Juvenile chronic arthritis occurs more often in girls, and usually develops between two and four years of age or around puberty.

TYPES
There are three main types, all of which cause joint pain, swelling, and stiffness. The most common form is pauciarticular juvenile arthritis, which affects four joints or fewer and usually occurs in very young girls. Polyarticular juvenile arthritis affects five or more joints, and is more common in girls. Still’s disease (systemic onset juvenile arthritis) affects both boys and girls. It starts with fever, rash, enlarged lymph nodes, abdominal pain, and weight loss. These symptoms last for several weeks. The joint problems may not develop for some months.

COMPLICATIONS
Possible complications include short stature, anaemia, pleurisy (inflammation of the membranes around the lungs), pericarditis (inflammation of the membran around the heart), and enlargement of the liver and spleen. Uveitis (inflammation of parts of the eye) may develop. Rarely, amyloidosis (in which an abnormal protein is deposited in body organs) or kidney failure may develop.

DIAGNOSIS
Diagnosis is based on the symptoms, together with the results of X-rays and blood tests; it is made only if the condition lasts for longer than three months.

TREATMENT AND OUTLOOK
Treatment may include antirheumatic drugs, corticosteroid drugs, nonsteroidal anti-inflammatory drugs, or aspirin. Splints may be worn to rest inflamed joints and to reduce the risk of deformities. Physiotherapy reduces the risk of muscle wasting and deformities. The arthritis usually clears up after several years, but in some children it persists into adult life.

juvenile muscular atrophy
A form of muscle atrophy (wasting and weakness) that occurs in children and adolescents, and is caused by an autosomal recessive genetic disorder. Muscle atrophy is most obvious in the legs, and later the arms. Respiratory muscles may also be involved. Most affected children eventually become wheelchair bound.

juvenile-onset diabetes
A form of type 1 (insulin-dependent) diabetes mellitus that develops suddenly in childhood or adolescence.

juvenile osteoporosis, idiopathic
A rare form of osteoporosis (loss of bone density) that occurs in children of eight to 14 years. Idiopathic juvenile osteoporosis causes leg and back pain; kyphosis (curvature of the upper spine); walking difficulty; and an increased susceptibility to fractures. The disorder usually begins suddenly and often disappears spontaneously after two to four years. Treatment is aimed at preventing fractures and maintaining mobility.
kala-azar
A form of the parasitic disease leishmaniasis, which is spread by sandflies. Kala-azar occurs in parts of Africa, India, the Mediterranean, and South America.

Kallmann’s syndrome
An inherited condition in which there is a deficiency of gonadotrophin-releasing hormone (GnRH). This hormone, which is produced in the hypothalamus, is responsible for regulating the release of other hormones in the pituitary gland that in turn stimulate the testes. The deficiency of GnRH delays or sometimes prevents normal sexual development at puberty. The condition is also associated with colourblindness and a lack of sense of smell. Kallmann’s syndrome is treated with hormones that replace GnRH.

kaolin
An aluminium compound used as an ingredient in some antidiarrhoeal drugs. Kaolin is an adsorbent and is taken by mouth to treat the diarrhoea and vomiting caused by food poisoning and other digestive disorders.

Kaposi’s sarcoma
A cancerous tumour arising from blood vessels in the skin or, less commonly, in internal organs. Almost all cases of Kaposi’s sarcoma occur in people who have AIDS. Several tumours are often present, appearing as pinkish-purple, raised areas of skin. The tumours can spread rapidly over the body; they usually develop first on the feet and ankles, spread up the legs, then occur on the hands and the arms. Internal tumours, such as those affecting the gastrointestinal and respiratory tracts, may cause severe bleeding.

Skin tumours may be treated with radiotherapy. Anticancer drugs may be used if the skin is widely affected, or for internal tumours. Antiretroviral drugs often control the cancerous growths and may shrink them.

Kaposi’s varicelliform eruption
A generalized, serious skin eruption, consisting of pus-filled blisters, caused by a viral infection in areas of pre-existing atopic dermatitis. The disorder is also known as eczema herpeticum. The viruses usually responsible are herpes simplex virus (HSV-1 and HSV-2) and coxsackievirus.

Kartegen's syndrome
An inherited disorder in which the heart is situated on the right instead of the left side of the chest (a condition known as dextrocardia). This is associated with abnormal functioning of the cilia (hair-like projections) lining the airways, which impairs clearance of mucus and results in bronchiectasis and sinusitis.

karyotype
The characteristics of chromosomes, in terms of number, size, and structure, in an individual or a species. The term “karyotype” is also applied to a diagram of chromosome pairs arranged in their assigned numerical order.

Kawasaki disease
A rare, acute illness of unknown cause that most commonly affects children under two years of age. The disease is characterized by fever lasting one to two weeks; conjunctivitis; dryness and cracking of the lips; swollen lymph nodes in the neck; reddening of the palms and soles; and a generalized rash. By the end of the second week of illness, the skin at the tips of the fingers and toes peels and other symptoms subside. The heart muscle and coronary arteries are affected in some cases.

High doses of gamma-globulin (see immunoglobulin injections) and aspirin may be given in order to prevent associated heart complications. The majority of children recover completely.

Keller’s operation
A type of surgery sometimes used to treat hallux valgus (a deformity of the big toe). The operation involves cutting away a piece of bone from the base of the first joint of the toe. Fibrous tissue forms in the gap, although the toe is left shorter. (See also bunion.)

Keloid
A raised, hard, irregularly shaped, itchy scar on the skin due to a defective healing process in which too much collagen (a tough, fibrous protein) is produced, usually after a skin injury. Keloids can develop anywhere on the body, but the breastbone and shoulder are common sites. Black people are affected more commonly than white people. After several months, most keloids flatten and cease to itch.

Injection of corticosteroid drugs into the keloid may reduce itchiness more quickly and cause some shrinkage.

keratin
A fibrous protein that is the main constituent of the tough outermost layer of the skin, nails, and hair.

keratitis
Inflammation of the cornea (the transparent front part of the eyeball). It often takes the form of a corneal ulcer and may result from injury, contact with chemicals, or an infection. Symptoms of keratitis include pain and excessive watering of the eye, blurring of vision, and photophobia (abnormal sensitivity to bright light).

Noninfective keratitis is treated by keeping the affected eye covered until it has healed. Drugs such as antibiotics may be given to treat infective keratitis. (See also disciformis keratitis.)

keratoacanthoma
A type of harmless skin nodule that commonly occurs in elderly people, most often on the face or arm. The cause is unknown, but many years of exposure to strong sunlight or long-term use of immunosuppressant drugs may be contributory factors. Initially, the nodule resembles a small wart, but it grows to 1–2 cm across in about eight weeks. Although the nodule usually disappears gradually after this time, surgical removal is often recommended to prevent scarring.
keratoconjunctivitis

Inflammation of the cornea (the transparent front part of the eyeball) that is associated with conjunctivitis (inflammation of the conjunctiva, the membrane covering the eyeball). The most common form of the disorder, epidemic keratoconjunctivitis, is caused by a virus and is highly infectious. The inflammation is often severe and in some cases may destroy the surface of the conjunctiva. Tiny, opaque spots develop in the cornea that may interfere with vision and persist for some months.

There is no specific treatment, but corneal spots may be minimized by using eye-drops containing corticosteroid drugs.

keratoconjunctivitis sicca

Persistent dryness of the cornea (the transparent front part of the eyeball) and the conjunctiva (the membrane covering the eyeball) caused by deficiency in tear production. The condition is associated with autoimmune disorders such as rheumatoid arthritis, Sjögren’s syndrome, and systemic lupus erythematosus, all of which can damage the tear glands. Prolonged dryness may lead to blurred vision, itching, grittiness, and, in severe cases, the formation of a corneal ulcer. The most effective treatment is frequent use of artificial tears (see tears, artificial).

keratoconus

An inherited disorder of the eye, in which the cornea (the transparent front part of the eyeball) becomes gradually thinned and conical. The condition affects both eyes and usually develops around puberty, giving rise to increasing myopia (short-sightedness) and progressive distortion of vision that cannot be fully corrected by glasses. Hard contact lenses improve vision in the early stages, but later it is generally necessary to perform a corneal graft to restore normal vision permanently.

keratolytic drugs

Drugs that loosen and remove the tough outer layer of skin. Keratolytic drugs, which include urea and salicylic acid preparations, are used to treat skin and scalp disorders, such as warts, acne, dandruff, and psoriasis.

keratomalacia

A progressive disease of the eye, caused by severe vitamin A deficiency, in which the cornea (the transparent front part of the eyeball) becomes opaque and ulcerated. Perforation of the cornea is also common, often leading to loss of the eye through infection. The disorder usually occurs only in severely malnourished children and is a common cause of blindness in developing countries.

In the early stages, the damage can be reversed by treatment with large doses of vitamin A but, if the condition is left untreated, blindness is usually inevitable.

keratopathy

A general term used to describe a variety of disorders of the cornea (the transparent front part of the eyeball).

TYPES

Actinic keratopathy is a painful condition in which the outer layer of the cornea is damaged by ultraviolet light emitted from the sun, reflected from surfaces such as snow (in which case the problem is called snow-blindness), or given off by artificial sources such as sunbeds or arc-welding torches.

Exposure keratopathy is corneal damage due to loss of the protection afforded by the tear film and blink reflex. It may occur in conditions in which the eyelids inadequately cover the cornea, including severe exophthalmos, facial poly, and ectropion.

keratoplasty

See corneal graft.

keratosis

A skin growth that is caused by an overproduction of the tough, fibrous protein keratin. Keratoses occur mainly in elderly people.

TYPES

Seborrhoeic keratoses are harmless growths that occur mainly on the trunk. They range in appearance from flat, dark-brown patches to small, wartlike protrusions. The growths do not need treating unless they are unsightly.

Solar keratoses are small, wartlike red or flesh-coloured growths that appear on exposed parts of the body as a result of overexposure to the sun over many years. Rarely, they may develop into skin cancer, usually squamous cell carcinoma.

TREATMENT

Seborrhoeic keratoses can be removed by curettage (scraping away). Surgery is required for solar keratoses that have become cancerous, however.

keratosis pilaris

A common condition, usually occurring in adolescents, in which patches of rough skin appear on the upper arms, thighs, and buttocks. The openings of the hair follicles become enlarged by plugs of keratin (a tough, fibrous protein), and hair growth may be distorted.

The condition is not serious and usually clears up on its own. In severe cases, applying a mixture of salicylic acid and soft paraffin and scrubbing with a loofah may help.

keratotomy, radial

An uncommon procedure in which radiating incisions are made in the cornea (the transparent front part of the eyeball) up to, but not through, its innermost layer, in order to reduce myopia (short-sightedness). Radial keratotomy has been largely replaced by laser procedures, such as LASIK, which carry less risk of permanent damage to the eye.

kerion

A red, painful swelling, oozing fluid, that appears on the scalp due to infection with scalp ringworm (see tinea). Treatment with oral antifungal drugs needs to be continued for several weeks before the scalp heals. The disorder may leave scarring and an area of permanent hair loss.

keratokeratosis

A skin growth that is caused by an overproduction of the tough, fibrous protein keratin. Keratoses occur mainly in elderly people.

Types

Seborrhoeic keratoses are harmless growths that occur mainly on the trunk. They range in appearance from flat, dark-brown patches to small, wartlike protrusions. The growths do not need treating unless they are unsightly.

Solar keratoses are small, wartlike red or flesh-coloured growths that appear on exposed parts of the body as a result of overexposure to the sun over many years. Rarely, they may develop into skin cancer, usually squamous cell carcinoma.

TREATMENT

Seborrhoeic keratoses can be removed by curettage (scraping away). Surgery is required for solar keratoses that have become cancerous, however.

keratopathy

A general term used to describe a variety of disorders of the cornea (the transparent front part of the eyeball).

TYPES

Actinic keratopathy is a painful condition in which the outer layer of the cornea is damaged by ultraviolet light emitted from the sun, reflected from surfaces such as snow (in which case the problem is called snow-blindness), or given off by artificial sources such as sunbeds or arc-welding torches.

Exposure keratopathy is corneal damage due to loss of the protection afforded by the tear film and blink reflex. It may occur in conditions in which the eyelids inadequately cover the cornea, including severe exophthalmos, facial poly, and ectropion.

keratoplasty

See corneal graft.

keratosis

A skin growth that is caused by an overproduction of the tough, fibrous protein keratin. Keratoses occur mainly in elderly people.

Types

Seborrhoeic keratoses are harmless growths that occur mainly on the trunk. They range in appearance from flat, dark-brown patches to small, wartlike protrusions. The growths do not need treating unless they are unsightly.

Solar keratoses are small, wartlike red or flesh-coloured growths that appear on exposed parts of the body as a result of overexposure to the sun over many years. Rarely, they may develop into skin cancer, usually squamous cell carcinoma.

TREATMENT

Seborrhoeic keratoses can be removed by curettage (scraping away). Surgery is required for solar keratoses that have become cancerous, however.

keratosis pilaris

A common condition, usually occurring in adolescents, in which patches of rough skin appear on the upper arms, thighs, and buttocks. The openings of the hair follicles become enlarged by plugs of keratin (a tough, fibrous protein), and hair growth may be distorted.

The condition is not serious and usually clears up on its own. In severe cases, applying a mixture of salicylic acid and soft paraffin and scrubbing with a loofah may help.

keratotomy, radial

An uncommon procedure in which radiating incisions are made in the cornea (the transparent front part of the eyeball) up to, but not through, its innermost layer, in order to reduce myopia (short-sightedness). Radial keratotomy has been largely replaced by laser procedures, such as LASIK, which carry less risk of permanent damage to the eye.

kerion

A red, painful swelling, oozing fluid, that appears on the scalp due to infection with scalp ringworm (see tinea). Treatment with oral antifungal drugs needs to be continued for several weeks before the scalp heals. The disorder may leave scarring and an area of permanent hair loss.

keratokeratosis

A skin growth that is caused by an overproduction of the tough, fibrous protein keratin. Keratoses occur mainly in elderly people.

Types

Seborrhoeic keratoses are harmless growths that occur mainly on the trunk. They range in appearance from flat, dark-brown patches to small, wartlike protrusions. The growths do not need treating unless they are unsightly.

Solar keratoses are small, wartlike red or flesh-coloured growths that appear on exposed parts of the body as a result of overexposure to the sun over many years. Rarely, they may develop into skin cancer, usually squamous cell carcinoma.

TREATMENT

Seborrhoeic keratoses can be removed by curettage (scraping away). Surgery is required for solar keratoses that have become cancerous, however.

keratopathy

A general term used to describe a variety of disorders of the cornea (the transparent front part of the eyeball).

Types

Actinic keratopathy is a painful condition in which the outer layer of the cornea is damaged by ultraviolet light emitted from the sun, reflected from surfaces such as snow (in which case the problem is called snow-blindness), or given off by artificial sources such as sunbeds or arc-welding torches.

Exposure keratopathy is corneal damage due to loss of the protection afforded by the tear film and blink reflex. It may occur in conditions in which the eyelids inadequately cover the cornea, including severe exophthalmos, facial poly, and ectropion.

keratoplasty

See corneal graft.

keratosis

A skin growth that is caused by an overproduction of the tough, fibrous protein keratin. Keratoses occur mainly in elderly people.

Types

Seborrhoeic keratoses are harmless growths that occur mainly on the trunk. They range in appearance from flat, dark-brown patches to small, wartlike protrusions. The growths do not need treating unless they are unsightly.

Solar keratoses are small, wartlike red or flesh-coloured growths that appear on exposed parts of the body as a result of overexposure to the sun over many years. Rarely, they may develop into skin cancer, usually squamous cell carcinoma.

TREATMENT

Seborrhoeic keratoses can be removed by curettage (scraping away). Surgery is required for solar keratoses that have become cancerous, however.

keratosis pilaris

A common condition, usually occurring in adolescents, in which patches of rough skin appear on the upper arms,
ketones are produced during the metabolism of fats; if excessive amounts build up in the body, they cause ketosis.

ketoprofen
A type of nonsteroidal anti-inflammatory drug (NSAID) that is prescribed as an analgesic drug (painkiller) for injuries to soft tissues, such as muscles and ligaments. Ketoprofen also reduces joint pain and stiffness in arthritic conditions. It may cause abdominal pain, nausea, indigestion, and an increased risk of peptic ulcer.

eketosis
A potentially serious condition in which excessive amounts of chemicals called ketones accumulate in the body. Ketones are normal products of fat metabolism, but are produced in excess when body cells cannot use glucose as an energy source. This occurs in starvation, in prolonged vomiting, and in untreated diabetes mellitus (see diabetic ketoacidosis) when a lack of insulin prevents glucose from entering cells. Symptoms include sweet, aceto-smelling breath, loss of appetite, nausea, and abdominal pain. Ketosis may eventually result in confusion, unconsciousness, and death. Treatment is of the underlying cause.

keyhole surgery
Another name for minimally invasive surgery.

kidney
Either of the two organs that filter the blood and excrete waste products and excess water as urine. The kidneys are situated at the back of the abdominal cavity, on either side of the spine.

STRUCTURE
Each kidney is surrounded by a fibrous capsule and is made up of an outer layer (cortex) and an inner layer (medulla). The cortex contains specialized capillaries (tiny blood vessels) called glomeruli; these vessels, together with a series of tubules, make up the nephrons, the filtering units of the kidney. Urine, the waste product from filtering, passes through tubules to the medulla, collects in an area called the renal pelvis, then travels through tubes called ureters to the bladder.

FUNCTIONS
The nephrons filter blood under pressure and then selectively reabsorb water and certain other substances into the blood. Urine is formed from substances that are not reabsorbed (see illustrated box: the function of the kidney).

The kidneys also regulate the body’s fluid balance. To do this, they excrete excess water, and when water is lost from the body (for example, as a result of sweating), they conserve it (see ADH). In addition, they control the body’s acid–base balance by adjusting urine acidity. Lastly, the kidneys produce hormones involved in the regulation of red blood cell production and blood pressure.

kidney biopsy
A procedure in which a small sample of kidney tissue is removed and examined under a microscope. Kidney biopsy is performed to investigate and diagnose serious disorders such as glomerulonephritis, proteinuria, nephrotic syndrome, and acute kidney failure, or to assess the kidneys’ response to treatment.

There are two basic techniques: percutaneous needle biopsy, in which a hollow needle is passed through the skin into the kidney under local anaesthesia; and open surgery under general anaesthesia.

kidney cancer
A cancerous tumour of the kidney. Most kidney cancers originate in the kidney itself, but in rare cases cancer spreads to the kidney from another organ.

TYPES
There are three main types of cancer that affect the kidney: renal cell carcinoma, nephroblastoma, and transitional cell carcinoma.

Renal cell carcinoma
Also known as hypernephroma or adenocarcinoma, this is the most common type of kidney cancer. It usually occurs in people over the age of 40 and affects twice as many men as women. A common symptom is blood in the urine. There may also be pain in the back, a lump in the abdomen, fever, or weight loss. The cancer often spreads to the lungs, bones, liver, and brain.

Nephroblastoma
Nephroblastoma (also called Wilms’ tumour) is a fast-growing tumour that mainly affects children under five years old. Nephroblastoma sometimes runs in families, but its cause is unknown. Symptoms may include swelling of the abdomen, abdominal pain or discomfort, and, occasionally, blood in the urine. Nephroblastoma may spread to the lungs, liver, and brain.

Transitional cell carcinoma
This type of kidney cancer arises from cells lining the renal pelvis (the urine-collecting system within the kidney); it is most common in smokers or in people

LOCATION OF THE KIDNEYS
The kidneys are situated at the back of the abdominal cavity, just above the waist, on either side of the spine. The right kidney lies below the liver (not shown), and the left kidney lies below the spleen. Each kidney is connected to the bladder by a ureter. The renal arteries, which supply the kidneys, arise directly from the aorta, and the renal veins join on to the inferior vena cava. The two adrenal glands sit on top of each kidney.

The kidneys also regulate the body’s fluid balance. To do this, they excrete excess water, and when water is lost from the body (for example, as a result of sweating), they conserve it (see ADH). In addition, they control the body’s acid–base balance by adjusting urine acidity. Lastly, the kidneys produce hormones involved in the regulation of red blood cell production and blood pressure.

kidney biopsy
A procedure in which a small sample of kidney tissue is removed and examined under a microscope. Kidney biopsy is performed to investigate and diagnose serious disorders such as glomerulonephritis, proteinuria, nephrotic syndrome, and acute kidney failure, or to assess the kidneys’ response to treatment.

There are two basic techniques: percutaneous needle biopsy, in which a hollow needle is passed through the skin into the kidney under local anaesthesia; and open surgery under general anaesthesia.

kidney cancer
A cancerous tumour of the kidney. Most kidney cancers originate in the kidney itself, but in rare cases cancer spreads to the kidney from another organ.

TYPES
There are three main types of cancer that affect the kidney: renal cell carcinoma, nephroblastoma, and transitional cell carcinoma.

Renal cell carcinoma
Also known as hypernephroma or adenocarcinoma, this is the most common type of kidney cancer. It usually occurs in people over the age of 40 and affects twice as many men as women. A common symptom is blood in the urine. There may also be pain in the back, a lump in the abdomen, fever, or weight loss. The cancer often spreads to the lungs, bones, liver, and brain.

Nephroblastoma
Nephroblastoma (also called Wilms’ tumour) is a fast-growing tumour that mainly affects children under five years old. Nephroblastoma sometimes runs in families, but its cause is unknown. Symptoms may include swelling of the abdomen, abdominal pain or discomfort, and, occasionally, blood in the urine. Nephroblastoma may spread to the lungs, liver, and brain.

Transitional cell carcinoma
This type of kidney cancer arises from cells lining the renal pelvis (the urine-collecting system within the kidney); it is most common in smokers or in people
The kidneys are susceptible to a wide range of disorders. Only one normal kidney is needed for good health, however, so disease is rarely life-threatening unless it affects both kidneys and is at an advanced stage. Hypertension (high blood pressure) can be both a cause and an effect of kidney damage. Other effects of serious damage include nephrotic syndrome and kidney failure.

**Congenital and genetic disorders**

Congenital abnormalities, such as duplex kidney (in which a kidney is partially duplicated) and horseshoe kidney (in which the two kidneys are joined at their base), are fairly common and usually harmless. Serious inherited disorders include polycystic kidney disease (see kidney, polycystic), in which multiple cysts develop on both kidneys; and Fanconi’s syndrome and renal tubular acidosis, in which the kidney tubules function abnormally so that certain substances are inappropriately lost in the urine.

**Impaired blood supply**

Various conditions may cause damage to, or lead to blockage of, the blood vessels within the kidneys, impairing blood flow. Such conditions include shock, haemolytic-uraemic syndrome, polyarteritis nodosa, diabetes mellitus, and systemic lupus erythematosus. Impaired blood flow through the kidneys can lead to tissue damage, hypertension, and kidney failure.

**Autoimmune disorders**

Glomerulonephritis includes a group of autoimmune disorders (in which the immune system attacks the body’s own tissues) that cause the filtering units of the kidneys to become inflamed and unable to function normally.

**Drugs**

Allergic reactions to drugs, prolonged treatment with analgesic drugs (painkillers), and some antibiotics can damage kidney tubules.

**Tumours**

Noncancerous kidney tumours are rare; kidney cancer is uncommon.

**Metabolic disorders**

Diabetes mellitus is the commonest cause of kidney failure in developed countries. Other metabolic disorders, such as hyperuricaemia, may cause kidney stones to form (see calculus, urinary tract).

**Infection**

Infection of the kidney is called pyelonephritis and can be a complication of cystitis. A predisposing factor to infection is obstruction of urine flow through the urinary tract due to a kidney or ureteral stone, tumour, or congenital defect.

**Other disorders**

Hydronephrosis (a kidney swollen with urine) is caused by obstruction of the urinary tract. Crush syndrome is a condition in which kidney function is disrupted by proteins released into the blood from damaged muscle.

Kidney disorders are investigated by kidney imaging techniques such as ultrasound scanning, urography, angiography, and CT scanning or MRI; by kidney biopsy (removal of a small amount of tissue for analysis); by blood tests; and by kidney function tests such as urinalysis.

**DISORDERS OF THE KIDNEY**

**Kidney cyst**

A fluid-filled sac in the kidney. Cysts commonly develop in people over 50, and can occur either singly or multiply in one or both kidneys. Most cysts occur for no known reason, are noncancerous, and do not usually produce symptoms unless they become large enough to cause lower back pain due to pressure on surrounding tissues. Large numbers of kidney cysts, however, may be associated with polycystic kidney disease (see kidney, polycystic), which often leads to kidney failure.

Simple cysts do not usually require treatment. For cases in which the cysts are painful or recurrent, however, aspiration (withdrawal of fluid) or surgical removal may be carried out.

**Kidney, duplex**

See duplex kidney.

**Kidney failure**

A reduction in the function of the kidneys. Kidney failure causes waste products such as urea and excess fluid to accumulate in the body, and also produces other chemical imbalances in the blood and body tissues.

**Types**

Kidney failure can be acute or chronic. In the acute form, kidney function often returns to normal once the underlying cause has been discovered and treated. In chronic kidney failure, however, kidney tissue is progressively damaged over several months or years. This condition may develop into end-stage kidney failure, a life-threatening condition in which kidney function is usually irreversibly lost.

**Causes**

Causes of acute kidney failure include a severe reduction in blood flow to the kidneys, as occurs in shock; an obstruction to urine flow, for example due to a bladder tumour; or certain rapidly developing types of kidney disease, such as glomerulonephritis.

Chronic kidney failure can be the result of a disease that causes progressive damage to the kidneys, such as polycystic kidney disease (see kidney,
polycystic), diabetes mellitus, and hypertension (high blood pressure), or from longstanding obstruction to urine flow.

**SYMPTOMS**
The most obvious symptom of acute kidney failure is oliguria (a reduced volume of urine). Urea and other waste products build up in the blood and tissues causing drowsiness, nausea, and breathlessness.

Symptoms of chronic kidney failure develop more gradually, and may include nausea, loss of appetite, and weakness. The kidney damage leads to conditions such as anaemia and hyperparathyroidism.

**DIAGNOSIS AND TREATMENT**
A person with suspected kidney failure will initially need blood and urine tests. Other tests, such as kidney biopsy (examination of a tissue sample) and intravenous urography (taking X-rays of the urinary tract), may be carried out to identify the cause of the kidney failure if this is not already obvious.

If acute kidney failure is due to a sudden reduction in blood flow, blood volume and pressure can be normalized by saline intravenous infusion or blood transfusion. If there is an obstruction in the urinary tract, surgery may be needed. Acute kidney disease may be treated with corticosteroid drugs. Treatment may also involve diuretic drugs and temporary dialysis (artificial purification of the blood).

A high-carbohydrate, low-protein diet with controlled fluid and salt intake is important in the treatment of acute and chronic kidney failure, because this reduces the workload on the kidneys.

For end-stage kidney failure, long-term dialysis or a kidney transplant is the only effective treatment.

**kidney function tests**
Tests that are performed to investigate kidney disorders. Urinalysis is a simple test in which a urine sample is examined under a microscope for blood cells, pus cells, and casts (cells and mucous material that accumulate in the tubules of the kidneys and pass into the urine). Urinalysis is used to test for substances, such as proteins, that leak into the urine when the kidneys are damaged. Kidney function can be assessed by measuring the concentration in the blood of substances that the kidneys normally excrete, such as urea and creatinine; by creatinine clearance, in which levels of creatinine in the blood are compared with creatinine excreted in urine over 24 hours; and by kidney imaging with radioisotopes.

**kidney imaging**
Techniques for visualizing the kidneys, usually performed for diagnosis.

Ultrasound scanning is often the first investigation and can be used to identify kidney enlargement, a cyst or tumour, and the site of any blockage. Conventional X-rays show the outline of the kidneys and most kidney stones, while intravenous urography shows the internal anatomy of the kidney and ureters. Angiography is used to image blood circulation through the kidneys. CT scanning and MRI provide detailed cross-sectional images of kidney tissue and the urine-collecting system, and can show abscesses or tumours.
KIDNEY, POLYCYSTIC

KIDNEY IMAGING

The various kidney imaging techniques can provide different types of information to help doctors investigate and diagnose kidney disorders.

MRI and CT scanning
These techniques produce cross-sectional images of body tissues, displayed as computer-generated pictures. They clearly show structural abnormalities such as tumours and cysts. This MRI scan of the abdomen shows a polycystic kidney (on the right of the image).

IVU (Intravenous urography)
This is a type of X-ray in which fluid containing a contrast medium (a substance opaque to X-rays) is introduced into the urinary system, then X-rays are taken. The images show how the fluid moves through the kidneys, ureters, and bladder, and can show up any obstructions, such as stones in the urinary tract.

Ultrasound scanning
This is a quick technique, which provides clear images of the structure of the kidney. It can reveal fluid-filled structures such as cysts, which can be clearly differentiated from the kidney tissue surrounding them.

Radionuclide scanning
This produces coloured images to show the functioning of the kidneys. (This scan is taken from the back.) Areas that are brighter than normal show overactive cells, as in a tumour; colours that are less intense than normal show underactivity, as in kidney failure.

Two types of radionuclide scanning are used: DMSA and DTPA scanning. DMSA is given by intravenous injection and binds to cells in the kidney tubules, giving a single, static picture of the kidneys. DTPA, also given intravenously, is filtered in the kidneys and passes out in the urine. Pictures taken at intervals record its clearance by the kidney, providing an indicator of kidney function.

kidney, polycystic
An inherited disorder in which both kidneys develop numerous cysts that gradually enlarge until most of the normal tissue is destroyed. Polycystic kidney disease is distinguished from multiple simple kidney cysts, which occur commonly with increasing age.

TYPES
There are two types of polycystic disease. The most common type usually appears in middle age, producing abdominal swelling, pain, and blood in the urine. As the disease progresses, hypertension (high blood pressure) and kidney failure may result.

The second type of polycystic disease, which is rare, causes enlargement of the kidneys and kidney failure in infants and young children.

TREATMENT AND PREVENTION
There is no effective treatment for preserving kidney function in either type of the condition, but symptoms of kidney failure can be treated by dialysis (artificial purification of the blood) and kidney transplant.

People with a family history of this disease may need genetic counselling before starting a family. The adult form is an autosomal dominant disorder and an affected parent has a 50 per cent chance of passing on the defective gene. If both parents carry the gene for the juvenile form (autosomal recessive disorder), their fetus can be examined using ultrasound scanning to detect kidney enlargement.

kidney stone
See calculus, urinary tract.

kidney transplant
An operation in which a person with chronic kidney failure receives a healthy kidney from a living or, more commonly, a dead donor. One donor kidney can maintain the health of the recipient.

The new kidney is placed in the pelvis through an incision in the abdomen and carefully positioned so that it can be connected easily to a nearby vein and artery and to the bladder. The diseased kidneys may be left in place.

The transplant removes the need for dialysis (artificial purification of blood) and often allows a return to a normal lifestyle. The procedure is more straightforward than transplantation of other organs. Unless the donor is an identical twin, immunosuppressant drugs are given to avoid rejection of the kidney.

kidney tumours
Growth in the kidney. Kidney tumours may be cancerous (see kidney cancer) or noncancerous. The latter type, which include fibromas, lipomas, and leiomyomas, are often symptomless, although a haemangioma (composed of a collection of blood vessels) may grow very large and cause blood to appear in the urine.

Two types of fibrous or glandular tumours are growing: fibromas and haemangiomas. The former do not spread, whereas the latter may spread to the lymph nodes or other internal organs. Symptoms depend on the size and position of the tumour. Ultrasound may reveal fluid-filled structures such as cysts, which can be clearly seen on the left kidney (right of image).
A kidney transplant is performed when a person’s kidneys have lost almost all of their normal function (so-called end-stage kidney failure). Just one healthy donor kidney can allow a patient to have a normal lifestyle. The donated kidney comes from a close relative of the patient, or from any person who consented to medical use of his or her organs after death. To prevent rejection of the kidney by the recipient’s immune system, the tissue-type and blood group of recipient and donor must be a close match (see Transplant surgery).

**PROCEDURE FOR A KIDNEY TRANSPLANT**

A significant proportion of patients with end-stage kidney failure are suitable for a kidney transplant, but many have to remain on dialysis for some time until a suitable donor kidney becomes available. A computer system is used to match donors with the most suitable recipients. The number of available donor kidneys is considerably less than the number of people waiting for a transplant.

**DIALYSIS AND TRANSPLANTATION**

The donor kidney is removed. Usually the left kidney is removed from living donors, because it has a longer vein than the right and is easier to remove safely. With donation from people who have died (cadavers), both kidneys are used and each kidney usually goes to a separate recipient. Kidneys from a cadaver can be maintained for transplantation by a machine that passes a cooling saline solution through them. Donor organs may need to be transported over long distances, and occasionally to other countries, to reach the recipient.

1. The donor kidney is removed. Usually the left kidney is removed from living donors, because it has a longer vein than the right and is easier to remove safely. With donation from people who have died (cadavers), both kidneys are used and each kidney usually goes to a separate recipient. Kidneys from a cadaver can be maintained for transplantation by a machine that passes a cooling saline solution through them. Donor organs may need to be transported over long distances, and occasionally to other countries, to reach the recipient.

2. After removal, a donor kidney is flushed with chilled saline solution in order to preserve the tissues and internal structures. The donor kidney should be transplanted as soon as possible, but there is a reasonable success rate even if transplantation is delayed for up to 48 hours.

3. The donor kidney is usually placed in the pelvis. The renal artery and vein of the donor kidney are joined to a convenient artery (usually a branch of the external iliac artery) and vein of the recipient. The lower end of the donor ureter is connected to the recipient’s bladder. The donor kidney usually begins working immediately after transplantation into the recipient.

**THE DONOR (AFTER THE OPERATION)**

The health of the donor is not affected by having a kidney removed because the body can work efficiently with just one. The remaining kidney enlarges to increase its capacity and takes over full function.
A biopsy of the tumour may be needed to confirm that it is not cancerous. Treatment is usually not needed for noncancerous tumours unless they are large or painful.

**Kiel classification**

A system that is used for ranking non-Hodgkin’s lymphoma (see lymphoma, non-Hodgkin’s), any of several cancerous tumours of the lymphoid tissues in which the cells divide unchecked. The cancer is classified as high-grade or low-grade according to the type of cell and how rapidly the cells are dividing. Once widely used, Kiel classification has now been replaced by WHO classification.

**Kienböck disease**

Death of tissue cells (see necrosis) in the wristbone known as the lunate bone. The disorder, characterized by pain and stiffness in the wrist, is caused by an inadequate blood supply, often the result of an undiagnosed or unsuccessfully treated fracture. Treatment usually consists of resting the joint; in a few cases, surgery is needed.

**killer T-cell**

A type of white blood cell, also known as a cytotoxic T-lymphocyte or a CD8 lymphocyte, that has an important role in the immune system. Killer T-cells destroy an abnormal, cancerous, or virus-infected cell after a foreign antigen on its surface has been recognized by helper T-cells. (See also natural killer cells.)

**kilocalorie**

The unit of energy equal to 1,000 calories, abbreviated to kcal. In dietetics, a kilocalorie is sometimes referred to simply as a calorie (or C).

**kilojoule**

The unit of energy equal to 1,000 joules, abbreviated to kJ. One kcal (see kilocalorie) equals 4.2 kJ.

**kinky-hair disease**

A genetic disorder, also called Menkes’ syndrome, in which body cells do not absorb sufficient copper. The condition is present from birth. It causes brittle, kinky hair; hypotonia (abnormal muscle slackness); feeding difficulties; seizures; and degeneration of brain tissue. Affected children die after a few years.

Kinky-hair disease is an X-linked disorder; it affects only male babies, but females may carry the gene. People with a family history of the disorder may wish to consider genetic counselling before having children.

**kiss of life**

A common name for artificial respiration.

**Klebsiella**

A genus of rod-shaped bacteria that is commonly found in the human intestine. They may cause pneumonia, lung abscess, or peritonitis in people with ascites (excess fluid in the peritoneal cavity) due to liver disease. One type, *Klebsiella granulomatis*, is the cause of the sexually transmitted infection granuloma inguinale or Donovanosis, which is common in the tropics and produces a rash and ulceration of the genital area.

**kleptomania**

A recurring inability to resist impulses to steal, often without any desire for the stolen objects. The condition is usually a sign of an immature personality. It is sometimes associated with depression, and may also result from dementia or some forms of brain damage.

**Klinefelter’s syndrome**

A chromosomal abnormality in which a male has one, or occasionally more, extra X chromosomes in his cells, giving a complement of XXY instead of XY. The risk of a baby having the condition increases with maternal age.

**SYMPTOMS AND SIGNS**

Features of the syndrome vary in severity and may not become apparent until the child reaches puberty, when gynaecomastia (breast enlargement) occurs and the testes remain small. Affected males are usually infertile (see infertility). They tend to be tall and thin with a female body shape and absence of body hair. Incidence of learning difficulties is higher in people with Klinefelter’s syndrome than in the general population.

**TREATMENT**

There is no cure, but hormonal treatment can induce signs of puberty (see sexual characteristics, secondary) such as the growth of facial hair, and surgery may be used to correct gynaecomastia.

**Klippel–Fiel syndrome**

A condition characterized by an abnormally short neck, due to fused cervical vertebrae. Affected people have restricted neck movement and a low hairline.

**Klippel–Trenaunay–Weber syndrome**

A rare condition, usually affecting a limb, in which massive malformation of blood vessels (including both arteries and veins) leads to overgrowth of the affected area.

**Klumpke’s paralysis**

Paralysis of the lower arm, with wasting of the small muscles in the hand, and numbness of the fingers (but not the thumb) and the inner forearm.

Klumpke’s paralysis is caused by injury to the eighth cervical and first thoracic nerves (two of the spinal nerves) in the brachial plexus (the network of nerves located behind the shoulderblade), which usually results from injury to the shoulder.

**knee**

The hinge joint between the femur (thighbone) and tibia (shin). The patella (kneecap) covers the front of the joint.

**LOCATION OF THE KNEE JOINT**

The knee is the joint between the femur and the tibia. The bones are separated by two menisci. The patella lies across the front of the knee joint.
the joint prevent overstraightening and overbending. The quadriceps muscles, at the front of the thigh, straighten the knee, and the hamstring muscles at the back of the thigh bend it.

**DISORDERS**

Injuries of the knee are common, and include ligament sprains, torn meniscus, dislocation of the patella, and fracture of any of the bones. A painful inflammatory condition, chondromalacia patellae, is common in adolescents, and knock-knee and bowleg are common temporary defects in children.

**kneecap**

See patella.

**knee-jerk reflex**

An involuntary response, also known as a patellar reflex, that occurs when the tendon just below the kneecap (patella) is tapped. The tendon stretches and the thigh muscles contract, straightening the knee. (See also reflex.)

**knee-joint replacement**

Surgery to replace a diseased knee joint with an artificial one, usually made of metal or plastic. Knee-joint replacement is most commonly carried out on older people whose knees are severely affected by the inflammatory conditions osteoarthritis or rheumatoid arthritis.

**Kniest syndrome**

A very rare inherited disorder due to abnormal collagen (a protein in bone, cartilage, and connective tissue). It causes severe dwarfism (see short stature) with curvature of the spine (kyphoscoliosis).

**knock-knee**

Inward curving of the legs so that the knees touch, causing the feet to be positioned further apart than normal.

**CAUSES**

Knock-knee is common in children between the ages of three and five and may be part of normal development. In some children, knock-knee may be caused by rickets, a disease that softens the bones. In adults, causes include osteoarthritis and rheumatoid arthritis of the knee. A leg fracture that has not healed correctly may also cause knock-knee in children or adults.

**TREATMENT**

In children, the condition usually disappears by about seven years. Knock-knee that persists, or is due to a disorder, may require osteotomy, a surgical procedure...
consequences. The advanced stages are marked by jaundice, drowsiness, and a fall in body temperature.

**TREATMENT**

Initially, the child is fed small, frequent amounts of milk, and vitamin and mineral tablets. A nutritious diet is then gradually introduced. Most treated children recover, but those under two years may have permanently stunted growth.

**kyphoscoliosis**

A combination of the two types of spinal curvature: **kyphosis** and **scoliosis**.

**kyphosis**

Excessive outward curvature of the spine. Kyphosis usually affects the spine at the top of the back, resulting in a hump or pronounced rounding of the back. When kyphosis is combined with a curvature of the spine to one side (scoliosis), it is known as kyphoscoliosis.

The condition may be caused by a variety of spine disorders, or a congenital abnormality. Treatment is of the underlying disorder, but is rarely successful.
LABIA

that is used to treat LABIA bacteria (see (high blood pressure) and, in men, tereps. Bacterial labyrinthitis or treatment with antibiotics, and then move the tears (inflammation of the membrane) and usually (ab- chest pain caused by an of the penicillin and cephalo-

An autosomal dominant genetic disorder affecting tissues throughout the body. It causes bone deformities; overly flexible joints; clubbing of the fingers, and missing nails. Other features include a bulbous nose, overgrowth of the gums, thickened ears, and an enlarged liver and spleen. Some people may also have learning disorders.

A beta-blocker drug that is used to treat hypertension (high blood pressure) and angina pectoris (chest pain caused by an impaired blood supply to the heart). Possible adverse effects include indigestion and nausea; in rare cases, the drug may cause depression and, in men, temporary impotence.

The folds of skin of the vulva that protect the vaginal and urethral openings. There are two pairs of labia. The outer pair, the labia majora, are fleshy folds that contain sweat glands and grow hair. They cover the smaller, hairless inner folds, the labia minora, which meet to form the hood of the clitoris.

A term meaning “unstable” or “likely to undergo change”.

See childbirth; induction of labour.

Painful muscle contractions in the uterus during childbirth. The contractions dilate (widen) the cervix and then move the baby through the birth canal for delivery.

The collective term for the structures of the inner ear. The first part of the labyrinth is the cochlea, which contains the mechanisms that enable hearing. Situated behind the cochlea are two sacs (the saccule and the utricle) and three fluid-filled semicircular canals, all of which are concerned with balance.

Inflammation of the labyrinth, in the inner ear. The disorder is almost always caused by bacterial or viral infection. Viral labyrinthitis may develop during illnesses such as influenza. The bacterial form is a complication of otitis media (middle-ear infection).

The main symptom of labyrinthitis is vertigo. Nausea, vomiting, nystagmus (abnormal, jerky movements of the eye), tinnitus (ringing in the ears), and hearing loss may also occur.

LOCATION OF THE LABIA

The labia majora extend forwards from the perineum and fuse at the front at the mons pubis. The labia minora lie within.

Mechanism of labyrinthitis

In labyrinthitis, inflammation of the fluid-filled chambers (labyrinth) of the inner ear causes disruption of the individual’s sense of balance. The inflammation is usually caused by viral or bacterial infection.

Viral labyrinthitis clears up on its own, but symptoms may be relieved by anti-histamine drugs. Bacterial labyrinthitis needs immediate treatment with antibiotic drugs, otherwise permanent deafness or meningitis (inflammation of the membranes covering the brain) may result.

A torn, irregular wound.

The system in the eye that produces and drains tears. The lacrimal apparatus includes the main and accessory lacrimal glands and nasolacrimal drainage duct (see lacrimal apparatus box, overleaf). The main lacrimal glands lie just within the upper and outer margin of the eye orbit and drain onto the conjunctiva (the transparent membrane covering the white of the eye and the inside of the eyelids). They secrete tears during crying and when the eye is irritated. The accessory glands lie within the conjunctiva, and maintain the normal tear film, secreting it directly onto the conjunctiva; the fluid is spread across the eye surfaces by blinking. Tears drain from the eye through the lacrimal puncta, tiny openings towards the inner ends of the upper and lower eyelids. The puncta are connected by narrow tubes to the lacrimal sacs, which lie within the lacrimal bones on the sides of the nose. Leading from the sacs are the nasolacrimal ducts, which open inside the nose.

An enzyme, also called penicillinase or beta-lactamase, that is produced by Staphylococcus bacteria (see staphylococcal infections). Lac tambase inactivates antibiotic drugs of the penicillin and cephalosporin groups, making them ineffective against the bacteria.

A condition in which there is an absence of lactase, an enzyme that breaks down lactose (milk sugar), in the cells of the small intestine. Lactase deficiency reduces ability to digest lactose. This is called lactose intolerance and usually appears in adolescence or adulthood; rarely, it is present at birth (especially in premature babies). Lactase deficiency may also occur temporarily after gastroenteritis or treatment with antibiotics, particularly in young children.
SYMPTOMS
The undigested lactose ferments in the intestines, causing symptoms such as abdominal cramps, bloating, flatulence, and diarrhoea.

DIAGNOSIS AND TREATMENT
The condition may be diagnosed by testing faeces for the presence of lactose. Alternatively, an exclusion diet may be used, in which consumption of dairy products is stopped for a few days and then resumed to see if this causes any changes in the symptoms.

Treatment is with a lactose-free diet. Some people are able to tolerate small amounts of dairy produce but others must avoid dairy products completely, including milk, yoghurt, cream, butter, and cheese. It is possible to obtain milk products in which lactose has already been broken down, and enzyme supplements containing lactase, which can be added to milk, or eaten with food.

lactobacillus
A type of rod-shaped bacteria found in fermented plant and dairy products. Some types of lactobacilli colonize the human intestine and the vagina, where they prevent the overmultiplication of harmful bacteria.

lactose
One of the sugars present in milk; a disaccharide carbohydate.

lactose intolerance
The inability to digest lactose (see lactase deficiency).

lactulose
An osmotic laxative drug that is used to treat constipation.

Lafora-body disease
A degenerative disease of the nervous system that causes epilepsy. The disease is an autosomal recessive genetic disorder that first appears in childhood or adolescence, often with seizures. Subsequent signs include impaired movement and coordination, and dementia. There is no treatment. Death usually occurs within 10 years of onset.

Lambert–Eaton syndrome
A neuromuscular disorder in which nerve cells fail to release sufficient amounts of the neurotransmitter acetylcholine. It is often associated with the type of lung cancer known as small cell carcinoma. The main symptom is profound muscle weakness in the trunk and limbs.

Lamisil
A brand name for the antifungal drug terbinafine.

lamivudine
A reverse transcriptase inhibitor drug used in the treatment of HIV infection, to slow the progression of the illness. It is always prescribed in combination with another drug for HIV, to prevent the
virus from becoming resistant to it. Often, when treatment is started, three drugs are used: two reverse transcriptase inhibitors and a third drug from another class, such as a protease inhibitor. Lamivudine may also be used to treat longstanding hepatitis B infections.

Nausea, vomiting, and diarrhoea are the most common side effects; others include a cough, headache, and pins and needles. Side effects such as fever, rash, hair loss, jaundice, or sore throat should be reported to a doctor. If severe abdominal pain develops, the person should seek urgent medical help.

**Lamotrigine**
An anticonvulsant drug used either alone or in combination with other anticonvulsants in the treatment of epilepsy. Lamotrigine can cause various minor side effects such as rash, nausea, headache, and blurred vision. Rarely, serious skin reactions may occur, particularly in children. In addition, there may be flu-like symptoms, bruising, sore throat, and facial swelling, which should be reported to a doctor promptly.

**Lancet**
To incise (cut into) using a lancet or a surgical scalpel.

**Lanolin**
A mixture of purified water and a yellow, oily substance that is obtained from sheep’s wool. Lanolin is used as an emollient in the treatment of dry skin and mild dermatitis. In occasional cases, lanolin may cause an allergic reaction.

**Lanoxin**
A brand name for the digitalis drug digoxin.

**Lansoprazole**
A drug used to treat disorders that are caused by excess stomach acid, such as peptic ulcer and acid reflux. Lansoprazole belongs to a group of drugs known as proton pump inhibitors. These drugs work by inhibiting the production of stomach acid.

Common side effects of lansoprazole include abdominal pain, constipation, diarrhoea, headache, fatigue, and dizziness. More serious side effects include muscle or joint pain, swollen hands and feet, and excessive bruising; all of these symptoms should be reported to a doctor. If a rash, itching, wheezing, or breathing difficulties develop, the affected individual should stop using the drug immediately and seek urgent medical help.

**Lanugo hair**
The fine, soft, downy hair that covers a fetus. Lanugo hair first appears in the fourth or fifth month of gestation and usually disappears by the ninth month. It can still be seen in some premature babies.

Lanugo hair sometimes reappears in adults who have cancer. It may also occur in those with the eating disorder anorexia nervosa or be a side effect of certain drugs, especially ciclosporin.

**Laparoscopy**
Examination of the interior of the abdomen using a viewing instrument called a laparoscope, which is a type of endoscope. Laparoscopy is carried out in order to investigate the possible causes of abdominal pain, such as appendicitis. The procedure is also used in gynaecology for the diagnosis of disorders and investigation of infertility. Laparoscopy is also used to perform minimally invasive surgery such as appendicectomy, cholecystectomy, and female sterilization (see sterilization, female).

**Laparotomy**
Any operation in which the abdomen is opened either for diagnostic purposes or for surgical treatment.

---

**PROCEDURE FOR LAPAROSCOPY**

A hollow needle is inserted into the abdomen just below the navel (under anaesthesia), and carbon dioxide gas is pumped through to expand the abdominal cavity. The laparoscope is inserted through another incision to view the internal organs. The gas is removed afterwards but small amounts may remain for a day or two and cause some discomfort.

---

**THE LAPAROSCOPE**

Viewing lens | Rigid tube | Eyepiece

---

**Gynaecological laparoscopy**
Laparoscopy is used in diagnosis and is also sometimes used for removing ova for in vitro fertilization. Laparoscopy is commonly used to perform female sterilization.
Largactil
A brand name for the antipsychotic and anti-emetic drug chlorpromazine.

large intestine
The last section of the gastrointestinal tract. It begins at a pouch called the caecum (from which the appendix hangs). The main part, the colon, has four sections: the ascending, transverse, descending, and sigmoid colon. The intestine ends at the rectum, which is connected to the anus.

The large intestine processes the remains of food after nutrients have been extracted. It reabsorbs water, vitamins, and mineral salts into the bloodstream, and expels the waste material as faeces.

Lariam
The brand name for the antimalarial drug mefloquine.

larva migrans
Infections that are characterized by the presence of the larval (immature) forms of certain parasitic worms in the body. Visceral larva migrans (toxocariasis) is caused by a type of worm that normally parasitizes dogs. Cutaneous larva migrans (creeping eruption) is caused by a form of hookworm infestation; the larvae penetrate the skin and move around, leaving intensely itchy red lines that are sometimes accompanied by blistering. Both types of larva migrans can be treated with anthelmintic drugs.

LOCATION OF LARYNGEAL NERVES
Both nerves leave the brain at the base of the skull and pass down the neck. One hooks around an artery behind the right clavicle, the other hooks around the aorta; both return to the larynx.

laryngeal nerve
One of a pair of nerves that carry instructions from the brain to the larynx (voicebox) and send sensations from the larynx to the brain.

laryngeal nerve palsy
Paralysis of one or both of the laryngeal nerves. Laryngeal nerve palsy may be caused by disorders that cause pressure on the nerve, such as an aneurysm (localized swelling) in the aorta or a tumour in the thyroid gland, oesophagus, or lung. The condition may also result from infections or poisoning affecting the nerves, or damage during surgery on the thyroid gland, lung, or heart. Laryngeal nerve palsy causes complete or partial vocal cord paralysis, resulting in varying degrees of voice loss.

laryngeal stridor
A form of stridor (an abnormal, high-pitched sound during breathing) that emanates from the larynx (voicebox). It may occur if the larynx is inflamed, or partially blocked by an inhaled object. The condition may also appear at birth, or soon after, when it is known as congenital stridor; the cause is thought to be abnormal softness of the cartilage in the larynx (laryngomalacia).

Congenital laryngeal stridor rarely causes serious problems and usually corrects itself as the baby grows. However, medical or surgical treatment may be needed if the condition interferes with breathing.

laryngectomy
Surgical removal of all or part of the larynx (voicebox) to treat advanced cancer (see larynx, cancer of). If the entire larynx is removed, a stoma (opening) is then made in the trachea (windpipe), through which the patient will breathe. After the operation (called a tracheotomy) normal speech is no longer possible, but many patients learn to speak using oesophageal speech. There are also electronic devices available that help to generate speech.

laryngitis
Inflammation of the larynx (voicebox) that may be acute, lasting only a few days, or chronic, persisting for a long period.
CAUSES
Acute laryngitis is usually caused by a viral infection, such as a cold. It can also be due to an allergy or straining the laryngeal muscles. Chronic laryngitis may be caused by overusing the voice; violent coughing; irritation from tobacco smoke or fumes; or damage during surgery. Alcohol, particularly spirits, may aggravate laryngitis.

SYMPTOMS
Hoarseness is the most common symptom and may progress to loss of voice. Throat pain or discomfort and a dry, irritating cough may also occur. Laryngitis due to a viral infection is often accompanied by fever and a general feeling of illness.

TREATMENT
Treatment depends on the cause. Acute laryngitis due to a viral infection usually disappears by itself. There is no treatment for chronic laryngitis other than resting the voice, taking mild analgesic drugs (painkillers) if needed, using steam inhalation, and avoiding tobacco smoke and alcohol. If hoarseness persists for more than two weeks, medical advice should be sought in order to exclude the possibility of laryngeal cancer (see larynx, cancer of). In some cases, chronic laryngitis responds to speech therapy.

laryngoscopy
Examination of the larynx (voicebox) using a mirror held against the back of the palate (indirect laryngoscopy), or a rigid or flexible viewing tube known as a laryngoscope (direct laryngoscopy).

Laryngoscopy is performed to investigate pain in the throat; difficulty in swallowing; persistent hoarseness; and abnormal noises during breathing (such as stridor). Indirect laryngoscopy can show clear abnormalities, such as inflammation, paralysis of the vocal cords (see laryngeal nerve palsy), singer’s nodes, or tumours. Direct rigid laryngoscopy is usually performed under general anaesthesia, and direct flexible laryngoscopy is usually carried out using local anaesthesia. These techniques enable doctors to examine the tissues of the larynx more closely, as well as to take a biopsy (sample of tissue) or remove foreign bodies or benign tumours.

laryngotracheobronchitis
Inflammation of the larynx (voicebox), trachea (windpipe), and bronchi (main airways to the lungs), caused by a viral or a bacterial infection. The disorder is usually mild but in some cases can be life-threatening. It is a common cause of croup in young children.

larynx
The organ in the throat responsible for voice production, commonly called the voicebox. It lies between the pharynx (throat) and the trachea (windpipe).

STRUCTURE AND FUNCTION
The larynx consists of areas of cartilage, the largest of which is the thyroid cartilage, which projects forwards to form the Adam’s apple. Below the thyroid cartilage is the cricoid cartilage, which joins it to the trachea. Situated on the back of the cricoid cartilage are two pyramid-shaped structures called the arytenoid cartilages. The inside of the larynx is lined with mucous membrane.

VISUALIZATION
Within the larynx, stretching between the thyroid and arytenoid cartilages, are two fibrous sheets of tissue called the vocal cords. The cords vibrate to produce vocal sounds when air from the lungs passes through them. These vibrations are modified by the tongue, mouth, and lips to produce speech.

Attached to the top of the thyroid cartilage is the epiglottis, which is a leaf-shaped flap of cartilage that closes

DISORDERS OF THE LARYNX

- Congenital defects
  - Rarely, a baby is born with a soft, limp larynx and epiglottis, a condition called laryngomalacia. This defect causes noisy breathing (see laryngeal stridor).

- Tumours
  - Various kinds of noncancerous tumour may develop on the vocal cords. The most common is a polyp (a noncancerous swelling caused by smoking, an infection such as influenza, or straining the voice).
  - Warts and small noncancerous growths called singer’s nodes can also occur on the vocal cords. The larynx may also develop cancerous tumours (see larynx, cancer of), which may cause persistent hoarseness.

Other disorders
Lesions, infection, or other disorders affecting the throat tissues, or surgery on the throat, may damage the nerves supplying the larynx. As a result, one or both of the vocal cords may become paralysed (see laryngeal nerve palsy).

INVESTIGATION

Disorders of the larynx are investigated by laryngoscopy. Sometimes a biopsy sample is taken.
over the larynx to prevent food and liquid from passing into the trachea during swallowing.

**larynx, cancer of**
A cancerous tumour of the larynx (voice-box). In more than half of the cases, the tumour develops on one of the vocal cords; in the remainder, tumours arise just above or below the cords.

**CAUSES**
The exact causes are not known, but smoking and high alcohol consumption are known risk factors.

**SYMPTOMS**
Hoarseness is the main symptom, particularly when the tumour originates on the vocal cords. At an advanced stage, symptoms may include difficulty in breathing and swallowing, and coughing up blood. The cancer may have spread to the lymph nodes in the neck; if so, the nodes will be enlarged.

**DIAGNOSIS AND TREATMENT**
If laryngoscopy reveals a tumour on the larynx, a biopsy (tissue sample) is taken. If the tumour is small, radiotherapy or laser treatment may be used to destroy it. For unresponsive or large tumours, partial or total laryngectomy (removal of the larynx) may be considered.

**laser**
A device that produces an intense beam of light. Lasers have many medical uses (see laser treatment).

**laser treatment**
Use of a laser beam in a variety of medical procedures. Lasers can cut through tissues, seal blood vessels, and destroy abnormal cells. They can be focused precisely so that tissues surrounding an operation site are not damaged.

**TYPES**
There are many different medical laser systems, and they can be operated in a variety of ways. Some emit light in brief bursts and are known as pulsed lasers; others emit a steady beam and are called continuous wave lasers.

One of the most commonly used devices is the carbon dioxide (CO₂) laser, which can be operated in either continuous or pulsed mode. Of all lasers, the CO₂ laser has an action most similar to that of a conventional scalpel. It is used both for internal surgery, including excision of brain tumours, and for skin treatments, such as the removal of noncancerous moles and scarring, and the reduction of wrinkles.

The argon continuous laser emits a light that is easily absorbed by the blood, causing it to clot. This laser has applications in ophthalmology (particularly in the treatment of abnormalities in the retina as a result of diabetes mellitus), surgery on the inner ear, and reduction of birthmarks such as port-wine stains. Another versatile laser is the yttrium-aluminium-garnet (YAG) system for treatments such as dentistry, hair and tattoo removal, and lithotripsy (breaking up of kidney stones). Tattoo removal and other dermatological treatments are also often carried out with a system known as the ruby laser, the light from which is strongly absorbed by the pigment melanin in hair and skin.

**LASIK**
The abbreviation for laser-assisted in-situ keratomileusis, a type of eye surgery in which a laser is used to reshape the cornea (transparent front part of the eye). LASIK is performed to correct refractive errors (see refraction) such as shortsightedness (see myopia) and astigmatism. A flap is cut partway through the cornea, some of the area beneath is removed by laser, and the flap is replaced.

**Lasix**
A brand name for the diuretic drug furosemide (frusemide).

**Lassa fever**
A serious infectious disease caused by a rodent-borne virus. Lassa fever, which is transmitted through contact with the urine, faeces, or saliva of rodents, is largely confined to West Africa. Symptoms appear after an incubation period of three to 21 days with fever, headache, muscular aches, and a sore throat. Later, severe diarrhoea and vomiting develop. In extreme cases, the condition leads to fatal heart or kidney failure. Treatment of Lassa fever is with the antiviral drug ribavirin, and serum containing antibodies to the virus.

**Lassar’s paste**
A traditional skin preparation that is used in scaling conditions such as psoriasis. Lassar’s paste contains salicylic acid and zinc oxide. Sometimes, dithranol is added to the paste.

**lassitude**
A term describing a feeling of tiredness, weakness, or exhaustion.

**USE OF A LASER**
The concentrated beam of light produced by a laser has a variety of medical uses. Among its applications are removal of skin lesions, including birthmarks and tattoos, surgery on the eye and inner ear, treatment of tumours, and dentistry. Laser devices operate at varying wavelengths and energy levels for precise control; some are used to treat specific conditions only.

**Removing skin blemishes**
These photographs, which were taken before and after laser treatment, show the removal of a port-wine stain (a type of haemangioma). In some cases, treatment is less successful, leaving scars.
laconoprost
A prostaglandin drug used as eye-drops in the treatment of the eye condition glaucoma (increased pressure of fluid within the eyeball).

lateral
Relating to, or situated on, one side. “Bilateral” means “on both sides”.

lateral cutaneous nerve entrapment
Compression of the thigh’s lateral cutaneous nerve, which supplies the skin of the front and outer areas of the thigh. The nerve passes underneath the inguinal ligament (the fibrous band of tissue that extends across the crease of the groin); if, for any reason, the ligament puts pressure on the nerve the result is a burning, tingling sensation and sometimes a condition known as meralgia paraesthetica (numbness in the thigh). In many cases, the problem is due to obesity. It may also result from overstretching of the hip joint, for example, when playing sport, or wearing constricting clothes around the hips.

There is no specific treatment. In obese people, weight loss may help to relieve the symptoms. Rarely, surgery is performed to try to reduce the pressure on the nerve.

latex fixation test
Also called the latex agglutination test, a procedure that is performed on body fluids, such as urine, blood, and saliva, in order to detect the presence of particular infections. Tiny beads of latex are coated with antibodies (proteins produced by the immune system) against a certain infectious organism and then added to a sample of body fluid. If the organism is present in the sample, it reacts with the antibodies on the beads, causing them to clump together.

latissimus dorsi
A large, flat, triangular muscle in the back. One end of the muscle is fixed to the lower chest vertebrae and the back of the pelvis, while the other end of the muscle is joined to the top of the humerus (upper arm bone). Contraction of the latissimus dorsi muscle moves the arm downwards and backwards.

laudanum
A solution of opium, formerly used as a sedative and painkiller and in the treatment of diarrhoea.

laughing gas
The popular name for nitrous oxide, used with oxygen in general anaesthesia.

Laurence–Biedl–Moon syndrome
A rare inherited disorder characterized by obesity, retinitis pigmentosa (degeneration of the retina that may lead to blindness), learning difficulties, polydactyly (extra digits), and hypogonadism (underactivity of the ovaries or testes). (See also genetic disorders.)

lavage, gastric
Washing out the stomach with water, usually to remove toxins. The person is laid on one side, with the head lower than the stomach. One end of a lubricated, flexible tube is passed down the oesophagus (gullet) into the stomach. The other end is attached to a funnel. Water is poured into the tube until the stomach is full, then the funnel end is lowered, allowing the stomach contents to drain into a bucket. The procedure is repeated until the water runs clear.

Lavage is not used if a corrosive poison has been swallowed because of the risk that the tube may perforate tissues in the oesophagus or stomach.

laxative drugs

| COMMON DRUGS |
|----------------|------------------|
| BULK-FORMING | Ispaghula + Methylcellulose + Sterculia |
| STIMULANT | Bisacodyl + Co-danthramer |
| | Co-danthrusate, Docusate sodium + Senna |
| | Sodium picosulfate |
| LUBRICANT | Docusate sodium |
| | Liquid paraffin |
| OSMOTIC | Lactulose + Magnesium citrate |
| | Magnesium hydroxide + Magnesium sulphate + Sodium acid phosphate |

A group of drugs used to treat constipation by making faeces pass through the intestines more quickly and easily. Laxatives are also given to people with haemorrhoids (piles), to prevent straining during defecation. In addition, they may be used to clear the intestine before investigative procedures such as colonoscopy or barium enema, or before abdominal surgery.

TYPES
There are various types of laxative, all of which work on the large intestine, either by increasing the speed with which faeces pass through the bowel, or by increasing their bulk and/or water content. Bulk-forming laxatives are not absorbed as they pass through the digestive tract. They contain particles that absorb many times their own volume of water, thereby increasing the volume and softness of the faeces and making them easier to pass. Stimulant laxatives prompt the intestinal wall to contract more strongly and speed up the elimination of faeces. Lubricant laxatives soften and facilitate the passage of faeces. Osmotic laxatives cause water to be retained in the intestine, thus increasing the softness and volume of the faeces.

POSSIBLE ADVERSE EFFECTS
If they are used in excess, laxative drugs may cause abdominal cramps, diarrhoea, flatulence, and disturbances in body chemistry. Lubricants may prevent the fat-soluble vitamins (A, D, E, and K) from being absorbed in the intestine. Prolonged use of stimulant laxatives may lead to dependence on them for normal bowel function. For these reasons, laxatives should be used only if absolutely necessary, and for as little time as possible. When taken to relieve constipation, their use should be discontinued as soon as normal bowel movements have resumed. If constipation lasts for more than a week, a doctor should be consulted.

lazy eye
A term for the visual defect that commonly results from squint (see amblyopia).

LDL
See low density lipoprotein.

lead poisoning
Damage to the brain, nerves, red blood cells, and digestive system caused by inhaling lead fumes or swallowing lead salts. Acute poisoning, which occurs when a large amount of lead is taken into the body over a short period of time, is sometimes fatal but is rare. Chronic poisoning can be caused by exhaust fumes from vehicles running on leaded petrol, or by old paint or water pipes containing lead.

SYMPTOMS AND SIGNS
Symptoms of acute poisoning include severe, colicky abdominal pain, diarrhoea, and vomiting. There may also be anaemia, appetite loss, and, in chronic lead poisoning, a blue, grey, or black line along the gum margins.

Chronic poisoning can have especially severe effects on children: it can damage the brain and nervous system, leading to behavioural and learning...
difficulties, and cause kidney problems and hearing difficulties. In adults, it can harm the kidneys, and the nervous and digestive systems.

**DIAGNOSIS AND TREATMENT**

Lead poisoning may be confirmed by blood and urine tests. *Chelating agents*, such as *penicillamine*, may be prescribed; they bind to the lead and enable the body to excrete it at a faster rate.

**Learning**

The process by which knowledge or abilities are acquired, or by which behaviour is modified.

Various theories about learning have been proposed. Behavioural theories emphasize the role of *conditioning*, and cognitive theories are based on the concept that learning occurs through the building of abstract “cognitive” models, using mental capacities such as insight, memory, intelligence, and understanding. No one theory, however, can account for the complexities of learning.

**Learning difficulties**

Problems with *learning*, which result from a range of mental and physical problems. Possible causes include deafness, speech disorders, and disorders of vision, as well as genetic and chromosomal problems. Learning difficulties may be either general or specific.

In general learning difficulties, all aspects of mental and physical functioning may be affected. Depending on the severity of the problem, a child with general learning difficulties may need to be educated in a special school.

Specific learning difficulties include dyslexia (difficulty in reading and/or writing), dyscalculia (inability to solve mathematical problems), and dysgraphia (a writing disorder). An affected child has problems in a particular area of learning but has normal intelligence. Treatment includes correction of any physical problems that interfere with learning, such as vision or hearing problems, and specialized teaching.

**Learning disability**

A learning difficulty.

**Leber’s hereditary optic atrophy**

See *optic atrophy*.

**Lecithin**

A *phospholipid* (fatty substance) that is an important component of cell membranes. Lecithin is found in foods such as egg yolk, offal, and whole grains, and can be extracted from soya to be used as an emulsifier in processed foods. (See also *nutrition*.)

**Leech**

A type of bloodsucking worm with a flattened body and a sucker at each end. Leeches of various types mainly inhabit tropical forests and waters. They bite painlessly, introducing their saliva into the wound before sucking blood. Leech saliva contains an anticoagulant substance called hirudin, which may cause the wound to bleed for hours.

Leeches are sometimes used in medicine (to drain a haematoma from the outer ear following injury, for example). The bites are painless, but the saliva contains an anticoagulant agent, and the wound may bleed for several hours.

**Leg, shortening of**

Shortening of the leg is usually caused by faulty healing of a fractured femur (thigh-bone) or tibia (shin). Other causes are an abnormality present from birth, surgery on the leg, or muscle weakness associated with *poliomyelitis* or another neurological disorder.

**Legs, restless**

See *restless legs*.

**Leg ulcer**

An open sore on the leg that is slow to heal, usually resulting from poor blood circulation in the area.

**Types**

There are two main types of leg ulcer: venous (also called gravitational or stasis) and arterial. Venous ulcers are by far

---

*Legionnaires’ disease*  
A form of pneumonia that is caused by *Legionella pneumophila*, a bacterium that breeds in warm, moist conditions and stagnant water. Legionnaires’ disease can occur in outbreaks. The source of infection is often an air-conditioning system in a large public building; the disease is contracted by the inhalation of droplets of contaminated water.

The first symptoms include headache, muscular and abdominal pain, diarrhoea, and a dry cough. Over the next few days, pneumonia develops, resulting in high fever, shaking chills, coughing up of thick sputum (phlegm), drowsiness, and sometimes delirium. Liver and kidney damage may occur.

Treatment is with antibiotic drugs such as clarithromycin and rifampicin. The majority of people recover but mortality rates are higher among the elderly.

---

**Venous ulcer on the leg**

This type of ulcer, also known as a stasis ulcer, is caused by impaired drainage of blood from the leg by the veins. It is usually accompanied by oedema (fluid accumulation) in the lower leg.
the most common and occur mainly near the ankles and on the lower legs. They are caused by valve failure in veins and usually appear in conjunction with varicose veins.

Arterial ulcers, which form on the foot, are caused by poor blood flow through arteries. These ulcers are most likely to occur in people with diabetes mellitus and sickle cell anaemia.

**TREATMENT**

Treatment depends on the cause of the ulcer. The affected area should be bandaged in order to prevent infection, reduce swelling, and improve the circulation. If an ulcer is exuding pus, a dressing is applied under bandages and changed every few days. Measures such as exercising regularly, wearing support stockings, and keeping the leg raised when sitting may also help to improve circulation. A leg ulcer may take several months to heal, however, and the problem often recurs. In rare cases, a skin graft is necessary.

**leiomyoma**

A noncancerous tumour of smooth muscle. Leiomyomas, also called fibroids, usually occur in the uterus. More rarely, they develop in the walls of blood vessels in the skin, forming tender lumps. Leiomyomas may require surgical removal if they cause symptoms.

**leiomyosarcoma**

Also known as LMS, leiomyosarcoma is a cancerous tumour of the smooth muscle. Leiomyosarcomas most commonly occur in the stomach, small intestine, bladder, uterus, and prostate and are among the most common types of sarcoma (connective tissue cancer) of soft tissue. Leiomyosarcomas mainly affect adults; they are rare in children.

Treatment of a leiomyosarcoma is with surgery, to remove the tumour and surrounding tissue, and chemotherapy and/or radiotherapy if the tumour cannot be removed completely.

**leishmaniasis**

Any of a variety of diseases caused by single-celled parasites called leishmania. These parasites are harboured by dogs and rodents and are transmitted by the bites of sandflies.

**TYPES**

The most serious form of leishmaniasis is called kala-azar or visceral leishmansion. This disease is prevalent in some parts of Asia, Africa, and South America, and also occurs in some Mediterranean countries. In addition, there are several types of cutaneous leishmaniasis, some of which are prevalent in the Middle East, North Africa, and the Mediterranean.

**SYMPTOMS**

Kala-azar causes persistent fever, enlargement of the spleen, anaemia, and, later, darkening of the skin. The illness may develop any time up to two years after infection, and, if untreated, may be fatal. The cutaneous forms of the disease have the appearance of a persistent ulcer at the site of the sandfly bite.

**TREATMENT**

All varieties of leishmaniasis can be treated with drugs, such as sodium stibogluconate, given by intramuscular or intravenous injection.

People visiting areas in which leishmaniasis occurs should take measures to minimize the risk of sandfly bites.

---

**LOCATION OF THE LENS**

This elastic, transparent structure lies behind the iris and is suspended on delicate fibres from the ciliary body. Its full name, the crystalline lens, differentiates it from the cornea (which also acts as a lens).

**lens dislocation**

Displacement of the crystalline lens from its normal position in the eye. Lens dislocation is almost always due to an injury that ruptures the fibres connecting the lens to the ciliary body. In people with the genetic disorder Marfan syndrome, these fibres are particularly weak; lens dislocation is common in such individuals.

A dislocated lens may produce severe visual distortion or double vision. If it slips forwards, it may cause a form of glaucoma (increased pressure within the eyeball) if drainage of fluid from the front of the eye is affected. If glaucoma is severe, the lens may need to be removed. (See also aphakia.)

**lens implant**

A plastic prosthesis (artificial substitute) used to replace the removed opaque lens in cataract surgery.

**lentigo**

A flat, brown area of skin that is also known as an age spot or liver spot. Lentigines (the plural of lentigo) are similar to freckles, except that they occur on both covered and exposed areas of skin and do not fade in winter. They are usually harmless and need no treatment. Any raised, darker brown areas within a lentigo need to be investigated, however, because they could develop into malignant melanomas (see melanoma, malignant).
leprosy
See: Hansen’s disease.

leptin
A protein that has a role in the regulation of fat storage by the body.

leptospirosis
A rare disease that is caused by a type of *spirochaeta* bacterium harboured by rodents and excreted in their urine. It is usually transmitted to humans by contact with contaminated water or soil.

Symptoms of leptospirosis develop one to three weeks after infection. They include fever, chills, intense headache, severe muscle aches, and a skin rash. If the disease is left untreated, the nervous system may also be affected, often producing signs of meningitis (inflammation of the membranes covering the brain). The most severe form of leptospirosis is known as Weil’s disease; it causes widespread internal bleeding, as well as kidney and liver damage. Antibiotic drugs are effective but the recovery of kidney and liver function may be slow.

lesion
An all-encompassing term for any abnormality of structure or function in any part of the body. The term may refer to a wound, infection, tumour, abscess, or chemical abnormality.

lethargy
A feeling of tiredness, drowsiness, or lack of energy.

leucocyte
An alternative spelling for leukocyte, a type of blood cell.

leukaemia
Any of several types of cancer in which there is a disorganized proliferation of abnormal white blood cells in the bone marrow. This increase in white cells interferes with production of normal blood cells in the marrow. A reduced number of red blood cells leads to anaemia, while a reduction in normal white cells increases the body’s susceptibility to infection. Inadequate numbers of platelets may cause abnormal bleeding (see thrombocytopenia). Also, organs such as the liver, spleen, lymph nodes, or brain may cease to function properly if they become infiltrated by abnormal cells.

Leukaemias are classified as acute or chronic (acute types generally develop faster than chronic). They are also classified according to the type of white cell that is proliferating abnormally. If the abnormal cells are lymphocytes or lymphoblasts (precursors of lymphocytes), the leukaemia is called lymphocytic or lymphoblastic leukaemia. If the abnormal cells are derived from other types of white cell or their precursors, the disease is called myeloid, myeloblastic, or granulocytic leukaemia. (See also leukaemia, acute; leukaemia, chronic lymphocytic; leukaemia, chronic myeloid.)

leukaemia, acute
A type of leukaemia in which excessive numbers of immature white blood cells called blasts are produced in the bone marrow. If left untreated, acute leukaemia can cause death within a few weeks or months.

**TYPES**
The abnormal cells may be of two main types: lymphoblasts (immature lymphocytes) in acute lymphoblastic leukaemia, or ALL, and myeloblasts (immature forms of other types of white blood cell) in acute myeloblastic leukaemia, or AML.

**CAUSES**
In most cases, the cause of acute leukaemia is unknown. However, exposure to certain chemicals (such as benzene) or high levels of radiation may be a risk factor. Previous treatments for cancer may also increase the risk of leukaemia developing. Inherited factors are thought to play a part; there is increased incidence in individuals who have certain genetic disorders (such as Fanconi’s anaemia) and chromosomal abnormalities (such as Down’s syndrome). In addition, people who have blood disorders such as aplastic anaemia (see anaemia, aplastic) or primary polycythaemia are at increased risk because their bone marrow is already abnormal.

**SYMPTOMS AND SIGNS**
The symptoms and signs of acute leukaemia are due to the abnormal white cells crowding the bone marrow and infiltrating the bloodstream and body tissues (see Leukaemia box, opposite). They include bleeding gums, headache, easy bruising, bone pain, enlarged lymph nodes, and symptoms of anaemia, such as tiredness, pallor, and breathlessness on exertion. There may also be repeated chest or throat infections.

**DIAGNOSIS AND TREATMENT**
Blood tests (and, in some cases, tests on the cerebrospinal fluid, which surrounds the brain and spinal cord) may reveal the presence of abnormal white cells, but diagnosis is confirmed by a bone marrow biopsy.

Treatment is divided into two phases: remission induction to control the disease, and consolidation, which prevents the disease from recurring. Procedures include transfusions of blood and platelets; the use of anticancer drugs to kill abnormal cells in the bone marrow; and possibly radiotherapy to destroy any abnormal cells in the brain. A bone marrow transplant or stem cell transplant may also be required.

**OUTLOOK**
Chemotherapy has increased success rates, but the outlook depends on the type of leukaemia and the age of the patient. People with ALL generally respond better to treatment than those with AML, and many children with ALL can now make a full recovery. Treatment of AML is less likely to be successful in people over the age of fifty.

leukaemia, chronic lymphocytic
A type of leukaemia caused by a proliferation of mature lymphocytes (white blood cells that are normally involved in fighting infection and harmful cells). There is no cure for the disease, but it is not always fatal. The cause is unknown.

**SYMPTOMS**
Symptoms develop slowly, often over many years. There may be enlargement of the liver, spleen, and lymph nodes, persistent raised temperature, and night sweats. Recurrent infections and anaemia also are common.

**DIAGNOSIS AND TREATMENT**
Diagnosis is by blood tests and a bone marrow biopsy. In many mild cases, treatment is not needed. If symptoms become troublesome, drug treatment is started, often with chlorambucil.

leukaemia, chronic myeloid
Also known as chronic granulocytic leukaemia, a type of leukaemia caused by overproduction of granulocytes (a type of white blood cell) or, in particular, neutrophils (a type of granulocyte). The cause of the condition is unknown but almost all affected people have a chromosomal abnormality called the Philadelphia chromosome, in which part of one chromosome is attached to another.

Chronic myeloid leukaemia usually has two phases: a chronic phase, which may last for several years, and an accelerated, or acute, phase that may last for several months.
SYMPTOMS

During the chronic phase, symptoms are not always obvious, although they may include fever, night sweats, and weight loss. High numbers of white cells may cause the blood to become very thick and unable to flow through the smallest vessels, leaving tissues starved of oxygen. The results include visual disturbances, as blood vessels in the eye are affected, and abdominal pain due to the death of tissues in the spleen; priapism (persistent, painful erection of the penis) may also occur.

The symptoms of the accelerated phase are like those of acute leukaemia (see leukaemia, acute).

DIAGNOSIS AND TREATMENT

The diagnosis is made from blood tests and a bone marrow biopsy. Treatment of the chronic phase includes anticancer drugs or alpha interferons. A bone marrow transplant is also possible if a suitable donor can be found. When the disease transforms into the acute phase, the treatment is similar to that given for acute leukaemia.

leukocyte

Any type of white blood cell.

leukodystrophies

A rare group of inherited childhood diseases in which the myelin sheaths in which the myelin sheaths form a protective covering around many nerves, particularly in the brain and the spinal cord, are destroyed. The leukodystrophies cause severely disabling conditions, such as impaired speech, blindness, deafness, and paralysis, and are always fatal.
**Leukoplakia**

Raised white patches on the mucous membranes of the mouth or vulva due to tissue thickening. It is most common in elderly people and in those with AIDS.

**Causes**

Leukoplakia in the mouth, which most commonly occurs on the tongue, is usually due to smoking or to rubbing by a rough tooth or denture. It is not known what causes the condition to develop on the vulva.

**Symptoms and Treatment**

The raised patches are usually harmless and painless, but they occasionally result in a cancerous change in the affected tissue. For this reason, leukoplakia should always be reported to a doctor.

If the condition persists, the patches are removed under either general or local anaesthesia and the tissue is examined microscopically for any signs of malignant change. (See also mouth cancer; vulva, cancer of.)

**Leukorrhoea**

See vaginal discharge.

**Leukotriene Receptor Antagonists**

A group of antiallergy drugs that are used to prevent the symptoms of mild to moderate asthma. Leukotriene receptor antagonists, which include montelukast and zafirlukast, work by blocking the effects of leukotrienes (naturally occurring substances that are released in the lungs during an allergic reaction).

Leukotriene receptor antagonists are not bronchodilator drugs and will not relieve an existing asthma attack. Instead, they are usually used with bronchodilators and inhaled corticosteroids to reduce the frequency of attacks.

Side effects of the drugs can include gastrointestinal disturbances and headache. In addition, hypersensitivity and skin reactions may occur.

**Levamisole**

An anthelmintic drug given by mouth in a single dose to eliminate roundworm infestation. Side effects are rare but can include mild nausea or vomiting.

**Levodopa**

A drug used to treat Parkinson’s disease. Levodopa is usually combined with carbidopa or benserazide, substances that enhance levodopa’s effects and help to reduce its side effects, including nausea, vomiting, nervousness, and agitation.

**Levonorgestrel**

A progestagen drug used in some oral contraceptives and, in combination with an oestrogen drug, in hormone replacement therapy (HRT). Norgestrel is a related drug with a similar action.

**Levothyroxine**

A synthetic version of the thyroid hormone thyroxine, which is used to treat hypothyroidism (underactivity of the thyroid gland). Side effects, such as rapid heartbeat and tremor, may occur if the initial dose is too high.

**Lewy-Body Dementia**

A form of dementia in which spherical structures called Lewy bodies develop in the brain. There may be fluctuating episodes of confusion and visual hallucinations. Falls are also common.

**Leyden–Mobius Muscular Dystrophy**

A form of muscular dystrophy, also called limb-girdle muscular dystrophy, that affects the areas where the limbs join the body. Leyden–Mobius muscular dystrophy can occur in either sex, and it usually appears in childhood. It causes muscle weakness and wasting in the pelvic girdle (pelvefemoral muscular dystrophy) or the shoulder girdle (scapulohumeral muscular dystrophy).

**LH**

The abbreviation for luteinizing hormone.

**LH-RH**

The abbreviation for luteinizing hormone-releasing hormone.

**Libido**

Sexual desire. Loss of libido may be a symptom of many physical illnesses; psychological difficulties such as and depression; drug abuse; and alcohol abuse. (See also sexual desire, inhibited.)

**Lice**

Small, wingless insects that feed on human blood. There are three species that infest humans: Pediculus humanus capitis (the head louse), Pediculus humanus corporis (the body louse), and Phthirius pubis (the crab, or pubic, louse). All have flattened bodies and may measure up to 3 mm across.

**Head Lice**

Head lice live on the scalp and are spread by direct contact. (The lice prefer clean hair, and their spread is not due to poor hygiene.) Their tiny eggs (nits) are attached to hairs close to the scalp. The bites from head lice cause intense itching.

**Body Lice**

Body lice live and lay eggs on clothing next to the skin. They can transmit epidemic typhus and relapsing fever.

**Crab Lice**

Crab lice live in pubic hair or, more rarely, in armpits, beards, or eyelashes; they are usually transmitted during sexual contact (see pubic lice).

**Treatment**

Various preparations can be applied to kill lice and their eggs. In addition, lice on clothes, bedding, and items such as hairbrushes can be killed by washing the items in very hot water.

**Lichenification**

Thickening and hardening of areas of the skin caused by repeated scratching, often to relieve the intense itching of skin disorders such as atopic eczema or lichen simplex.

**Lichen Planus**

A common skin disease of unknown cause that usually affects middle-aged people. Small, shiny, intensely itchy, pink or purple raised spots appear on the skin of the inner wrists, forearms, or lower legs. There is often a lacy network of white spots covering the inside lining of the cheeks. The disease is treated with topical corticosteroid drugs.

**Lichen Sclerosus et Atrophicus**

A chronic skin condition of the anogenital area. The skin is scarred and white, and the anatomy of areas such as the vaginal opening or foreskin may become distorted. Treatment is with potent topical corticosteroid drugs.

**Lichen Simplex**

Patches of thickened, itchy, and sometimes discoloured, skin that result from repeated scratching. Typical sites are the neck, wrist, elbow area, and ankles. Lichen simplex is most common in women and is often stress-related. Treatment is with oral antihistamine drugs and creams containing corticosteroid drugs, and may also involve addressing any underlying stress or anxiety.

**Lid Lag**

A momentary delay in the normal downward movement of the upper eyelids that occurs when the eye looks
down. Lid lag is a characteristic feature of thyrotoxicosis (overactivity of the thyroid gland), and usually occurs in conjunction with exophthalmos (protrusion of the eyeball).

**lidocaine**
A local anaesthetic (see anaesthesia, local) that is used to numb tissues prior to minor surgical procedures. Lidocaine is also used as a nerve block. The drug is commonly given by injection, but it may also be applied to the surface of the skin as an anaesthetic cream; to mucous membranes as a spray or gel; or to the eyes as eye-drops.

In addition, lidocaine may be given by intravenous injection after a myocardial infarction (heart attack), to suppress ventricular tachycardia and reduce the risk of ventricular fibrillation (both of which are life-threatening abnormalities in the heart rhythm).

**lie**
In pregnancy, the position of the fetus relative to the mother’s body. Normally, by the end of pregnancy, the long (head to tailbone) axis of the fetus is parallel to that of the mother. If the fetus is lying at an angle to the mother’s body, or is horizontal (transverse lie), this may cause malpresentation in labour: the fetus’s shoulder or body, rather than the head, is positioned over the cervix and delivery by caesarean section is needed.

**life cycle**
The series of stages through which an organism passes as it begins its life, reaches maturity, reproduces, and eventually dies. The term is most often used in the context of animals that assume various forms at different stages of life, such as insects and worms.

**life expectancy**
The number of years for which an individual at a specified age can expect to live. Life expectancy is often measured from birth. Assuming that patterns of health and illness in a community do not change, it is possible to estimate life expectancy. The proportion of a population that reaches its natural lifespan (the number of years for which people live in the absence of disease) depends on the general health of the population; for this reason, life expectancy may be used to compare levels of general health within or between countries.

**life support**
The process of keeping a person alive by artificially inflating the lungs (see ventilation) and, if necessary, maintaining the heartbeat.

**ligament**
A band of tough, fibrous, partly elastic tissue that connects or supports certain body structures. Ligaments are most commonly found in joints; they bind the ends of the bones together and prevent excessive movement. Some ligaments are also involved in supporting various internal organs, such as the uterus, bladder, and liver.

Ligaments, especially those in the ankle or knee joints may sometimes be damaged by injury. Minor ligament injuries such as sprains are treated with ice, bandaging, and sometimes physiotherapy. If a ligament has been torn (ruptured), the joint is either immobilized by a plaster cast, which allows healing to occur, or is repaired surgically.

**ligation**
The surgical process of tying off a duct or a blood vessel with a ligature (a piece of thread or similar material). Ligation is carried out to stop bleeding from blood vessels, or to close a duct or other tubal body structure. The term is used in tubal ligation, a form of sterilization in which the fallopian tubes are tied off (see sterilization, female).

**ligature**
A length of thread or other material used for ligation.

**lightening**
A feeling that is experienced by many pregnant women at the time when the baby’s head descends into the pelvic cavity. Lightening usually occurs in the final three weeks of pregnancy, and, because it leaves more space in the upper abdomen, it relieves pressure under the diaphragm.

**lightheadedness**
A general term for unsteadiness and a feeling of faintness. (See also dizziness; fainting.)

**light reflex**
A form of inborn reflex in which the pupil of the eye automatically responds to the amount of light falling on the eye. Normally, the pupil constricts in response to bright light, to restrict the amount of light entering the eye, and dilates (widens) in response to dim light. Abnormal light reflex can be a sign of disease in the eye or brain.

**light treatment**
See phototherapy.

**lignocaine**
The former name for lidocaine.

**limb, artificial**
An artificial leg or arm, known medically as a prosthesis, which is fitted to replace a limb that has been missing from birth (see limb defects) or lost as a result of amputation.

Prosthetic limbs enable the wearer to carry out many normal activities, such as walking. In addition, some prosthetic arms and hands contain electronic circuitry that detects and responds to impulses from the wearer’s nervous system. This enables the wearer to perform complex hand and finger actions, such as gripping objects.
limb defects
The incomplete development of one or more limbs at birth. Limb defects are rare and may be inherited or form part of a syndrome.

In a condition called phocomelia, hands, feet, or tiny finger- or toe-buds are attached to limb stumps or grow directly from the trunk. The sedative drug thalidomide, when taken by pregnant women, is known to have caused phocomelia in fetuses.

limbic system
A ring-shaped area in the centre of the brain consisting of a number of connected clusters of nerve cells. The limbic system plays a role in influencing the autonomic nervous system, which automatically regulates body functions; the emotions; and the sense of smell. The system is extensive, and contains various different substructures including the hippocampus, the cingulate gyrus, and the amygdala.

limb, phantom
See phantom limb.

limited cutaneous systemic sclerosis
See systemic sclerosis.

limp
An abnormal pattern of walking in which the movements of one leg (or of the hip on one side of the body) are different from those of the other. If a child is limping, a doctor should be consulted within 24 hours, because the problem may result from a hip disorder that requires prompt treatment.

linctus
A bland, usually sweetened mixture taken to soothe irritation caused by an inflamed throat. A simple linctus contains no active drug, but linctuses are commonly used as a basis for cough suppressants (see cough remedies).

lindane
A drug formerly used to treat infestations by scabies and some types of lice. Lindane has now been replaced by other, less toxic drugs.

linea alba
A vertical line of fibrous tissue running down the middle of the abdominal wall. The linea alba is the site of attachment of the rectus abdominis muscles and extends from the xiphoid process (the lowest part of the breastbone) to the pubic symphysis (the joint between the two pubic bones). The skin over the linea alba becomes pigmented during pregnancy (see linea nigra).

linea nigra
A pigmented, vertical line that appears down the front of the abdomen during pregnancy. The linea nigra is a visible form of the linea alba and often fades again after childbirth.

linear accelerator
A device for accelerating subatomic particles, such as electrons, to a speed approaching that of light so that they have extremely high energies. A linear accelerator can also be used to generate high-energy X-rays. High-energy electrons or X-rays are used in radiotherapy to treat certain cancers.

lingual
A term meaning “of the tongue”, as in “sublingual drug” (a drug that is administered under the tongue).

liniment
A liquid that is rubbed on the skin to relieve aching muscles and stiff joints. Liniments may contain rubefacients (substances that increase blood flow beneath the skin), or certain drugs, such as nonsteroidal anti-inflammatory drugs.

linkage analysis
A type of gene mapping. Linkage analysis determines the presence or absence of an abnormal gene by detecting another gene located close to it on the same chromosome.

linkage, sex
The association of a particular genetic disorder with the sex chromosomes (see sex-linked inheritance).

linoleic acid
An essential fatty acid found principally in plant seed oils, such as maize oil and soya bean oil. Linoleic acid is used by the body in the synthesis of prostaglandins and cell membranes. Linoleic acid has to be obtained from the diet because the body cannot manufacture its own supplies.

linolenic acid
An essential fatty acid, found in fish oils and some plant seed oils, that is used by the body to form prostaglandins; linolenic acid can be synthesized by the body from linoleic acid obtained in the diet.

lint
A soft, absorbent fabric used in surgical dressings.

liothyronine
A thyroid hormone used as replacement therapy in hypothyroidism (underactivity of the thyroid gland). Liothyronine acts faster than levothyroxine and is cleared from the body more rapidly.

lip
One of two fleshy folds around the entrance to the mouth. The main substructure of the lips is a ring of muscle that helps to produce speech. Smaller muscles at the corners of the lips are responsible for facial expression.

Disorders of the lips include chapped skin, chelitis (inflammation, cracking, and dryness), cold sores, and lip cancer.

lipaemia
An abnormally high level of fat in the blood. (See also hyperlipidaemias.)

lip cancer
A malignant tumour (usually a squamous cell carcinoma), commonly on the lower lip. Lip cancer is largely confined to older people, particularly those who have been exposed to a lot of sunlight and those who have smoked cigarettes or a pipe for many years.

The first symptom is a white patch that develops on the lip and soon becomes scaly and cracked with a yellow crust. The affected area grows and eventually becomes ulcerated. In some cases, the cancer spreads to the lymph nodes in the jaw and neck.

Lip cancer is diagnosed by biopsy (taking a sample of the lip tissue for microscopic examination). Treatment is surgical removal, radiotherapy, or a combination of both.

lipectomy, suction
A type of body contour surgery, commonly known as liposuction, in which excess fat is sucked out through small skin incisions, using a cannula (thin tube) attached to a vacuum device.

lipid disorders
Metabolic disorders that result in abnormal amounts of lipids (fats) in the body. The most common lipid disorders are the hyperlipidaemias, which are charac-
terized by high levels of lipids in the blood. Hyperlipidaemia can cause atherosclerosis (narrowing of the arteries by deposits of fatty material) and pancreatitis (inflammation of the pancreas). There are also some very rare lipid disorders, such as Tay–Sachs disease, that are due solely to heredity.

**lipid-lowering diet**

A diet containing low levels of cholesterol and of saturated fats (which are found in meat and whole-milk dairy products). By lowering the blood levels of lipids, such diets help to prevent atherosclerosis (the accumulation of fatty deposits on the walls of arteries).

**lipid-lowering drugs**

**COMMON DRUGS**

- FIBRATES • Bezafibrate • Ciprofibrate
  • Fenofibrate • Gemfibrozil
- STATINS • Atorvastatin • Fluvastatin
  • Pravastatin • Simvastatin
- NICOTINIC ACID AND DERIVATIVES • Acipimox
  • Nicotinic acid
- DRUGS THAT BIND TO BILE SALTS • Colestipol
  • Colesteryamine
- OTHER DRUGS ACTING ON THE LIVER • Omega-3
  marine triglycerides
- OTHER DRUGS • Ispaghula

A group of drugs that are used to treat, or provide protection against, hyperlipidaemia (abnormally high levels of the fatty substances cholesterol and triglycerides in the blood). These drugs help to prevent, or slow the progression of, severe atherosclerosis (narrowing of the arteries due to deposits of fatty material) and coronary artery disease.

**HOW THEY WORK**

Most groups of lipid-lowering drugs act on the liver to inhibit the processes by which fatty acids are converted into lipids. Statins cause the liver to produce less cholesterol, while fibrates and nicotinic acid reduce the formation of both cholesterol and triglycerides. Omega-3 marine triglycerides reduce the levels of triglycerides.

Drugs that bind to bile salts reduce the absorption of these salts (which contain high levels of cholesterol) from the small intestine into the bloodstream. The lowered blood levels of bile salts stimulate the liver into converting more cholesterol into bile salts.

**POSSIBLE ADVERSE EFFECTS**

Drugs that bind to bile salts may cause constipation, and sometimes nausea and diarrhoea, as a result of the increased amount of bile in the digestive tract. They may also reduce the absorption of fat-soluble vitamins.

Fibrates may cause an increased susceptibility to gallstones, while statins need to be used with care in people who have a history of liver disease. Rarely, combinations of drugs that act on the liver may cause a painful muscle condition called rhabdomyolysis.

**lipidosis**

Any disorder involving the metabolism (chemical transformation) of lipids in body cells. An example of a lipidosis is Gaucher’s disease, which causes a build-up of fatty deposits in the liver, spleen, bone marrow, and sometimes the brain.

**lipids**

A general term for fats and oils. Lipids include triglycerides (simple fats), phospholipids (important constituents of cell membranes and nerve tissue), and sterols, such as cholesterol.

**lipodystrophy**

A type of disorder in which the metabolism (chemical transformation) of fat in the body is disturbed, leading to abnormalities in body fat distribution.

**lipoprotein**

A small particle that is made up of a fatty core surrounded by a water-soluble form of fat (known chemically as a phospholipid) and a protein (apoprotein). Lipoproteins are the form in which fats are transported in the bloodstream.

**liposarcoma**

A rare cancer of fatty tissue that most commonly develops during late middle age. Liposarcomas produce firm swellings, usually in the abdomen or the thigh. The tumours can generally be removed by surgery but tend to recur.

**Lipostat**

The brand name for the lipid-lowering drug pravastatin.

**liposuction**

The popular term for suction lipectomy (see lipectomy, suction).

**lip-reading**

A way of understanding speech by interpreting movements of the mouth and tongue. Lip-reading is often used by people who are deaf.

**liquid paraffin**

A lubricant laxative drug obtained from petroleum. It can cause anal irritation, and prolonged use may impair the absorption of vitamins from the intestine into the blood. It has largely been superseded by docusate sodium.

**liquor**

A medical term for a liquid, particularly a water-based solution, that contains a medicinal substance. The term is also used to describe body fluids, such as amniotic fluid.

**liquorice**

The dried root of the liquorice plant (Glycyrrhiza glabra) used as a sweetener; a liquorice derivative is used to treat peptic ulcers; and it is used as an expectorant (a medication that encourages coughing up of sputum from the airways).

**lisinopril**

An ACE inhibitor drug commonly used to treat hypertension (high blood pressure) and heart failure. The first dose of lisinopril may cause a rapid fall in blood pressure,
especially in someone who is also taking a diuretic; a person should lie down for a couple of hours after taking it. The drug may also produce various minor side effects, such as a persistent dry cough or a disturbance in taste sensation.

**lisp**
A common speech disorder caused by protrusion of the tongue between the teeth so that the “s” sound is replaced by “th”. In most cases, there is no physical cause, but sometimes it is due to a cleft palate (see cleft lip and palate).

Unless there is an underlying cause, lisp usually disappears by the age of about four. If it persists beyond this time, speech therapy may be needed.

**listeriosis**
An infection that is common in animals and also affects humans.

**CAUSE**
Listeriosis is caused by the bacterium Listeria monocytogenes, which is widespread in the environment, especially in soil. Possible sources of human infection with listeriosis include soft cheese, ready-prepared coleslaw and salads, and improperly cooked meat.

**SYMPTOMS**
In most otherwise healthy adults, the only symptoms may be fever, aching muscles, diarrhoea, and abdominal pain. However, in elderly people, those with reduced immunity, and newborn babies, listeriosis can be life-threatening. Pneumonia, septicaemia (blood poisoning), and meningitis (inflammation of the membranes covering the brain) may develop. In pregnant women, infection may cause a miscarriage or stillbirth.

**DIAGNOSIS AND TREATMENT**
The condition is diagnosed by blood tests and analysis of other body fluids, such as cerebrospinal fluid. Treatment is with antibiotic drugs such as ampicillin and gentamicin.

**lithium**
A mood-stabilizing drug used in the long-term treatment of mania and manic-depressive illness, and to help prevent recurrence of severe depression. Side effects include nausea, vomiting, tremor, and excessive thirst. The dosage must be monitored by regular blood tests to prevent serious adverse effects. High levels of lithium may cause blurred vision, drowsiness, rash, and possibly hypothyroidism and kidney damage. Side effects should be reported promptly to a doctor.

**lithotripsy**
The use of highly concentrated shock waves or ultrasonic waves to break up calculi (stones) inside the kidneys, upper ureters, and gallbladder so that they can be comfortably excreted.

The most common type is extracorporeal shock-wave lithotripsy (ESWL), which is performed to break up small stones. ESWL uses a machine called a lithotripter, which produces shock waves that are transmitted into the body through a water- or gel-filled cushion placed over the organ being treated.

**Ureteric colic** (severe spasmodic pain in the side, occurring if the ureter is obstructed by small fragments of stone)

**LITHOTRIPSY**
Calculi (stones) can sometimes be broken up by lithotripsy, a procedure that uses ultrasonic or shock waves. In extracorporeal shock-wave lithotripsy (ESWL), the most common form of the treatment, no major surgery is needed. If the stones are in the kidney or ureter, fragments of the stones are passed in the urine.

**EXTRACORPOREAL SHOCK-WAVE LITHOTRIPSY (ESWL)**
Calculi (stones) can sometimes be broken up by lithotripsy, a procedure that uses ultrasonic or shock waves. In extracorporeal shock-wave lithotripsy (ESWL), the most common form of the treatment, no major surgery is needed. If the stones are in the kidney or ureter, fragments of the stones are passed in the urine.

**Patient receiving ESWL**
The patient is given a general or epidural anaesthetic. The lithotripter produces shock waves that are focused on the stone. The X-ray equipment allows the operator to locate the stones and adjust the lithotripter to ensure that the shock waves target the stones accurately. Nearly all the energy is dissipated in the stone, shattering it. The patient then drinks liberally to flush out stone fragments. There may be some blood in the urine and abdominal bruising, but serious complications are uncommon.

**Kidney stone**
This X-ray shows a staghorn calculus (stone) in the left kidney (on the right in the X-ray). With lithotripsy, stones such as these can be removed without the need for surgery.
may occur after ESWL. People treated for gallstones may need drug treatment to aid the elimination of stone residues.

**lithotripter**
The machine used in extracorporeal shock-wave lithotripsy (ESWL) to destroy small calculi (stones).

**Little's area**
An area near the front of the nasal septum (partition between the nostrils) that is richly supplied with blood vessels and is a common site of nosebleeds.

**Little's disease**
See spastic diplegia.

**live birth**
The delivery of a baby that breathes spontaneously and has a heartbeat. Statisticians may calculate the number of live births per year per 1000 women of childbearing age (usually 15 to 44), a measure called the fertility rate, to help them assess the health and growth of a population (see statistics, vital).

**livedo reticularis**
A netlike, purple or blue mottling of the skin, usually on the lower legs, caused by enlargement of blood vessels under the skin. It is more common in people with vasculitis (inflammation of the blood vessels) and those who suffer from excessive sensitivity to cold. The condition is harmless, and tends to be worse in cold weather.

**liver**
The largest organ within the body, this wedge-shaped, reddish-brown structure lies in the upper right abdominal cavity, directly below the diaphragm.

**STRUCTURE**
The liver is divided into two main lobes, each consisting of many lobules. The lobules are surrounded by branches of the hepatic artery, which supplies the liver with oxygenated blood, and the portal vein, which supplies nutrient-rich blood from the small intestine. Deoxygenated blood from the liver drains into the hepatic veins. A network of ducts carries the digestive juice bile from the liver to the gallbladder and the small intestine.

**FUNCTION**
The liver plays a vital role in the body because it produces and processes a wide range of chemical substances (see Disorders of the liver box and Structure and function of the liver box overleaf).

The chemicals produced by the liver include important proteins for blood plasma, such as albumin and clotting factors. The liver also produces cholesterol and proteins that help the blood to carry fats around the body. In addition, liver cells secrete bile, which removes waste products from the liver and aids the breakdown and absorption of fats in the small intestine (see biliary system).

Another major function is the processing of nutrients for use by cells. The liver also stores excess glucose as glycogen. In addition, it controls the blood level of amino acids (the building blocks of proteins). If the level of amino acids is too high, the liver converts the excess into glucose, proteins, other amino acids, or urea (for excretion).

Finally, the liver helps to clear the blood of drugs and poisons. These substances are broken down and excreted in the bile.

**liver abscess**
A localized collection of pus in the liver. The most common cause is an intestinal infection. Bacteria may spread from areas inflamed by diverticulitis or appendicitis, and amoebae may invade the liver as a result of amoebiasis. Symptoms are high fever, pain in the upper right abdomen, and (especially in the elderly) confusion. Ultrasound scanning usually reveals the abscess, and the organism responsible may be identified by examination of a blood or tissue sample. The abscess can sometimes be treated by aspiration (sucking out the pus through a needle), but often surgery is needed.

**liver biopsy**
A diagnostic test in which a small sample of tissue is removed from the liver, usually under local anaesthesia. The main purpose of this test is to aid diagnosis of liver diseases. (See also biopsy.)

**liver cancer**
A cancerous tumour in the liver. The tumour may be primary (originating in the liver) or, far more commonly, secondary (having spread from elsewhere, often the stomach, pancreas, or large intestine). There are two main types of primary tumour: a hepatocellular carcinoma, also known as a hepatoma, which develops in the liver cells; and a cholangiocarcinoma, which arises from cells lining the bile ducts. Hepatocellular carcinomas are often linked to hepatitis B infection and to cirrhosis.

**SYMPTOMS**
The most common symptoms of any liver cancer are loss of appetite, weight loss, lethargy, and sometimes pain in the upper right abdomen. The later stages of the disease are marked by jaundice (yellowing of the skin and the whites of the
The most common cause of liver disease in developed countries is excessive alcohol consumption. Alcohol-related disorders (see liver disease, alcoholic) include hepatitis (liver inflammation) and cirrhosis. Many other types of liver disorder may occur, including infections, tumours, metabolic disorders, and congenital defects.

Liver failure (complete loss of liver function) may occur as a result of acute hepatitis, poisoning, or cirrhosis. Jaundice and hepatomegaly (enlargement of the liver) are common signs of liver disease.

Infection and inflammation
Hepatitis is a general term for inflammation of the liver. It can be caused by viruses (see hepatitis, viral) or bacteria, which may spread up the biliary system to the liver, causing cholangitis (inflammation of the bile duct) or liver abscess. Parasitic diseases, including schistosomiasis, liver fluke, amoebiasis, and hydatid disease, can also affect the liver.

Tumours
The liver is a common site for cancerous tumours that have spread from elsewhere in the body (in which case they are known as secondary tumours of the liver). Primary tumours of the liver (those that originate in the liver) are much rarer. (See liver cancer.)

Metabolic disorders
Two main metabolic disorders affect the liver: haemochromatosis (in which there is too much iron in the body) and Wilson’s disease (in which there is an excess of copper in the liver).

Congenital defects
Occasionally, defects of liver structure are present from birth. Abnormalities such as these principally affect the bile ducts. A choledochal cyst is a malformation of a main bile duct. These cysts require surgery because, in infants, they may obstruct the flow of bile, causing jaundice. Biliary atresia, in which the bile ducts are missing, also causes jaundice.

Poisoning and drugs
Normally, the liver can break down drugs and toxins. However, drug overdose or allergy may damage liver cells in the process, and overdose of paracetamol can lead to severe liver damage. Poisoning by certain types of mushroom can cause acute liver failure.

Other disorders
In Budd–Chiari syndrome, the veins draining the liver become blocked by blood clots, which causes painful swelling of the liver. Obstruction of the portal vein is one cause of portal hypertension (high blood pressure in the portal vein), which can lead to oesophageal varices (swollen veins in the oesophagus) and ascites (collection of fluid in the abdomen).

Enlargement of the liver is a common symptom of leukaemias and lymphomas. Liver failure (complete loss of liver function) may be caused by acute hepatitis, poisoning, or cirrhosis.

**INVESTIGATION**

Disorders of the liver may be investigated by liver biopsy (removal of a tissue sample for examination), liver-function tests, and liver imaging (which includes ultrasound scanning, CT scanning, and MRI).

---

eyes, due to accumulation of the bile pigment bilirubin and ascites (excess fluid in the abdomen).

**DIAGNOSIS AND TREATMENT**

Blood tests (see liver-function tests) may be used to assess liver function, which can be disturbed by cancer. Tumours are often detected by ultrasound scanning, CT scanning, or MRI; diagnosis may be confirmed by liver biopsy (tissue sampling).

A hepatocellular carcinoma can sometimes be cured by total removal of the tumour and a surrounding area of normal tissue. In other cases, anticancer drugs can help to slow the disease’s progress. It is usually not possible to cure secondary liver cancer, but anticancer drugs or, in some cases, removal of a solitary metastasis (secondary cancerous tumour) may significantly improve the outlook.

liver, cirrhosis of
See cirrhosis.

liver disease, alcoholic
Damage to the liver resulting from excessive alcohol consumption. Alcohol-related liver disease increases the risk of developing liver cancer.

The longer that heavy alcohol consumption goes on, the more severe the damage. The initial effect is the formation of fat globules inside liver cells, a condition called fatty liver, followed by alcoholic hepatitis (liver inflammation). Damage progresses to cirrhosis (scarring of liver tissue), resulting in severe structural damage eventually leading to loss of liver function.

LIVER-function tests show a characteristic pattern of abnormalities, and liver biopsy (tissue sampling) may be needed to assess the severity of damage. There is no particular treatment, but abstinence from alcohol prevents further damage. Treatment for alcohol dependence may be required in some cases.

liver failure
Severe impairment of liver function that develops suddenly (acute liver failure) or at the final stages of a chronic liver disease (chronic liver failure). Because the liver breaks down toxins in the blood, liver failure causes the levels of the toxins to rise, affecting the functioning of other organs, particularly the brain.

**SYMPTOMS**

Symptoms of acute liver failure develop rapidly; they may include impaired memory, agitation, and confusion, followed by drowsiness. The functioning of other organs may also become impaired, and the condition may lead to coma and death.

Features of chronic liver failure develop much more gradually. They include jaundice; itching; easy bruising and bleeding; ascites (swollen abdomen due to accumulated fluid); red palms; and, in males, gynaecomastia (enlarged breasts) and shrunken testes. Chronic liver failure may suddenly deteriorate into acute liver failure.

**TREATMENT**

Acute liver failure requires urgent hospital care. Although no treatment can repair damage that has already occurred in acute or chronic liver failure, certain measures, such as prescribing diuretic
drugs to reduce abdominal swelling, may be taken to reduce the severity of symptoms. Consumption of alcohol should cease in all cases.

OUTLOOK
The prognosis for sufferers of chronic liver failure varies depending on the cause, but some people survive for many years. For both chronic and acute liver failure, a liver transplant is necessary to increase the chances of survival.

liver fluke
Any of various species of flukes (flatworms) that infest the bile ducts in the liver. The only significant fluke in the UK is *Fasciola hepatica*, which causes the disease fascioliasis.

Fascioliasis has two stages. During the first stage, young flukes migrate through the liver, causing it to become tender and enlarged; other symptoms include fever and night sweats. In the second stage, adult worms occupy the bile ducts. Their presence may lead to cholangitis (inflammation of the bile duct) and bile duct obstruction, which can cause jaundice. Treatment with an anthelmintic drug may be effective.

liver-function tests
Tests of blood chemistry that can detect changes in the way the liver is making new substances and breaking down and/or excreting old ones. The tests can also show whether liver cells are healthy or damaged (see Liver function tests table, overleaf).

liver imaging
Techniques that produce images of the liver, gallbladder, bile ducts, and blood vessels supplying the liver, to aid the detection of disease.

Ultrasound scanning is the most widely used technique for imaging the liver; CT scanning and MRI are also commonly used. Radionuclide scanning may reveal cysts and tumours and show bile excretion. X-ray imaging techniques include cholangiography, cholecystography, and ERCP (endoscopic retrograde cholangiopancreatography). In these procedures, a contrast medium, which is opaque to X-rays, is used to outline the biliary system. Angiography reveals the blood vessels in the liver.

liver palms
Redness accompanied by warmth in the palms of the hands. This combination of symptoms is often associated with chronic liver disease. (See liver failure.)
### LIVER-FUNCTION TESTS

<table>
<thead>
<tr>
<th>Test</th>
<th>Significance</th>
</tr>
</thead>
<tbody>
<tr>
<td>Serum bilirubin</td>
<td>Bilirubin is the yellow breakdown product of red blood cells that is passed to the liver and excreted in bile. It is this substance that gives the yellow colour to the skin in jaundice. High blood bilirubin levels may indicate excessive breakdown of red blood cells, obstruction to bile flow, defective processing of bile by the liver, or Gilbert’s syndrome.</td>
</tr>
<tr>
<td>Serum albumin</td>
<td>Albumin is one of the main proteins in blood. Made by the liver, one of its actions is to hold fluid inside the blood vessels. A low level is found in many chronic liver disorders and is often associated with ascites and ankle oedema (fluid collection in the abdomen and around the ankles).</td>
</tr>
<tr>
<td>Serum alkaline phosphatase</td>
<td>Alkaline phosphatase is an enzyme found in the cells that line the bile ducts and also in other tissues such as bone. The blood level of this enzyme rises when there is obstruction to the flow of bile (cholestasis).</td>
</tr>
<tr>
<td>Gamma-glutamyl transpeptidase</td>
<td>An enzyme present in liver cells. When the flow of bile is obstructed, the blood level of this enzyme is raised, along with a raised level of alkaline phosphatase. A gamma-glutamyl transpeptidase level raised in isolation is related to alcohol intake. Its measurement can also be used as a screening test for glutamyl transpeptidase deficiency.</td>
</tr>
<tr>
<td>Serum aminotransferases (transaminases)</td>
<td>The aminotransferases are enzymes released from liver cells into the blood when the liver cells are damaged. The levels will be raised in any condition that damages liver cells, including poisoning, and acute and chronic hepatitis.</td>
</tr>
<tr>
<td>Prothrombin time</td>
<td>A normal result in this test of blood clotting depends on the presence in the blood of a protein made by the liver from a fat-soluble vitamin, vitamin K. The test result can be abnormal in two types of disorder: when the protein is not made because of liver cell damage, and when there is a blockage to bile flow in the liver, causing a lack of bile in the intestines (which interferes with fat and vitamin K absorption).</td>
</tr>
</tbody>
</table>

### HOW IT IS DONE

During this procedure, the liver, the gallbladder, and portions of the connected blood and bile vessels are removed. The donor organs and blood vessels are then connected to the recipient’s vessels.

### RECOVERY PERIOD

After the transplant, the recipient is monitored in an intensive care unit for a few days and remains in hospital for up to four weeks. Immunosuppressant drugs to prevent rejection of the new organ must be taken for life.

### live vaccine

A vaccine containing live but weakened (attenuated) forms of an infectious organism. Live vaccines include those for measles, mumps, rubella, poliomyelitis, and tuberculosis.

### Livial

The brand name for tibolone, a drug that is used in the treatment of the symptoms of menopause.

### living will

A written declaration, signed by an adult of sound mind, that outlines the extent of life-prolonging treatment desired in the event of the person being incapable of communication. In the UK, a living will has no legal force, but doctors try to respect patients’ wishes.

### LMS

The abbreviation for leiomyosarcoma.

### Loa loa

The parasitic worm responsible for the disease loiasis.

### lobar pneumonia

A form of pneumonia (inflammation of the lung) in which only one lobe of a lung is affected.

### lobe

One of the clearly defined parts into which certain organs, such as the brain, liver, and lungs, are divided. The term may also be used to describe the earlobe.

### lobectomy

An operation performed to cut out a lobe in the liver (see hepatectomy, partial), the lung (see lobectomy, lung), or the thyroid gland (see thyroideectomy).

### lobectomy, lung

An operation to cut out one of the lobes of a lung, usually to remove a cancerous tumour in the lung.

### lobotomy, prefrontal

The cutting of some of the fibres that link the brain’s frontal lobes to the rest of the brain. This operation was formerly used to treat severe psychiatric disorders. It often caused harmful personality changes, however, and is now very rarely performed.

### Lobstein’s syndrome

See osteogenesis imperfecta.

### lobular

A word meaning “relating to a lobule”.

### lobule

A smaller division of a lobe of an organ such as the liver or lung. Lobules are separated by boundaries such as septa (dividing walls).

### local anaesthetic

See anaesthetic, local.

### localized amnesia

Loss of memory for all events occurring within a particular period of time. See also amnesia.

### localizing sign

A sign that is found during a physical examination that pinpoints the cause of a disorder.

### lochia

The discharge, after childbirth, of blood and fragments of uterine lining from the area where the placenta was attached. The discharge is bright red for the first three or four days and then becomes paler. The amount of lochia decreases as the placental site heals, and the discharge usually ceases completely within six weeks.

### locked knee

A temporary loss of the ability to move the knee joint. A locked knee may be the result of a torn cartilage or of small fragments of bone or cartilage in the joint (loose bodies).
lockjaw
A painful spasm of the jaw muscles that makes it difficult or impossible for a person to open the mouth. Lockjaw is the most common symptom of tetanus.

locomotor
Relating to movement from one place to another, as in locomotor ataxia.

locus
The medical term for a region or site in the body. In genetics, the word is used to describe the position of a gene on a chromosome.

lofepramine
A tricyclic antidepressant drug used in the long-term treatment of depression. Lofeperamine is particularly helpful if the depression is accompanied by lethargy. Possible side effects include dry mouth, sweating or flushed skin, drowsiness, or blurred vision. If the drug causes constipation, difficulty in passing urine, or dizziness, a doctor should be consulted.

Löffler’s syndrome
A rare form of allergic reaction affecting the lungs. Possible causes of Löffler’s syndrome include drug allergy and roundworm infestation of the lungs (see ascariasis). The symptoms include a dry cough, fever, wheezing, shortness of breath, and chest pain. The disease often disappears spontaneously.

log-roll technique
A method of turning a casualty on to his or her back without altering the position of the spine. The technique is used if a spinal injury is suspected and resuscitation is needed (see cardiopulmonary resuscitation). The aim is to prevent further injury by keeping the head, trunk, and toes in a straight line.

loiasis
A form of the tropical parasitic disease filariasis, which is caused by an infestation by the worm Loa loa. The worms travel beneath the skin, producing itchy areas of inflammation known as Calabar swellings, and can sometimes be seen moving across the front of the eye. Loiasis is treated with a course of diethylcarbamazine to kill the worms.

loin
The part of the back on each side of the spine between the lowest pair of ribs and the top of the pelvis.

Lomotil
A brand-name antidiarrheal drug containing atropine and diphenoxylate.

longevity
A term meaning length of life or the condition of being long-lived.

longsightedness
See hypermetropia.

loop of Henlé
Part of the long renal tubule within each of the kidney’s filtering units, or nephrons. The U-shaped loop of Henlé absorbs water and certain soluble substances back into the bloodstream.

loose bodies
Fragments of bone, cartilage, or capsule linings within a joint. Loose bodies may occur whenever there is damage to a joint, as in injury, osteoarthritis, or osteochondritis dissecans.

The fragments can cause a joint to lock, resulting in severe pain. X-rays or arthroscopy (viewing of the interior of a joint with an endoscope) may reveal their presence. Gentle manipulation of the joint may be required, in order to unlock it. If locking occurs frequently, the loose bodies may be removed during arthroscopy or by surgery.

loperamide
An antidiarrheal drug that slows intestinal activity and reduces the loss of water and salts from the body. It is usually used to treat sudden and recurrent bouts of diarrhoea (but not if the diarrhoea is due to infection).

Loperamide occasionally produces a rash; other rare adverse effects are abdominal cramps, and bloating. If these effects are severe, they require prompt attention from a doctor.

Lorain-Lévi syndrome
A form of dwarfism in which a child retains the appearance of an infant, due to insufficient secretion of growth hormone and a lack of gonadotrophin.

Lorain’s disease
See Lorain-Lévi syndrome.

loratadine
An antihistamine drug used to relieve symptoms of allergic rhinitis, such as sneezing, runny nose, and itching eyes, and to treat allergic skin problems such as chronic urticaria. It is less likely to cause drowsiness than some other antihistamines. Side effects are uncommon; they include headache, fatigue, and nausea. Fainting or palpitations (the sensation of a rapid, forceful heartbeat) may also occur; in this situation, the affected person should stop taking the drug and consult a doctor.

lorazepam
A benzodiazepine drug used in the treatment of insomnia and anxiety, or for premedication prior to an operation or other procedure.

lordosis
Inward curvature of the spine. This curvature is normally present to a minor degree in the lower back, but lordosis can become exaggerated by poor posture or by kyphosis (excessive curvature of the upper spine). Pronounced lordosis is usually permanent and can lead to disc prolapse (slipped disc) or osteoarthritis of the spine.

Normal and abnormal lordosis
The normal inward curvature of the spine (left) is exaggerated in abnormal lordosis (right).

losartan
An angiotensin II antagonist drug used to treat hypertension (high blood pressure). Side effects are rare and mild; they include dizziness, diarrhoea, and fatigue.

Losec
The brand name for the anti-ulcer drug omeprazole.

lotion
A liquid drug preparation applied to the skin. Some examples of drugs prepared as a lotion include calamine and betamethasone, both of which are used to treat skin inflammation.
Lou Gehrig’s disease
The most common type of motor neuron disease; also known as amyotrophic lateral sclerosis (ALS).

low birthweight
See birthweight.

low-density lipoprotein
One of a group of proteins combined with lipids in the blood plasma. Low-density lipoproteins (LDLs) are involved in the transport of cholesterol in the bloodstream; they also deposit cholesterol around the body. An excess of LDLs (see hyperlipidaemias) is associated with atherosclerosis (narrowing of the arteries by deposits of fatty material). (See also high-density lipoprotein.)

lower back pain
See back pain.

Lowe’s syndrome
A rare, X-linked genetic disorder affecting the eyes, kidneys, and brain. Lowe’s syndrome is a metabolic disorder in which an enzyme found in cell membranes does not function. Only males are affected.

Eye problems include glaucoma; cataracts; and nystagmus (abnormal, jerky eye movements). The kidney dysfunction causes chemical imbalances such as acidosis and a form of rickets that is resistant to vitamin D treatment. The brain disorders include learning difficulties, behavioural problems, and sometimes seizures.

lozenge
A medicated sweet or tablet that dissolves in the mouth, usually taken to relieve a sore mouth or throat.

LSD
The abbreviation for lysergic acid diethylamide, a synthetic hallucinogenic drug that is derived from the fungus ergot. LSD is used illegally as a recreational drug. It causes visual and sometimes auditory hallucinations (perceptions that occur with no external stimulus); it may also produce unusual emotional states such as “mystical” experiences. The user may also have abnormal thoughts, such as believing that he or she can fly unaided.

LSD sometimes produces panic and physical side effects such as nausea and dizziness. In addition, individuals who have used it frequently may experience “flashbacks” (recurrences of the hallucinations) for months or even years after their last use of the drug. LSD is not addictive but regular users rapidly develop tolerance.

Ludwig’s angina
A rare bacterial infection that affects the floor of the mouth, usually due to an infected tooth or area of gum. Ludwig’s angina occurs most commonly in people who tend to have poor oral hygiene habits.

Symptoms include fever; pain and swelling in the mouth; and difficulty in opening the mouth and swallowing. If left untreated, the disorder may cause life-threatening swelling in the throat that obstructs breathing and needs immediate treatment with antibiotic drugs.

lumbago
A general term for lower back pain. Lumbago may be due to an intervertebral disc prolapse (slipped disc). It may also arise if synovium (joint membrane) is trapped between the surfaces of a small intervertebral joint, or if there is momentary subluxation (partial dislocation) of an intervertebral joint with sprains of the ligaments. In many cases, however, no cause is found.

Treatment is with analgesic drugs (painkillers) and gentle physical activity. (See also lumbosacral spasm.)

lumbar
A word referring to the part of the back between the lowest ribs and the top of the pelvis. The lumbar part of the spine is made up of the five lumbar vertebrae.

lumbar disc protrusion
See disc prolapse.

LOCATION AND STRUCTURE OF THE LUNGS

The lungs lie in the chest within the ribcage. Air entering the body through the nose and mouth travels down the trachea to the main bronchi, which divide into smaller bronchi and then into bronchioles. These in turn lead to alveoli, where the exchange of oxygen and carbon dioxide takes place. During expiration (breathing out), air leaves the body by the same routes.
**lumbar lordosis**
See lordosis.

**lumbar puncture**
A procedure in which a hollow needle is inserted into the lower part of the spinal canal, between two lumbar vertebrae, to withdraw cerebrospinal fluid or to inject drugs or other substances.

Lumbar puncture is usually carried out to collect a sample of cerebrospinal fluid in order to diagnose and investigate disorders of the brain and spinal cord (such as meningitis and subarachnoid haemorrhage). The procedure takes about 15 minutes and is carried out under local anaesthesia.

**lumbosacral spasm**
Excessive tightening of the muscles that surround and support the lower region of the spine, causing back pain. Treatment of lumbosacral spasm may include analgesic drugs (painkillers) and muscle-relaxant drugs.

**lumbosacral spine**
The area of the lower spine consisting of the lumbar vertebrae and the sacrum (the fused vertebrae that form the back of the pelvis).

**lumen**
The space within a tubular organ or structure such as the intestine.

**lumpectomy**
A surgical treatment for breast cancer in which only the cancerous tissue is removed, rather than the entire breast. (See also mastectomy; quadrantenectomy.)

**lumpy jaw**
A nonmedical name for actinomycosis.

**lunacy**
An outdated term for serious mental disorder.

**lung**
One of the two main organs of the respiratory system. The lungs supply the body with the oxygen needed for aerobic metabolism and eliminate the waste product carbon dioxide.

**STRUCTURE AND FUNCTION**
Air is delivered to the lungs through the trachea (windpipe); this air passage divides into two main bronchi, with one bronchus supplying each lung. The main bronchi divide again into smaller bronchi and then into bronchioles, which lead to air passages that open out into grapelike air sacs called alveoli (see alveolus, pulmonary). Oxygen and carbon dioxide diffuse into or out of the blood through the thin walls of the alveoli.

Each lung is enclosed in a double membrane called the pleura; the two layers of the pleura secrete a lubricating fluid that enables the lungs to move freely as they expand and contract during breathing. (See also respiration.)

**lung cancer**
The second most common form of cancer in the UK (after skin cancer).

**CAUSES**
Smoking of tobacco is the main cause of lung cancer. Passive smoking (the inhalation of tobacco smoke by non-smokers) and environmental pollution (with radioactive minerals or asbestos, for example) are also risk factors.

**TYPES**
There are several types of lung cancer, each of which affects a different group of lung cells. The most common types are squamous cell carcinoma and small cell (or oat cell) carcinoma; the other main types are adenocarcinoma and large cell carcinoma.

Each form of lung cancer has a particular growth pattern and response to treatment. The most significant of these disorders is asthma. Another such disorder is allergic alveolitis, which is usually a reaction to dust of plant or animal origin.

**Tumours**
Lung cancer is one of the most common of all cancers; cancerous tumours may also spread to the lungs from other areas. Noncancerous tumours of the lung are far less common.

**Injury**
Injury to the lung, usually by penetration of the chest wall, can allow air or blood to collect between the two layers of the pleura (the membrane around each lung), and the lung may collapse (see pneumothorax; haemothorax). Injury to the interior of the lungs can be due to inhalation of toxic substances (see asbestosis; silicosis).

**Other disorders**
The blood supply to the lungs may be reduced by pulmonary embolism (a condition in which a clot obstructs a blood vessel in the lung).

Oxygen intake may be severely impaired by diseases affecting the tiny air sacs in the lungs (see alveolus, pulmonary). In emphysema, the alveoli are destroyed, thereby reducing the area of lung tissue where oxygen is absorbed into the blood (see also pulmonary disease, chronic obstructive). Respiratory distress syndrome in adults occurs when fluid leaks into the alveoli from the tiny blood vessels surrounding them, thereby preventing the alveolar walls from absorbing sufficient oxygen.

**INVESTIGATION**

Lung disorders are investigated by chest X-ray, CT scanning, bronchoscopy, pulmonary function tests, sputum analysis, and blood tests. Sometimes, a lung biopsy (removal of a tissue sample) is performed.
treatment. Small cell carcinoma is the most highly malignant form of lung cancer; it grows rapidly and spreads very quickly throughout the body. In contrast, squamous cell carcinoma grows more slowly than the other forms and does not spread outside the lung until late in the course of the disease.

SYMPTOMS
The first and most common symptom of lung cancer is a persistent cough. Other symptoms include coughing up blood, shortness of breath, and chest pain. The tumour may obstruct the airway, causing pneumonia (inflammation in the lung), or involve the pleura (the double-layered membrane covering the lung), causing an accumulation of fluid called pleural effusion. A tumour developing at the top of the lung may press on the nerves supplying the arm on that side, causing pain and weakness in the arm.

Lung cancer can spread to other parts of the body, especially the liver, brain, and bones, causing pain and other problems in these areas.

DIAGNOSIS AND TREATMENT
In most cases, the cancer is revealed in a chest X-ray or diagnosed from abnormal cells in a sputum sample. A doctor may also perform a bronchoscopy to view inside the airways. To confirm the diagnosis, a biopsy (tissue sample) is taken and is examined microscopically for the presence of cancerous cells (see cytology). Blood tests, and CT scanning or MRI, may be used in order to determine whether or not the cancer has spread to other areas.

If lung cancer is diagnosed at an early stage, pneumonectomy (removal of the whole lung) or lobectomy (removal of the diseased lobe of the lung) may be a possibility. Surgery is usually considered only in cases in which the tumour is still relatively small and has not spread beyond the lung. Anticancer drugs and radiotherapy may be used in order to contain the spread of the tumour and to treat any metastases (cancerous cells that have spread to other areas of the body). Small cell carcinoma is usually treated by means of radiotherapy and chemotherapy.

**lung function tests**
See pulmonary function tests.

**lung imaging**
Techniques that are used to provide images of the lungs in order to facilitate the diagnosis of lung disease. Most lung disorders can be detected by means of chest X-ray. CT scanning and MRI play an important role in detecting the presence and the spread of lung tumours. Ultrasound scanning is sometimes used to reveal pleural effusion (buildup of fluid around a lung). Radioisotope scanning is used to detect evidence of pulmonary embolism (in which a clot obstructs a blood vessel in a lung); alternatively, a pulmonary angiogram contrast X-ray may be performed.

**lung lobectomy**
See lobectomy, lung.

**lung tumours**
Growths in the lungs. These tumours may be either cancerous (see lung cancer) or noncancerous. Noncancerous tumours occur less frequently than cancers. The most common of these tumours is a bronchial adenoma, which arises in the lining of a bronchus. Adenomas often cause bronchial obstruction; affected people may also cough up blood. Treatment of adenoma involves surgical removal of the tumour.

Other rare noncancerous tumours include fibromas (which consist of fibrous tissue) and lipomas (which consist of fatty tissue). No treatment is necessary for these, unless the tumours are causing problems.

**lupus erythematosus**
An autoimmune disorder that causes inflammation of connective tissue. The most common type of this disorder is discoid lupus erythematosus (DLE), which affects only exposed areas of skin. The more serious form, systemic lupus erythematosus (SLE), affects many of the body systems, including the skin.

**symptoms**
In both varieties of lupus erythematosus, the symptoms periodically subside and recur with varying severity.

In DLE, the rash starts as one or more red, circular, and thickened areas of skin. These areas of skin subsequently become scarred. The patches may occur on the face, behind the ears, and on the scalp.

SLE causes a variety of symptoms. A characteristic red, blotchy, butterfly-shaped rash may appear on the cheeks and the bridge of the nose; other symptoms include fatigue, fever, nausea, loss of appetite, joint pain, and weight loss. There may also be associated problems including anaemia, neurological or psychiatric problems, kidney failure, pleurisy (inflammation of the membrane that lines the lungs), arthritis, and pericarditis (inflammation of the membrane surrounding the heart).

**diagnosis and treatment**
Diagnosis is made by blood tests and sometimes a skin biopsy. DLE is usually treated with topical corticosteroid drugs. Both DLE and SLE may be treated with the antimalarial drug hydroxychloroquine. Sufferers of mild forms of SLE may have near normal health for many years, and treatment with corticosteroid drugs and immunosuppressant drugs can improve life expectancy. Other treatments are available to treat specific features of the disease; however, SLE is still a potentially fatal disorder.

vessels (see lymphatic system) in order
that the vessels and lymph nodes, and
any abnormalities, can be seen on X-rays.
Lymphangiography has been superseded
largely by CT scanning and MRI.
Lymphangioma
A rare, noncancerous tumour consisting
Lymphangitis
Inflammation of the lymphatic vessels
(see lymphatic system) due to the spread of bacteria (commonly streptococci)
from an infected wound. The inflammation
causes the appearance of tender red
streaks on the skin overlying the lymphatic vessels. These red streaks extend
from the infection site towards the
nearest lymph nodes. The affected nodes
become swollen and tender, and the
affected individual usually has a fever
and a general feeling of illness.
Lymphangitis requires urgent treatment with antibiotic drugs to prevent septicaemia (a life-threatening disorder
resulting from high levels of bacteria,
and bacterial toxins, in the blood).
LYMPHATIC SYSTEM

lymphatic system
A system of vessels (lymphatic vessels) that drains lymph from tissues all over the body back into the bloodstream. The lymphatic system is part of the immune system and has a major function in defending the body against infection and cancer. The lymphatic system also plays a part in the absorption of fats from the intestine.

STRUCTURE AND FUNCTION
All body tissues are bathed in lymph, a watery fluid that is derived from the bloodstream. Much of this fluid is returned to the bloodstream through the walls of the capillaries (see circulatory system), but the remainder of the fluid is transported to the heart through the lymphatic system.

Lymph is moved along the lymphatic vessels during physical activity, in which the contraction of muscles compresses the vessels; valves inside the vessels ensure that the lymph always flows in the correct direction.

Situated on the lymphatic vessels are lymph nodes, through which the lymph passes. These nodes filter the lymph and trap or destroy infectious microorganisms or other foreign bodies. Also included in the lymphatic system are the spleen and the thymus, which produce lymphocytes (white blood cells that fight infection or harmful cells).

DISORDERS
If infection or inflammation occurs in any part of the body, the lymph nodes in that particular area may become swollen and tender as the white blood cells within them try to combat the organisms or cells causing the problem. If an infection is particularly severe, the lymphatic vessels leading from the nodes may also become inflamed (see lymphangitis).

If a lymphatic vessel becomes obstructed (for example, by worms or by cell debris), lymph will collect in the nearby tissues, which will lead to lymphoedema.

Cancer commonly spreads to other parts of the body through the lymphatic system. If a primary tumour invades the lymphatic vessels, cells from the tumour may break off and enter the vessels (see metastasis). They may then become lodged in lymph nodes situated nearby, where they may then grow into secondary tumours. In breast cancer, for example, the cells from a breast tumour may spread to the lymph nodes in the armpit.

lymph gland
A popular name for a lymph node. (See also lymphatic system.)

lymph node
A small organ lying along the course of a lymphatic vessel (see lymphatic system). Lymph nodes are commonly, but incorrectly, called lymph glands. Lymph nodes vary in size; they can be microscopic or can be up to about 2.5 cm in diameter.

STRUCTURE
A lymph node is composed of a thin, fibrous outer capsule and an inner mass of lymphoid tissue. Penetrating the capsule are several small lymphatic vessels, which transport lymph into the node. Each lymph node contains sinuses (spaces) in which the lymph is filtered. A single, larger vessel carries lymph out of the node.

FUNCTION
Lymph nodes act as a barrier to the spread of infection by destroying or filtering out bacteria before they can pass into the bloodstream. As lymph passes through a node, narrow channels in the sinuses slow down its movement; this reduction in the flow of lymph allows macrophages (white blood cells that engulf and destroy foreign and dead material) to filter microorganisms from the lymph. In addition, germinal centres, which are located in the lymph node, release white blood cells known as lymphocytes. These cells also help to fight infection.

lymphocyte
Any one of a group of white blood cells that are of crucial importance to the immune system because they combat infectious organisms and cancer. There are two principal types of lymphocyte: B- and T-lymphocytes.

B-LYMPHOCYTES
B-lymphocytes produce immunoglobulins or antibodies (proteins that attach themselves to antigens (proteins) on the surfaces of bacteria). This action starts a process that leads to the destruction of the bacteria.

T-LYMPHOCYTES
The T-lymphocytes are classified in two main groups, according to the type of antigens found on their surfaces. One group (known as CD8) includes killer (cytotoxic) and suppressor cells; the other group (CD4) includes helper cells. The killer T-lymphocytes attach themselves to abnormal cells (such as tumour cells, cells that have been invaded by viruses, and those in transplanted tissue) and release chemicals that help to destroy the abnormal cells. Suppressor T-cells act to “damp down” the immune response. Helper T-cells enhance the activities of the killer T-cells and the B-cells, and also orchestrate the immune response.

MEMORY FUNCTION
Some B- and T-lymphocytes do not participate directly in immune responses but serve as a memory bank for antigens that have been encountered. These lymphocytes are created when the immune system cells respond to an infection, and they contain information on how to deal with that infection. Once the immune response is over, the memory cells are then stored in the body in order to aid subsequent immune responses to that infection.

lymphocytosis
An increase in the number of lymphocytes, a type of white blood cell that mounts the immune response, either by attacking foreign cells directly or by producing antibodies that cause their destruction. Lymphocytosis, which can be detected by blood test, most commonly occurs in viral infections. Rarely, a massive increase in lymphocytes may be due to leukaemia.

lymphoedema
An abnormal accumulation of lymph in the tissues, which occurs when the normal drainage of lymph is disrupted (see lymphatic system).

CAUSES
There are various possible causes for lymphoedema. Cancer can lead to the condition if the vessels become blocked by deposits of cancer cells. Surgical removal of lymph nodes under the arm (as in radical mastectomy) or in the groin, or radiotherapy to an area containing lymph nodes, may also result in lymphoedema. In the tropical disease filariasis, the lymphatic vessels may be blocked by parasitic worms. Rarely, the condition is due to a congenital abnormality of the lymphatic vessels known as Milroy’s disease. In addition, lymphoedema may occur for no known reason.

SYMPTOMS
Lymphoedema causes painless swelling in the tissues and thickening of the skin over the affected area. It usually develops in the legs; the swelling may start at the ankle and extend up the leg, and
The lymphatic system is a collection of organs, ducts, and tissues that has the dual role of draining tissue fluid (lymph) back into the bloodstream and of fighting infection. Lymph is drained by a system of channels (the lymphatic vessels).

White cells that are produced by the bone marrow, thymus, and spleen are present in lymph nodes, or they circulate through the lymphatic system and the bloodstream, providing defences against infection.

**MOVEMENTS OF BODY FLUIDS**

Lymph is constantly moving around the body, but the lymphatic system has no central pump equivalent to the heart. Lymph is circulated by the movement of the body’s muscles; a system of one-way valves in the lymphatic vessels ensures that it moves in the right direction. Exertion also pushes fluid from body tissues into the bloodstream.

**Structure of a lymph node**
Any fluid absorbed into the lymphatic system passes across at least one lymph node before it returns to the circulation. The fluid filters through a mesh of tightly packed white blood cells – some of which are grouped into follicles consisting of similar cells – which attack and destroy harmful organisms. Every lymph node is supplied by its own tiny artery and vein.

**Enlarged lymph nodes**
This photograph shows a child with an enlarged lymph node in the neck. One cause of such enlargement is infection. Enlarged nodes may also be a result of Hodgkin’s disease, a rare cancer of the lymph nodes.
may occur to an incapacitating degree in some individuals. If a limb that is affected by lymphoedema is subsequently injured, infection can easily enter the site of injury and spread rapidly through the body tissues.

**TREATMENT**
There is no known cure for lymphoedema. Treatment consists of taking diuretic drugs, wearing an elastic bandage or compression sleeve, massage, and special exercises; these measures may bring about some improvement.

**lymphogranuloma venereum**
A sexually transmitted disease caused by a chlamydial infection; it is most common in tropical areas.

The first sign of lymphogranuloma venereum may be a small genital blister that heals in a few days. There may also be fever, headache, muscle and joint pains, and a rash. The lymph nodes, particularly in the groin, become painfully enlarged and inflamed. Abscesses may form, and persistent ulcers may develop, on the skin over the affected nodes. Treatment is with antibiotic drugs.

**lymphoma**
Any of a group of cancers in which the cells of lymphoid tissue (found principally in the lymph nodes and the spleen) multiply unchecked.

Lymphomas fall into two principal categories. If certain characteristic abnormal cells (Reed–Sternberg cells) are present, the condition is called Hodgkin’s disease. All other forms are known as non-Hodgkin’s lymphoma (see lymphoma, non-Hodgkin’s).

**lymphoma, non-Hodgkin’s**
Any cancer that affects the lymphoid tissue (found mainly in the lymph nodes and spleen) other than the condition Hodgkin’s disease.

**CAUSES**
In most cases, non-Hodgkin’s lymphoma has no known cause. Occasionally, however, the disease is associated with suppression of the immune system, particularly after an organ transplant. One type of non-Hodgkin’s lymphoma, called Burkitt’s lymphoma, is associated with the Epstein–Barr virus.

**SYMPTOMS**
There is usually painless swelling of lymph nodes in the neck or groin. The liver and spleen may enlarge, and lymphoid tissue in the abdomen may be affected. Many other organs may become involved, leading to diverse symptoms ranging from headache to skin ulceration. In some cases, there may be fever, marked weight loss, and recurrent infections.

**DIAGNOSIS**
Diagnosis is based on a biopsy, usually taken from a lymph node. Further investigations, such as chest X-ray, CT scanning, MRI, bone marrow biopsy, and lymphangiography, may be needed to assess the extent of the disease.

**TREATMENT**
In cases where the lymphoma is confined to a single group of lymph nodes, treatment consists of radiotherapy. More often, however, the disease is more extensive, and in such cases anticancer drugs are given. A bone marrow transplant, with drug treatment and/or radiotherapy, may be considered for some people.

**lymphopenia**
A decrease in the number of lymphocytes, a type of white blood cell that mounts the immune response, either by a direct attack on abnormal cells or invading organisms or by producing antibodies that cause their destruction. This condition may occur when the bone marrow fails to produce enough blood cells, as in aplastic anaemia (see anaemia, aplastic) or treatment with radiotherapy or anticancer drugs.

**lymphosarcoma**
The former name for a condition that is now classified as a type of non-Hodgkin’s lymphoma (see lymphoma, non-Hodgkin’s).

**lysergid**
see LSD.

**lysis**
A medical term for breaking down or destruction. The term lysis is usually applied to the destruction of cells by disintegration of their outer membrane. A common example is haemolysis, the breakdown of red blood cells.

Lysis may be caused by chemical action, for example the action of an enzyme, or by physical action, for example the action of heat or cold. The term “lysis” is also occasionally used to refer to a sudden recovery from a fever.

**lysosomal storage disease**
One of several different conditions, also known as inborn errors of metabolism (see metabolism, inborn errors of) in most
macro-
A prefix meaning “large”, as in macrophage (a large type of cell found in the immune system) or macroglossia (enlargement of the tongue).

macrobiotics
A dietary system in which foods with a balance of yin and yang are eaten. Foods are classed as yin or yang depending on factors such as colour, texture, and taste.

macrocytosis
A condition in which the red blood cells are larger than normal. Macrocytosis has many possible causes, the most common of which are megaloblastic anaemia (see anaemia, megaloblastic) and the effects of alcohol.

macroglobulinaemia, Waldenström’s
A type of lymphoma in which lymphocytes (a type of white blood cell) produce excessive amounts of a protein called immunoglobulin M (IgM), which is normally created to fight disease (see immunoglobulins). It tends to occur most commonly in men over 50 years old.

The excess IgM causes the blood to become overly viscous (thick), impairing its flow through the smallest blood vessels. Signs and symptoms include fatigue; headache; dizziness; visual disturbances; easy bruising and bleeding; and numbness and tingling in the hands and feet. The spleen, liver, and lymph nodes may become enlarged.

There is no cure, but treatment can relieve the symptoms. Blood viscosity can be lowered by plasmapheresis, in which a machine removes excess IgM from the blood plasma. Anticancer drugs and corticosteroids may also be given.

macroglossia
Abnormal enlargement of the tongue. Macroglossia is a feature of the chromosomal abnormality Down’s syndrome; hypothyroidism (an underactive thyroid gland); and acromegaly (a hormonal disorder causing enlargement of several body parts). It is also caused by some tumours of the tongue, such as a haemangioma or a lymphangioma.

macroglossia
An abnormally large upper and/or lower jaw. Macroglossia can be a feature of the condition acromegaly. (See also prognathism).

macrolide drugs
A class of antibiotic drugs used to treat a wide range of infections including those of the ear, nose, throat, respiratory and gastrointestinal tracts, and skin. Common macrolides include azithromycin and erythromycin.

macrophage
A cell in the immune system. Macrophages are large phagocytes, which can engulf and destroy microorganisms and other foreign particles. They are found in most body tissues.

macrosopic
Visible to the naked eye.

macula
The specific area of the retina (the light-sensitive layer at the back of the eye) that is responsible for seeing fine detail. The macula surrounds the fovea, the part of the retina that contains the highest density of visual cells.

macular degeneration
A progressive, painless deterioration of the macula. It is a common disorder in elderly people, and is the most common cause of visual impairment in the UK. The cause is unknown.

There are two forms of macular degeneration: dry and wet. In dry macular degeneration, cells within and just beneath the macula die. In wet macular degeneration, fragile new blood vessels grow beneath the macula; and these vessels may easily leak blood or other fluid, which damages the cells. Both forms of macular degeneration produce a roughly circular area of blindness that increases in size. It does not cause total blindness because the vision is retained around the edges of the visual fields.

Diagnosis is by ophthalmoscopy and vision tests. If wet macular degeneration is suspected, fluorescein angiography (imaging of the blood vessels in the retina) may be performed to detect abnormal blood vessels.

Wet macular degeneration is usually remedied by laser treatment. There is no treatment for the dry form of the condition, although the affected individual may benefit from visual aids such as magnifying instruments.

macule
A spot that is level with the skin’s surface and discernible only by difference in colour or texture.

maculopathy, diabetic
A complication of diabetes mellitus that is characterized by damage to the macula, at the back of the retina. Usually, the remainder of the retina is also affected (see retinopathy).

madarosis
Loss of the eyelashes or eyebrows.

mad cow disease
The commonly used name for bovine spongiform encephalopathy (BSE).

Madelung’s disease
The development of multiple, symmetrical, fatty masses resembling lipomas under the skin of the head, neck, upper trunk, and upper arms. The disease, also called multiple symmetrical lipomatosis or Lanois–Bensaude syndrome, occurs primarily in adult men.

The cause is unknown, but Madelung’s disease has been associated with long-term, excessive alcohol use (see alcohol-related disorders).

Madopar
A brand-name drug, containing levodopa with benserazide (a drug that enhances the effect of levodopa), used in the treatment of Parkinson’s disease.

Madura foot
A fungal and/or bacterial infection of the foot that occurs in tropical or subtropical regions such as Central and South America, Africa, India, and Southeast Asia. Madura foot usually affects men aged 20 to 40, often as a result of outdoor work.

The infection enters the foot through broken skin. A nodule or abscess forms, and grows into a mass of diseased tissue with sinuses (abnormal channels) that discharge bloody or pus-filled fluid. The fluid typically contains very small granules, which are fragments of infectious organisms. The infection may progress to involve the foot bones.
Treatment involves removal of diseased tissue (or, if necessary, amputation) and the use of antibiotics or antifungal drugs to destroy the infection.

**Maffucci’s syndrome**

A syndrome characterized by enchondromas (benign tumours of cartilage) together with haemangiomas (benign tumours of the blood vessels) on the skin or internal organs. The condition develops during childhood, and is more common in males than in females.

**Magnapen**

A brand-named antibiotic drug containing ampicillin with flucloxacillin.

**magnesium**

A mineral that is essential for the formation of bones and teeth, muscle contraction, nerve impulse transmission, and activation of many enzymes. Dietary sources include cereals, milk, nuts, soya beans, and fish.

**magnesium sulphate**

A magnesium compound used as a laxative drug and an anticonvulsant drug.

**magnesium trisilicate**

A magnesium compound that is used in antacid drugs.

**magnetic resonance imaging**

See MRI.

**malabsorption**

Impaired absorption of nutrients by the lining of the small intestine.

**CAUSES**

Malabsorption may be caused by many conditions. One possible cause is an inflammatory disorder, such as chronic pancreatitis (long-term inflammation of the pancreas) or Crohn’s disease (an inflammatory bowel condition). Another is infection, such as giardiasis (an infection of the small intestine).

Genetic disorders resulting in abnormal intestinal structure or function can also cause malabsorption, as in lactase deficiency (lack of an enzyme needed to digest milk sugar), cystic fibrosis (a disorder in which an excess of mucus is produced in the intestines), or coeliac disease (hypersensitivity to gluten, a substance in certain cereals).

Other causes of malabsorption include amyloidosis (a condition in which a starchy substance is deposited in vital organs), Whipple’s disease (a rare bacterial disorder), and lymphoma (cancer of lymph tissue). In addition, the removal of some of the small intestine, and certain operations on the stomach, may also result in malabsorption.

**SYMPTOMS**

Common symptoms of malabsorption are diarrhoea and weight loss. In severe cases, there may also be malnutrition (see nutritional disorders), vitamin deficiency, mineral deficiency, or anaemia.

**DIAGNOSIS AND TREATMENT**

Diagnosis may be made by tests on faeces, blood tests, barium X-ray examination and jejunal biopsy. In most cases, dietary modifications or supplements are successful in treating the disorder. In severe cases, intravenous infusion of nutrients is needed (see feeding, artificial).

**maladjustment**

Failure to adapt to a change in one’s environment, resulting in inability to cope with daily activities. Maladjustment can occur as a reaction to stressful situations such as divorce or moving house.

The person may have feelings of depression or anxiety; children and adolescents may show disturbed behaviour (see behavioural problems in children). Maladjustment often disappears when a person is removed from the stressful situation or if he or she manages to adapt to it.

**malaise**

A vague feeling of being unwell.

**malalignment**

Positioning of the teeth in the jaw so that they do not form a smooth arch shape when viewed from above or below (see malocclusion).

The term “malalignment” may also refer to a fracture in which the bone ends are not in a straight line.

**malar flush**

A high colour over the cheekbones, with a bluish tinge caused by reduced oxygen concentration in the blood. Malar flush is considered to be a sign of mitral stenosis (narrowing of one of the heart valves), which often follows rheumatic fever. However, malar flush is not always present in mitral stenosis, and many people with this colouring do not have heart disease.

**malaria**

A serious disease caused by protozoa called plasmodia. The infection is spread by the bite of Anopheles mosquitoes and is prevalent throughout the tropics. Malaria causes severe fever, and, in some cases, fatal complications affecting the kidneys, liver, brain, and blood.

**CAUSES**

There are four species of plasmodia that cause malaria: *Plasmodium falciparum*, *Plasmodium vivax*, *Plasmodium ovale*, and *Plasmodium malariae*. When a mosquito carrying the infection bites a human, the plasmodia enter the bloodstream. They invade the liver and red blood cells, where they multiply. The red cells then rupture, releasing the new parasites. Some of them infect new red cells, and the others develop into forms that can infect more mosquitoes. Falciparum malaria infects more red cells than the other species and thus causes a more serious infection. Most cases of this form occur in Africa.

**SYMPTOMS**

Symptoms of malaria include fever, shaking, and chills. There may also be severe headache, general malaise, and vomiting. The fever often develops in cycles, occurring every other day (in vivax and ovale infections) or every third day (in malariae infections).

Falciparum malaria can be fatal within days. Infected red cells become sticky and block blood vessels in vital organs. The spleen becomes enlarged and the brain may be affected, leading to coma and convulsions. Destruction of red blood cells causes haemolytic anaemia (see anaemia, haemolytic). Kidney failure and jaundice often occur.

**DIAGNOSIS AND TREATMENT**

A blood film examination is carried out to detect the parasites. Falciparum malaria is treated with quinine or mefloquine, or proguanil and atovaquone, or arte-mether with lumefantrine. Chloroquine is the usual treatment for species other than falciparum. People with vivax or ovale malaria must also take the drug primaquine to eradicate parasites in the liver. In severe cases, blood transfusions may be necessary.

**PREVENTION**

People who live in or visit malarial areas should take precautions in order to avoid mosquito bites; such measures include keeping the arms and legs covered and using insect repellents and mosquito nets. In addition, travellers to such areas should take preventive antimarial drugs. The course of drugs must be started up to three weeks before the person enters the area, and should be continued for one to four weeks after...
Malaria parasites (plasmodia) are transmitted by the bites of infected *Anopheles* mosquitoes. The plasmodia invade the liver and then the red blood cells, where they multiply. When the red blood cells rupture, they release the parasites; some of the plasmodia invade more red cells, while others develop into forms that can infect mosquitoes.

**Prevalence of malaria**
Malaria, although rare in the UK, is a major problem in the tropics. It affects about 300 million people worldwide, and kills more than one million people a year in Africa alone.

**Malarial infection of blood cells**
Some of the red blood cells on this TEM (transmission electron micrograph) contain the typical “signet ring” forms of one type of malarial parasite.

**Key**
- Areas in which malaria is prevalent
- Areas with limited risk
- Areas with no malaria

---

**THE SPREAD OF MALARIA**

Malarial infection

- Plasmodium develop in an infected mosquito.
- Some parasites mature, invade more red cells.
- Plasmodia inside red blood cells multiply.
- Infected red blood cells rupture, releasing plasmodia.
- Plasmodia invade the liver and then the blood stream.
- Uninfected mosquito bites the infected person, becoming infected.
- Mosquito breeds, developing into adults.
- Adult mosquito, in turn, bites a human.

---

**male**
The term that is used for a man or a boy. Male sex is determined by the possession of a Y sex chromosome, and by the presence of a penis and testes (see sexual characteristics, primary).

**male-pattern baldness**
The most common type of alopecia.

**malformation**
A deformity, particularly one that results from the faulty development of a baby in the mother's uterus. (See embryo and uterus).

**malignant**
A term used to describe a condition that tends to become progressively worse and eventually result in death. The term “malignant” is primarily used with reference to a cancerous tumour whose cells spread from the original site to form secondary tumours in other parts of the body.

**malignant hypertension**
Severe hypertension in which the blood pressure rises suddenly to a very high level, usually for no obvious cause, resulting in damage to arterioles and capillaries (tiny blood vessels). The condition occurs in a small minority of people with existing hypertension, particularly if it is due to kidney disorders; it is more common in young adults.

Most of the symptoms are caused by increased pressure in blood vessels in the head; they include headache, blurred vision, confusion, drowsiness, nausea, and vomiting. There may also be chest pain and shortness of breath. In addition, the pressure may produce changes in internal organs; for example, it causes...
papilloedema (swelling of the optic nerve) and enlargement of the heart, and may also cause retinal bleeding and acute kidney failure. If left untreated, it can cause death within six months.

Diagnosis is based on measurement of blood pressure and tests to detect damage to organs such as the kidneys. An affected person will need hospital treatment to lower blood pressure.

**malignant hyperthermia**
See: hyperthermia, malignant.

**malignant melanoma**
See: melanoma, malignant.

**malingering**
The deliberate simulation of symptoms for a particular purpose, such as taking time off work or obtaining compensation. Malingering is different from factitious disorders and hypochondriasis, in which the motivation for illness is not under the individual’s voluntary control.

**malleus**
The bony protuberance on each side of the ankle.

**mallet finger**
Injury to the tendon or bone in a fingertip that forces the tip into a bent position. A common sports injury, it occurs when a ball strikes a finger.

Treatment is with a splint or by temporary insertion of wire through the bones to hold the finger straight. The injury heals in two to three months.

**mallet toe**
See: claw-toe.

**malleus**
One of the three tiny bones (known collectively as the auditory ossicles) that are situated in the middle ear. The malleus, together with the incus and the stapes, transmits sound vibrations from the eardrum to the inner ear.

**Mallory–Weiss syndrome**
A tear at the lower end of the oesophagus, causing vomiting of blood. The syndrome is commonly caused by retching and vomiting after drinking excess alcohol, or as a result of food poisoning. Less often, violent coughing, a severe asthma attack, or epileptic convulsions may be the cause.

An endoscope is passed down the oesophagus to confirm the diagnosis. The tear generally heals within about ten days, with no special treatment required; however, a blood transfusion may sometimes be necessary.

**malnutrition**
See: nutritional disorders.

**malocclusion**
An abnormal relationship between the upper and lower sets of teeth when they are closed, affecting the bite or the appearance of the teeth.

**CAUSES**
Malocclusion usually develops during childhood. In some cases, it may be inherited. Alternatively, it may be due to thumb-sucking or to a mismatch between the teeth and jaws – for example, the combination of large teeth and a small mouth (see overcrowding, dental).

**TREATMENT**
Orthodontic appliances (braces) may be used to reposition the teeth; if there is dental overcrowding, some of the teeth may be extracted. Orthognathic surgery is used to treat severe recession or protrusion of the lower jaw. Treatment is best carried out in childhood or adolescence.

**malpresentation**
A condition in which a baby is not in the usual head-first position for childbirth. Malpresentation includes breech presentation (in which the baby’s bottom appears first), face presentation, and shoulder presentation (in which the baby is lying across the uterus). Breech presentations are the most common. A breech baby may be born by breech delivery or caesarean section. A shoulder presentation baby usually has to be delivered by caesarean section.

**MALT**
The abbreviation for mucosa-associated lymphoid tissue. This tissue is part of the lymphatic system, which helps to defend the body against infection. It is found in the digestive tract, particularly in the tonsils and in areas called Peyer’s patches in the small intestine.

**maltose**
A sugar composed of two glucose molecules (see disaccharide). Maltose is found in germinating cereal seeds.

**mammary dysplasia**
Normal variations in breast tissue that cause thickening and general lumpiness of the breasts. It may develop just before menstruation and subside afterwards. The condition is common in women between 30 and 50 years of age but is lower in those taking oral contraceptives.

The condition is not a disorder and does not lead to breast cancer. In many cases, no treatment is needed; in more severe cases, oral contraceptives may be prescribed. In contrast, any distinct breast lump should be assessed by a doctor.

**mammary gland**
See: breast.

**mammography**
An X-ray procedure for examining the breast. The breast is flattened between an X-ray plate and a plastic cover so that
as much tissue as possible can be imaged. Two images are taken of each breast. Mammography is used to investigate breast lumps, and to screen for breast cancer, because it reveals tumours too small to be found in a physical examination. It is offered every three years to all women between the ages of 50 and 65 years.

mammoplasty
An operation that is performed in order to make large breasts smaller, to enlarge small breasts, or to reconstruct a breast following surgery for breast cancer. In many cases, mammoplasty is performed for cosmetic reasons. However, the reduction of excessively large breasts may have the physical benefit of reducing back pain.

PROCEDURES
In breast reduction, excess tissue and skin is removed and the tissue is raised and reshaped to correct drooping. Breast enlargement or augmentation involves the insertion of a soft, fluid-filled breast implant behind the breast tissue or behind the muscles of the chest wall. In women undergoing a mastectomy (removal of a breast) for cancer, breast reconstruction may be carried out either at the same time or as a separate procedure. The normal contours of the breast are restored by the insertion of an implant.

RISKS
Breast reduction carries few risks, but enlargement may cause complications. These problems include leakage from the implant, hardening of the surrounding breast tissue, and scarring. Further surgery may be needed.

mandible
The lower jaw. The mandible consists of two fused pieces of bone forming a U shape. The upper surface bears the lower
set of teeth. The mandible is joined to the rest of the skull at the temporomandibular joint. It is the only skull bone capable of movement; it is moved by the cheek muscles for chewing and speech.

mania
A mental disorder characterized by episodes of overactivity, elation, or irritability. Mania usually occurs as part of a manic–depressive illness.

SYMPTOMS
Manic behaviour may include extravagant spending; repeatedly starting new tasks; sleeping less than normal; an increased appetite for food, alcohol, sex, and exercise; outbursts of inappropriate anger or laughter; a sudden increase in socializing; and delusions of grandeur. Milder forms are called hypomania.

TREATMENT
Severe mania is usually treated in hospital with antipsychotic drugs. Taking lithium or carbamazepine may prevent relapses.

manic–depressive illness
A mental disorder that is characterized by a disturbance of mood. The disturbance may be unipolar (consisting of either depression or mania) or bipolar (swinging between the two). In a severe form sometimes referred to as manic–depressive psychosis, there may also be grandiose ideas or negative delusions.

CAUSES
Some people inherit a tendency to manic–depressive illness. In addition, it is thought that abnormalities in brain biochemistry, or in the structure and/or function of certain nerve pathways in the brain, may underlie the illness.

TREATMENT
Severe illness often needs hospital treatment. Antidepressant drugs and/or ECT are used to treat depression, and antipsychotic drugs are given to control manic symptoms. Carbamazepine or lithium may be used to prevent relapse.

Group therapy, family therapy, and individual psychotherapy may be useful in certain circumstances. Cognitive–behavioural therapy may also help.

OUTLOOK
With treatment, most affected people improve or remain stable. Even those with severe illness may be restored to near-normal health with lithium therapy.

manipulation
A therapeutic technique involving the use of the hands to move parts of a patient’s body in order to treat certain disorders. Manipulation is important in orthopaedics, physiotherapy, osteopathy, and chiropractic. It may be used to treat deformity and stiffness caused by bone and joint disorders, to realign bones in a displaced fracture, to reposition a joint after a dislocation, or to stretch a contracture. Occasionally, manipulation is used to help treat frozen shoulder.

mannitol
An osmotic diuretic drug used to treat oedema (accumulation of fluid) in the brain and to relieve glaucoma (a buildup of fluid, and pressure, in the eyeball).

manometry
The measurement of pressure (of either a liquid or a gas) using an instrument called a manometer. Manometry is used to measure the blood pressure by means of an instrument called a sphygmomanometer.

Manson’s disease
See schistosomiasis.

mantoux test
A skin test that is performed to detect tuberculosis (see tuberculin tests).

manubrium
The top part of the sternum (breastbone).

MAOI
An abbreviation for monoamine oxidase inhibitor drugs.

maple syrup urine disease
See MSUD.

maple syrup urine disease (MSUD)
An inherited defect in body chemistry (see metabolism, inborn errors of) that interferes with the normal breakdown of amino acids. Abnormal acids accumulate in the blood and urine, giving the urine a characteristic smell of maple syrup, and causing severe ketoacidosis, seizures, and coma.

If left untreated, MSUD leads to learning difficulties and eventually to death during infancy. The condition can, however, be controlled with a low-protein diet.

marasmus
A severe form of protein and calorie malnutrition that usually occurs in famine or semi-starvation conditions. Marasmus is common in young children in developing countries. It causes stunted growth, emaciation, and loose folds of skin on the limbs and buttocks due to loss of muscle and fat. Other signs include sparse, brittle hair; diarrhoea; and dehydration.

Treatment includes keeping the child warm and giving a high-energy, protein-rich diet. Persistent marasmus can lead to learning difficulties and can also cause impaired growth. (See also kwashiorkor.)

marble bone disease
See osteopetrosis.

Marburg virus disease
A rare form of haemorrhagic fever, also called green monkey disease, that is transmitted by African vervet monkeys.

The onset of the disease is sudden, with fever; severe headache; chest and abdominal pain; vomiting; diarrhoea; and a rash on the trunk. The symptoms become increasingly severe; they may include weight loss, delirium, jaundice, massive haemorrhaging (internal bleeding), failure of the liver and other organs, and shock.

There is no specific treatment for the disease; affected people must be admitted to hospital, where their blood and fluid levels will be maintained and any further infections treated.

march fracture
A break in one of the metatarsal bones (the long bones in the foot) that is caused by running or walking for long distances on a hard surface. The fracture results in pain, tenderness, and swelling; however, it may not show on X-rays until callus (new bone) has started to form. Treatment for a march fracture involves rest and, occasionally, immobilization of the foot in a plaster cast. (See also stress fracture.)

Marfan syndrome
A genetic disorder of connective tissue (material that holds body structures together) that results in skeletal, heart, and eye abnormalities. It is inherited in an autosomal dominant manner. Marfan syndrome is one of the most common disorders of connective tissue.

The features of Marfan syndrome usually appear after the age of 10. Affected people are very tall and thin. They have long, thin limbs, fingers, and toes, and weak ligaments and tendons. The chest and spine are often deformed and the lens of the eye may be dislocated. The heart is often abnormal and the aorta weakened.
Features of Marfan syndrome
One of the characteristic features of Marfan syndrome is long, thin, "spider" fingers (arachnodactyly). The condition is apparent when the hand of a person with Marfan syndrome (left) is compared to that of a normal person.

There is no cure for Marfan syndrome, but children are monitored and any complications are treated as they arise. Many affected children need glasses. Children may also be given beta-blockers to help prevent weakening of the aorta, and those with defects of the heart valve or aorta may undergo corrective surgery.

If a family has a member with Marfan syndrome, tests may be used (see genetic counselling) to find out whether or not relatives will pass on the gene.

marijuana
The flowering tops and dried leaves of the Indian hemp plant Cannabis sativa, containing the active ingredient THC (tetra-hydrocannabinol). The leaves are usually smoked but can also be drunk as tea or eaten in food.

Physical effects of marijuana include dry mouth, mild reddening of the eyes, slight clumsiness, and an increased appetite. The main subjective feelings are usually of calmness and wellbeing, but depression occurs occasionally.

Large doses may cause panic, fear of death, and delusions. In rare cases, drug psychosis occurs, with symptoms such as paranoid delusions and confusion, which usually disappear in a few days.

There is increasing evidence that regular use of marijuana can aggravate mental health problems, particularly depression and schizophrenia, in people with these illnesses. Adolescents are most at risk. In addition, regular smoking of marijuana may cause worse lung damage than that caused by tobacco; the effect of three joints (marijuana cigarettes) is thought to be equivalent to 20 tobacco cigarettes.

Maroteaux–Lamy syndrome
A form of mucopolysaccharidosis caused by a deficiency in levels of the enzyme arylsulphatase B. The condition causes features similar to those of Hurler's syndrome, such as coarsening of the facial features, skeletal deformities, cardiac abnormalities, and enlargement of the liver and spleen; however, the affected child's level of intelligence is normal. The condition often appears early in childhood. There is no specific treatment, and death from heart failure often occurs between 20 and 30 years of age.

marriage guidance
See relationship counselling.

marrow, bone
See bone marrow.

marsupialization
A surgical procedure carried out to drain some types of abscess or cyst and to prevent further abscesses. It is used to treat certain types of cyst affecting the pancreas and liver, and cysts affecting the Bartholin's glands at the entrance to the vagina.

In marsupialization, the cyst is first cut open and drained, then its edges are stitched to the surrounding skin or tissue (to form a pouch) so that it is kept open until it has healed.

Marvelon
A brand-named oral contraceptive containing the synthetic female hormones ethinylestradiol (an oestrogen drug) and desogestrel (a progestogen).

masculinization
See virilization.

masking
A technique used in a hearing test that involves applying a noise to one ear while testing the hearing of the other.

The term “masking” may also be used in connection with pairs of genes in which the effects of an abnormal gene are concealed by its normal equivalent. (See genetic disorders; inheritance.)

masochism
A desire to be physically, mentally, or emotionally abused. The term “masochism” is primarily used to refer to obtaining sexual excitement through one's own sufferings in activities such as bondage, flagellation, and verbal abuse. (See also sadism; sadomasochism.)

masseter
The large muscle in the cheek that stretches between the cheekbone and the angle of the lower jaw. The muscle lifts the lower jaw during chewing.

mass hysteria
Intense emotion and irrational behaviour that spreads through a group of people in response to a highly exciting or upsetting event. The term may also be used to describe the occurrence of identical physical or emotional symptoms simultaneously in a particular group of people, such as children in the same class or school.

mastalgia
The medical term for pain in the breast.

mast cell
A type of cell that plays an important part in allergy. In an allergic response, antibodies (proteins produced by the immune system to neutralize an allergen) attach themselves to mast cells. The cells burst and release a chemical called histamine, which produces an inflammatory response in surrounding tissues, thereby causing many of the symptoms of allergic conditions.

mastectomy
The surgical removal of all of the breast, usually performed to treat breast cancer. Mastectomy may be used if the cancer cannot be removed by lumpectomy (removal of the tumour and a small area of surrounding tissue) or quadrantectomy (removal of part of the breast) because of its size or position. Less commonly, a procedure known as subcutaneous mastectomy may be recommended for women who have a very high risk of developing breast cancer because they carry an abnormal gene that causes the disease.

HOW IT IS DONE
Formerly, a procedure called radical mastectomy was used; this involved removal of the breast together with an extensive area of muscle down to the chest wall. Today, however, the usual procedure is a total mastectomy. This operation involves
**MASTICATION**

**TYPES OF MASTECTOMY**

The type of operation depends on many factors, including the size and site of the tumour and the woman’s wishes. A small tumour may be treated by lumpectomy; other cases may require more extensive surgery.

**LUMPECTOMY**

Site of incision for a lumpectomy

Only the cancerous tissue (shown here by a dotted line) and some of the surrounding normal tissue is removed. Lumpectomy leaves the breast looking relatively normal.

**TOTAL MASTECTOMY**

1 A large, elliptical incision that encompasses the nipple and sometimes the entire breast, is made. Part of the incision is extended into the armpit. All of the breast tissue, including the skin and some of the fat, is dissected (separated by cutting) down to the chest muscles. The dissection is continued under the skin into the armpit, to free the upper and outer "tail" of breast tissue with its lymph nodes.

2 All of the bleeding vessels are tied off, then a drainage tube is inserted and the skin is closed with stitches or clips. The scar runs diagonally across the chest. The woman may wear a prosthesis or may have an implant inserted later.

**RISKS**

After the operation, the scar may be tender. If the lymph nodes have been removed, there is a risk of lymphoedema developing in the arm.

**mastitis**

Inflammation of breast tissue. Mastitis is usually caused by bacterial infection and sometimes by hormonal changes.

**CAUSES**

Mastitis usually occurs when bacteria enter the nipple during breast-feeding. It can also be caused by changes in levels of sex hormones in the body—for example, at the onset of puberty.

**SYMPTOMS**

The condition causes pain, tenderness, and swelling in one or both breasts. Bacterial mastitis during breast-feeding also causes redness and engorgement and may result in a breast abscess.

**TREATMENT**

Mastitis due to infection is treated with antibiotic drugs and analgesic drugs, and by expressing milk to relieve engorgement. Mastitis caused by hormonal changes usually clears up in a few weeks without treatment.

**mastocytosis**

An unusual condition in which itchy, irregular, yellow or orange-brown swellings occur on the skin, most commonly on the trunk. Mastocytosis may also affect body organs, including the liver, spleen, and intestine, and may cause symptoms such as diarrhoea, vomiting, and fainting. Very rarely, it leads to anaphylactic shock (a severe form of allergic reaction), which can be fatal.

**mastoid**

The lower part of the temporal bone in the skull. The mastoid has a projection, called the mastoid process, which can be felt behind the ear. The bone is honeycombed with cavities called air cells; these spaces are connected to a larger cavity called the mastoid antrum, which leads into the middle ear.

In some cases, infections of the middle ear (see otitis media) spread through the mastoid bone to cause acute mastoiditis.

**LOCATION OF MASTOID**

The mastoid is the lower part of the temporal bone. The mastoid process can be felt as a hard prominence just behind the ear.

**mastoiditis**

Inflammation of the mastoid, in the skull.

**CAUSE**

Mastoiditis is due to infection spreading from the middle ear (see otitis media) to the air cells in the mastoid through a cavity called the mastoid antrum.

**SYMPTOMS**

The condition causes earache and severe pain, swelling, and tenderness behind the ear. There is usually also fever, a creamy discharge from the ear, progressive hearing loss, and displacement of the outer ear. If the infection spreads, it may lead to meningitis, a brain abscess, blood clotting in veins within the brain, or facial palsy.

**TREATMENT**

Treatment is with antibiotic drugs. If the infection persists, an operation called a
mastectomy may be carried out; in this procedure, the mastoid is opened and the infected air cells removed.

**masturbation**

Sexual self-stimulation, usually to produce orgasm. Massaging the penis or the clitoris with the hand is the usual method of masturbation.

**maternal mortality**

The death of a woman during pregnancy, or within 42 days of childbirth, miscarriage, or an induced abortion, from any pregnancy-related cause. Maternal mortality rate is the number of such deaths per 100,000 live births as measured over a given year.

Maternal deaths may be a direct result of complications of pregnancy or may be caused indirectly by a medical condition that is worsened by pregnancy. The major direct causes of death include pulmonary embolism (blood clots in the lungs), antepartum haemorrhage, postpartum haemorrhage, hypertension (high blood pressure), eclampsia (a condition causing seizures in late pregnancy), and puerperal sepsis (infection following childbirth). Indirect causes include heart disease, epilepsy, and some cancers.

Maternal mortality is lowest for second pregnancies. After the age of 20, it rises with age, being greatest for women over the age of 40.

**maturation**

The process by which full development is reached. The term “maturation” is used with reference to cells (particularly ova and sperm) and some microorganisms; it may also be used of physical and emotional development in people.

**maxilla**

Each of a pair of bones that together form the centre of the face, the upper jaw, and the roof of the mouth. In addition, the top of the maxilla forms the base of the orbit (eye socket). Each bone contains a large, air-filled cavity called the maxillary sinus (see sinus, facial), which is connected to the nasal cavity.

**McArdle’s disease**

A rare genetic disorder characterized by muscle stiffness and painful cramps that increase during exertion and afterwards. The cause is a deficiency of an enzyme in muscle cells that stimulates breakdown of the carbohydrate glycogen into the simple sugar glucose. The result is a buildup of glycogen and low levels of glucose in the muscles. Damage to the muscles occurs, causing myoglobinuria (the presence of pigment from muscle cells in the urine); this condition, in turn, may lead to kidney failure.

There is no treatment, but symptoms may be relieved by eating glucose or fructose before exercise.

**MDMA**

The hallucinogenic substance methylenedioxymethamphetamine, which has the street name Ecstasy.

**ME**

The abbreviation for the condition myalgic encephalomyelitis (see chronic fatigue syndrome).

**measles**

A potentially dangerous viral illness that causes fever and a rash. Measles mainly affects children, but can occur at any age. It is spread primarily by airborne droplets of nasal secretions. It can be transmitted during the incubation period (eight to 14 days after infection) and up to seven days after symptoms appear.

**SYMPTOMS AND SIGNS**

The illness starts with a fever, runny nose, sore eyes, cough, and a general feeling of being unwell. After three to four days, a red rash appears, usually starting on the head and neck and spreading to cover the body. The spots sometimes join to produce large red blotches, and the lymph nodes may be enlarged. After three days, the rash starts to fade and the symptoms subside.

**COMPLICATIONS**

The most common complications are ear and chest infections, which usually develop two to three days after the rash has appeared. Diarrhoea, vomitting, and abdominal pain may occur. Febrile convulsions (see convulsion, febrile) are also common, but are not usually serious.

In a tiny minority of cases, encephalitis (inflammation of the brain) occurs, causing headache, drowsiness, and vomiting. Seizures and coma may follow, sometimes leading to brain damage or even death. In very rare cases, a progressive brain disorder called subacute sclerosing panencephalitis develops several years after infection.

If a woman has measles during pregnancy, the infection may be fatal to the fetus; however, there is no evidence that measles causes birth defects.

**TREATMENT**

There is no specific treatment. Plenty of fluids and paracetamol are given for fever. In addition, antibiotic drugs may be given to treat bacterial infections that occur as complications.

**PREVENTION**

To help prevent measles, immunization with the MMR vaccination is recommended at between 12 and 15 months of age. This measure produces immunity in about 90 per cent of cases, with a booster shot given before a child enters school or nursery school.

**meatus**

A canal or passageway through part of the body. The term usually refers to the external auditory meatus, the canal in the outer ear that leads from the outside of the ear to the eardrum.

**mebendazole**

An anthelmintic drug that is used to treat various worm infestations of the intestine. Possible adverse effects include abdominal pain and diarrhoea.

**mebeverine**

An antispasmodic drug used to treat irritable bowel syndrome.

**Meckel’s diverticulum**

A common abnormality, present at birth in about 1 in 40 people, in which a small, hollow, wide-mouthed sac protrudes from the ileum. Symptoms only occur if the diverticulum becomes...
Meckel’s diverticulum

In this common birth defect, an appendix-type sac protrudes from the ileum (the last section of the small intestine). Anatony of Meckel’s diverticulum

Inflammation may cause symptoms very similar to those of appendicitis, such as lower abdominal pain. Meckel’s diverticulum occasionally causes intussusception (telescoping) or volvulus (twisting) of the small intestine.

Diagnosis of the abnormality may be made by using technetium radionuclide scanning. If any complications develop, they will be treated by surgical removal of the diverticulum.

Meconium

Occasionally, the fetus passes meconium into the amniotic fluid while still in the uterus. This problem is more common in those babies who experience fetal distress during labour or who are over 40 weeks’ gestation. Meconium in the amniotic fluid may be inhaled when the baby starts to breathe, sometimes blocking the airways and damaging the lungs. In some babies with cystic fibrosis, the meconium is so thick and sticky that it blocks the intestine (see intestine, obstruction of).

Median nerve

One of the main nerves of the arm. The median nerve is a branch of the brachial plexus and runs down the arm from the shoulder into the hand. It controls the muscles that carry out bending movements of the wrist, fingers, and thumb, and the muscles that rotate the forearm palm-inwards. The nerve also conveys sensations from the thumb and first three fingers, and from the region of the palm at their base.

Disorders

Damage to the nerve may result from injury to the shoulder, a Colles’ fracture just above the wrist, or pressure on the nerve where it passes through the wrist (carpal tunnel syndrome). Symptoms of damage include numbness and weakness in areas controlled by the nerve.

Mediastinoscopy

Viewing of the mediastinum using an endoscope inserted through an incision just above the sternum (breastbone). The procedure is performed under general anaesthesia.

Mediastinoscopy is used mainly to perform a biopsy of a lymph node, often in diagnosing lymphoma. The tissue sample is removed by tiny blades attached to the endoscope.

Mediastinum

The membranous partition between the lungs and the other structures within the chest cavity. These other structures include the heart and associated blood vessels; the trachea (windpipe); the oesophagus; the thymus gland; lymph nodes; lymphatic vessels; and nerves.

MedicAlert bracelet

An item, available from a charitable organization called the MedicAlert foundation, that provides vital information about a person’s identity and medical status in case he or she needs urgent medical help. The items are designed to be worn by individuals with a hidden medical condition (such as epilepsy or diabetes mellitus) or a serious allergy (such as penicillin allergy).

MedicAlert bracelets, and necklaces, are engraved with an emblem that is instantly recognizable to medical workers and carries details of important medical conditions affecting the wearer. They also carry a personal identification number and a 24-hour telephone number so that further medical details can be accessed anywhere in the world.

Medical ethics

The professional values and guidelines that govern medical decisions, particularly medical practitioners’ treatment of patients and their relatives and of colleagues. Ethical requirements also play a part in medical research; for example, when new drugs or other treatments are tested on patients, the trials must be designed so that they will not cause any harm to the patients involved.

Medical history

See history-taking.

Medical tests

See tests, medical.

Medication

Any substance prescribed to treat disease. (See also drug; medicine.)

Medicine

The study of human diseases and their causes, frequency, treatment, and prevention. The term “medicine” is also used of a substance that is prescribed to treat an illness. In some circumstances, it is used to refer to treatments that do not involve surgery.

Medicolegal

A term used of matters in which medicine and the law overlap. Among the issues on which medicolegal experts advise people are laws concerning damages for injuries that are due to medical negligence or malpractice; evidence concerning the extent of injury in a civil action; the use of paternity tests; the mental competence of people who have drawn up wills; and restrictions placed on mentally ill people.

Medicolegal issues also include an individual’s right to die (see brain death; euthanasia; living will); the necessity for informed consent to any surgical procedure; the legal aspects of artificial insemination, in vitro fertilization, sterilization, and surrogacy; and a patient’s right to confidentiality concerning his or her illness. (For the medical aspects of criminal law, see forensic medicine.)

Meditation

Concentration on an object, a word, or an idea with the aim of inducing an altered state of consciousness. At its deepest level, meditation can resemble a trance. More commonly, it is a calming therapy and can be a way to reduce stress levels and treat stress-related dis-
orders. A common form of meditation practised in Europe and North America is transcendental meditation (TM).

**Mediterranean diet**
A diet based on the traditional foods eaten in Mediterranean countries, where people have a lower risk of cardiovascular disease and cancer than people in northern European countries. The bulk of the diet consists of fruit, vegetables, and grain-based foods such as pasta and couscous. The major source of fat is olive oil, a monounsaturated fat (see fats and oils). The diet also includes fish, but only small amounts of meat, poultry, eggs, and dairy products.

**Mediterranean fever**
See brucellosis.

**Mediterranean fever, familial**
See familial Mediterranean fever.

**medroxyprogesterone**
A progestogen drug used to treat endometriosis (a condition in which fragments of uterine lining are found in the pelvic cavity), as well as certain types of breast cancer and uterine cancer (see uterus, cancer of). In addition, it is sometimes used to treat menstrual disorders such as amenorrhoea (absence of menstruation). The drug can also be used as a contraceptive, given by injection at three-month intervals (see contraception, hormonal methods of). Possible adverse effects include weight gain, swollen ankles, and breast tenderness.

**medulla**
The innermost part of a body structure; for example, the adrenal medulla is the central area of an adrenal gland. In addition, the word “medulla” is sometimes used to refer to the medulla oblongata.

**medulla oblongata**
Also called the medulla, the lowest part of the brainstem. The medulla oblongata lies at the base of the skull. It connects the brain to the spinal cord.

**medulloblastoma**
A type of cancerous brain tumour that occurs mainly in children. A medulloblastoma usually arises from the cerebellum, the region of the brain that is concerned with posture, balance, and coordination. The tumour grows rapidly and may spread to other parts of the brain and also to the spinal cord.
mefenamic acid

An NSAID (see nonsteroidal anti-inflammatory drugs) used to relieve pain and inflammation. Mefenamic acid may be given for conditions such as headache, toothache, and dysmenorrhoea (painful menstrual periods), and to reduce menorrhagia (excessive menstrual bleeding). It may also be prescribed for long-term relief of joint pain and stiffness in osteoarthritis and rheumatoid arthritis.

Possible adverse effects are typical for NSAIDs; they include abdominal pain, indigestion, nausea, and vomiting.

mefloquine

A drug used to prevent and treat malaria in parts of the world where the parasite that causes it is resistant to chloroquine. Mefloquine is one of the preferred treatments for falciparum malaria.

Side effects include nausea, vomiting, and diarrhoea. Rarely, there may be panic attacks, hallucinations, and psychosis. Mefloquine is not recommended for people who have a history of disorders such as depression or epilepsy.

mega-

A prefix meaning "very large", as in megacolon, a condition in which the colon is greatly enlarged. The prefix "megalo-" has the same meaning.

megacolon

A gross distension (enlargement) of the colon, usually accompanied by severe, chronic constipation.

CAUSES

In children, the main causes of megacolon are anal fissures, Hirschsprung's disease, and psychological factors that may have arisen during toilet-training. In elderly people, causes include the long-term use of strong laxative drugs. People suffering from chronic depression or schizophrenia often have megacolon. Other, rarer causes include hypothyroidism, spinal injury, and the use of drugs such as morphine and codeine.

SYMPTOMS

Megacolon causes constipation and abdominal bloating. Some affected individuals experience loss of appetite, which

morning headache, repeated vomiting, and a clumsy gait develop. There are also frequent falls.

The tumour is diagnosed by CT scanning or MRI and can often be treated with radiotherapy. Surgery and anticancer drugs may also be needed.
may lead to weight loss. Diarrhoea may occur if semi-liquid faeces leak around the obstructing hard faeces.

**DIAGNOSIS AND TREATMENT**
The diagnosis is made by **proctoscopy** (viewing of the rectum with an endoscope), **barium X-ray examination**, and tests to assess the functioning of the intestinal muscles. If Hirschsprung’s disease is suspected, **biopsy** of the large intestine may be performed.

Impacted faeces are often removed using **enemas**. In severe cases, the faeces must be removed manually.

**megaloblastic anaemia**
See **anaemia, megaloblastic**.

</table>

An exaggeration of one’s importance or ability that often occurs in **mania**. Megalomania may take the form of a delusion of grandeur, or may manifest itself as a desire to organize large-scale activities that are expensive and involve many people.

**megaly**
A suffix meaning “enlargement”, as in **acro-megaly**, a disorder in which the jaw, skull, hands, and feet are enlarged.

**megaloureter**
Gross distension (widening) of a **ureter**, the tube that carries urine from each kidney to the bladder. One possible cause of megaureter is a long-standing blockage in the ureter that stops the flow of urine. Another is backward flow of urine from the bladder into the ureters while the bladder is being emptied (see **vesico-ureteric reflux**). In some cases, the condition is congenital (present at birth) and has no known cause.

Megaureter is treated by surgery to remove blockages or to relieve reflux.

**megestrol**
A progestogen drug that is used to treat uterine cancer (see **uterus, cancer of**) and certain types of **breast cancer**. Megestrol may be prescribed when a tumour is inoperable, if a tumour has recurred after surgery, or when other **anticancer drugs or radiotherapy** prove ineffective.

Possible adverse effects of the drug include swollen ankles, weight gain, nausea, dizziness, headache, rash, and, rarely, raised blood calcium levels.

**meibomian cyst**
See **chalazion**.

**meibomian gland**
A small sebaceous (oil-secreting) gland situated under the **conjunctiva** (mucous lining) of each eyelid. If one of the glands becomes blocked, it enlarges to create a swelling within the lid, which is known as a **chalazion**.

**meibomianitis**
Inflammation of the **meibomian glands**, the sebaceous (oil-secreting) glands within the eyelids. The condition is caused by excessive or unusually thick glandular secretions, which result in an overgrowth of bacteria on the eyelids. Conditions that can increase the secretions include skin disorders affecting the face (such as **acne or rosacea**), allergic reactions, and the hormonal changes that occur in adolescence.

Symptoms of meibomianitis include swelling of the eyelid edges, brief blurring of the vision due to oily tears, and frequent **styes**. Careful cleansing of the eyelids may relieve the symptoms. Antibiotic eye ointment may be prescribed to clear up infection.

**Meig’s syndrome**
A rare condition in which a tumour of an **ovary** is accompanied by **ascites** (an accumulation of fluid in the abdomen) and a **pleural effusion** (fluid around one of the lungs). The fluid usually disappears when the tumour is removed.
meiosis
A type of cell division that occurs in the ovaries and testes during the production of egg and sperm cells. During meiosis in humans, a cell containing 23 pairs of chromosomes (46 in total) divides to form four sperm or egg cells, each with 23 single chromosomes.

First, each chromosome is duplicated (making a total of 92); the doubled chromosomes are joined at a point called the centromere. Matching pairs of doubled chromosomes line up and exchange genetic material. The cell then divides twice to form four daughter cells, with each taking one copy of each chromosome.

Egg and sperm cells therefore have 23 single chromosomes, which is only half the usual chromosome content of a body cell, so each parent contributes half of the offspring’s genetic material. The exchange between chromosomes means that each daughter cell has a unique genetic make-up. (See also mitosis).

melaena
Black, tarry faeces caused by bleeding, usually in the upper gastrointestinal tract. The blood is blackened by the action of secretions during digestion. Melaena is usually caused by a peptic ulcer but may indicate cancer.

melancholia
Former term for depression.

melanin
The brown or black pigment that gives skin, hair, and the iris of the eyes their colouring. Melanin is produced by cells called melanocytes.

Exposure to sunlight increases the production of melanin, which protects the skin from the harmful effects of ultraviolet rays and causes the skin to darken. Localized overproduction of melanin in the skin can result in a pigmented spot, most commonly a freckle or mole (see naevus).

melanocyte
A specialized skin cell that produces the pigment melanin. The cells can be damaged by overexposure to the sun; this damage may result in skin cancer (see melanoma, malignant).

melanoma, juvenile
A raised, reddish-brown skin blemish, also called a Spitz naevus, which sometimes appears on the face or legs in
early childhood (see naevus). Despite the name, it is noncancerous. Although it is harmless, an unsightly growth, or one that is suspected of being skin cancer, may be removed surgically.

**melanoma, malignant**
The most serious of the three types of skin cancer. (The other two forms of the disorder are basal cell carcinoma and squamous cell carcinoma.) If left untreated, the cancer may be fatal.

**CAUSE AND INCIDENCE**
Malignant melanoma is a tumour of melanocytes, the cells that produce the pigment melanin, and is due to long-term exposure to strong sunlight. It is most common in middle-aged and elderly people with pale skin and fair hair who have spent many years in sunny climates. Severe sunburn during childhood doubles the risk of developing melanoma in later life.

There is an increasing number of new cases and deaths in the UK each year from this skin cancer, probably due to people sunbathing and taking holidays in sunny countries.

**SYMPTOMS**
Tumours usually develop on areas of exposed skin but may occur anywhere on the body, including in the eye. A mole usually grows from an existing mole. An affected mole may change colour, increase in size, or develop an irregular edge. Other signs include a mole becoming lumpy, bleeding or crusting, forming a scab, or becoming itchy or inflamed. Such changes should be reported to a doctor. Occasionally, a melanoma develops in normal skin. If left untreated, the cancer can grow down through the layers of skin and rapidly spread to other parts of the body.

**DIAGNOSIS AND TREATMENT**
Early diagnosis is vital to help prevent life-threatening spread of the cancer.

Diagnosis is by a skin biopsy, in which tissue from the growth, together with some of the surrounding skin, is removed for microscopic examination. Samples from nearby lymph nodes may also be examined; the presence of any cancerous cells in these samples would indicate that the cancer has spread.

The melanoma will be removed surgically. If the cancer has spread from the primary site, radiotherapy or anticancer drugs may also be necessary. Immuno-therapy may be used to help the body fight the cancer; this treatment involves the use of substances such as interferon or interleukin-2.

**melanonychia**
Black or dark coloration of a fingernail or toenail, due to an excess of the pigment melanin. The colour often forms a vertical streak down the nail.

**melanosis coli**
Black or brown discoloration of the colon lining. Melanosis coli is associated with chronic constipation and prolonged use of certain laxative drugs, such as senna, rhubarb, and cascara.

The discoloration is most common in elderly people and is usually symptomless. It clears up when the laxatives are no longer used. Rarely, it is associated with colon cancer (see colon, cancer of).

**melasma**
See chloasma.

**melatonin**
A hormone secreted by the pineal gland in the brain that is thought to play a part in controlling daily body rhythms and regulating the sleep–wake cycle. Levels of melatonin rise in response to decreasing light, preparing the body for sleep. Some people believe that taking supplements of melatonin can help to minimize the effects of jet-lag, but this has not been proved.

**Melleril**
A brand name for the antipsychotic drug thioridazine.

**melphalan**
An anticancer drug used to treat multiple myeloma as well as certain types of breast cancer and ovarian cancer (see ovary, cancer of). Possible adverse effects include nausea, vomiting, sore throat, loss of appetite, reduced numbers of red and other blood cells (see anaemia, aplastic), abnormal bleeding, and increased susceptibility to infection.

**membrane**
A layer of tissue that covers or lines a body surface or forms a barrier.

**memory**
The ability to remember. Memory is usually regarded as comprising three stages: registration, retention, and recall. In registration, information is perceived, is understood, and is then held in the short-term memory. In retention, more important information is transferred into the long-term memory and stored. Recall involves bringing information into the conscious mind at will. There are a number of factors that determine how well information is remembered, including its familiarity and how much attention has been paid to it.

Where in the brain the memory process takes place is not known. However, the temporal lobe and limbic system may be involved. The mechanisms for storing memory are also unknown.

### THE STAGES OF MEMORY

**Stage 1: Registration**
Information is perceived and understood, then held in a short-term memory system. This system seems to be very limited in the amount of material that it can store at one time. Unless refreshed by constant repetition, the contents of short-term memory are lost within minutes, to be replaced by other material.

**Stage 2: Retention**
If information is sufficiently important, it is transferred into long-term memory for storage. The process of storage involves association of the information with certain words or meanings, with visual imagery evoked by it, or with other experiences, such as smell or sound.

**Stage 3: Recall**
Information that has been stored at an unconscious level, in long-term memory, is brought into the conscious mind by an act of will. The reliability of the recall process depends on how well the information was encoded in stage 2.
DISORDERS
Most memory disturbances are due to failure at the retention or recall stage (see amnesia). In some cases, the problem occurs at the registration stage. Some people with temporal lobe epilepsy have uncontrollable flashbacks of distant past events. The most common memory disorder is the normal difficulty in recall that develops with age. More severe loss of memory may be an early symptom of dementia.

memory B-cell
A type of white blood cell, also known as a memory B-lymphocyte (see lymphocyte), that is involved in the immune system response to viruses, parasites, and cancer cells. Memory B-cells recognize bacteria that the body has previously encountered. They promptly produce huge quantities of antibodies that inactivate the bacteria, thus preventing or shortening the organisms’ effects. (See also memory T-cell.)

memory, loss of
See amnesia.

memory T-cell
A type of white blood cell, also known as a memory T-lymphocyte (see lymphocyte), that is involved in the immune system response to viruses, parasites, and cancer cells. Memory T-cells recognize viruses, parasites, or cancer cells that the body has previously encountered. Some belong to the class of killer T-cells, which attach themselves to infected cells and then release toxic proteins to destroy the cells. (See also memory B-cell.)

menarche
The onset of menstruation. Menarche usually occurs around the age of 12 or 13, two years after puberty starts.

Mendelian inheritance
A form of inheritance first described by the Austrian monk Gregor Mendel. He discovered that certain distinct, unchanging physical characteristics are controlled by factors that are now called genes, which are transmitted through many generations. He also revealed the existence of dominant and recessive genetic characteristics.

Mendel formulated two laws concerning inheritance. Mendel’s first law, or the law of segregation, states that the characteristics of an organism are determined by pairs of genes, and that during reproduction the genes in each pair separate, with only one allele (gene from a pair) being carried in a gamete (egg or sperm cell) and passed on to an offspring (see meiosis). Mendel’s second law, or the law of independent assortment, states that each gene in a pair can be combined with either of the genes from any other pair, so that gametes can show all possible combinations of non-paired genes.

Mendelson’s syndrome
Inhalation of regurgitated stomach contents by someone who is under general anaesthesia; also called pulmonary aspiration syndrome. Stomach acid can damage the mucous membranes lining the airways; it can also cause bronchospasm (sudden constriction of the airways leading to each lung), and pulmonary oedema (a buildup of fluid in the lungs). Breathing may be severely impaired and the person may die.

The problem is particularly associated with general anaesthesia for emergency obstetric procedures during labour. It can be prevented by giving drugs to inhibit stomach acid secretion before operating.

Ménière’s disease
An inner ear disorder characterized by recurrent vertigo (a spinning sensation), deafness, and tinnitus (ringing in the ears). It is uncommon before the age of 40.

cause
The cause of the disorder is an accumulation of fluid in the labyrinth. The buildup may damage the labyrinth and sometimes the adjacent cochlea.

symptoms
There is a sudden attack of vertigo, lasting from a few minutes to several hours. This is usually accompanied by nausea, vomiting, nystagmus (abnormal jerky eye movements), and deafness, tinnitus, and a feeling of pressure or pain in the affected ear.

diagnosis and treatment
Diagnosis is usually made with audiology (see hearing tests) or other hearing tests, and a caloric test.

Treatment with certain antihistamine drugs, such as cinnarizine, or with beta-histine usually relieves the symptoms. Prochlorperazine may be given, either rectally or by injection, for severe attacks. Ménière’s disease can also be treated by surgery to the inner ear if symptoms are not controlled by drugs. If deafness eventually becomes total, the other symptoms usually disappear.

meningioma
A rare, noncancerous tumour of the meninges (the membranes surrounding the brain). A meningioma arises from the arachnoid mater (the middle membrane) and, in most cases, it then becomes attached to the dura mater (the outer membrane).

The meningioma slowly expands and may become very large before any symptoms appear. The symptoms may include headache, vomiting, and impaired mental function. There may also be speech loss or visual disturbance. If the tumour invades the overlying skull bone, there may be thickening and bulging of the skull.

meninges
The three membranes that cover and protect the brain and the spinal cord. The outermost membrane, the dura mater, is tough and fibrous; it lines the inside of the skull and forms a loose sheath around the spinal cord. The middle membrane, the arachnoid mater, is elastic and weblike. The innermost membrane, the pia mater, lies next to the surface of the brain.

The pia mater is separated from the arachnoid mater by the subarachnoid space, which contains cerebrospinal fluid. Another space, called the subdural space, separates the arachnoid mater from the dura mater.

meningioma
A rare, noncancerous tumour of the meninges (the membranes surrounding the brain). A meningioma arises from the arachnoid mater (the middle membrane) and, in most cases, it then becomes attached to the dura mater (the outer membrane).

The meningioma slowly expands and may become very large before any symptoms appear. The symptoms may include headache, vomiting, and impaired mental function. There may also be speech loss or visual disturbance. If the tumour invades the overlying skull bone, there may be thickening and bulging of the skull.

Ménière’s disease
An inner ear disorder characterized by recurrent vertigo (a spinning sensation), deafness, and tinnitus (ringing in the ears). It is uncommon before the age of 40.

cause
The cause of the disorder is an accumulation of fluid in the labyrinth. The buildup may damage the labyrinth and sometimes the adjacent cochlea.

symptoms
There is a sudden attack of vertigo, lasting from a few minutes to several hours. This is usually accompanied by nausea, vomiting, nystagmus (abnormal jerky eye movements), and deafness, tinnitus, and a feeling of pressure or pain in the affected ear.

diagnosis and treatment
Diagnosis is usually made with audiology (see hearing tests) or other hearing tests, and a caloric test.

Treatment with certain antihistamine drugs, such as cinnarizine, or with beta-histine usually relieves the symptoms. Prochlorperazine may be given, either rectally or by injection, for severe attacks. Ménière’s disease can also be treated by surgery to the inner ear if symptoms are not controlled by drugs. If deafness eventually becomes total, the other symptoms usually disappear.
Meningiomas can be detected by X-ray or CT scanning, or by MRI. The tumours can often be completely removed by surgery. Otherwise, treatment is by radiotherapy.

**meningitis**

Inflammation of the meninges (membranes covering the brain and spinal cord), usually due to infection.

**CAUSES**

Viral meningitis tends to occur in epidemics in winter; it is usually relatively mild. Bacterial meningitis, however, is life-threatening. It is mainly caused by *Haemophilus influenzae*, *Streptococcus pneumoniae*, or *Meningococcus* types B and C.

The infection usually reaches the meninges via the bloodstream from an infection elsewhere in the body, often in the nose or throat. Less commonly, it passes through skull cavities from an infected ear or sinus, or from the air following a skull fracture.

**SYMPTOMS**

The main symptoms are fever, severe headache, nausea and vomiting, dislike of light, and a stiff neck. In viral meningitis, the symptoms are mild and may resemble influenza. In bacterial meningitis, the main symptoms may develop over only a few hours, followed by drowsiness and, occasionally, loss of consciousness. In about half the cases of meningococcal meningitis, there is also meningococcaemia (a potentially life-threatening condition in which bacteria multiply rapidly in the blood). This condition causes a reddish-purple rash under the skin, which does not fade with pressure (see glass test). The rash starts as pin-prick spots that can expand to give a bruise-like appearance.

**DIAGNOSIS AND TREATMENT**

To make a diagnosis, a lumbar puncture is performed to remove a small sample of cerebrospinal fluid.

Viral meningitis needs no treatment and usually clears up in a week or two with no after-effects. Bacterial meningitis is a medical emergency. It is treated with intravenous antibiotic drugs. With prompt treatment, a full recovery is usually made; the earlier treatment is given, the better the outlook. In some cases, however, deafness or brain damage may occur, or the person may lose an area of skin, or fingers or toes, as a result of the rash.

**PREVENTION**

Vaccines are now given to protect children and teenagers against two of the major types of bacterial meningitis: those caused by *Haemophilus influenzae* and by *Meningococcus* type C (see immunisation). Antibiotic drugs may be given as a protective measure to people who have come into contact with these infections.

Immunisation against some forms of meningitis is recommended for Muslims travelling to Saudi Arabia for the Hajj and Umrah pilgrimages, and for people travelling to Nepal and some parts of sub-Saharan Africa.

**meningococcal meningitis**

One of the most common forms of bacterial meningitis. Most cases occur in children or young adults. The disease is transmitted by exhaled droplets; it can spread rapidly through groups of people who are in close contact with each other, such as children in boarding schools. If not treated promptly, it may progress to the life-threatening disorder meningococcaemia.

**meningococcal rash**

A rash that occurs in about half of all cases of *meningococcal meningitis* and meningococcal septicaemia. The rash arises as pin-prick spots beneath the skin that join together to give the appearance of a bruise (see purpura). The rash associated with meningococcal infection does not fade when pressure is applied (see glass test).

**meningoencephalitis**

Inflammation of the brain and the meninges (the membranes surrounding the brain), usually as a result of a viral infection. See encephalitis.

**meningomyelocele**

Another name for myelomeningocele.

**meniscectomy**

A surgical procedure in which all or part of a damaged meniscus (cartilage disc) is removed from a joint, almost always from the knee.

**WHY IT IS DONE**

Meniscectomy may be performed when damage to the meniscus causes the knee to lock or to give way repeatedly. It cures these symptoms and reduces the risk of premature osteoarthritis in the joint.

**HOW IT IS DONE**

Arthroscopy (in which a viewing instrument is inserted into the joint through a small incision) may be carried out to confirm and locate the damage. The damaged area may then be removed by instruments passed through the arthroscope. Alternatively, the meniscus may be removed through an incision at the side of the patella (kneecap).

**OUTLOOK**

In either case, there may be an increased risk of osteoarthritis in later life, but this is less than if the damaged meniscus had been left in place.

**meniscus**

A crescent-shaped disc of cartilaginous tissue found in several joints. The knee joint has two menisci, and the wrist...
and help to reduce friction given as a drug, which controls. This hormone, to mature. The egg follicles, drugs that affect (the release of a mature egg and Lateral and radiotherapy and continues (the cessation polyps production. (the occur during

of reduced chological changes that occur as a result

years. The term “menopause” usually

ovaries), (which protect premenopausal women against heart disease). Excessive loss of blood during menstruation. The imbalance leads to an excessive buildup of endometrium (the uterine lining). Disorders affecting the uterus, such as fibroids, polyps, or a pelvic infection, can also cause menorrhagia. Treatment may include nonsteroidal anti-inflammatory drugs, drugs that affect blood clotting, hormones, or the fitting of an IUD (intrauterine device) that releases small amounts of progestogen. Menorrhagia may also be treated by endometrial ablation.

The occurrence of a menstrual period when ovulation (the release of an egg from an ovary) has not occurred (see menstruation). Anovular menstruation is common in girls who have just started to menstruate, and in women who are approaching the menopause. It may produce irregular menstrual cycles.

MENISCUS

The diagram (right) shows the sites of the menisci. The menisci of the knee are shown in detail below.

Menopause

The cessation of ovulation (egg production) and of menstruation (discharge of blood and tissue from the uterus). This process usually occurs between the ages of 45 and 55, the average age being 52 years. The term “menopause” usually refers to a period of physical and psychological changes that occur as a result of reduced oestrogen production.

The menopause usually occurs gradually; it is signalled by a change in menstrual patterns (see perimenopause) followed by amenorrhoea (the cessation of menstrual periods). It can also be brought on by medical procedures that halt the activity of the ovaries, such as oophorectomy (surgical removal of the ovaries), radiotherapy, or chemotherapy. In a few women, the menopause may occur abnormally early, usually before age 40 (see premature menopause).

Symptoms

Some women have few difficulties with the menopause. Other women may have symptoms including hot flushes and night sweats; vaginal dryness caused by thinning of the vaginal lining; and a decrease in vaginal secretions. The tissues in the neck of the bladder and the urethra also become thinner, which can cause a feeling of needing to urinate frequently. In addition, the breasts tend to decrease in size. Some women experience psychological symptoms, such as poor concentration, tearfulness, loss of interest in sex, and depression.

Changes in metabolism occur during the menopause but they may not cause symptoms until later. In all women, the bones become thinner; this process happens most rapidly in the years immediately after the menopause. The loss of bone density may result in osteoporosis. The risk of heart disease also increases, gradually approaching that for men of a similar age, due to the drastic reduction in oestrogen hormones (which protect premenopausal women against heart disease).

Treatment

Women going through the menopause can protect themselves from losing bone density by regularly taking weight-bearing exercise, such as walking, and by eating foods that are rich in calcium, such as dairy products and green, leafy vegetables. Measures such as avoiding fatty foods, stopping smoking, and limiting alcohol intake can help to protect women against heart disease.

Hormone replacement therapy (HRT) may relieve menopausal symptoms and reduce the risk of fractures associated with osteoporosis. However, it is not usually recommended as the first line of treatment because it may increase the risk of abnormal blood clotting and is associated with an increased risk of breast cancer.

Menorrhagia

Excessive loss of blood during menstruation. Menorrhagia may be caused by an imbalance of oestrogen hormones and progesterone hormone, which control menstruation. The imbalance leads to an excessive buildup of endometrium (the uterine lining). Disorders affecting the uterus, such as fibroids, polyps, or a pelvic infection, can also cause menorrhagia.

Treatment may include nonsteroidal anti-inflammatory drugs, drugs that affect blood clotting, hormones, or the fitting of an IUD (intrauterine device) that releases small amounts of progestogen. Menorrhagia may also be treated by endometrial ablation.

Menotrophin

A gonadotrophin hormone given as a drug to stimulate cell activity in the ovaries and testes. It is used as a treatment for certain types of male and female infertility, as it prepares the ovary for ovulation and may help stimulate sperm production. It is used along with human chorionic gonadotrophin (see gonadotrophin, human chorionic).

In women, menotrophin may cause multiple pregnancy, abdominal pain, bloating, and weight gain. In men, it may cause enlargement of the breasts.

Menses

Another name for a menstrual period. The word “menses” may also mean the blood, tissue, and fluid that is discharged from the uterus during a menstrual period (see menstruation).

Menstruation

The periodic shedding of endometrium (the lining of the uterus), accompanied by bleeding, that takes place in women who are not pregnant. Menstruation usually begins at puberty and continues until the menopause.

The loss of the endometrium occurs at the end of the menstrual cycle, which usually lasts for 28 days (with the normal range being between 21 and 35 days). At the beginning of the cycle, a hormone from the pituitary gland, known as follicle-stimulating hormone (FSH), prompts several follicles (collections of cells containing eggs) within the ovaries to mature. The egg follicles secrete oestrogen hormones, which cause the endometrium to thicken.

Ovulation (the release of a mature egg from a follicle) usually occurs in the middle of the cycle. The empty follicle (called the corpus luteum) produces progesterone hormone. This hormone causes the endometrium to retain fluid and grow thicker, so that a fertilized egg can implant in the tissue. If pregnancy does not occur, production of oestrogens and progesterone diminishes. The endometrium is shed about 14 days after ovulation. Uterine contractions force the tissue, together with fluid and blood, to be expelled via the vagina; this process lasts for one to eight days.

Menstruation, anovular

The occurrence of a menstrual period when ovulation (the release of an egg from an ovary) has not occurred (see menstruation). Anovular menstruation is common in girls who have just started to menstruate, and in women who are approaching the menopause. It may produce irregular menstrual cycles.
**THE MENSTRUAL CYCLE**

During menstruation, the endometrium (the lining of the uterus) is shed. Following menstruation, a pituitary hormone called follicle-stimulating hormone (FSH) triggers the growth of follicles containing eggs. The follicles secrete oestrogen. Another hormone, luteinizing hormone (LH), causes one of them to release a mature egg. The empty follicle produces progesterone, which, along with oestrogen, prepares the endometrium to receive the egg. If the egg is unfertilized, then levels of oestrogen and progesterone fall and a new menstrual cycle begins.

**menstruation, disorders of**

Abnormalities in menstrual bleeding. Menstrual disorders may indicate a problem in the pelvic area, such as fibroids, endometriosis, or pelvic inflammatory disease, but the cause is often unknown.

Dysmenorrhoea (painful periods) is the most common type of menstrual disorder. Other types are amenorrhoea (absence of menstruation), polymenorrhoea (overly frequent menstruation), oligomenorrhoea (infrequent periods or scanty blood loss), and menorrhagia (excessive bleeding).

Some women have extreme variations in the length of menstrual cycles or periods, or in the amount of blood lost (see menstruation, irregular).

**menstruation, irregular**

A variation in the normal pattern of menstruation. Irregular menstruation includes variations in the interval between periods, the duration of bleeding, or the amount of blood that is lost.

The most common cause is a disturbance in the balance between oestrogen hormones and progesterone hormone. Other causes include stress, travel, a change in contraception, unsuspected pregnancy, or early miscarriage. Menstruation is often irregular for the first few years, and for several years before the menopause.

**menstruation, retrograde**

The backward flow of tiny amounts of menstrual discharge (see menstruation) from the uterus through the fallopian tubes instead of the vagina. Retrograde menstruation is thought to be a possible cause of endometriosis.

**menstruation, suppressed**

The failure of menstrual (monthly) bleeding (see menstruation) to occur. (See also amenorrhoea).

**mental**

A word meaning “relating to the mind”.

**mental age**

A measurement of the intellectual development of a person, with regard to the normal age at which that level of achievement is attained. For example, a 13 year-old child with learning difficulties may have a mental age of five years.

**mental handicap**

Impaired intellectual development. This condition is also known as general learning difficulties or disability.

**Mental Health Act**

The Mental Health Act (1983) details the rights of people with mental illness and the grounds for admitting people to psychiatric hospitals against their will. It also outlines forms of legal guardianship for such patients. The Act applies in England and Wales.

The Act is divided into several sections for different situations. (These divisions have given rise to the term “being sectioned” to describe compulsory admission to a mental hospital.)

When individuals are endangering their own or other people’s health or safety (for example, threatening harm or suicide) because of a recognized mental illness, they may be compulsorily taken into hospital to be given treatment. If people break the law because of a mental disorder, the courts may remand them to hospital.

**mental hospital**

A type of hospital, formerly known as an asylum, that specializes in the treatment of psychiatric illness.

Patients who have psychiatric illnesses are increasingly being integrated into mainstream hospitals for their care. Admission to a mental hospital occurs when a patient is sectioned under the Mental Health Act.

**mental illness**

A general term that describes any form of disorder affecting mental functions such as thought, emotion, perception, or memory. Such illnesses are distinct from learning difficulties.

Mental illnesses include forms of psychosis, in which a person loses contact with reality, and disorders such as anxiety, obsessive-compulsive disorder, and post-traumatic stress disorder, in which mental processes are abnormal but the affected person is fully aware of his or her condition.

**mental retardation**

See learning difficulties.
menthol
An alcohol prepared from mint oils. Menthol is an ingredient of several over-the-counter inhalation preparations used to treat a blocked or stuffy nose.

mentum
The medical term for the chin.

meprobamate
An antianxiety drug occasionally used in the treatment of anxiety and stress. It also acts as a muscle relaxant. Meprobamate can, however, induce dependence (see drug dependence).

meptazinol
An opioid analgesic drug used for the short-term relief of moderate to severe pain, such as after surgery and during childbirth. Possible side effects include nausea, vomiting, and dizziness.

meralgia paraesthetica
Abnormal sensations such as burning pain, numbness, and tingling, in the outer surface of the thigh. The condition occurs in the area supplied by the lateral femoral cutaneous nerve, and is due to the nerve being trapped at the point where it passes under the inguinal ligament, in the groin. (See also lateral cutaneous nerve entrapment.)

mercaptopurine
An anticancer drug used to treat certain types of leukaemia. Adverse effects include nausea, mouth ulcers, and loss of appetite. Rarely, it may cause liver damage, anaemia, and abnormal bleeding.

Mercilon
A brand-named oral contraceptive containing the synthetic female hormones ethinylestradiol (an oestrogen drug) and desogestrel (a progestogen).

mercury
The only metal that is liquid at room temperature. Mercury is used in certain instruments, such as thermometers and sphygmomanometers (instruments for measuring blood pressure). It is also included in compounds used as fillings for teeth (see amalgam, dental).

mercury poisoning
Toxic effects of mercury on the body.

causes
The most common cause of mercury poisoning is breathing in vapour given off by liquid mercury, usually as a result of industrial exposure. Also, mercury compounds may be absorbed through the intestines (producing symptoms such as nausea, vomiting, diarrhoea, and abdominal pain) or through the skin (causing severe inflammation).

symptoms
After entering the body, mercury accumulates in organs, principally the brain and kidneys. Mercury deposits in the brain cause tiredness, incoordination, excitability, tremors, and numbness in the limbs. In severe cases, there may be impaired vision and dementia. Deposits of mercury in the kidneys may lead to kidney failure.

TREATMENT
Treatment of mercury poisoning may involve the use of chelating agents, which help the body to excrete the mercury quickly; haemodialysis (see dialysis); and induced vomiting or pumping out the stomach, if mercury has been swallowed within the previous few hours.

Merkel cell tumour
A rare form of cancerous skin tumour that occurs in people over 60 years old, on areas of skin that have been exposed to the sun. The tumour arises from Merkel cells, which are found deep in the skin, close to nerve endings; these cells are thought to be part of the neuroendocrine system, which produces hormones that trigger nerve signals.

The cancer is initially treated by surgery, but metastasis (migration of cancer cells to other parts of the body) may occur. In this case, radiotherapy or chemotherapy may be given, but these treatments rarely produce a cure.

mesalazine
A drug that is used to reduce intestinal inflammation in ulcerative colitis. It may be prescribed to relieve symptoms in acute attacks or given as a preventive measure. Adverse effects of mesalazine include nausea, diarrhoea, abdominal pain, and headache.

mesalazine poisoning
Toxic effects of mesalazine on the body.

causes
The main symptoms are pain and tenderness in the abdomen, which may mimic appendicitis. There may also be mild fever. Mesenteric lymphadenitis usually clears up rapidly, needing only analgesic drugs to reduce pain and fever.

mesentery
A membrane that attaches organs to the abdominal wall. The term particularly refers to the membranous fold that encloses the small intestine, attaching it to the back of the abdominal wall. The mesentery contains the blood vessels, nerves, and lymphatic vessels for the intestines.

mesial
A word meaning the same as “medial” (relating to, or situated at, the centre of an organ, tissue, or the body). The term “mesial” is often used in dentistry, to refer to a tooth surface or position.

mesomorph
A term used for an individual whose body is characterized by a square head; a large heart; broad and muscular chest and shoulders; powerful arms and legs; and little body fat. The term has no clinical significance, however. (See also ectomorph; endomorph.)

mesothelioma
A cancerous tumour of the pleura (the membrane that lines the chest cavity and covers the lungs). Exposure to asbestos dust is a risk factor (see asbestos-related diseases). Symptoms do not always occur. Those that do include cough, chest pain, and breathing difficulty, especially if a pleural effusion (a collection of fluid around the lung) develops.

Diagnosis is made with a chest X-ray followed by pleural biopsy or examination of a sample of fluid from any effusion. If the tumour is small, surgery is often successful. There is no effective treatment for large tumours, although radiotherapy may alleviate symptoms.

mesothelium
A type of epithelium (surface cell layer) covering the peritoneum (the membrane lining the abdominal cavity), the pleura (the membrane lining the chest cavity and surrounding the lungs), and the pericardium (the covering of the heart).

messenger RNA
An RNA chain (see nucleic acids), also called mRNA, involved in protein synthesis within cells. The mRNA is made
from free nucleotide bases (of which three types are the same as those of DNA, and one is unique to mRNA); these attach themselves to corresponding bases on a single strand of DNA. By following the sequence of bases in a length of DNA, the mRNA copies instructions for making a protein. It then passes from the cell’s nucleus to its cytoplasm, where the sequence of bases is decoded to form the protein.

mesterolone
An androgen hormone (male sex hormone) used as replacement therapy in hypogonadism. Adverse effects of mesterolone can include prostate problems, headache, and depression.

mestranol
An oestrogen drug that is used in some oral contraceptives.

metabolic acidosis
Increased acidity of the blood and tissues due to chemical processes in the body. It may result from uncontrolled or abnormal processes, as in diabetic ketoadidosis and lactic acidosis, or from a failure to remove waste from normal processes, as in kidney disease (see renal tubular acidosis). Alternatively, it may be due to loss of alkali in conditions such as diarrhoea. Acidosis may also be due to poisoning with antifreeze (ethylene glycol) or aspirin. If untreated, it can be fatal. Treatment involves giving sodium bicarbonate to correct the acidosis, and measures to relieve the underlying cause. (See also acidosis; acid–base balance.)

metabolic alkalosis
Increased alkalinity of the blood and body tissues, due to chemical processes in the body. One possible cause is loss of stomach acids through prolonged vomiting. Metabolic alkalosis can also result from excessive consumption of alkaline substances, such as sodium bicarbonate in antacid drugs.

Treatment is for the underlying cause. (See also alkalosis; acid–base balance.)

metabolic disorders
A group of disorders in which some aspect of body chemistry is disturbed. Some metabolic disorders result from an inherited malfunction or deficiency of an enzyme involved in a particular chemical reaction (see metabolism, inborn errors of). Others result from under- or overproduction of a hormone that controls metabolic activity, as occurs in diabetes mellitus and hypothyroidism.

metabolism
A collective term for all of the chemical processes that take place in the body. It is divided into catabolism (in which complex substances are broken down into simpler ones) and anabolism (in which complex substances are built up from simpler ones). Usually, catabolism releases energy, while anabolism uses it. These chemical processes are regulated by proteins called enzymes.

metabolic rate
The energy needed to keep the body functioning at rest is called the basal metabolic rate (BMR). It is measured in kilojoules (or kilocalories) per square metre of body surface per hour. The BMR increases in response to factors such as stress, fear, exertion, and illness. It is chiefly controlled by hormones such as thyroxine, adrenaline (epinephrine), and insulin. (See also metabolism, inborn errors of; metabolic disorders.)

metabolism, inborn errors of
Inherited defects of body chemistry.

cause and types
Inborn errors of metabolism are caused by single gene defects, which lead to the abnormal functioning of an enzyme. Some defects are harmless, but others are severe enough to cause death or physical or mental disability. Examples are Tay–Sachs disease, phenylketonuria, Hurler’s syndrome, and Lesch–Nyhan syndrome.

metabolite
Any substance involved in a metabolic reaction (a chemical reaction in the body). The term “metabolite” is sometimes used only for the products of such a reaction. (See also metabolism.)

metacarpal bone
One of five long, cylindrical bones in the hand. The bones run from the wrist to the base of each digit, with the heads of the bones forming the knuckles.

metaphysis
The part of a long bone that forms new tissue to lengthen the bone during normal childhood growth. The metaphysis is situated between the diaphysis (bone shaft) and epiphysis (bone end). In children the area consists of spongy bone, but in adults it has become hard and fused with the epiphysis.

metaplasia
A change in tissue that results from the transformation of one type of cell into another. Metaplasia is usually harmless but is occasionally precancerous. It can affect the lining of various organs, such as the bronchi (airways) and the bladder. Metaplasia of the cervix (the neck of the uterus), which occurs in cervical erosion, can be detected by means of a cervical smear test.
metastasis
A secondary cancerous tumour (one formed from cells that have spread from a primary cancer to another part of the body). The term metastasis also applies to the process by which such migration occurs. Metastases can spread through the lymphatic system, in the bloodstream, or across a body cavity.

metastatic abscess
An abscess (localized collection of pus) formed by bacteria that have spread from another site via the blood or lymph. The bacteria may come from an existing (primary) abscess or from an infected wound. One example of this process is the spread of bacteria from the heart valves (see endocarditis) to form an abscess in the brain.

metatarsal bone
One of five long, cylindrical bones in the foot. The metatarsal bones make up the central skeleton of the foot, connecting the phalanges (the bones of each toe) to the tarsal bones (which form the ankle). The bones are held together in an arch by the ligaments that surround them.

metatarsalgia
Pain in the foot. Causes include fracture of a metatarsal bone, flat-feet, or neuroma of a nerve in the foot.

metatarsophalangeal joint
The joint between each metatarsal bone and its adjoining toe bone (see phalanges). The metatarsophalangeal joint at the base of the big toe is commonly affected by gout and by hallux rigidus (immobility due to osteoarthritis).

metformin
An oral hypoglycaemic drug (see hypoglycaemics, oral) that lowers blood glucose levels and is used to treat type 2 diabetes mellitus. Possible adverse effects include loss of appetite, a metallic taste in the mouth, nausea, vomiting, and diarrhoea.

methadone
A synthetic opioid analgesic drug that resembles morphine. Methadone is administered, under supervision, in gradually decreasing doses, to people who are undergoing a heroin or morphine withdrawal programme. It may also be used to treat severe pain in people who cannot tolerate morphine. Side effects may include nausea, vomiting, constipation, dizziness, and dry mouth.

methaemoglobin
An abnormal substance formed by oxidation of the iron in haemoglobin (the pigment in red blood cells). Unlike oxyhaemoglobin, this compound cannot take up and transport oxygen.
Normal blood usually carries a small amount of methaemoglobin. Excessive blood levels (methaemoglobinemia) may result from poisoning with substances such as nitrates and chlorates. In some cases, the excess is due to a congenital defect in haemoglobin. The resulting symptoms include cyanosis (blue-grey colouring of the extremities and lips), headache; drowsiness; and shortness of breath. Very high levels of methaemoglobin lead to coma and death. Treatment is with a substance called methylene blue.

methane
A colourless, odourless, highly inflammable gas that occurs naturally in oil wells and coal mines. Methane is also produced by the decomposition of organic matter; it is one of the gases present in intestinal gas (see flatus).

methanol
A poisonous type of alcohol that is used as a solvent or paint remover and in some types of antifreeze. Methanol poisoning usually occurs as a result of drinking it as a substitute for ordinary alcohol. Symptoms of poisoning include headache, dizziness, nausea, vomiting, and unconsciousness. Damage may also occur to the retina and the optic nerve, causing blurred vision. Repeated or large doses of methanol may result in permanent blindness.

methicillin-resistant staphylococcus aureus
See MRSA.

methotrexate
An anticancer drug used to treat lymphoma (cancer of the lymph nodes) and some forms of leukaemia. Methotrexate is also used for cancers of the uterus, breast, ovary, lung, bladder, and testis, and severe psoriasis when other treatments are ineffective. It may cause nausea, vomiting, diarrhoea, mouth ulcers, anaemia, increased susceptibility to infection, and abnormal bleeding.

methyl alcohol
An alternative name for methanol.

methylcellulose
A bulk-forming laxative drug that is used in the treatment of constipation, irritable bowel syndrome (IBS), and diverticular disease. It increases the firmness of faeces in chronic watery diarrhoea and regulates their consistency in people who have a colostomy or ileostomy.

The drug causes a feeling of fullness, so it is sometimes used to help treat obesity.

methyldopa
An antihypertensive drug that controls high blood pressure by acting on the part of the brain that regulates the diameter of blood vessels.

Methyldopa does not affect unborn babies, so may be prescribed for women who have high blood pressure during pregnancy. It may also be used for people with kidney disorders, because it does not impair the blood flow to the kidneys. Side effects include drowsiness, depression, and nasal congestion. The drug may also cause premature destruction of red blood cells (see anaemia, haemolytic).

methylenedioxymethamfetamine
See Ecstasy.

methylphenidate
A central nervous system stimulant drug used, under specialist supervision, to treat attention deficit hyperactivity disorder (ADHD) in children. Possible adverse effects include loss of appetite, tremors, sleeplessness, and rashes.

methylprednisolone
A corticosteroid drug used to treat severe asthma, skin inflammation, inflammatory bowel disease, and certain types of arthritis.
Methysergide is used to treat infections used to treat (heart that is used to in chest pain due to or that is used to in the urine, usually due to is in which there is a (heart attack) to reduce the in people who that is used to and (overactiv that is used topically (high blood pres or latex (tiny organisms). Miconazole that is used to prevent are therefore car. (See also

metoclopramide
An antiemetic drug that is used to prevent and treat nausea and vomiting, including that which is associated with migraine or caused by anticancer drugs, radiotherapy, or anaesthetic drugs. Metoclopramide may be given with a premedication to reduce the risk of a person inhaling vomit when he or she is under general anaesthesia (see anaesthesia, general).

metolazone
A diuretic drug used to treat hypertension (high blood pressure). Metolazone is also given to reduce oedema in people who have heart failure, kidney disorders, or cirrhosis. In addition, it is used to treat certain types of kidney stone (see calculus, urinary tract). Adverse effects can include weakness, lethargy, and dizziness.

metoprolol
A cardioselective beta-blocker drug that acts mainly on nerve endings in the heart and blood vessels. It is used to prevent the heart from beating too fast, in angina pectoris (chest pain due to insufficient blood supply to the heart), and for hypertension (high blood pressure). It is also given after a myocardial infarction (heart attack) to reduce the risk of further damage to the heart. In addition, metoprolol is used to relieve symptoms of hyperthyroidism (overactivity of the thyroid gland). Adverse effects include lethargy, cold hands and feet, nightmares, and rash.

metronidazole
An antibiotic drug used to treat infections caused by anaerobic bacteria, such as dental abscess and peritonitis. Metronidazole is also used to treat protozoan infections such as trichomoniasis and amoebiasis. In addition, it may be applied topically as a gel to treat skin conditions such as acne and rosacea, and it is used to treat gum disease.

metapathia haemorrhagica
Abnormal, excessive, sometimes continuous menstrual bleeding (see menstrual cycle) due to excessive production of oestrogen hormones. The high oestrogen levels cause hyperplasia (overgrowth) of the endometrium (uterus lining).

mexiletine
An antiarrhythmic drug that is used to treat certain heart-rhythm disorders, usually after a myocardial infarction (heart attack). Possible adverse effects include nausea, vomiting, dizziness, and tremor.

mianserin
An antidepressant drug that is used to treat severe depression, especially if the illness is accompanied by anxiety or insomnia. Mianserin usually takes several weeks to become fully effective. Possible adverse effects include dry mouth, blurred vision, constipation, dizziness, and diarrhoea. Rarely, the drug may cause reduced blood cell production; regular blood counts are therefore carried out during treatment.

miconazole
An antifungal drug that is used topically (applied directly to the skin), in the form of creams, ointments, or powder, to treat tinea skin infections such as athlete’s foot, or as vaginal suppositories for vaginal candidiasis (thrush). Miconazole in the form of a cream or vaginal suppository may, in rare cases, cause a burning sensation or a rash. Preparations used in the vagina may damage diaphragms or latex condoms.

microbe
A prefix meaning “small”, as in microorganisms (tiny organisms).

microalbuminuria
A slight increase in the level of the protein albumin in the urine, usually due to early kidney damage. Microalbuminuria is a very early sign of kidney disease in people with diabetes mellitus. (See also albuminuria.) If left untreated, it may lead to diabetic kidney disease (see diabetic nephropathy) in people with type 1 diabetes, or may increase the risk of cardiovascular disorders in those who have type 2 diabetes.

The increase is too small to be measured by routine dipstick tests on urine, but can be confirmed by testing urine over 24 hours or with a special kit. Treatment with ACE inhibitor drugs is usually advised, even if the affected person’s blood pressure is normal.

microaneurysm
A tiny, localized swelling in a capillary (the smallest form of blood vessel). Microaneurysms in the vessels of the retina are a characteristic sign of diabetic retinopathy in diabetes mellitus; they may also be due to blockage of a retinal vessel. The swellings can be seen as small red dots when the retina is examined with an ophthalmoscope.

microangiopathy
Any disease or disorder of the smallest blood vessels. It may be a feature of conditions such as diabetes mellitus, septicaemia, eclampsia, glomerulonephritis, and advanced cancer. When microangiopathy occurs with these conditions, the small blood vessels become distorted and the red blood cells are damaged, leading to microangiopathic haemolytic anaemia (see anaemia, haemolytic).

microbe
A popular term for a microorganism, particularly a type that causes disease.

microbiology
The study of microorganisms, particularly of pathogenic types (organisms that cause disease).

microcephaly
An abnormally small head. Microcephaly is associated with learning difficulties. It may be the result of certain chromosomal abnormalities; in addition, it may occur if the brain is damaged before or during birth, or if it is injured or diseased in early infancy.

microcytic anaemia
Any form of anaemia in which there is a defect in the production of haemoglobin (the oxygen-carrying pigment in the blood), causing a reduction in size of
the red blood cells. An example of microcytic anaemia is iron-deficiency anaemia. (See also normocytic anaemia.)

**microlisectomy**
Surgery to relieve pressure on the spinal cord, or on a nerve root emerging from it, due to protrusion of the core of an intervertebral disc (see disc prolapse). The procedure is performed under general anaesthesia and involves removing the protruding tissue via a small incision in the outer coat of the disc.

**microfilaria**
The immature forms of certain types of worm. Microfilaria are produced by adult worms that have infected a human being or an animal (see filariasis), and circulate in the blood or lymph. They complete their life cycle when they are ingested by mosquitoes or other insects that bite infected people or animals; they turn into larvae within the insect, and are then passed on when it bites another victim.

The presence of microfilaria in the body can be determined by microscopic examination of blood samples.

**microglioma**
An obsolete term for a primary central nervous system lymphoma (PCNSL).

**microglossia**
An abnormally small tongue. The condition is often due to a genetic disorder and associated with micrognathia (an abnormally small jaw).

**micrognathia**
An abnormally small jaw (usually the lower jaw). Micrognathia is congenital (present at birth), and may stop a baby from feeding properly. It is a feature of various chromosomal abnormalities. In many cases, the problem disappears as the child’s skull grows.

**micrograph**
A photographic image of a tiny object seen through a microscope.

**Microgynon 30**
A brand-named oral contraceptive that contains the female hormones ethinyl estradiol (an oestrogen drug) and levonorgestrel (a progestogen).

**microinvasion**
The spread of cancerous cells into normal tissue adjacent to the tumour. It is detectable only by microscopic examination of a tissue sample. This is a transitional stage between carcinoma in situ and invasion (see staging).

**Micronor**
A brand-named oral contraceptive that contains the female hormone norethisterone (a progestogen).

**microorganism**
A single-celled living organism. Most microorganisms are too small to be seen by the naked eye. The main groups of disease-causing microorganisms are bacteria, viruses, protozoa, and fungi.

**microphthalmos**
A rare congenital eye disorder. Affected children are born with an abnormally small eye on one or both sides.

**microscope**
An instrument for producing a magnified image of a very small object. Microscopes are used to examine the structure and chemical composition of cells and tissues, and to investigate microorganisms and diseased tissues. In the operating theatre, microscopes are used in microsurgery.

**light microscopes**
Compound microscopes are the most widely used type. They have two lens systems (the objective and the eyepiece), mounted at opposite ends of a tube called the body tube. There is a stage to hold the specimen, a light source, and an optical condenser which concentrates the light. The maximum magnification is about 1,500 times.

Phase-contrast and interference microscopes are modified light microscopes that allow unstained transparent specimens to be seen. They are used for examining living cells and tissues.

Fluorescence microscopes use ultraviolet light to study specimens stained with fluorescent dyes.

**electron microscopes**
Electron microscopes give much higher magnifications than light microscopes by using a beam of electrons instead of light. There are two types: transmission electron microscopes (TEMs) and scanning electron microscopes (SEM). Microwaves can magnify objects up to about 5,000,000 times, enabling tiny viruses and molecules to be seen. SEMs have a lower maximum magnification (100,000 times), but produce three-dimensional images, so are useful for studying surface structures of cells and tissues.

**microwaves**
Surgery on minute, delicate, or not easily accessible tissues in the body. In procedures involving microsurgery, the surgeon views the operation site using a special binocular microscope with pedal-operated magnification, focusing, and movement. He or she carries out the procedure using tiny, specially adapted surgical instruments, such as forceps, clamps, and very fine suturing needles and thread.

The technique of microsurgery is applied to a variety of procedures. It is used for eye operations such as repairing a detached retina or replacing a diseased lens. Microsurgery may be carried out to fit a prosthesis to replace a diseased bone in the inner ear (see stapedectomy). After serious injuries, it may be performed to rejoin the severed ends of blood vessels or nerves. Microsurgery may also be used to reverse female or male sterilization (see sterilization, female; vasectomy), by rejoining structures that have been surgically severed.

**microvillus**
One of the many microscopically small, hair-like structures covering the surface of a villus (a tiny projection from the wall of the small intestine).

**microwaves**
A form of diathermy that uses microwaves (electromagnetic waves of very short wavelength). One form of microwave therapy in which the waves are directed through probes into tumours, to kill or shrink the abnormal tissue, is currently being investigated as a possible treatment for breast cancer and prostate cancer. Microwave therapy is also used to treat benign prostatic hyperplasia, although it is less effective than other treatments.

**micturition**
A medical term for passing urine.

**micturition syncope**
A brief loss of consciousness (see syncope) that occurs during or just after micturition (passing urine), usually when a person has got out of bed to urinate at night. The condition is more common in older men. It is thought to result from a drop in blood pressure as the person gets up (see orthostatic hypotension), combined with changes in blood flow as the bladder empties.
TECHNIQUES OF MICROSURGERY

Microsurgery started with ophthalmic surgeons, whose demands for more delicate operating instruments led to the adoption of the operating microscope. The results were so favourable that surgeons working in other specialties began to use the technique for intricate operations.

The operating microscope
This surgeon is performing microsurgery with the aid of an operating microscope. The photograph below shows a blood vessel as seen through the microscope.

midazolam
A benzodiazepine drug that is used as premedication. Adverse effects of midazolam include confusion, drowsiness, and dizziness. If benzodiazepines are taken for a long time, dependence may result.

midbrain
The top part of the brainstem, situated above the pons. The midbrain is also called the mesencephalon.

middle ear
See ear.

middle-ear effusion, persistent
See glue ear.

middle-ear infection
See otitis media.

mid-life crisis
A popular term for the feelings of distress that affect some people in early middle age when they realize that they are no longer young. Counselling and support are usually effective in helping people to come to terms with aging.

midwifery
The profession concerned with assisting women in pregnancy and childbirth, and in the weeks just after a birth.

mifepristone
A sex hormone drug that is used to induce medical termination of a very early pregnancy (see abortion, induced).

Possible adverse effects include malaise, faintness, nausea, rash, and, rarely, uterine bleeding. Women over 35 who smoke should not be given the drug.

migraine
A severe headache, typically lasting from four to 72 hours, accompanied by light and noise sensitivity and/or nausea and vomiting. Migraine attacks are due to spasm, followed by excessive dilation, of blood vessels in the brain.

CAUSES
There is no single cause of migraine, although it tends to run in families. Stress-related, food-related, or sensory-related factors (such as eating cheese or chocolate, or drinking red wine) may trigger attacks. In women, menstruation, oral contraceptives, and HRT may also be triggers.

TYPES AND SYMPTOMS
There are two types: migraine with aura and migraine without aura. In migraine without aura, there is a slowly worsening headache, often on one side of the head, with nausea and sometimes vomiting and/or light and noise sensitivity.

In migraine with aura, there may be visual disturbances for up to an hour, followed by a severe, one-sided headache, nausea, vomiting, and sensitivity to light and noise. Other temporary neurological symptoms, such as weakness in one half of the body, may occur.

DIAGNOSIS AND TREATMENT
Diagnosis is usually made from the history and a normal outcome from any physical examinations between attacks. Treatment for an attack is an analgesic drug such as aspirin, paracetamol, or a nonsteroidal anti-inflammatory drug, with an antiemetic drug, if needed.

If this is not effective, drugs called 5HT1 agonists (see serotonin agonists), such as sumatriptan, may be prescribed. These drugs are taken as early as possible at the start of an attack, and may prevent the development of a full-blown attack. Sleeping in a darkened room may hasten recovery.

For frequent attacks, preventive treatment may be required. Keeping a diary can help people to identify trigger factors, and prophylactic drugs may be prescribed. Drugs that contain ergotamine may prevent an attack if taken before the headache begins, but are now rarely used; they have largely been replaced by serotonin antagonists such as pizotifen. Beta-blocker drugs, or low doses of tricyclic antidepressants, may also be used to prevent attacks. (See also cluster headaches.)

migrainous neuralgia
See cluster headaches.

Migraleve
A brand-named drug for migraine relief that contains the analgesic drugs (painkillers) paracetamol and codeine and the antiemetic drug buclizine.
Migril
A brand-named drug for migraine relief containing caffeine, ergotamine (to relieve migraine symptoms), and the antihista-mine drug cyclizine (to relieve nausea).

milia
Tiny, harmless, hard, white spots that usually occur in clusters around the nose and on the upper cheeks in newborn babies and also in young adults.

miliary tuberculosis
A potentially life-threatening form of tuberculosis in which bacteria from the original site of infection enter the bloodstream and spread throughout the body to form millions of tiny tubercles (nodular masses) in other organs and tissues. The condition occurs in only a small minority of people with tuberculosis; it is most common in immunocompromised people such as those with AIDS or those taking corticosteroid drugs.

milk
A nutrient fluid produced by the mammary glands of female mammals. Milk contains fat, carbohydrate, protein, vitamins, and minerals. The composition of milk varies between species; for example, human breast milk contains more sugar (lactose) and less protein than cows’ milk.

milk–alkali syndrome
A rare type of hypercalcaemia (abnormally high level of calcium in the blood) together with alkalosis (reduced acidity of the blood) and kidney failure. The syndrome is caused by excessive, long-term intake of antacid drugs containing calcium and of milk. It is most common in people with a peptic ulcer. Symptoms include weakness, muscle pains, irritability, and apathy. Treatment is to reduce the intake of milk and antacids.

milk of magnesia
A magnesium preparation used as an antacid and laxative drug.

milk teeth
See primary teeth.

Milroy’s disease
An inherited form of lymphoedema (the accumulation of lymph in the tissues) that is caused by a malformation of the lymphatic vessels that prevents the free flow of lymph. The disease is a genetic disorder inherited in an autosomal dominant manner and is congenital (present from birth). The condition usually affects the legs.

Minamata disease
The name given to a severe form of mercury poisoning that occurred in the mid-1950s, in people who had eaten polluted fish taken from Minamata Bay, Japan. Many affected people suffered severe nerve damage, and some died.

mineral
A chemical element that is defined in nutrition as being essential in the diet for the maintenance of health. At least 20 minerals, including calcium, iron, potassium, and sodium, are vital for health. Some, such as zinc, are needed in only tiny amounts (see trace elements). A well-balanced diet that has sufficient amounts of nutrients should provide all the minerals that the body needs. (See also Minerals and main food sources table, opposite; Reference nutrient intake (RNI) table, below.)

* Insufficient for women with heavy menstrual periods, who should take iron supplements.

**Units:** mg = milligrams (thousandths of a gram)
mcg = micrograms (millionths of a gram)
mineralization, dental
The deposition of calcium crystals and other mineral salts in developing teeth. (See calcification, dental.)

mineralocorticoid
The term used for a corticosteroid hormone that controls the amount of salts that are excreted in urine.

mineral supplements
Dietary supplements containing one or more minerals in tablet or liquid form. Most people obtain sufficient amounts from their diet; supplements are only necessary for those with a recognized deficiency. Some mineral supplements may even be harmful if taken in excess. (See also entries for individual minerals.) Iron, the most commonly taken mineral supplement, is used to treat people with iron-deficiency anaemia, which may occur in women who have heavy menstrual periods or are pregnant or breast-feeding; vegans (people who eat no meat, eggs, or dairy products), and people with persistent internal bleeding (for example, from a peptic ulcer).

miner’s lung
See pneumoconiosis.

minilaparotomy
A procedure for female sterilization (see sterilization, female).

minimal access surgery
See minimally invasive surgery.

minimal brain dysfunction
A hypothetical condition that is thought to account for behavioural and other problems in children for which no physical cause is found. It may be a possible cause of some learning difficulties, difficulty in concentrating, impulsiveness, and hyperactivity.

minimally invasive surgery
Surgery using a rigid endoscope passed into the body through a small incision. Further small openings are made for instruments so that the operation can be performed without a long incision.

Minimally invasive surgery may be used for a range of operations on the abdomen (see laparoscopy), including appendicectomy, cholecystectomy, hernia repair, and many gynaecological procedures. Operations on the knee (see arthroscopy) are also often performed by minimally invasive surgery.

minipill
Also known as the progestogen-only pill (POP), an oral contraceptive that contains only a progestogen drug. The mini-pill makes the mucus that lines the cervix so thick that sperm cannot pass and has other effects that impede conception. Possible adverse effects include menstrual irregularities, bleeding between periods, and ovarian cysts.

minocycline
A tetracycline antibiotic drug used to treat acne, respiratory-tract infections such as pneumonia, and some genitourinary infections, such as gonorrhoea and nongonococcal urethritis. It is also used to prevent meningococcal meningitis.

The most common side effects are nausea, dizziness, and diarrhoea. The drug may also interfere with the balance mechanism within the inner ear, causing dizziness or vertigo, but these problems usually disappear once the drug is no longer being used.

minoxidil
A vasodilator drug used to treat severe hypertension (high blood pressure) when other drugs have been ineffective.

Prolonged use can stimulate hair growth, especially on the face. This effect may be a problem for people using the drug to control high blood pressure. It can, however, be beneficial for male-pattern baldness (see alopecia); preparations containing minoxidil are applied topically to stimulate hair regrowth.

miosis
Constriction of the pupil of the eye. Miosis may be caused by drugs such as pilocarpine or opium, by a disease

</table>
affecting the autonomic nervous system, or by bright light. A degree of miosis is normal in older people.

miotic drugs

Drugs used in the treatment of glaucoma to reduce pressure in the eye. When applied to the eye, miotic drugs cause the pupil to contract, which opens up the drainage channels and drains fluid from the front of the eye. Side effects include headache, particularly over the eye, and blurred vision. Common miotics include carbachol and pilocarpine. (See also mydriatic drugs.)

Mirena

A brand-named intrauterine contraceptive device (see IUD) containing the female hormone levonorgestrel (a progestogen). The Mirena device is fitted inside the uterus, then releases a low dose of the drug continually. It will need to be replaced after five years.

The device may cause irregular bleeding or slightly heavier menstrual periods (see menstrual cycle) just after being fitted, but the periods usually become much lighter after about three months. Some women cease to have periods at all, although most continue to ovulate. The device is particularly useful for those women who need to use an IUD but have heavy periods.

miscarriage

Loss of the fetus before the 24th week of pregnancy or viability (the ability to survive outside the uterus without artificial support). The medical term is "spontaneous abortion". The majority of miscarriages occur in the first 12 weeks of pregnancy, and may be mistaken for a late menstrual period.

CAUSES

Miscarriages may occur because of chromosomal abnormalities or developmental defects in the fetus, or because of severe illness, exposure to toxins, or an autoimmune disorder in the mother. Miscarriages that occur later in pregnancy may be due to genetic disorders, cervical incompetence, a defect in the uterus, or large uterine fibroids (non-cancerous growths).

SYMPTOMS

The symptoms are heavy vaginal bleeding with cramping. Slight blood loss accompanied by severe pain can be a symptom of either a threatened miscarriage or ectopic pregnancy (development of the embryo outside the uterus).

TYPES

Miscarriages are classified medically as different types of abortion. In a threatened abortion, the fetus remains alive in the uterus. In an inevitable abortion, the fetus dies and is expelled from the uterus. In a missed abortion, the fetus dies but remains in the uterus.

INVESTIGATION AND TREATMENT

A pelvic examination and ultrasound scanning may be performed in order to assess the pregnancy. If all of the contents of the uterus are expelled, no further treatment may be necessary. Otherwise, a D and C may be performed. Missed abortion requires a D and C or induction of labour depending on the duration of the pregnancy. Rh-negative women are given anti-D (Rho) immunoglobulin to prevent complications related to Rhesus incompatibility from occurring in any future pregnancies. (See also abortion.)

misoprostol

A synthetic prostaglandin drug that inhibits the secretion of stomach acid. Misoprostol may be used alone to treat peptic ulcers, or it may be combined with a nonsteroidal anti-inflammatory drug (NSAID), such as diclofenac, to prevent the development of peptic ulcers that may be associated with the use of these drugs. The most likely side effects of misoprostol are diarrhoea and indigestion. If severe, or if problems such as vomiting, abnormal vaginal bleeding, abdominal pain, or rash occur, a doctor should be consulted promptly.

mites and disease

Mites are very small animals, usually less than about 1 mm long, with eight legs. Many species of mites have piercing and blood-sucking mouthparts.

Species that may cause disorders include the scabies mite, which burrows in human skin causing intense itching; the house-dust mite, which can cause asthma when inhaled; and chiggers (American harvest mites), which are found in grass and cause an itchy rash when they bite. Mites in grain or fruit may cause skin irritation – sometimes called grocers’ or bakers’ itch. Certain mites transmit diseases, particularly scrub typhus and rickettsial pox.

mitochondria

Small organelles found inside cells in which cell respiration occurs. The mitochondrial wall has two membranes. The inner one is highly folded to provide a surface for respiration reactions. Cells that use a lot of energy, such as muscle cells, contain many mitochondria.

mitochondrial DNA

A particular form of DNA existing in mitochondria. In human mitochondria, the DNA is a double-helical circle that codes for 13 proteins. Mitochondria have a distinctive genetic code, and their genomes are not changed by meiosis during reproduction; these features make the DNA useful in genetic studies.

The significance of mitochondria having their own DNA is that diseases can be inherited via abnormalities of mitochondrial DNA, and inheritance of the DNA is maternal, directly from the egg.

mitosis

A type of cell division in which the chromosomes in a cell nucleus are duplicated into each of two daughter cells.

Before cell division, the chromosomes duplicate themselves and coil up with the two copies joined together. The doubled chromosomes line up in the centre of the cell and are pulled apart to opposite ends of the cell, which then divides. Each daughter cell therefore has the same chromosome content as the original cell. (Egg and sperm cells, in contrast, divide by means of a process called meiosis.)

mitral incompetence

Failure of the mitral valve of the heart to close properly, allowing blood to leak back into the left atrium (upper chamber) when it has been pumped out of the left ventricle (lower chamber). The disorder, also known as mitral regurgitation, may occur in conjunction with mitral stenosis (narrowing of the valve).

SYMPTOMS

Symptoms include increasing breathlessness and fatigue, sometimes with palpitations. Later, as heart failure develops, the ankles may swell.

DIAGNOSIS AND TREATMENT

Diagnosis may be made by hearing a characteristic heart murmur; from X-rays; ECG; and echocardiography. The heart’s interior may also be investigated with a catheter (see catheterization, cardiac).

Treatment may include diuretic drugs, ACE inhibitor drugs, and anticoagulant drugs. If symptoms are disabling, heart-valve surgery may be considered.

Before dental or other surgery, people with mitral incompetence are given antibiotic drugs to prevent endocarditis.
mitral stenosis

Narrowing of the opening of the mitral valve in the heart. The left atrium (upper chamber) has to work harder to force blood through the narrowed valve. Mitral stenosis is more common in women and may be accompanied by mitral incompetence (failure of the valve to close properly). It is usually due to damage caused by rheumatic fever.

SYMPTOMS

The main symptom is breathlessness on exertion. As mitral stenosis worsens, breathing difficulty eventually occurs when the person is at rest. Other signs include palpitations, atrial fibrillation (a rapid, uncoordinated, irregular heartbeat), and flushed cheeks. The person may also cough up blood and feel fatigued. Possible complications are as for mitral incompetence.

DIAGNOSIS AND TREATMENT

A diagnosis is made from the patient’s history, listening to heart sounds, and by various investigations such as ECG, chest X-rays, echocardiography, and cardiac catheterization. Drug treatment is broadly the same as for mitral incompetence.

If symptoms persist, balloon valvuloplasty may be carried out in order to stretch the valve. Alternatively, heart-valve surgery may be performed to replace the valve.

mitral valve

A valve in the left side of the heart. The mitral (or bicuspid) valve is made up of two flaps, allowing one-way blood flow from the left atrium (upper chamber) into the left ventricle (lower chamber).

mitral valve prolapse

A common, slight deformity of the mitral valve, in the left side of the heart, that can produce a degree of mitral incompetence (failure of the valve to close properly). The prolapse is most common in women and causes a heart murmur. It may be inherited, but the cause is often unknown.

Usually, there are no symptoms. Occasionally, however, the condition may produce chest pain, arrhythmia (irregular heartbeat), or, rarely, heart failure.

Often, no treatment is required for mitral valve prolapse, but some people may be treated with beta-blocker drugs, diuretic drugs, antiarrhythmic drugs, or, rarely, heart-valve surgery.

mixed connective tissue disorder

An autoimmune disease that affects the connective tissue (which supports body structures) throughout the body. It combines features of systemic lupus erythematosus, systemic sclerosis, polymyositis, and rheumatoid arthritis.

Mixed connective tissue disorder is diagnosed by blood tests that reveal antibodies to a cellular protein called ribonucleic protein (RNP). Treatment is similar to that for systemic lupus erythematosus, with corticosteroid drugs and immunosuppressant drugs.

MMR vaccination

Administration of a combined vaccine that gives protection against measles, mumps, and rubella. The vaccination is offered to all children between 12 and 15 months of age, with a booster shot at three to five years. Vaccination is postponed if a child is feverish, and it is not given to children with untreated cancer or allergies to aminoglycoside antibiotic drugs such as neomycin.

Mild fever, rash, and malaise may occur after vaccination. In a minority of cases, mild, noninfectious swelling of the parotid glands develops three to four weeks after vaccination. There is no evidence for a link between MMR and Crohn’s disease or autism.
mobilization
The process of making a part of the body capable of movement. Mobilization is treatment that is designed to increase mobility in a part of the body that is recovering from injury or affected by disease.

Surgeons use the term to refer to the freeing of an organ or structure from surrounding connective tissue or fibrous adhesions (bands of tissue joining normally unconnected parts of the body).

Möbius’ syndrome
A rare genetic disorder characterized by paralysis of both sides of the face, due to absence or underdevelopment of the sixth and seventh cranial nerves. The condition is congenital (present from birth). An affected child has a mask-like facial expression and cannot move the eyes fully from side to side. Newborn babies are unable to feed properly. In some cases, the syndrome is associated with abnormalities of the limbs or with learning difficulties. There is no specific treatment, but surgery may restore some facial expression.

moclobemide
An antidepressant drug that is used to treat severe resistant depression and social phobia. Moclobemide is a reversible monoamine oxidase inhibitor and is less likely than other MAOIs to cause high blood pressure. As with all MAOIs, however, interactions occur with some foods, and dietary restrictions still apply: people taking the drug should not consume foods such as cheese and red wine. Moclobemide, however, is a type called a reversible MAOI, or RIMA, which makes the adverse reactions less likely to occur.

monoarthritism
Inflammation that affects a single joint, causing pain and stiffness. Common causes of monoarthritism include osteoarthritis, gout, and infection.

monoclonal antibody
See antibody, monoclonal.

monocyte
One of the main types of white blood cell. Monocytes are phagocytes (cells that surround and engulf invading microorganisms) and play an important role in the immune system.

mononucleosis, infectious
An acute viral infection, commonly called glandular fever, that is characterized by a high temperature, sore throat, and swollen lymph nodes.

Cause
The infection is caused by the Epstein–Barr virus. It is transmitted via saliva, through close personal contact (including kissing), or possibly on cups or cutlery.

Symptoms
In the body, the virus multiplies in the lymphocytes (also called mononuclear cells). If the infection occurs in early childhood, it may cause no symptoms. However, symptoms are common in adolescence or early adulthood; and the first to appear are a fever and headache, followed by swollen lymph nodes (particularly in the neck) and a severe sore throat. In rare cases, enlargement of the tonsils may obstruct breathing. The spleen may become enlarged. In addition, the liver may become inflamed, sometimes causing jaundice.

Diagnosis and Treatment
Diagnosis of the condition is often made from the symptoms and from a blood test (see monospot test); affected lymphocytes have an atypical appearance. Recovery usually takes four to six weeks, with rest the only treatment needed. In rare cases, corticosteroid drugs are given to reduce severe inflammation of the tonsils, particularly if the breathing is obstructed. Contact sports should be avoided until the spleen has returned to its normal size. For two to three months after recovery, people often feel depressed, lacking in energy, and sleepy during the day.
montelukast
A specific leukotriene receptor antagonist drug used in the management of asthma. It is not, however, used to treat acute attacks.

Montgomery’s tubercles
Raised sebaceous glands on the areola (the pigmented area around the nipple). The glands tend to become more obvious during pregnancy.

mood
See affect, affective disorders.

mood swings
Rapid changes in mood. Milder forms of mood swings, such as changes from a calm state to a state of anxiety, irritability, or tearfulness, may occur in women suffering from premenstrual syndrome or those who are going through the menopause. Extreme mood swings, from mania (abnormal overactivity and elation) to depression, are associated with bipolar affective disorder (see manic-depressive illness).

moon face
Rounding of the face that is due to abnormally high levels of natural corticosteroid hormones in the body, as in Cushing’s syndrome, or to prolonged courses of corticosteroid drugs.

Moraxella
A group of bacteria that exist in a variety of mammals, including humans. The bacteria can cause a wide range of disorders; for example, the bacterium Moraxella lacunata may cause conjunctivitis and infections of the cornea (the transparent covering over the front of the eye), and M. catarrhalis occasionally causes otitis media (infection of the middle ear) and certain infections of the upper respiratory tract, such as sinusitis and bronchitis.

morbid anatomy
Also called pathological anatomy, the study of the structural changes that occur in body tissues as a result of disease, especially the changes that are visible to the naked eye.
**morula**
A stage in the development of an *embryo* following *fertilization*. The fertilized egg divides repeatedly as it travels down the *fallopian tube* towards the *uterus*. Once it has developed into a ball of cells, it is called a morula.

**mosaicism**
The presence of two or more groups of cells containing different genetic material within one person.

Some people who have syndromes that are caused by *chromosomal abnormalities* (such as *Down’s syndrome* and *Turner’s syndrome*) also have mosaicism. Depending on the proportion of the abnormal cells and the type of abnormality, they range from appearing physically normal to having features typical of the syndrome.

**mosquito bites**
Mosquitoes are flying insects found throughout the world. The females bite humans or animals to obtain blood, which they need to produce eggs. The males do not bite. A doctor should be consulted if there is a severe skin reaction to a mosquito bite.

**DISEASE TRANSMISSION**
In addition to causing skin irritation, mosquito bites are also capable of transmitting diseases. The main types of disease-transmitting mosquitoes belong to three different groups: *Anopheles* (which transmits *malaria*), *Aedes* (which carries *yellow fever*), and *Culex* (which transmits *filaria*).

**PREVENTION**
Preventive measures should be taken in any area where mosquitoes are rampant. The most effective measures are wearing long-sleeved shirts and socks, fitting mosquito screens over windows, and using insect-repellent sprays or slow-burning impregnated coils that release insecticidal smoke. In addition, mosquito nets should be placed over beds. (See also *insect bites; insects and disease*.)

**motility stimulant drugs**
Drugs that stimulate movement through the gastrointestinal tract. There are two main types of motility stimulant: those that work as *antiemetic drugs* and affect the upper gastrointestinal tract (*metoclopramide* and *domperidone*, for example); and intestinal stimulant *laxative drugs*, such as *dantron* and *senna*, which are used to treat constipation.

**motion sickness**
A problem that some people experience during road, sea, or air travel. Symptoms range from uneasiness and headache to distress, excessive sweating and salivation, pallor, nausea, and vomiting.

Motion sickness is caused by the effect of repetitive movement on the organ of balance in the inner ear. Factors such as anxiety, a fume-laden atmosphere, or the sight of food may make the condition worse. So, too, can focusing on nearby objects; sufferers should look at a point on the horizon. The sickness may be prevented or controlled by *antiemetic drugs* or by wearing acupressure bands on the wrist.

**motor**
A term used to describe any body structure that brings about movement, such as a *muscle* or a *nerve*.

**motor nerve**
A bundle of *nerve* fibres that carry electrical impulses from the *central nervous system* (the brain and spinal cord) to a muscle to bring about activity. (See also *sensory nerve*.) A group of muscle fibres that are activated by a single motor nerve fibre is called a motor unit.

**motor neuron disease**
A group of disorders in which there is degeneration of the *nerves* in the *central nervous system* that control muscular activity. This nerve degeneration causes weakness and wasting of the muscles. The cause is unknown.

**TYPES AND SYMPTOMS**
The most common type of the disease is amyotrophic lateral sclerosis (also called ALS, or Lou Gehrig’s disease). It usually affects people over the age of 50 and is more common in men. Some cases run in families. Usually, symptoms start with weakness in the hands and arms or legs, and muscle wasting. There may be irregular muscle contractions, and muscle cramps or stiffness. Soon, all four extremities are affected.

Progressive muscular atrophy and progressive bulbar palsy are conditions that both start with patterns of muscle weakness different from ALS but usually develop into ALS.

There are two types of motor neuron disease that first appear in childhood or adolescence. In most cases, these disorders are inherited. *Werdig–Hoffman disease* affects infants at birth or soon afterwards. In almost all cases, progressive muscle weakness leads to death within only a few years. Chronic spinal muscular atrophy begins in childhood or adolescence, causing progressive weakness but not always serious disability.

**DIAGNOSIS**
There are no specific tests for motor neuron disease. Diagnosis is based on careful clinical examination by a neurologist. Tests including *EMG*, muscle *biopsy*, *blood tests*, *myelography*, *CT scanning*, or *MRI* may be performed.

**TREATMENT AND OUTLOOK**
The disease typically progresses to affect the muscles involved in breathing and swallowing, leading to death within two to four years.

The nerve degeneration cannot be slowed down, but *physiotherapy* and the use of various aids may help to reduce disability. The drug *riluzole* is used to
extend life (or the time until mechanical ventilation is required) in people who have ALS.

mould
Any of a large group of fungi that exist as many-celled, filamentous colonies. Some moulds are the source of antibiotic drugs. Others, however, can cause diseases such as aspergillosis.

mountain sickness
An illness that can affect people who have ascended rapidly to heights above 2,400–3,000 m. Mountain sickness, also called altitude sickness, is caused by the reduced atmospheric pressure and oxygen levels that exist at high altitude.

SYMPTOMS AND SIGNS
Affected people breathe abnormally fast and deeply (see hyperventilation) to compensate for the lack of oxygen; as a result, the level of carbon dioxide in the blood falls abnormally low. Other symptoms include nausea, headache, anxiety, and exhaustion. In severe cases, pulmonary oedema (the accumulation of fluid in the lungs) may occur, leading to acute shortness of breath (see respiratory distress syndrome). Fluid may also accumulate in the brain (see cerebral oedema), causing confusion, loss of consciousness, or coma.

TREATMENT
An affected person should be returned to a lower altitude as rapidly and safely as possible. He or she may need extra oxygen. Pulmonary or cerebral oedema will need treatment in hospital.

PREVENTION
Mountain sickness can be prevented or minimized if the affected person ascends gradually, stopping for one or two days of rest for every 600 m above 2,400 m. He or she should drink plenty of fluids, have regular high-carbohydrate meals, and avoid drinking alcohol. Those with existing heart or lung disorders should avoid ascending to high altitudes.

mouth
The oral cavity. The mouth breaks down food for swallowing (see mastication) and is used in breathing. In addition, it helps to convert sound vibrations from the larynx into speech.

mouth breathing
Breathing through the open mouth, rather than through the nose. It may be due to obstruction of the nasal passages by thick secretions (as in a heavy cold or sinusitis) or by enlarged tonsils or adenoids. Noisy mouth breathing that occurs during sleep is called snoring.

mouth cancer
Forms of cancerous tumour that develop in the lips, tongue, and oral cavity. Lip cancer and tongue cancer are the most common types.

CAUSES AND INCIDENCE
Predisposing causes of mouth cancer are smoking, poor oral hygiene, drinking alcoholic spirits, chewing tobacco, and inhaling snuff. Irritation from ill-fitting dentures or jagged teeth are other risk factors. Men are affected twice as commonly as women; most cases occur in men over the age of 40.

SYMPTOMS
In the majority of cases, the cancer begins with a whitish patch, called leukoplakia, or a small lump. These lesions may cause a burning sensation, but are usually painless. As a tumour grows, it may develop into an ulcer or a deep fissure, which may bleed and erode surrounding tissue.

DIAGNOSIS AND TREATMENT
Diagnosis is based on a biopsy. Treatment consists of surgery, radiotherapy, or both. Surgical treatment may cause facial disfigurement and problems with eating and speaking, which may then necessitate plastic surgery to restore appearance and function. Radiotherapy may be given either externally or with implants in the area (brachytherapy); however, it sometimes damages the salivary glands (see mouth, dry).

When mouth cancer is detected and treated early, the outlook is good. Any nonhealing ulcer or lump in the mouth should be assessed by a doctor or dentist within two weeks, to maximize the chance of effective treatment.

mouth, dry
A condition caused by inadequate production of saliva. Dry mouth is usually a temporary problem resulting from fear, infection of a salivary gland, or the action of anticholinergic drugs.

Rarely, permanent dry mouth may result from Sjögren's syndrome or radiotherapy for mouth cancer. The dryness causes swallowing and speaking difficulty, impaired taste, and tooth decay (see caries, dental). Spraying the inside of the mouth with artificial saliva or taking pilocarpine tablets may help.

mouth-to-mouth resuscitation
See artificial respiration.

mouth ulcer
An open sore that is caused by a break in the mucous membrane that lines the mouth. Mouth ulcers are white, grey, or yellow spots with an inflamed border. The most common types are aphthous ulcers (see ulcer, aphthous) and ulcers caused by the herpes simplex virus.

ANATOMY OF THE MOUTH

The mouth has a complex structure, which reflects its various functions. For example, the tongue, lips, teeth, and palate play an essential role in speech production. The same parts of the mouth, with the salivary glands, also begin the process of digestion by taking in and swallowing food and drink.
A mouth ulcer may be an early stage of mouth cancer. Those that fail to heal within a month may need to be investigated with a biopsy.

**Mouthwash**

A solution for rinsing the mouth. Many only leave the mouth feeling fresh and remove loose food debris from the teeth. Some, such as those containing hydrogen peroxide, can help to clean the teeth if the gums are too tender for proper toothbrushing, as in some types of gingivitis. Those containing chlorhexidine are effective against plaque when routine dental hygiene is impossible.

Fluoride mouthwashes help to prevent tooth decay (see caries, dental), and a mouthwash of warm salt water can help to ease painful inflammation caused by tooth disorders. Antiseptic mouthwashes intended to combat halitosis are usually ineffective because they do not treat the cause of the problem.

**Movement**

Any motion of limbs or other areas of the body, or any motion within soft tissues and body organs. All movements are caused by the actions of muscles. They may be either voluntary (willed) or involuntary (automatic). Certain movements occur as reflex actions.

**Skeletal movements**

These movements involve the bones, the joints, and the skeletal muscles. Most of them are voluntary. They are initiated in a part of the cerebrum (the main mass of the brain) called the motor cortex. Signals are sent down the spinal cord along some nerve fibres, and, from there, along separate nerve fibres to the appropriate muscles. Control relies on information supplied by sensory nerve receptors, in the muscles and elsewhere, that record the position of different body parts and the degree of contraction in each muscle. This information is integrated in specific regions of the brain (including the cerebellum and basal ganglia) that control the coordination, initiation, and cessation of movement.

Skeletal movements can also occur as simple reflexes in response to certain sensory warning signals. These movements are automatic and less controlled, involving far fewer nerve connections.

**Other movements**

Some body movements do not involve the skeleton. For example, eye and tongue movements result from the con-
traction of muscles attached to other soft tissues. These movements may be voluntary or reflex.

The movements of the internal organs are involuntary; they include the heartbeat and peristalsis.

**movement, loss of**
See akinesia.

**moxibustion**
A form of treatment, often used with acupuncture, in which a cone of wormwood leaves (moxa) or certain other plant materials is burned just above the skin to relieve internal pain.

**moxisylyte**
A vasodilator drug used to treat Raynaud’s disease. Side effects include nausea, diarrhoea, hot flushes, headache, and dizziness.

**MRI**
The abbreviation for magnetic resonance imaging. MRI is a diagnostic technique that produces cross-sectional or three-dimensional images of organs and other body structures.

**HOW IT IS DONE**
The patient lies inside a scanner surrounded by a large, powerful magnet. A receiving magnet is placed around the part of the body to be investigated. If large areas, such as the abdomen, are to be imaged, the receiving magnet is fitted inside the scanner; for a smaller area, such as a joint, a magnet may be placed around the part to be scanned.

The scanner generates a strong magnetic field, which causes the atoms in the body to align parallel to each other. Short pulses of radio waves from a radiofrequency source briefly knock the atoms out of alignment. As the atoms realign they emit tiny signals, which are detected by the receiving magnet. Information about these signals is passed to a computer, which builds up an image based on the signals’ strength and location.

MRI images can be enhanced by use of a contrast medium to highlight particular body structures, such as tumours and blood vessels.

**WHY IT IS DONE**
Images from MRI are similar to those produced by CT scanning, but they give greater contrast between normal and abnormal tissues. MRI is useful for studying the brain and spinal cord, the internal structure of the eye and ear, the internal organs, and blood flow.

---

**THE SCANNING PROCESS**

An MRI scanner consists of a powerful electromagnet, a radio-wave emitter, and a radio-wave detector. A plane of the body is selected for imaging and the electromagnet is turned on.

1. Normally, the protons (nuclei) of the body’s hydrogen atoms point randomly in different directions, but under the influence of the scanner’s powerful magnetic field they align themselves in the same direction.

2. Next, the radio-wave source emits a powerful pulse of radio-waves, which knocks the protons out of alignment.

3. However, milliseconds later, the protons realign themselves. As they do so, they emit faint radio signals, which are picked up by the scanner’s radio-wave detector.

---

**MAGNETIC RESONANCE IMAGING (MRI)**

A valuable diagnostic technique, MRI has been in use since the early 1980s. The patient lies down and is surrounded by a massive electromagnet and is exposed to short bursts of powerful magnetic fields and radio-waves. The bursts stimulate protons (hydrogen nuclei) in the patient’s tissues to emit radio signals, which are detected and analysed by computer to create an image of a “slice” of the patient’s body.
mucopolysaccharidoses
A group of rare inherited metabolic disorders (see metabolism, inborn errors of) of which Hurler’s syndrome is the most well known. Mucopolysaccharidoses are genetic disorders in which there is an abnormality of a specific enzyme, causing the accumulation of substances called mucopolysaccharides in body cells.

SYMPTOMS
Features may include abnormalities of the skeleton and/or the central nervous system, with learning difficulties and, in some cases, a characteristic facial appearance. There may also be clouding of the cornea, enlargement of the liver, and stiffness in the joints.

TREATMENT AND OUTLOOK
No specific treatment is available; however, a bone marrow transplant may be used to treat Hurler’s syndrome.

Mild forms of mucopolysaccharidoses allow a child to have a relatively normal life. More severe types usually cause death in childhood or adolescence.

mucosa
A term for mucous membrane.

mucous membrane
The soft, pink, skinlike layer that lines many of the cavities and tubes in the body, including the respiratory tract and the digestive tract. Mucous membranes contain cells called goblet cells, which secrete a fluid containing mucus.

mucoviscidosis
See cystic fibrosis.

mucus
The thick, slimy fluid that is secreted by mucous membranes. Mucus moistens, lubricates, and protects parts of the body lined by mucous membranes, such as the digestive and respiratory tracts.

mucosal dysplasia
See contraconception, natural methods of.

mucosal method of contraception
See contraception, natural methods of.

MUGA scan
A method of investigating how much blood the heart can pump with each heartbeat and whether different parts of the heart wall are contracting properly. The patient’s red blood cells are injected with a radioactive isotope to enable an image to be formed of the blood pool within the heart at different times during the heart cycle. A MUGA scan, or multiple-gated acquisition scan, uses ECG, a gamma camera, and a computer.

multi-infarct dementia
A deterioration in brain function (see dementia) resulting from the death of small areas of brain tissue. It is the second most common cause of dementia after Alzheimer’s disease. The disorder occurs when clots block small blood vessels within the brain, preventing the flow of blood to particular areas and thereby starving the tissue of oxygen. The risk of developing multi-infarct dementia is increased in people with hypertension (high blood pressure) and atherosclerosis (narrowing of the arteries by fatty deposits on the artery walls).

Symptoms vary depending on the part of the brain that is affected, but they become progressively worse, in distinct steps, after each attack. Symptoms include disruption of memory, so that the person cannot recall recent events or get lost in familiar surroundings; difficulty in making decisions or carrying out simple tasks; and changes in mood, such as depression or agitation. Affected people often experience repeated transient ischaemic attacks or strokes.

Diagnosis is based on the symptoms and, if necessary, confirmed by MRI or CT scanning of the brain. Antihypertensive drugs may be prescribed to control blood pressure, and aspirin is often prescribed to reduce the risk of the condition progressing. People can also help to protect themselves from any further infarcts by following a low-fat diet and exercising regularly.

multiparous
A term for a woman who has had two or more pregnancies resulting in birth (whether or not the fetuses were alive at the time of birth).

multiple endocrine neoplasia (MEN)
The name for a group of rare, autosomal dominant genetic disorders that cause tumours to develop in several of the endocrine glands. Each disorder is caused by a different abnormal gene. One form of MEN causes tumours in the pancreas, parathyroid glands, and pituitary gland, and sometimes also in the adrenal gland and the thyroid gland. Another, less common form produces tumours in the adrenal, thyroid, and parathyroid glands. Tumours may arise simultaneously or at different times over several years. The affected glands may produce excess hormones. One type of thyroid tumour, which secretes...
the hormone calcitonin, is usually cancerous, but most tumours in other endocrine glands are not.

Tumours are usually removed by surgery, and the person will be monitored afterwards so that any further endocrine abnormalities can be detected. The person’s relatives may be offered screening for the abnormal gene or the effects of the disorder (see familial screening).

**multiple-gated acquisition scan**
See MUGA scan.

**multiple myeloma**
A rare, cancerous disorder, also called myelomatosis, in which plasma cells in the bone marrow proliferate uncontrollably and function incorrectly. It is more common in elderly people.

**CAUSE**
Plasma cells are a type of B-lymphocyte that produce immunoglobulins, which help protect against infection. In multiple myeloma, the proliferating plasma cells produce excessive amounts of one type of immunoglobulin while the production of other types is impaired. This makes infection more likely.

**SYMPTOMS**
Proliferation of the abnormal cells in the bone marrow causes pain and destroys the bone tissue. Affected vertebrae may collapse and compress the spinal cord or spinal nerves, causing numbness or paralysis. As bone is destroyed, levels of calcium in the blood increase, as may the levels of one or more immunoglobulins. These changes in the blood may lead to damage of the kidneys, resulting in kidney failure. There may also be anaemia and a tendency for abnormal bleeding.

**DIAGNOSIS AND TREATMENT**
The disease is diagnosed by a bone marrow biopsy, blood tests or urinalysis, and X-rays. Treatment includes radiotherapy for localized bone deposits, to relieve pain and reduce the risk of fractures; anticancer drugs to slow the course of the disease; correction of associated problems, such as kidney failure; and supportive measures, including blood transfusions, antibiotic drugs, and analgesic drugs (painkillers). No treatment provides a cure, however.

The outlook for multiple myeloma varies depending on the severity of the illness. Some people remain well for months or years, and then the progression of the disease accelerates.

**multiple organ failure**
Loss of function in several organs at once. This life-threatening condition affects the lungs (see respiratory distress syndrome), kidneys and other organs, and the circulation. It is most often triggered by overwhelming infection, but may also be due to shock following severe injury.

**multiple personality disorder**
A rare disorder in which a person has two or more distinct personalities, each of which dominates at different times. Each personality may be unaware that the others exist. The transition from one personality to another is often sudden, and may be triggered by stress. The condition is thought to result from severe emotional trauma, such as violent sexual abuse, during childhood.

**multiple pregnancy**
See pregnancy, multiple.

**multiple sclerosis**
A progressive disease of the central nervous system, in which patches of myelin (the protective covering of nerve fibres) in the brain and the spinal cord are disrupted. The damaged patches are called plaques. The nerves cannot conduct electrical impulses, so functions such as movement and sensation may be lost. Any part of the central nervous system may be affected.

**CAUSES AND INCIDENCE**
There may be a genetic predisposition, because MS sometimes runs in families. There may also be an environmental cause. It is more common in temperate zones than in the tropics.

**SYMPTOMS**
MS usually develops between the ages of 20 and 45, and is more common in women. Symptoms depend on the area of the brain or spinal cord that is involved in an attack. Spinal cord damage may cause tingling, numbness, weakness in the extremities, spasticity, paralysis, and incontinence. Damage to white matter (myelinated nerves) in the brain may cause fatigue, vertigo, clumsiness, muscle weakness, slurred speech, blurred vision, facial numbness, or facial pain. For further information see Features of multiple sclerosis box, overleaf.

An attack may last for several weeks or months. It is followed by a variable period of remission, in which dramatic improvements may be made. After a remission period, a further attack or a relapse occurs. Most people have mild relapses and long periods of remission (relapsing–remitting MS), with few permanent effects. Others have a form called chronic–progressive MS, becoming gradually more disabled from the first attack. A few have a form called fulminant MS, which progresses rapidly in the first year of illness.

**DIAGNOSIS**
There is no single diagnostic test, but MRI may show damage to white matter in the brain, and a lumbar puncture may show abnormal proteins in the fluid around the spinal cord. Evoked response tests on the eyes may reveal disruption of the nerve pathways from the optic nerves.

**TREATMENT**
There is no specific treatment. A short course of corticosteroid drugs may reduce the severity of relapses, while beta interferon can lengthen the time between attacks; however, these drugs do not improve the outlook. The use of rehabilitation, physiotherapy, and occupational therapy is essential so that people can carry out daily activities more easily.

Some people try remedies such as taking sunflower seed oil, following a gluten-free diet, hyperbaric oxygen therapy, or having various vaccines. To date, however, there is no evidence that any of these measures are beneficial.

**multivitamins**
Over-the-counter preparations, containing a combination of vitamins, that are used as a dietary supplement. (See vitamin supplements.)

**mumps**
An acute viral illness usually occurring in childhood. The main symptom is inflammation and swelling of one or both
**MUNCHAUSEN’S SYNDROME**

**FEATURES OF MULTIPLE SCLEROSIS**

The disease can affect any area of the white matter of the brain and spinal cord. The plaques of demyelination are areas in which the fatty myelin sheaths of the nerve fibres have been destroyed. The affected fibres cannot conduct nerve impulses, so functions such as movement and sensation may be lost. The patchy distribution of plaques causes very varied effects.

---

**SYMPTOMS**

Infected children often have no symptoms, or they may feel slightly unwell and have some discomfort around the parotid glands. In more serious cases, there is pain around the glands and chewing becomes difficult; one or both glands then become swollen and tender. A fever and headache may develop. The swelling subsides within a week to ten days. When only one gland is affected, the second gland often swells as the swelling in the first subsides.

**COMPLICATIONS**

Mumps may lead to a number of other conditions including viral meningitis (inflammation of the membranes covering the brain and spinal cord), pancreatitis (inflammation of the pancreas), or, in adolescent or adult males, epididymo-orchitis (inflammation of the testes).

**DIAGNOSIS AND TREATMENT**

Diagnosis is usually made from the symptoms. There is usually no treatment; rest and painkillers may ease symptoms.

---

**MUNCHAUSEN’S SYNDROME**

A chronic factitious disorder in which a person complains of physical symptoms that are pretended or self-induced in order to play the role of patient.

The usual complaints are abdominal pain, bleeding, neurological symptoms, rashes, and fever. People typically invent dramatic histories. Most sufferers are repeatedly admitted to hospital, and many have detailed medical knowledge and scars from self-injury or previous treatment. In Munchausen’s syndrome by proxy, parents simulate disorders in children.

Treatment consists of protecting the sufferers from unnecessary operations and drug treatments.
mupirocin
An antibacterial cream or ointment used to treat skin infections such as impetigo.

mural aneurysm
A dilated, weakened area in the wall of the left ventricle in the heart; also called a ventricular aneurysm.

mural thrombus
A thrombus (blood clot) on the inner wall of a heart chamber, usually a ventricle (lower chamber). The clot develops on an area of tissue that has been damaged by a myocardial infarction (heart attack).

murmur
A sound caused by turbulent blood flow through the heart, as heard through a stethoscope. Heart murmurs are regarded as an indication of possible abnormalities in the blood flow. Apart from innocent murmurs, the most common cause of extra blood turbulence is a disorder of the heart valves. Murmurs can also be caused by some types of congenital heart disease (see heart disease, congenital) or by rarer conditions such as a myxoma in a heart chamber. (See also systolic murmur.)

muscle
A structure composed of bundles of specialized cells, which are capable of contraction and relaxation to create movement. There are three types of muscle: skeletal, smooth, and cardiac.

SKELETAL MUSCLE
The skeletal muscles are the most prominent muscle group in the body (see muscular system). They are called voluntary muscles because they are under conscious control (see The body’s muscles box, overleaf).

Skeletal muscles comprise groups of muscle fibres arranged in bundles called fascicles. A fibre is made up of longitudinal units called myofibrils, the working units of which are filaments of actin and myosin (two proteins that control contraction). Impulses from the brain cause the myosin filaments to slide over the actin, making the muscle fibres contract and move the body. Conversely, nerve fibres in the muscle register the force of contraction (while nerves in the tendon register how much it has stretched) and transmit this information back to the brain, which limits the strength of the contraction. The muscle activity is affected by changes in the chemical composition of the fluid that surrounds the muscle cells. A fall in the level of potassium ions causes muscle weakness; a decrease in calcium ions causes muscle spasm.

A state of partial contraction is constantly maintained, even when the muscles are not moving; this is called muscle tone (see tone, muscle). Some disorders may cause abnormalities in muscle tone, such as excessive rigidity (spasticity) or floppiness (hypotonia).

SMOOTH MUSCLE
This type of muscle exists in the walls of internal organs. It produces movements such as peristalsis in the intestine and contractions of the uterus in childbirth. Smooth muscle also forms part of the lining of hollow structures such as the blood vessels, airways, and bladder. It is also called involuntary muscle, because it is not under conscious control.

The muscle is made of long, spindle-shaped cells, and contracts by the same action of actin and myosin as skeletal muscle. It is stimulated by the autonomic nervous system; it also responds to hormones and to levels of chemicals in the fluid around the muscle.

CARDIAC MUSCLE
Cardiac muscle (also called myocardium) is found only in the heart. It is able to contract continually and rhythmically, about 100,000 times a day. Contraction is stimulated by the autonomic nervous system, by hormones, and by the stretching of muscle fibres. The initial electrical stimulus comes from the sinoatrial node; it spreads through specialized conduction cells that form a network throughout the muscle fibres. The fibres are joined end to end by areas of extensive folds that enable contractions to be transmitted rapidly from one fibre to another.

DISORDERS
The most common disorders are injury and lack of blood supply to a muscle. (See also Disorders of muscle, overleaf.)

muscle enzymes
Proteins that regulate the rate of chemical reactions in muscle cells. Measuring the blood levels of muscle enzymes (see blood tests) can help doctors to diagnose certain disorders. One such disorder is myocardial infarction (heart attack), in which damaged heart muscle leaks higher than normal levels of enzymes into the blood. Another is muscular dystrophy,
The most prominent muscles in the body are the skeletal muscles, which account for 40 to 45 per cent of body weight. These muscles are defined as voluntary because they are under conscious control; some important voluntary muscles are indicated on the illustration below. In contrast, many of the internal organs, such as the heart and the intestines, consist partly or entirely of involuntary muscle, which is not under conscious control.
in which the raised levels of muscle enzyme are due to the death of muscle cells. Enzymes leaked from the heart muscle differ from those from skeletal muscle; this distinction helps doctors to identify the site of the muscle damage.

**muscle-relaxant drugs**

A group of drugs that are used to relieve muscle spasm and spasticity. Muscle-relaxant drugs are used mainly in the treatment of nervous-system disorders such as multiple sclerosis and painful muscular conditions such as torticollis. They are occasionally used to relieve muscle rigidity due to injury. Some types of muscle-relaxant drugs are used to cause temporary paralysis during surgery under general anaesthesia.

Most muscle-relaxant drugs partially block nerve signals that stimulate muscle contraction. Dantrolene, in contrast, interferes with the chemical activity in muscle cells needed for contraction. The drugs may cause muscle weakness and drowsiness. In rare cases, dantrolene causes liver damage.

**muscle spasm**

Sudden and involuntary contraction of a muscle. Spasm is a reaction to pain and inflammation around a joint. Common causes are strain, disc prolapse (slipped disc), and stress. Usually, the underlying cause is treated. Muscle-relaxant drugs may also be needed. (See also spasticity.)

### DISORDERS OF MUSCLE

<table>
<thead>
<tr>
<th>The most common muscle disorder is injury, followed by symptoms caused by a lack of blood supply to a muscle (including the heart muscle). There are also various other, rare disorders that can affect the muscles.</th>
</tr>
</thead>
</table>
| **Injury**

Muscle injuries, such as tears and strains, are very common. They cause bleeding into the muscle tissue. Healing may lead to the formation of a scar in the muscle, which shortens its natural length. Blunt injury may result in the formation of a haematoma (a localized collection of blood) from bleeding into the muscle. Rarely, bone may form in a blood clot, causing myositis ossificans.

**Impaired blood supply**

Muscles depend on a good blood supply in order to function normally. A temporary lack of blood flow, which is sometimes associated with severe exertion, may cause cramp. Peripheral vascular disease, in which blood vessels in the legs (and sometimes the arms) are narrowed, restricts the blood supply, causing claudication (muscle pain on exercise). Angina pectoris (chest pain caused by lack of blood supply to heart muscle) may occur in people with coronary artery disease.

The compartment syndrome is pain in muscles as a result of pressure that limits their blood supply. It may be brought on by injury or exercise, and occurs most often in athletes who have well-developed muscles.

**Infection**

The most serious infection of muscle is gangrene, which may complicate deep wounds (especially those contaminated by soil). Tetanus is acquired in a similar way; it causes widespread muscle spasm through the release of a powerful toxin. Viruses (especially influenza B) may also infect muscles (causing myalgia), as may the organism causing toxoplasmosis. Lastly, a parasitic disease called trichinosis can occur in muscle tissue. This disease results from infestation with the worm Trichinella spiralis, which is acquired by eating undercooked meat (usually pork).

**Tumours**

Various forms of tumour may originate in the muscles. Such tumours, called primary muscle tumours, may or may not be cancerous. Noncancerous tumours are called myomas; those affecting smooth muscle are called leiomyomas, and those developing in skeletal muscle are called rhabdomyomas. Myomas of the uterus (see fibroids) are among the most common of all tumours. Cancerous tumours, called myosarcomas, are very rare; they include rhabdomyosarcomas, which are cancers of the skeletal muscle.

Secondary tumours, which spread from a primary site of cancer elsewhere in the body, very rarely involve muscle.

**Hormonal and metabolic disorders**

Muscle contraction depends on the maintenance of proper levels of sodium, potassium, and calcium in and around muscle cells. Any alteration in the concentration of these substances affects muscle function. For example, a severe drop in the level of potassium (hypokalaemia) causes profound muscle weakness and may stop the heart. A drop in blood calcium (hypocalcaemia) causes increased excitability of muscles and, occasionally, muscle spasms.

Thyroid disease is often associated with muscle disorders, the most common of which is swelling of the small muscles that move the eyes, causing a bulging eyeball (see exophthalmos). Adrenal failure (see Addison’s disease) causes general muscle weakness.

**Poisons and drugs**

Several toxic substances can damage muscle tissue. Alcohol can cause damage following a prolonged drinking bout. Other substances that may cause muscle damage include the drugs chloroquine and vincristine.

**Genetic disorders**

These disorders include the various forms of muscular dystrophy, which cause progressive weakness and disability. Some types appear at birth, some in infancy, and some develop as late as the fifth or sixth decade. Cardiomyopathy (disease of the heart muscle) is also inherited in some cases.

**Autoimmune disorders**

Myasthenia gravis is a disorder involving the transmission of nerve impulses to muscles; it usually begins with drooping of the eyelids and double vision. Other autoimmune diseases that may affect the muscles are lupus erythematosus, rheumatoid arthritis, systemic sclerosis, sarcoidosis, and dermatomyositis.

### INVESTIGATION

Muscle disorders are investigated by EMG (electromyography), which measures the response of muscles to electrical impulses, and by biopsy (removal of a sample of tissue for analysis). In addition, blood tests may be used to detect abnormal levels of muscle enzymes.
muscle wasting
See: muscular atrophy.

muscular atrophy
Weakness and shrinking of muscle tissue. Muscular atrophy may have many possible causes, including injury, starvation, loss of function in a body part, degeneration of muscle cells, and disorders of the nerves supplying muscles.

Muscles can atrophy rapidly if a body part is not used and if no measures are taken to prevent the problem. In a broken leg, for example, muscle loss may be visible after only a week. The muscle fibres are not lost, however; they can return to normal if the muscle is stimulated and used.

muscular dystrophy
A group of rare inherited muscle disorders that cause slow, progressive wasting of muscle fibres. This degeneration may lead to disability and death.

TYPES AND SYMPTOMS
The most common and severe form of muscular dystrophy is Duchenne muscular dystrophy. This is caused by a recessive gene carried on the X chromosome (see sex-linked inheritance). Boys only have one X chromosome, so if they inherit a copy of the defective gene from their mother they develop the disorder. Girls (with two X chromosomes) are not affected but become carriers of the defective gene.

Affected boys walk with a waddle, find climbing difficult, and may have curvature of the spine. The disorder progresses rapidly: the ability to walk is lost by the age of 12, and few boys survive beyond the teenage years.

Becker’s muscular dystrophy starts later in childhood and progresses at a slower rate. Myotonic dystrophy affects the muscles of the hands, face, neck, and feet, and causes learning difficulties. Limb-girdle muscular dystrophy mainly affects muscles in the hips and shoulders, and facioscapulohumeral muscular dystrophy affects muscles in the upper arms, shoulder girdle, and face. In this last form, severe disability is rare.

DIAGNOSIS
A diagnosis for Duchenne muscular dystrophy can be made with gene testing before symptoms develop. Once muscle weakness has developed, other tests may be used, including measurement of muscle enzymes and an EMG.

TREATMENT
There is no cure, and physiotherapy is the main treatment. Remaining as active

### DUCHENNE MUSCULAR DYSTROPHY: A TYPICAL FAMILY TREE

Affected males always inherit the gene for the disorder from their mothers, who are carriers of the gene but are themselves unaffected. About half the sons of carriers are affected; the other sons are neither affected nor carriers. The daughters of carriers have a 50 per cent chance of being carriers themselves. Complex blood tests provide the only means of knowing whether or not a certain daughter (or granddaughter) is a muscular dystrophy carrier.

---

### TYPES OF MUSCULAR DYSTROPHY

<table>
<thead>
<tr>
<th>Muscular dystrophy</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Duchenne muscular dystrophy</td>
<td>In this type, the child is slow in learning to sit up and walk, and does so much later than normal. The condition is rarely diagnosed before the age of three, but progresses rapidly. Affected children tend to walk with a waddle and have difficulty climbing stairs. In getting up from the floor, the child “climbs up his legs”, pushing his hands against his ankles, knees, and thighs. Sometimes there is curvature of the spine. Despite their weakness, the muscles (especially those in the calves) appear bulky; this is because wasted muscle is replaced by fat. By about the age of 12, affected children are no longer able to walk; few survive beyond their teenage years. Affected boys often have below-average intelligence.</td>
</tr>
<tr>
<td>Becker’s muscular dystrophy</td>
<td>This type produces the same symptoms as the Duchenne type, but starts later in childhood and progresses much more slowly. Patients often reach the age of 50. Both types of dystrophy have sex-linked inheritance.</td>
</tr>
<tr>
<td>Myotonic dystrophy</td>
<td>This form affects muscles of the face, hands, and feet. Infants are floppy and slow to develop. The main feature is that the muscles contract strongly but do not relax easily. Myotonic dystrophy is associated with cataracts in middle age, baldness, mental retardation, and endocrine problems. The condition has an autosomal dominant pattern of inheritance.</td>
</tr>
<tr>
<td>Limb-girdle muscular dystrophy</td>
<td>This type takes different forms. It starts in late childhood or early adult life, and progression is slow. The muscles of the hips and shoulders are mainly affected. Other nerve and muscle conditions must be eliminated before this form of dystrophy can be diagnosed confidently.</td>
</tr>
<tr>
<td>Facioscapulohumeral muscular dystrophy</td>
<td>This form usually appears first between the ages of 10 and 40; it affects only the muscle so the upper arms, shoulder girdle, and face. It is inherited in an autosomal dominant pattern. In this form of muscular dystrophy, progression of the weakness is slow, and severe disability is rare.</td>
</tr>
</tbody>
</table>
as possible keeps healthy muscles in good condition. Surgery to the heel tendon may aid walking in some cases.

OUTLOOK
The long-term outlook depends on the particular form. Families in which a child or adult has developed any form of muscular dystrophy may wish to consider genetic counselling.

muscular system
The muscles of the body that are attached to the skeleton. These muscles are responsible for voluntary movement, and also support and stabilize the skeleton. In most cases, a muscle attaches to a bone (usually by means of a tendon) and crosses over a joint to attach to another bone.

FUNCTION
Muscles produce movement by contracting and shortening to pull on the bone to which they are attached. They can only pull, not push, and are therefore arranged so that the pull of one muscle or group of muscles is opposed to another, enabling a movement to be reversed. Although most actions of the skeletal muscles are under conscious control, reflex movements can occur in response to certain stimuli.

TYPES OF MUSCLE
There are more than 600 muscles in the body, classified according to the type of movement they produce. An extensor opens out a joint, a flexor closes it; an adductor draws a part of the body inwards, an abductor moves it outwards; a levator raises it, a depressor lowers it; and constrictor or sphincter muscles surround and close orifices.

musculoskeletal
Relating to muscle and/or bone. The musculoskeletal system is the skeleton and the muscles attached to it.

musculoskeletal pain
Pain in the bones, joints, muscles, or other parts of the musculoskeletal system. Such pain may have a wide variety of causes, from fever and temporary injuries to soft tissues (such as muscle or tendon strains and ligament sprains) to severe diseases such as arthritis.

mushroom poisoning
There are numerous species of poisonous mushrooms and toadstools in the UK, but many have an unpleasant taste and are therefore unlikely to be eaten in sufficient amounts to cause problems.

DEATH CAP
Most fatal cases of mushroom poisoning in the UK are caused by Amanita phalloides (death cap). This mushroom can be confused with the edible field mushroom, although it has white gills instead of pinkish-brown ones.

The death cap and some related species, such as Amanita virosa (destroying angel), contain poisons called amanitins, which attack cells in the liver, kidneys, and small intestine. Symptoms such as severe abdominal pain, vomiting, and diarrhoea usually develop 8 to 14 hours after eating the mushrooms. Later, there may be liver enlargement and jaundice, which may lead to death from liver failure. There is no antidote; treatment consists of supportive measures only. For people who survive, recovery usually occurs after about a week.

FLY AGARIC
Amanita muscaria (fly agaric) has a red cap flecked with white. Symptoms of poisoning appear within 20 minutes to two hours and may include drowsiness, visual disturbances, delirium, muscle tremors, nausea, and vomiting. This type of poisoning (and other types that have rapidly developing symptoms) is treated with gastric lavage (see lavage, gastric) and activated charcoal. Recovery usually occurs within 24 hours.

MAGIC MUSHROOMS
“Magic” mushrooms contain the hallucinogen psilocybin. They may also cause high fever in children. The effects usually last for four to six hours.

mutagen
Any agent that increases the rate of mutation (genetic changes) in cells. The main mutagens are ionizing radiation (see radiation hazards), some chemicals, and certain illnesses.

mutation
A change in a cell’s DNA. Many mutations are harmless; however, some are harmful, giving rise to cancers, birth defects, and hereditary diseases. Very rarely, a mutation may be beneficial.

CAUSES
A mutation results from a fault in the replication of DNA when a cell divides. A daughter cell inherits some faulty DNA, and the fault is copied each time the new cell divides, creating a cell population containing the altered DNA.

Some mutations occur by chance. Any agent that makes mutations more likely is called a mutagen.

TYPES
There are several types of mutation. Point mutations affect only one gene and may lead to the production of defective enzymes or other proteins. In other mutations, chromosomes (or parts of them) are deleted, added, or rearranged. This type may produce greater disruptive effects than point mutations.

EFFECTS
If a mutated cell is a somatic (body) cell, it can, at worst, multiply to form a group of abnormal cells. These cells often die out, are destroyed by the body’s immune system, or have only a minor effect. Sometimes, however, they may become a tumour.

A mutation in a germ cell (immature egg or sperm) may be passed on to a child, who then has the mutation in all of his or her cells. This may cause an obvious birth defect or an abnormality in body chemistry. The mutation may also be passed down to the child’s
Genetic disorders (such as haemophilia and achondroplasia) stem from point mutations that occurred in the germ cell of a parent, grandparent, or more distant ancestor. Chromosomal abnormalities (such as Down’s syndrome) are generally due to mutations in the formation of parental eggs or sperm.

**mutism**
Refusal or inability to speak. Mutism may be a symptom of profound congenital deafness, severe manic–depressive illness, catatonic schizophrenia, or a rare form of conversion disorder. The term “mutism” may also be used of a religious vow of silence.

Elective mutism is a rare childhood disorder (usually starting before age five) in which a child can speak properly but refuses to do so most of the time.

Akinetic mutism is a state of passivity caused by some brain tumours or by hydrocephalus (fluid surrounding the brain). Affected people are incontinent, require feeding, and respond at most with a whispered “yes” or “no”.

**myalgia**
Medical term for muscle pain.

**myalgic encephalomyelitis**
Also known as ME, an alternative name for chronic fatigue syndrome.

**myasthenia gravis**
A rare disorder in which the muscles become weak and tire easily. The muscles of the eyes, face, throat, and limbs are most commonly affected.

**CAUSE**
Myasthenia gravis is an autoimmune disorder. In many cases, abnormalities in the thymus gland are present, and in some cases a thymoma (tumour of the thymus gland) is found. Women are affected more often than men.

**SYMPTOMS**
The disease is extremely variable in its effects. In most cases, it causes drooping eyelids, double vision, a blank facial expression, and a weak, hoarse, nasal voice that is hesitant and becomes slurred during extended conversation. The arm and leg muscles may also be affected. In severe cases, the respiratory muscles may become weakened, causing breathing difficulty.

**DIAGNOSIS**
One common test is injection of the drug edrophonium into a vein, which temporarily restores power to the weak muscles. Blood tests and EMG are also sometimes used. In some cases, CT scanning or MRI may be performed to detect a thymoma.

**TREATMENT AND OUTLOOK**
Drugs that facilitate the transmission of nerve impulses can often restore a person’s condition to near normal. In some people, the condition may improve, and is sometimes cured, with thymectomy (removal of the thymus gland). In more severe cases, regular plasmapheresis may be carried out. Corticosteroid drugs may also be given to suppress immune system activity. In a few people, paralysis of the throat and respiratory muscles may lead to death.

**mycetoma**
An uncommon tropical infection affecting skin and bone. Mycetoma is caused by fungi or by bacteria called actinomycetes. It usually occurs on one limb, causing a hard swelling and a discharge of pus. Infections caused by actinomyces are treated with antibiotic drugs. Surgical removal of diseased tissue may be necessary for a fungal infection.

**mycobacterial infections**
Diseases caused by bacteria from the Mycobacterium group (see tuberculosis; Hansen’s disease). An increasing range of mycobacterial infections is recognized in immunocompromised people, such as those with AIDS.

**mycology**
The study of fungi.

**mycophenolate mofetil**
An immunosuppressant drug used after organ transplants to reduce the risk of the body rejecting the organ.

**mycoplasma**
Any of a group of bacteria that are the smallest type capable of free existence. Mycoplasmas are about the same size as viruses but, unlike viruses, are capable of reproducing outside living cells. One species, Mycoplasma pneumoniae, causes primary atypical pneumonia.

**mycosis**
Any disease caused by a fungus. (See fungal infection; fungi.)

**mycosis fungoides**
A rare type of lymphoma that primarily affects the skin of the buttocks, back, or shoulders. The cause is unknown. In its mildest form, mycosis fungoides produces a non-itchy, red, scaly rash, which may spread slowly or remain unaltered for many years. In more severe forms, thickened patches of skin, ulcers, and enlarged lymph nodes may develop.

Diagnosis is confirmed with a skin biopsy. Treatment may include PUVA, radiotherapy, nitrogen mustard, anticancer drugs, and corticosteroid drugs.

**mydriasis**
Dilation (widening) of the pupil of the eye. Mydriasis occurs in the dark; with emotional arousal; after the use of certain eye-drops (for example those containing atropine); and also after drinking alcohol.

**mydriatic drugs**
A group of drugs used to treat uveitis and to dilate the pupil during examination of the inside of the eye and for surgery. Mydriatics work by relaxing the circular muscles of the iris, causing the pupil to dilate. Common mydriatic drugs include tropicamide, cyclopentolate, homatropine, and phenylephrine. (See also cyclopia; miotic drugs.)

**myectomy**
Surgical removal of part or all of a muscle. Myectomy may be performed to treat severely injured and infected muscles or to remove a fibroid (an operation called a myomectomy) from the muscular wall of the uterus.

**myel-**
A prefix denoting a relationship to bone marrow (as in multiple myeloma) or to the spinal cord (as in myelitis). The prefix “myelo-” has the same meaning.

**myelin**
The fatty material made of lipid (fat) and protein that forms a protective sheath around some nerve fibres and increases the efficiency of nerve impulse transmission. (See also demyelination.)

**myelitis**
Inflammation of the spinal cord. It is often caused by a viral infection. In transverse myelitis, the spinal cord becomes inflamed around the middle of the back. Common symptoms are back pain and gradual paralysis of the legs; in some cases, the paralysis becomes permanent. (See also poliomyelitis.)

**myelocele**
Another name for myelomeningocele.
The myelin nerve sheath
The axon is the conducting fibre of a nerve. To transmit impulses more efficiently, some nerve axons have a myelin sheath.

**myelofibrosis**
An alternative term for *myelosclerosis*.

**myelography**
X-ray examination of the spinal cord, nerves, and other tissues within the spinal canal after injection of a contrast medium (a substance that is opaque to X-rays). The procedure has now been replaced by CT scanning and MRI.

**myeloid leukaemia**
See leukaemia, chronic myeloid.

**myeloma, multiple**
See multiple myeloma.

**myelomatosis**
See: multiple myeloma.

**myelomeningocele**
A congenital abnormality seen in spina bifida. An affected baby has a raw swelling over the spine, containing an exposed, malformed section of the spinal cord and its meninges (protective membranes).

**myelopathy**
A disease or disorder of the spinal cord.

**myeloproliferative disorders**
Conditions characterized by the abnormal proliferation of one or more blood cell groups within the bone marrow. (See leukaemia; polycythæmia.)

**myelosclerosis**
An increase of fibrous tissue within the bone marrow (also called myelofibrosis), which interferes with the ability of the marrow to produce blood cells. Myelosclerosis may be primary (with no obvious cause) or secondary (resulting from another bone marrow disease).

The main symptoms of myelosclerosis are those of *anaemia*. In addition, enlargement of the *spleen*, night sweats, loss of appetite, and weight loss commonly occur. In secondary myelosclerosis, the underlying disease may cause other symptoms.

Treatment of primary myelosclerosis includes *blood transfusions* to relieve the symptoms. A few people, however, may develop acute *leukaemia*. Treatment of secondary myelosclerosis depends on the underlying cause.

**myiasis**
Infestation by fly larvae; the condition is primarily restricted to tropical areas. In Africa, the tumbu fly lays eggs on wet clothing left outside; the larvae hatch and penetrate the skin to cause swellings like boils. Other flies lay eggs in open wounds, on the skin, or in the ears or nose. Sometimes, larvae penetrate deeply into the tissues. Intestinal infestation can occur after eating food that has been contaminated.

Myiasis of the skin is treated by applying drops of oil to the swelling. The larva comes to the surface, where it can be carefully removed. In deeper tissues, surgery may be required. Intestinal myiasis is treated with a *laxative*. Preventive measures include keeping flies away from food, keeping open wounds covered, and ironing clothes that have been dried outdoors.

**myo-**
A prefix denoting a relationship to muscle (as in *myocarditis*).

**myocardial infarction**
Sudden death of part of the heart muscle due to a blockage in the blood supply to that area of the heart. The disorder is popularly known as a heart attack. Myocardial infarction is the most common cause of death in the UK.

**CAUSES**
The usual cause is *atherosclerosis* of the coronary arteries. In this condition, plaques (fatty deposits) develop on the artery walls; a clot may then form over a plaque and block an artery (see Features of myocardial infarction box, overleaf).

Men are more likely to have a heart attack than women, and smokers are at greater risk than nonsmokers. Other risk factors include increased age, an unhealthy diet, obesity, and disorders such as *hypertension* (high blood pressure) and *diabetes mellitus*.

**SYMPTOMS**
There is a sudden, crushing pain that starts in the centre of the chest and may spread into the arms or up to the jaw. Breathlessness, restlessness, clammy skin, and nausea and/or vomiting may also occur. In some cases, the first symptom is sudden collapse and loss of consciousness. A few people have only mild symptoms or have none at all; this type of heart attack is known as a silent myocardial infarct.

The damage to the heart tissue may cause immediate *heart failure* (reduced pumping efficiency) or *arrhythmias* (irregular heartbeat). *Ventricular fibrillation* is the most dangerous form of arrhythmia; it prevents the heart from pumping effectively and, if untreated, is fatal within a few minutes.

**DIAGNOSIS**
Diagnosis is made from the patient’s history, together with an ECG. Tests are also carried out to measure levels of certain enzymes, and of a protein called troponin, which are released into the blood from damaged heart muscle.

**TREATMENT**
A myocardial infarction is a medical emergency. A person who suspects that he or she is having a heart attack should chew an *aspirin* tablet, which will help to dissolve the clot in the artery. He or she should then be taken to hospital as soon as possible.

Initially, oxygen and *diamorphine* are given in order to relieve the pain and intravenous *thrombolytic drugs* may be given to dissolve the blood clot (unless there is a risk that the drugs will cause excessive bleeding).

Afterwards, patients are monitored in an intensive care or coronary care unit so that any complications, such as *heart failure*, arrhythmias (see arrhythmia, cardiac), or rupture of a heart valve can be detected and treated as early as possible. If thrombolytic drugs have failed to restore blood flow in the affected artery, surgery may be considered (see angio-plasty, balloon; coronary artery bypass graft).

On leaving hospital, patients may be advised to take aspirin, *beta-blocker drugs* to protect the heart muscle, and *statin drugs* to lower blood *cholesterol*. *ACE inhibitors* are also given to treat heart failure or impaired function of the left ventricle. In addition, people will
undergo a rehabilitation programme to help them return to full activity and to increase awareness of risk factors.

**myocardial ischaemia**

An insufficient blood supply to the heart muscle. It is usually caused by narrowing or blockage of the coronary blood vessels (which supply the heart muscle), due to atherosclerosis (an accumulation of fatty deposits on the walls of arteries). Myocardial ischaemia causes the heart muscle to be deprived of oxygen, and may give rise to problems such as angina pectoris and myocardial infarction (heart attack).

**myocarditis**

Inflammation of heart muscle, usually due to coxsackievirus infection. It is also a characteristic feature of rheumatic fever.

**SYMPTOMS**

There are often no symptoms. Rarely, there may be a serious disturbance of the heartbeat, breathlessness, chest pain, and heart failure. In severe cases of myocarditis, death may result from cardiac arrest.

**DIAGNOSIS AND TREATMENT**

Myocarditis may be suspected from the patient’s history and from a physical
examination. An ECG will show characteristic abnormalities of the heartbeat. Diagnosis also involves echocardiography and blood tests.

There is no specific treatment. Bed rest is usually recommended and corticosteroid drugs may be prescribed.

myocardium
The middle of the three layers of muscle that make up the wall of the heart. The myocardium is composed of cardiac muscle. (See also cardiomyopathy; myocardial infarction; myocardial ischaemia; myocarditis.)

myoclonus
Rapid, uncontrollable jerking or spasm of one or more muscles, either at rest or during movement. Myoclonus may be associated with a muscular or nervous disorder, but it also occurs in healthy people; for example, when the limbs twitch before sleep.

myofascial pain syndrome
See temporomandibular joint syndrome.

myoglobin
An oxygen-carrying pigment found in muscles. Myoglobin consists of a combination of iron and protein. It stores oxygen, releasing it when it is needed by the muscles.

Myoglobin may be released into the urine, causing myoglobinuria. Slight myoglobinuria may result from prolonged exercise. Severe myoglobinuria is usually due to the release of myoglobin from a large area of damaged muscle, and may cause kidney failure.

myoma
A noncancerous muscle tumour. (See also fibroid.)

myomectomy
Surgical removal of a myoma. The term is also used to describe the surgical removal of fibroids from the uterus.

myometrium
The muscular wall of the uterus. It is composed of smooth muscle and lined with endometrium. The myometrium contracts strongly during childbirth in order to dilate the cervix and push the fetus (and the placenta) out of the uterus. It also undergoes much smaller contractions during menstrual periods, which help to expel blood and tissue (see menstruation).

myopathy
A disease of muscle that is not caused by disease of the nervous system. A myopathy may be an inherited disorder, such as muscular dystrophy; it may also be caused by chemical poisoning, a chronic disorder of the immune system, or a metabolic disorder.

myopia
An error of refraction, commonly called shortsightedness, in which distant objects appear blurred. It is caused by the eye being too long from front to back. As a result, images of distant objects are focused in front of the retina.

Myopia, which tends to be inherited, usually appears around puberty, increasing until the early 20s. If it starts in early childhood it may become severe. The condition is detected during a vision test. Treatment is with concave glasses (or contact lenses) or by photorefractive keratectomy or LASIK.

myosin
A major protein component of muscle fibres. Together with actin, it provides the mechanism for muscles to contract. The myosin molecules slide along the actin filaments in order to make the muscles appear shorter.

myositis
Inflammation of muscle tissue, causing pain, tenderness, and weakness. Types include myositis ossificans, polymyositis, and dermatomyositis.

myositis ossificans
A congenital (present from birth) or acquired condition in which bone is deposited in muscles. The congenital form is rare. The first symptoms are painful swellings in the muscles, which gradually harden and extend until the affected child is encased in a rigid sheet. There is no treatment, and death results.

The acquired form may develop after a bone injury, especially around the elbow; it causes severe pain and a swelling that hardens. Treatment with diathermy, and gentle, active movements, may be helpful.

myotomy
A surgical procedure that involves cutting into a muscle.

myotonia
Inability of a muscle to relax after the need for contraction has passed. It is a feature of myotonic dystrophy, a form of muscular dystrophy.

myringitis
Inflammation of the eardrum. Myringitis occurs in otitis media.

myringoplasty
Surgical closure of a perforation (hole) in the eardrum (see eardrum, perforated) by means of a tissue graft (see grafting).

myringotomy
A surgical opening made through the eardrum to allow drainage of the middle-ear cavity. It is usually performed to treat persistent glue ear in children. A grommet may be inserted into the eardrum at the same time.

myxoedema
A condition in which the skin and other body tissues (most noticeably in the face) thicken and coarsen. Myxoedema is usually due to hypothyroidism. The term “myxoedema” is sometimes used of adult hypothyroidism.

myxoma
A noncancerous, jellylike tumour composed of soft mucous material and loose fibrous strands. Myxomas usually occur singly, and may sometimes grow very large. They may develop under the skin, in the abdomen, or, very rarely, in the heart chambers. In this last case, thrombi (blood clots) may form, and the blood flow through the heart may be obstructed. Myxomas can usually be successfully removed by surgery.

myxovirus
One of a group of RNA-containing viruses that are responsible for various human and animal diseases. There are two families of myxovirus: the paramyxovirus and the orthomyxovirus.
nabilone
An antiemetic drug derived from marijuana. Nabilone is used to treat patients suffering from the nausea and vomiting caused by anticancer drugs that have not responded to other treatments.

nabothian cyst
A cyst (a small fluid-filled swelling or lump) that develops on the cervix (the neck) of the uterus when the ducts of a mucous gland become obstructed. A nabothian cyst, which is also known as a nabothian follicle, is harmless and requires no treatment.

NAD
The abbreviation for nicotinamide adenine dinucleotide, which is a coenzyme (an organic compound that plays an essential role in a reaction catalyzed by an enzyme) derived from nicotinic acid. NAD acts as a hydrogen acceptor (forming NADH) in the chemical process that produces energy within cells.

nadolol
A beta-blocker drug used to treat hypertension (high blood pressure), angina pectoris (chest pain due to impaired blood supply to the heart muscle), and certain types of arrhythmia (irregularity of the heartbeat). Nadolol is also used to control symptoms of hyperthyroidism (overactivity of the thyroid gland).

Possible side effects are typical of other beta-blocker drugs; they include a reduction in the patient’s capacity for strenuous exercise and aggravation of any existing symptoms of lung disease and peripheral vascular disease.

Naegeli syndrome
A rare inherited condition that has its onset in the first few years of life. Symptoms include weblike skin pigmentation, diminished function of the sweat glands, hypodontia (fewer teeth than normal), hyperkeratosis (thickening of the outer layer of skin) affecting the palms and soles, and blistering Naegeli syndrome has an autosomal dominant pattern of inheritance (see genetic disorders) and affects both males and females.

naevus
A type of blemish on the skin. There are two main groups of naevus: pigmented naevi, which are caused by an abnormality in or overactivity of melanocytes (skin cells that produce the brown pigment melanin); and vascular naevi, which result from an abnormal collection of blood vessels near the surface of the skin.

PIGMENTED NAEVI
The most common type of pigmented naevus is a freckle, which is a small, flat, light-brown to dark-brown area that may occur on any part of the body exposed to the sun. The tendency to develop freckles on exposure to the sun is inherited; they are more common in people with fair skin and red hair. A lentigo, sometimes called an age spot or liver spot, is a light-brown spot similar to a freckle. These spots most commonly affect people over the age of 40 and appear both on covered and on sun-exposed areas of the body. Café au lait spots are another type of light-brown pigmented naevus.

Another common type of pigmented naevus is a mole, which is sometimes called a melanocytic naevus. Moles are brown to dark-brown in colour and usually measure less than 1 cm in diameter. Moles can form anywhere on the body and a tendency to develop them sometimes runs in families. Moles may appear soon after birth (see birthmark) or during childhood and early adolescence; almost all adults have between ten and 20 moles by the time they are 30. Most moles are noncancerous, but, rarely, a mole may undergo changes that make it cancerous (see melanoma, malignant). Red-brown naevi that occur in childhood are juvenile melanomas (see melanoma, juvenile).

Some naevi have a bluish coloration. Many black and Asian infants are born with blue-black spots on their lower backs (see Mongolian blue spot).

VASCULAR NAEVI
Port-wine stains and strawberry marks (see haemangioma) are vascular naevi. These types of naevi are usually present at birth. A port-wine stain is visible as an irregularly shaped red patch and may be distressing, especially if it affects the individual’s face. The mark is usually permanent. Strawberry marks are common birthmarks and appear as raised, red swellings; they usually disappear by the time a child is about five years old.

A spider naevus is another example of a vascular naevus. These are common in children and pregnant women.

TREATMENT
Most naevi are harmless. If, however, a naevus suddenly appears, grows, bleeds, or changes colour, medical advice should be sought immediately to exclude skin cancer. Permanent birthmarks can be treated with laser treatment.

nail
A hard, curved plate, found on each of the fingers and toes, composed of keratin (a tough protein that is also the main constituent of skin and hair). Nails grow from an area called the nail bed. At the base of each nail, a half-moon shape (the lunula) is crossed by a flap of skin known as the cuticle. The surrounding skin is the nail fold. A fingernail takes about six months to grow from its base to its tip, although there are seasonal growth variations; and toenails take twice as long.

DISORDERS
The nails are susceptible to damage through injury, usually as a result of crushing or pressure on the nail. Nails may also be damaged by bacterial or fungal infections, especially tinea and candidiasis (thrush). In paronychia, it is the nail folds that are infected. Sometimes the nails can become abnormally...
thick and curved, a condition known as onychogryphosis. This mainly affects the big toes of elderly people.

The nails may also be affected by skin diseases. Examples of the effects of skin disease on the nails include pitting of the nails in alopecia areata; pitting and separation of the nail from its bed in psoriasis; and scarring of the nails in lichen planus. Certain nail abnormalities may be signs of more generalized illness. Brittle, ridged, concave nails are a sign of iron-deficiency anaemia (see anaemia, iron-deficiency) and fibrous growths on the nail are a sign of tuberous sclerosis. Splinterlike black marks develop beneath the nails in particular bleeding disorders, indicating bleeding into the nail bed.

Abnormalities of nail colour may also indicate disease. A greenish discoloration may be caused by a bacterial infection under the nail; blue nails may be a sign of respiratory or heart disease; and yellow nails that are hard and curved develop in the lung disorder bronchiectasis and in lymphoedema (an accumulation of lymph in the tissues). Nails may also become discoloured by smoking (due to nicotine) and by the use of nail polish.

Treatment of nail disorders can be difficult. Creams and lotions seldom penetrate sufficiently; oral medication may take months to be effective.

nail-biting
A common habit in children during their early years at school. Most children grow out of it, although nail-biting sometimes continues as a nervous habit in adolescents and adults. Persistent nail-biting may make the nails unsightly and cause pain and, sometimes, bleeding.

Various preparations with an unpleasant taste can be painted on the nails as a preventive measure.

nalidixic acid
An antibiotic drug used in the prevention and/or treatment of urinary tract infections. Possible side effects of nalidixic acid include nausea, vomiting, increased sensitivity to sunlight, blurred vision, drowsiness, and dizziness.

naloxone
An opioid antagonist (a drug that counteracts the effects of opioid analgesic drugs). Naloxone reverses the breathing difficulty caused by high doses of opioid drugs given during surgery. It may also be given to people who have taken an overdose of an opioid drug. Naloxone may be given to newborn babies who are affected by opioid drugs used to relieve the mother’s pain during childbirth.

Possible side effects of naloxone include nausea, vomiting, abdominal cramps, diarrhoea, and tremors.

naltrexone
An opioid antagonist (a drug that counteracts the effects of opioid analgesic drugs) that is used in the treatment of opioid addiction. Naltrexone works by blocking the action of opioid drugs and precipitating withdrawal symptoms in opioid-dependent people. The drug may be given to former addicts to help to prevent relapse. (See also drug abuse; drug dependence.)

nandrolone
An anabolic steroid (see steroids, anabolic) sometimes used in the treatment of certain types of aplastic anaemia (see anaemia, aplastic). Nandrolone is also used illegally by some body builders and athletes to increase their protein production and, therefore, muscle bulk.

Possible side effects of nandrolone include swollen ankles, nausea and vomiting, and jaundice (yellowing of the skin and the whites of the eyes). Nandrolone may cause irregular menstruation and abnormal hair growth, in women.

nappy rash
An inflammatory skin condition common in babies, causing soreness and a red rash in the skin covered by a nappy.

CAUSES AND SYMPTOMS
Nappy rash is most commonly caused by urine or faeces irritating the skin. It usually occurs only where the skin and the soiled nappy have been in direct contact; it does not spread to creases in the baby’s skin. Nappy rash becomes worse if the baby’s nappy is not changed frequently or if the nappy area is not cleaned thoroughly. Perfumed skin products and some washing powders used to clean fabric nappies can also result in a rash.

Nappy rash may also be caused by a fungal infection of the skin, such as candidiasis (thrush), or, less commonly, by a bacterial infection, such as impetigo. A rash caused by infection affects the whole nappy area, including the creases in the baby’s skin.

Discomfort from the rash may make a baby irritable. A severe rash may progress to blistering.

TREATMENT
If nappies are changed frequently and the affected area is regularly cleaned and covered in a barrier cream (such as zinc and castor oil cream), nappy rash generally clears up within a few days. In more severe cases, an ointment containing a mild corticosteroid drug may be prescribed to suppress the inflammation. If the area has become infected, oral or topical antibiotic drugs or antifungal drugs may also be given.

naproxen
A nonsteroidal anti-inflammatory drug (NSAID) that is used to relieve pain in the joints and stiffness in arthritis (including juvenile arthritis). Naproxen is also prescribed to speed recovery following injury to soft tissues, such as muscles or ligaments.

Side effects of naproxen may include nausea, abdominal pain, and peptic ulcer.

naratriptan
A serotonin agonist drug used in the treatment of acute attacks of migraine.

narcissism
Intense self-love. A narcissistic personality disorder is characterized by an exaggerated sense of self-importance, constant need for attention or praise, inability to cope with criticism or defeat, and poor relationships with other people. People with a narcissistic personality believe themselves to be unique, special, and superior to others; in addition, they may lack concern for the wellbeing or problems of others.

narcolepsy
A sleep disorder characterized by chronic daytime drowsiness with recurrent episodes of sleep occurring throughout the day. The exact cause of narcolepsy is unknown, although it can run in families. The condition usually develops before the age of 20.

SYMPTOMS
People who suffer from narcolepsy tend to fall asleep at any time of the day, often when they are carrying out a monotonous task. Sleep may occur at inappropriate times, such as while eating. Narcoleptic attacks may last from a few seconds to more than an hour. In narcolepsy, the REM (rapid eye movement) state of sleep is entered abnormally rapidly. Affected people can be awakened easily but may fall asleep again a short time afterwards.
Some people with narcolepsy have vivid hallucinations just before falling asleep. Others find that they are unable to move while they are falling asleep or waking up (see sleep paralysis). About three in four people with narcolepsy also have cataplexy, in which there is a temporary loss of strength in the limbs that causes the person to fall to the ground. Cataplexy is sometimes triggered by an emotional response, such as fear or laughter.

**TREATMENT AND OUTLOOK**

Treatment of narcolepsy usually involves regular naps, along with stimulant drugs to control drowsiness and antidepressant drugs to suppress cataplexy.

Although narcolepsy is usually a lifelong condition, in some cases there is spontaneous improvement over time.

**narcosis**

A state of stupor, usually caused by an opioid analgesic drug or other chemical. Narcosis resembles sleep, being marked by reduced awareness and diminished ability to respond to external stimulation. However, unlike someone who is sleeping, a person in narcosis cannot be roused completely.

**narcotic drugs**

The former name for opioid drugs. (See also analgesic drugs.)

**nasal congestion**

Partial blockage of the nasal passage by the swelling of the mucous membrane that lines the nose. Nasal congestion is sometimes accompanied by the accumulation of thick nasal mucus, which further impedes breathing. Nasal congestion produces the feeling of a stuffy, “full” nose. There is a frequent desire to blow the nose, but blowing usually has little effect on the congestion.

**CAUSES**

Nasal congestion is a symptom of the common cold (see cold, common) and hay fever (see rhinitis, allergic). In these conditions, the swelling is due to inflammation of the membrane lining the inside of the nose. The swelling may become persistent in disorders such as chronic sinusitis or nasal polyps. The congestion may also be caused by certain drugs, such as methyldopa (an antihypertensive drug).

**TREATMENT**

Placing the head over a basin of hot water, possibly containing aromatic oils such as menthol or eucalyptus, and inhaling the steam for several minutes can help loosen the mucus.

**Decongestant drugs** that are taken as drops and sprays should be used sparingly, but tablets and syrups may be recommended for long-term use. Persistent nasal congestion should be investigated by a doctor.

**nasal discharge**

The emission of fluid from the nose. Nasal discharge is commonly caused by inflammation of the mucous membrane lining the nose and is often accompanied by nasal congestion.

A discharge of mucus may indicate hay fever (see rhinitis, allergic), a cold (see cold, common), or an infection that has spread from the nearby sinuses (see sinusitis). A persistent runny discharge may be an early indication of a tumour (see nasopharynx, cancer of).

Bleeding from the nose (see nosebleed) is usually caused by injury or by a foreign body in the nose. In rare cases, bleeding from the nose may be a sign of an underlying bleeding disorder or a tumour. A discharge of cerebrospinal fluid from the nose may follow a fracture at the base of the skull (see skull, fracture of).

**nasal obstruction**

Blockage of the nasal passage on one or both sides of the nose, which interferes with breathing. The most common cause is inflammation of the mucous membrane lining the passage (see nasal congestion). Other causes include deviation of the nasal septum; nasal polyps; a haematoma (a collection of clotted blood), which is usually caused by injury; and, rarely, a cancerous tumour. In children, enlargement of the adenoids is a common cause of nasal obstruction.

**nasal polyp**

A growth in the lining of the nose, usually attached by a small stalk. Large or numerous nasal polyps may cause nasal obstruction, a runny nose, and an impaired sense of smell.

**CAUSES**

The exact cause of nasal polyps is not known. However, they are more common in people with asthma or rhinitis (a condition in which the membrane that lines the nose and throat becomes inflamed). Although nasal polyps rarely occur in children, they do sometimes develop in those children who have the inherited condition cystic fibrosis.

**DIAGNOSIS**

Nasal polyps are diagnosed by physical examination and sometimes also by endoscopy (inspection and examination of the nasal cavity using a viewing instrument). Most nasal polyps are non-cancerous; however, a biopsy (removal of a small sample of tissue for microscopic analysis) may be performed to exclude the possibility of cancer.

**TREATMENT**

Nasal polyps do not need treatment unless they are interfering with breathing, are cancerous, or are causing other symptoms. Small nasal polyps may be treated by using a corticosteroid nasal spray (see corticosteroid drugs), which shrinks the polyps over a few weeks. Larger or cancerous polyps may be removed during an endoscopic procedure or by surgery. In certain people, polyps may recur after treatment.

**nasal septum**

The dividing partition in the nose. The nasal septum consists of cartilage (connective tissue formed of collagen) at the front and bone at the rear, both of which are covered by mucous membrane.

**DISORDERS**

A deviated septum (twisting of the septum to one side) may be present from birth or caused by injury. The condition is rarely troublesome, but surgery may be needed if breathing is obstructed.

Injury may also lead to formation of a haematoma (a collection of clotted blood) between the cartilage of the septum and the wall of one of the nasal cavities. A haematoma may obstruct breathing and may become infected, causing an abscess (collection of pus) that may require surgical drainage. Occasionally, an abscess develops on a child’s septum without prior injury.

Rarely, a hole may be eroded in the nasal septum by tuberculosis, syphilis, Wegener’s granulomatosis, or as a result of snorting cocaine.

**Naseptin**

A brand name for a combination of chlorhexidine (an antiseptic for the skin) with neomycin (an antibiotic drug). Naseptin cream is used to eliminate organisms, such as staphylococci, from the inside of the nostrils.

**nasogastric tube**

A narrow plastic tube that is passed through the nose, down the oesophagus (gullet), and into the stomach.

**WHY IT IS USED**

Nasogastric tubes are commonly used to suck or drain digestive juices from
the stomach when there is a blockage in the intestine (such as in pyloric stenosis) or it is not working properly (as may occur after an abdominal operation). A nasogastric tube is also used to give liquid nourishment to patients who cannot eat (see feeding, artificial), to obtain specimens of stomach secretions for examination, and to wash out the stomach after a drug overdose or after swallowing poison (see lavage, gastric).

**HOW IT IS USED**
Inserting the tube is a quick, simple procedure that causes little discomfort and does not require an anaesthetic. After it has been lubricated, the tube is passed into one nostril and then, while the patient is swallowing, slid down the throat and into the stomach. To ensure that the tube is in the stomach, a sample of fluid is withdrawn through a syringe and forms the upper section of the pharynx and connects the nasal cavity to the top of the throat.

**nasolacrimal duct**
A channel that drains tears into the nose. The nasolacrimal duct forms part of the lacrimal apparatus.

**nasopharynx**
The passage that connects the nasal cavity behind the nose to the top of the throat behind the soft palate. The nasopharynx is part of the respiratory tract and forms the upper section of the pharynx. During swallowing, the nasopharynx is sealed off by the soft palate pressing against the back of the throat, thereby preventing food from entering.

The nasopharynx contains the lower openings of the eustachian tubes (passages connecting the back of the nose to the middle ear). In children, it also contains the adenoids, which can enlarge to block the nasopharynx, forcing the child to breathe through the mouth.

**nasopharynx, cancer of**
A cancerous tumour that originates in the nasopharynx (the uppermost part of the throat, behind the nose) and usually spreads to the nasal cavity, nasal sinuses, base of the skull, and neck lymph nodes.

**CAUSES AND INCIDENCE**
Cancer of the nasopharynx is rare in the West but relatively common in the Far East; the reasons for this are not clear. It occurs most often in people between the ages of 30 and 60.

Factors that increase the risk of this cancer include diet (a high intake of salt-cured fish); smoking; and viral infections, especially infection with the Epstein–Barr virus. People who inhale hardwood dust or nickel dust at work over a long period are also at increased risk and should take precautions.

**SYMPTOMS**
Initially, cancer of the nasopharynx may not cause any symptoms. It may remain unnoticed until the tumour spreads to a lymph node, causing a painless swelling in the neck.

If symptoms do develop, they may include facial swelling, recurrent nosebleeds, a runny nose, and discomfort on swallowing. Loss of the sense of smell, double vision, deafness, paralysis of one side of the face, voice change, and severe facial pain may also develop if nearby nerves are affected.

**DIAGNOSIS AND TREATMENT**
Diagnosis is through endoscopy (internal examination and inspection using a viewing tube), during which a biopsy (removal of a small sample of tissue for microscopic analysis) can also be taken. An MRI scan (a technique that produces cross-sectional or three-dimensional images of internal body structures) and X-rays are required to assess the extent of the tumour and the involvement of nearby structures.

Treatment is usually with radiotherapy, but, in some cases, the tumour may be surgically removed. If the tumour is treated early, the outlook can be good.

**natriuretic peptide**
See atrial natriuretic peptide.

**natural childbirth**
See childbirth, natural.

**natural immunity**
A type of immunity (protection against disease) that is manifested by a species not previously sensitized to the disease in question either through infection or through vaccination.

The mechanisms that are involved in natural immunity are still poorly understood. This condition, however, is not believed to be stimulated by specific antigens (substances that trigger an immune response), as is the case with acquired immunity. Natural immunity (also known as innate immunity) is inherited and present at birth.

**natural killer cells**
A specific type of lymphocyte (a type of white blood cell) that is able to destroy cells infected with viruses as well as some types of cancer cell. Natural killer cells, also known as NK cells, constitute the immune system’s first line of defence against cancerous or infected cells. NK cells are neither T nor B lymphocytes (unlike killer T-cells, for example).

**naturopathy**
A form of complementary medicine based on the principle that disease occurs as a result of the accumulation of waste products and toxins in the body; symptoms are thought to reflect the attempts of the body to rid itself of these substances. Practitioners of naturopathy believe that health is maintained by avoiding anything artificial or unnatural in the diet or in the environment.

**nausea**
The sensation of needing to vomit. Although nausea may occur without vomiting, the causes are the same.

**navel**
A popular term for the umbilicus, the depression in the abdomen that marks the point at which the umbilical cord was attached to the fetus.

**navicular bone**
A foot bone that articulates with the head of the talus (one of the bones in the ankle joint) and with three of the bones in the tarsus (which makes up the back of the foot and the ankle).
nebulizer
An aerosol device used to administer drugs, such as bronchodilators, especially in the emergency treatment of asthma. Usually an electric pump sends a stream of air or oxygen across a chamber that contains the drug. This stream of air disperses the drug into a fine mist, which is then conveyed to the face mask and inhaled by the user.

neck
The part of the body that supports the head and serves as a passageway between the head (and brain) and the rest of the body. The neck contains many important structures: the spinal cord (which carries nerve impulses to and from the brain); the trachea (windpipe); the larynx (voice-box); the oesophagus (gullet); the thyroid and parathyroid glands; lymph nodes; and several major blood vessels. Seven spinal vertebrae are located in the neck; they are surrounded by a complex system of muscles.

DISORDERS
Torticollis (wry neck), in which the head is twisted to one side, may result from injury to a neck muscle or from skin contracture (shrinkage) after burns or other injuries. Fractures and dislocations of vertebrae in the neck, as well as whiplash injury, can cause injury to the spinal cord, causing paralysis or even death (see spinal injury).

Degeneration of the joints between the neck vertebrae may occur as a result of cervical osteoarthritis, resulting in neck pain, stiffness, and sometimes tingling and weakness in the arm and hand. Similar symptoms may also be caused by a disc prolapse. In ankylosing spondylitis, fusion of the vertebrae may result in permanent neck rigidity.

Cervical rib is a rare congenital defect in which there is a small extra rib in the neck. This condition often causes no symptoms until middle age, when it may result in pain, numbness, and a pins-and-needles sensation in the forearm and hand.

Neck pain of unknown origin is very common. However, as long as there are no neurological symptoms (such as loss of sensation or a decrease in muscle power), the condition is unlikely to be serious and usually disappears over the course of a few weeks. However, any condition causing a large swelling in the neck (such as enlargement of the thyroid gland) may interfere with breathing or swallowing.

neck dissection, radical
A surgical procedure for the removal of cancerous lymph nodes in the neck. The operation is often part of the treatment for cancer of the tongue, the tonsils, or other structures in the mouth and throat.

Under general anaesthetic (see anaesthesia, general), a flap of skin on the affected side of the neck is raised to expose the underlying sternomastoid muscle. The muscle is cut just above the clavicle (collarbone) and lifted up. All the components of the lymphatic system in the neck (the lymph vessels as well as the lymph nodes) are then removed, together with the internal jugular vein, the lower salivary gland, and other surrounding tissue.

neck rigidity
Marked stiffness of the neck caused by spasm of the muscles in the neck and spine. Neck rigidity is an important clinical sign of meningitis (inflammation of the membranes that envelop the brain and spinal cord). Severe neck rigidity may cause the head to arch backwards, especially in babies.

necrobiosis lipoidica
A skin condition, usually associated with diabetes mellitus, in which reddened patches with yellowish centres develop, most commonly on the shins. The skin in the centre of the patches becomes thin and may ulcerate.

necrolysis, toxic epidermal
A severe, blistering rash in which the surface layers of the skin peel off, exposing large areas of red, raw skin. The condition carries a risk of widespread infection and loss of body fluids and salts.

The most common cause of toxic epidermal necrolysis is an adverse reaction to a drug, particularly a barbiturate, sulphonamide, or penicillin. The condition usually clears up when the causative drug is discontinued. Intravenous fluid replacement is sometimes necessary.

In newborn babies, the condition may be due to a staphylococcal infection and is called scalded skin syndrome. Treatment is with antibiotic drugs and fluid replacement.

necrophilia
A rare sexual perversion in which orgasm is achieved by means of sexual acts with dead bodies.

necropsy
A little-used medical term for an autopsy (postmortem examination of a body).

necrosis
The death of tissue cells. Necrosis can occur as a result of ischaemia (inadequate blood supply), which may lead to gangrene (tissue death); infection; or damage by extreme heat or cold, noxious chemicals, or excessive exposure to X-rays or other forms of radiation.
The appearance of the dead tissue depends on the cause of the necrosis and on the type of tissue affected. In necrosis due to *tuberculosis*, the dead tissue is soft, dry, and cheesylike. Fatty tissue beneath the skin that has died as a result of damage or infection develops into tough scar tissue that may form a firm nodule.

**necrotizing fasciitis**
A rare but serious infection of tissues beneath the skin by a type of streptococcal bacterium (see *streptococcal infections*) and other bacteria. Necrotizing fasciitis is most likely to occur as a complication of surgery. Initial symptoms of the infection are inflammation and blistering of the skin. The infection spreads very rapidly and the bacteria release enzymes and toxins (poisons) that can cause extensive destruction of deeper tissues and damage to internal organs. Urgent treatment with *antibiotic* drugs and surgical removal of all infected tissue are essential. The infection is life-threatening.

**nedocromil**
A drug similar to *sodium cromoglicate* that is used to prevent *asthma attacks*.

**needle aspiration**
See *biopsy*.

**needle exchange**
A health scheme that enables intravenous drug abusers to exchange used hypodermic needles for new, sterile ones. The scheme is aimed at reducing the risks of infections, such as *HIV* and *hepatitis*, that are transmitted by the sharing of contaminated needles.

**needlestick injury**
Accidental puncture of the skin by a contaminated hypodermic needle. Hospital staff are most likely to be at risk. Needlestick injuries carry the risk of serious infections, such as *HIV* and *hepatitis*, and need immediate medical attention. The wound should be cleaned thoroughly; *blood tests* may be needed to determine whether infection has been transmitted.

**nefopam**
An *analgesic drug* used to relieve moderate pain caused, for example, by injury, surgery, or cancer. Nefopam reduces the perception of pain by the brain. Unlike most analgesics that act on the brain, it neither interferes with breathing nor causes dependence.

The possible side effects of nefopam include nausea, dry mouth, nervousness, and difficulty sleeping.

**negativism**
The tendency to resist or oppose advice, suggestions, or commands. There are two principal types of negativism: active negativism and passive negativism. In active negativism, the individual does the opposite of what he or she is requested to do; such behaviour is seen in toddlers and is uncommon in adult life, although it may be a feature of *catatonia*. In passive negativism, the person does not cooperate simply by failing to do something that has been suggested. This often occurs in *depression* and may also be a feature of *schizophrenia*.

**neisserial infections**
Infections caused by bacteria belonging to the *Neisseria* genus. *Neisseria gonorrhoeae* (*gonococcus*) causes *gonorrhoea* (a common *sexually transmitted infection*) in humans. *Neisseria meningitidis* (meningococcus), is the causative agent of the condition *meningococcal meningitis* (inflammation of the membranes covering the brain and spinal cord).

**Nelson’s syndrome**
A rare disorder of the *endocrine system* that causes increased skin pigmentation. Nelson’s syndrome results from enlargement of the *pituitary gland*, which can follow removal of the *adrenal glands* (to treat *Cushing’s disease*). Nelson’s syndrome is treated by *hypophysectomy* (removal or destruction of the pituitary gland).

**nematodes**
The scientific name for a group of cylindrically shaped worms (see *roundworms*); some are human parasites.

**neologism**
The act of making up new words that have a special meaning for the inventor. The term neologism also refers to the invented word itself. Persistent neologism can be a feature of speech in people with *schizophrenia*.

**neomycin**
An *antibiotic drug* used to treat ear, eye, and skin infections, often in combination with other drugs. Neomycin is also given to prevent infection of the intestine prior to surgery. Possible adverse effects include a rash and itching.

**neonatal death**
The death of a live-born infant in the first four weeks of life. Neonatal death is classified as early or late: early neonatal deaths are deaths in the first week of life; late neonatal deaths are those occurring between the end of the first week of life and 27 days after birth. About half of all neonatal deaths in the UK are attributed to *prematurity*; about a quarter to congenital malformations; and the remainder to various causes, including infection and difficulties with delivery. (See also *infant mortality; stillbirth*.)

**neonatal hypoglycaemia**
An abnormally low blood glucose level (see *hypoglycaemia*) in an infant that is under four weeks of age. Neonatal hypoglycaemia commonly causes problems in the first 24 hours of life. Persistent low glucose levels may result in permanent damage to the brain (see *cerebral palsy*).

**CAUSES AND INCIDENCE**
Neonatal hypoglycaemia is uncommon in healthy babies carried to full term. The condition is likely to occur in premature infants and those of low birth weight, due to their reduced reserves of *glycogen* (main form of the body’s stored carbohydrate). It is also more common in babies whose mothers had *diabetes mellitus* during pregnancy. These babies produce the extra insulin they require before delivery, but their glucose levels fall after birth. Also at risk of neonatal hypoglycaemia are infants with inborn errors of metabolism (see *metabolism, inborn errors of*) and those who are unwell at birth. Difficulties with *breastfeeding* during the first days of life may also cause the condition to develop.

**SYMPTOMS AND SIGNS**
Neonatal hypoglycaemia is usually characterized by jittersiness, *seizures*, irritability, floppiness, *apnoea* (interruption in breathing), and poor feeding.

**DIAGNOSIS AND TREATMENT**
A diagnosis of neonatal hypoglycaemia is confirmed using *blood tests* to check blood glucose levels.

In babies at increased risk of the condition, preventive treatment involves the immediate establishment of regular feeding, ideally breast-feeding. Hypoglycaemia that is severe enough to cause symptoms requires an intravenous infusion of glucose along with, if possible, treatment of the underlying cause.

**neonatal jaundice**
See *jaundice, neonatal*. 

---

535
neonatal urticaria  
See urticaria, neonatal.

neonate  
A newly born infant, specifically up to the age of 27 days. (See also newborn.)

neonatology  
The branch of paediatrics concerned with the care of newborn infants and the treatment of disorders that occur during the first few weeks of life. Such problems may be short-term (such as those associated with prematurity or low birth weight) or lifelong (such as spina bifida).

neoplasia  
A medical term for the process of tumour formation, characterized by progressive, abnormal cell multiplication. The term neoplasia does not necessarily imply that the new growth is cancerous; neoplasia also results in noncancerous tumours.

neoplasm  
A medical term for a tumour (any new abnormal growth). Neoplasms may be cancerous or noncancerous.

neostigmine  
A drug that is used in the treatment of myasthenia gravis (a rare autoimmune disorder that causes muscle weakness). Neostigmine increases the activity of acetylcholine, a neurotransmitter (a chemical released from nerve endings) that stimulates the contraction of muscles. Possible side effects of neostigmine include nausea and vomiting, increased salivation, diarrhoea, abdominal cramps, blurred vision, muscle cramps, sweating, and twitching.

nephrectomy  
The surgical removal of one or both of the kidneys.  
WHY IT IS DONE  
One of the most common reasons for nephrectomy is to remove a cancerous tumour (see kidney cancer). A kidney may also be removed if it is not functioning properly because of injury, infection, or the presence of stones (see calculus, urinary tract) or if it is causing severe hypertension (high blood pressure). Nephrectomy may also be necessary if a kidney is so badly injured that bleeding cannot be stopped.  
HOW IT IS DONE  
Nephrectomy takes place under general anaesthetic (see anaesthesia, general). An incision is made along the lower edge of the ribs, from the spine to the front of the abdomen, in order to expose the kidney. The ureter (the tube that carries urine from the kidney to the bladder) and the renal blood vessels are tied off, then the kidney is removed. The incision is stitched up after insertion of a drainage tube, which is left in place for between 24 and 48 hours.

nephritis  
Inflammation of one or both of the kidneys. Nephritis may be caused by an infection (see pyelonephritis), by abnormal responses of the immune system (see glomerulonephritis), or by drugs – for example, penicillin. (See also Disorders of the kidney box.)

nephroblastoma  
A type of kidney cancer that mainly affects children.

nephrocalcinosis  
Deposits of calcium within the tissue of one or both of the kidneys. Nephrocalcinosis is not the same as kidney stones (see calculus, urinary tract), in which particles of calcium develop inside the drainage channels of the kidney. Nephrocalcinosis may occur in any condition in which the level of calcium in the blood is raised – for example, in hyperparathyroidism (overactivity of the parathyroid gland) and renal tubular acidosis (in which the kidney produces urine of lower-than-normal acidity). Nephrocalcinosis may also occur as a result of taking excessive amounts of certain antacid drugs or vitamin D.

Treatment is of the underlying cause in order to prevent further calcification.

nephrolithotomy  
The surgical removal of a kidney stone (see calculus, urinary tract) by cutting into the main part of the kidney. Nephrolithotomy may be performed through an abdominal incision, an incision in the back, or using pyelolithotomy (a surgical procedure in which a kidney stone is removed through an incision at the renal pelvis). Instruments are used to grasp and remove the calculus; the breaking up of large calculi may be necessary before removal.

It is now often possible to avoid surgery by using lithotripsy (a procedure that uses ultrasonic waves to break up calculi for excretion in the urine).

nephrology  
The medical speciality concerned with the normal functioning of the kidneys and with the causes, diagnosis, and treatment of kidney disease.

Methods of investigating the kidneys include kidney biopsy (removal of a small sample of tissue for microscopic analysis), kidney function tests, and kidney imaging techniques, such as ultrasound scanning and intravenous urography.

Treatment of kidney disorders may involve drugs (for example, to control high blood pressure, inflammation, or infection) and surgery (for the treatment of stones or tumours). In advanced cases, regular dialysis (artificial purification of the blood) or a kidney transplant may be required. (See also Disorders of the kidney box.)

nephron  
The functional microscopic unit of the kidney that consists of a glomerulus (a filtering unit made up of a cluster of capillaries) and a tuft. Each kidney contains about one million nephrons.

The nephrons filter waste products from the blood and modify the amount of salt and water excreted in the urine, according to the body’s needs. This process involves blood filtration in the glomerulus followed by further processing of the filtrate as it flows through the various parts of the tubule: the proximal convoluted tubule, the loop of Henlé, and the distal convoluted tubule.

nephropathy  
A term for any disease of, or damage to, the kidneys. The term is usually combined with a word that indicates the cause of the damage, for example diabetic nephropathy, obstructive nephropathy, hypertensive nephropathy, and toxic nephropathy. The treatment and outlook are dependent on the cause. (See also Disorders of the kidney box.)

nephrosclerosis  
Hardening of the arterioles and arteries within the kidney, usually as a result of atherosclerosis (the deposition of fatty material within blood vessels).

nephrosis  
See nephrotic syndrome.
nephrostomy
The introduction of a small tube into the kidney to drain urine to the abdominal surface, thereby bypassing the ureter and bladder. Nephrostomy is sometimes performed after an operation (typically removal of a kidney stone) on the ureter or the kidney–ureter junction.

nephrotic syndrome
A collection of symptoms and signs resulting from damage to the glomeruli (the filtering units of the kidney), which causes severe proteinuria (leakage of protein from the blood into the urine), low blood levels of protein, and swelling.

CAUSES
Nephrotic syndrome may occur as a result of diabetes mellitus, amyloidosis (accumulation of amyloid, an abnormal protein, in the tissues), or any type of glomerulonephritis (inflammation of the glomeruli). The conditions may also be due to severe hypertension (high blood pressure), reactions to poisons (such as mercury or cadmium), or adverse reactions to drugs, such as gold or penicillamine.

Nephrotic syndrome may also be a complication of an infection elsewhere in the body, such as hepatitis B or malaria. In children, the syndrome is most commonly due to a condition known as minimal change glomerulonephritis.

SYMPTOMS
The symptoms of nephrotic syndrome appear gradually over days or weeks and worsen as more and more protein is lost in the urine. Early signs include frothy urine and decreased urine production. The main symptom is swelling of the legs and face as a result of oedema (accumulation of fluid in the tissues). Fluid may also collect in the chest cavity, resulting in pleural effusion and shortness of breath, or in the abdomen, causing ascites. Lethargy and loss of appetite (leading to weight loss) may also occur.

DIAGNOSIS AND TREATMENT
Diagnosis involves blood tests; the urine must also be examined under a microscope and the amount and type of protein lost assessed over a 24-hour period (see urinalysis). In most cases, a kidney biopsy (removal of a small sample of tissue for microscopic analysis) is also required to establish the exact cause and help with treatment decisions.

Treatment is aimed at the underlying condition. A low-sodium diet may be recommended and diuretic drugs may be given to reduce oedema. Protein may need to be given intravenously, but the effects are short lived. Corticosteroid drugs may also be prescribed and are often effective in cases of nephrotic syndrome in childhood.

OUTLOOK
The outlook for someone with nephrotic syndrome depends on the extent of the kidney damage. Recurrent episodes may occur even after treatment. Problems with excessive blood clotting are common and may require treatment with anticoagulant drugs. Infections may occur as a result of immunoglobulin loss into the urine. Nephrotic syndrome is usually associated with raised cholesterol, which increases the risk of myocardial infarction (heart attack) due to atherosclerosis (fatty deposits on the artery walls). In the most severe cases, chronic kidney failure, and eventually an irreversible loss of kidney function, may develop.

nephrotoxic
A term meaning toxic (poisonous) to kidney cells, resulting in damage to or destruction of the cells.

nerve
A bundle of nerve fibres travelling to a common location. Nerve fibres, which are also known as axons, are the filamentous projections of many individual neurons (nerve cells).

STRUCTURE
The most obvious nerves in the body are the peripheral nerves, which extend from the central nervous system (consisting of the brain and the spinal cord) to other parts of the body. Of these, 12 pairs of cranial nerves link directly to the brain and 31 pairs of spinal nerves join the spinal cord. In the shoulder and hip regions, the spinal nerves join to form plexuses, from which branch the main nerves to the limbs, such as the median nerve in the arm and the sciatic nerve in the leg. Most nerves divide at numerous points to send branches to all parts of the body, particularly to the sense organs, the skin, the skeletal muscles, the internal organs, and the glands.

FUNCTION
Nerve fibres may have a sensory function, carrying information from a receptor or sense organ towards the central nervous system (CNS), or they may have a motor function, carrying instructions from the CNS to a muscle or a gland. The messages are carried by electrical impulses propagated along the fibres. Some nerves carry only sensory or motor fibres, but most carry both.

DISORDERS
Nerve function is sensitive to cold, pressure, and injury (see nerve injury). The peripheral nerves can be damaged by a variety of disorders, including infection, inflammation, poisoning, nutritional deficiencies, and metabolic disorders (see neuropathy). (See also radiculopathy.)

nerve block
The injection of a local anaesthetic (see anaesthesia, local) around a nerve in order to produce loss of sensation in a part of the body supplied by that nerve. For example, the palm of the hand may be anaesthetized by giving injections at sites up the arm, thereby blocking the ulnar and median nerves.

WHY IT IS DONE
A nerve block is performed when it is not possible to inject anaesthetic directly into the tissues being treated because the area is painfully inflamed or because there is a risk of spreading infection.

The technique may also be used to anaesthetize a large area or an area not suitable for injection because it is deep within the body or is covered with bone.

TYPES
Spinal nerve block A nerve may be blocked as it leaves the cord. This happens both in epidural anaesthesia, which is used mainly in childbirth, and in spinal anaesthesia, which is used for surgery on the lower abdomen and limbs.

Caudal block In a caudal block, an anaesthetic is injected around the nerves leaving the lowest part of the spinal cord. It produces a loss of sensation in the buttock and genital areas and is occasionally used in childbirth.

Pudendal block A pudendal nerve block involves the injection of an anaesthetic into nerves passing under the pubic bone into the floor of the vagina. This type of nerve block is sometimes used during childbirth in a forceps delivery.

nerve conduction studies
Electrical tests carried out to assess the extent of nerve damage caused by disorders of the peripheral nervous system (see neuropathy). In the test, an electrical stimulus is applied to a nerve; the speed at which the nerve responds to the stimulus and transmits its signal is recorded by specialized equipment.

nerve injury
Damage or severedness of conducting fibres within a nerve as a result of trauma, resulting in the loss of skin
sensation and muscle power. (See neuropathy for nerve damage from causes other than injury.)

Nerves may be damaged in many different injuries, including knife wounds, bullet wounds, penetrating injuries (such as from flying glass), or from accidental contact with powered devices (such as rotary saws and propellers).

**Peripheral Nerve Injury**

If injury to a peripheral nerve (a nerve outside the brain or spinal cord) results in severance of some, but not all, of the individual fibres within the nerve, the cut fibres degenerate on both sides of the injury. This leads to loss of power in the muscles and loss of sensation in the skin area supplied by the fibres.

In cases of partial severance in which the ends of the severed fibres are still aligned, new fibres can regenerate along channels left by the degenerated ones. These new fibres begin to grow within a few days of injury, but they grow slowly (at a rate of about 1 mm per day).

If there is total severance of a nerve, the individual fibres try to regenerate but, with no directing channels, simply bunch up to form a lump of tissue. In such cases, function does not recover.

Regenerating nerve fibres sometimes pass down the wrong channels. So, when function is restored, actions may differ from what was intended (for example, an attempt to move the index finger may move the middle finger as well). Movement skills and the interpretation of sensations may need to be relearned.

**Brain and Spinal Cord Injury**

Nerve tracts within the brain and spinal cord are structurally different from the peripheral nerves, and severed fibres in these tracts do not regenerate. Vision cannot be restored if, for example, the optic nerves are cut.

**Treatment**

Surgery can sometimes repair a severed nerve, but such treatment is possible only for peripheral nerves. In microsurgery, the neurosurgeon ensures that the severed fibres are meticulously brought together and stitched into place using delicate needles and sutures. Careful realignment of the nerve ends gives the fibres the best chance of regenerating along the correct channels. However, even with the best surgical repair, recovery is rarely complete.

A programme of physiotherapy is needed to keep paralysed muscles healthy and free from contracture (abnormal shortening) during the recovery period.

**Nerve, Trapped**

Compression or stretching of a nerve, causing numbness, tingling, weakness, and, sometimes, pain in the area supplied by the nerve. Common examples of a trapped nerve include carpal tunnel syndrome, in which pressure on the median nerve as it passes through the wrist causes symptoms in the thumb, index, and middle fingers; a disc prolapse, in which pressure on the nerve root leading from the spinal cord produces symptoms in the back and legs; and crutch palsy, in which the radial nerve presses against the humerus (upper arm bone), producing symptoms in the wrist and hand.

A damaged nerve may take some time to heal. In severe cases, surgical decompression to relieve pressure on the nerve may be necessary.

**Nervous Breakdown**

A nontechnical term used to describe unusual behaviour (such as episodes of tearfulness or shouting and screaming) that may be part of a crisis of severe anxiety, depression, or other psychiatric illness. The condition affects the sufferer’s ability to cope with everyday life.

**Nervous Energy**

A nontechnical term for the increased drive and activity of individuals who are always restless, anxious, and on the go.

**Nervous Habit**

A nontechnical term for a minor repetitive movement or activity. A nervous habit can consist of involuntary twitches and facial tics, such as in Gilles de la Tourette’s syndrome and some forms of dyskinesia. Voluntary nervous habits, such as nail-biting and thumb-sucking, are common in young children, but usually disappear naturally with time. All nervous habits increase during periods of tension or anxiety and may be severe in some forms of depression, anxiety disorder, or drug withdrawal.

**Nervous System**

The body system that gathers and stores information. It is in control of the body. (See Nervous system box, overleaf.)

**Structure**

The brain and spinal cord form the central nervous system (CNS), which consists of billions of interconnected neurons (nerve cells). The input of information to the CNS comes from the sense organs. Motor instructions are sent out to skeletal muscles, the muscles controlling speech, internal organs and glands, and the sweat glands in the skin. This information is carried along nerves that fan out from the CNS to the entire body, together making up what is known as the peripheral nervous system (PNS).

Each nerve is a bundle consisting of the axons (filamentous projections) of many individual neurons.

**Function**

There are also functional divisions. Two of the most important are the autonomic nervous system, which is concerned with the automatic regulation of internal body functions, and the somatic nervous system, controlling the muscles responsible for voluntary movement.

The overall function of the nervous system is to gather and analyse information about the external environment and the body’s internal state and to initiate appropriate responses aimed at satisfying certain drives.

The most powerful drive is for survival. Many survival responses, which range from avoiding physical pain and danger to shivering in response to the cold, are initiated unconsciously and automatically by the nervous system. Other drives are more complex, revolving around a need to experience positive emotions (such as pleasure and excitement) and to avoid negative emotions (such as pain, anxiety, and frustration).

The nervous system functions largely through automatic responses to stimuli (see reflex), but it can also improve its performance through learning, which relies on memory. Voluntary actions can be initiated via activity in conscious areas of the brain. Certain functions (such as visual perception, memory, thought, and speech production) are extremely complex and still not fully understood.

**Disorders**

Disorders of the nervous system may be caused by damage to or dysfunction of any of its parts (see disorders of the brain box; spinal cord; neuropathy; nerve injury). They may also be due to impaired sensory, analytical, or memory functions (see vision, disorders of; deafness; numbness; anosmia; agnosia; amnesia), or motor functions (see aphasia; dysarthria; ataxia).

**Netilmicin**

An antibiotic drug usually prescribed only to treat serious infection in hospital, when other antibiotic drugs have proved ineffective. In rare cases, netilmicin can damage the inner ear or the kidneys.
NERVOUS SYSTEM

The nervous system detects and interprets changes in conditions inside and outside the body and responds to them. The central nervous system analyses information and initiates responses; the peripheral nervous system gathers information and carries the response signals. Some responses are involuntary; others are dictated by conscious thought. All nervous system activity consists of signals passed through pathways of interconnected neurons (nerve cells).

Peripheral nervous system
This system comprises all the nerves connecting the brain and spinal cord to the rest of the body. Of these, 31 pairs (the spinal nerves) connect to the spinal cord and 12 pairs (cranial nerves) connect to the brain. The main nerves of the limbs are labelled.

Central nervous system
This system consists of the brain and spinal cord, protected by the skull and spine. The CNS receives input from sense organs and receptors and sends signals to muscles and glands, via the peripheral nervous system.

HOW IT WORKS

Some possible events in response to a finger touching a hot object are shown. A receptor sends a message, via a sensory fibre, to the spinal cord. This triggers a signal that travels, via a motor fibre, back to a muscle, which contracts to move the finger away from the heat. This action is called a reflex arc. Other signals pass to the brain.

Sensory and motor fibres
Although the sensory and motor fibres carry signals in opposite directions, along part of their lengths they may occupy exactly the same nerve.
neuralgia

Pain caused by irritation of, or damage to, a nerve. The pain usually occurs in brief bouts, may be severe, and can often be felt shooting along the affected nerve.

TYPES AND CAUSES

Some types of neuralgia are features of a disorder. Migraine suffers commonly experience a form of neuralgia comprising attacks of intense, radiating pain around the eye. Postherpetic neuralgia is a burning pain that may recur at the site of an attack of herpes zoster (shingles) for months or even years after the illness.

Other types of neuralgia result from disturbance of a particular nerve. In glossopharyngeal neuralgia, intense pain is felt at the back of the tongue and in the throat and ear, all of which are areas supplied by the glossopharyngeal nerve. The cause is unknown. The same is true of trigeminal neuralgia, a severe paroxysm of pain affecting one side of the face supplied by the trigeminal nerve.

TREATMENT

Neuralgia may be relieved by analgesic drugs (painkillers), such as paracetamol. Glossopharyngeal, trigeminal, and postherpetic neuralgia may respond to treatment with carbamazepine or other anticonvulsant drugs, or to tricyclic antidepressants.

neural tube defect

A once common developmental failure affecting the spinal cord or brain of the embryo. The neural plate, which develops along the back of the embryo by about the third week of pregnancy, then folds to form the neural tube that later becomes the brain, the spinal cord, and their coverings (the meninges). If the neural tube does not form properly, defects in any of these parts can result.

TYPES AND SYMPTOMS

The most serious neural tube defect is anencephaly (failure of the skull and brain to develop), which is fatal before birth or soon afterwards. More common is spina bifida, in which the vertebrae do not form a complete ring around the spinal cord. Spina bifida can occur anywhere on the spine, but it is most common in the lower back.

There are different forms of spina bifida. In spina bifida occulta, the only defect is a failure of the bony arches behind the spinal cord to fuse, which is sometimes associated with a tuft of hair over the area or a dimple in the skin. This may cause no problems, although there may be tethering of the spinal column, which may need releasing surgically.

If the bone defect is more extensive, there may be a meningocele (a protrusion of the meningeal membranes) or a myelomeningocele (a malformation in which part of the spinal cord and the meninges overlying it are completely exposed). Myelomeningocele is likely to cause severe handicap, with paralysis of the legs, loss of sensation in the lower body, and paralysis of the anus and bladder, causing incontinence (see incontinence, faecal; incontinence, urinary). The higher up the spine the malformation is, the more severe the handicap.

Associated problems include hydrocephalus, in which extra fluid forms in the brain; insertion of a shunt to relieve the pressure is often needed in the first few weeks of life. However, some children will also have cerebrovascular accidents, epilepsy, or learning difficulties. Children with neural tube defects are at particular risk of developing meningitis, a serious infection of the membranes covering the brain and spinal cord.

CAUSES

The cause of neural tube defects is not fully understood, but they tend to run in families, which suggests that genetic factors are involved. Certain types of anticonvulsant drug are associated with neural tube defects if they are taken by women during pregnancy.

TREATMENT AND OUTLOOK

Surgery is usually performed a few days after birth. In mild cases, the defect can usually be corrected completely; but in myelomeningocele, some handicap will remain and affected children usually need lifelong care. Physiotherapy and mobility aids may be useful to maintain activity and allow as great a degree of independence as possible.

Children with extensive damage to the brain and/or spinal cord usually have a reduced life expectancy.

PREVENTION

The risk of a neural tube defect can be substantially reduced if the mother takes folic acid supplements before conception and during the early part of the pregnancy. A mother who has previously had a child affected by a neural tube defect should seek specialist advice before planning another pregnancy. In such cases, a higher dose of folic acid may be recommended in order to reduce the risk of having another affected child.

Blood tests and ultrasound scanning in pregnancy can help to detect neural tube defects before birth. Over the last 25 years, there has been a substantial decline in the numbers of babies born with these defects.

neurapraxia

A type of nerve injury in which the outward structure of a nerve appears intact, but some conducting fibres have been damaged and thus do not transmit signals normally.

neurasthenia

An outdated term that literally means "nervous exhaustion". The term neurasthenia was once used to describe a number of physical and mental symptoms, such as insomnia, loss of energy, aches and pains, depression, irritability, and reduced concentration.

neuritis

A term that literally means inflammation of a nerve. True nerve inflammation may be caused by infection (for example, by a virus in herpes zoster or by a bacterium in Hansen's disease). The term neuritis is also often applied to nerve damage or disease from causes other than inflammation. It has become virtually synonymous with neuropathy.

neuroblastoma

A cancerous tumour that develops from nervous tissue in the adrenal glands or in part of the sympathetic nervous system (see autonomic nervous system). Neuroblastomas from the sympathetic nervous system usually develop in the sympathetic nerves along the back wall of the abdomen. Less commonly, tumours originate in the sympathetic nerves of the chest or neck. The tumours often spread to other sites in the body.

INCIDENCE AND CAUSE

Neuroblastomas are the most common extracranial (outside the skull), solid tumour of childhood. Most cases develop during the first ten years of life, especially in the first five. The disorder is slightly more common in boys than in girls.

The cause of these tumours is not known, although a genetic factor is thought to be involved.

SYMPTOMS

The symptoms of neuroblastoma may be present from birth or may develop gradually during childhood. Typical symptoms of the condition include a lump in the abdomen, tiredness, weight...
loss, aches and pains, pallor, and irritability. In some cases, there is also diarrhoea, hypertension (high blood pressure), and flushing of the skin.

If a tumour spreads through the body, other symptoms, such as bone pain or, if the lymph nodes are affected, swellings in the neck or armpits, may occur. Anaemia (a reduced level of the oxygen-carrying pigment haemoglobin in the blood) may result if the cancer spreads to the bone marrow.

**DIAGNOSIS**
The diagnosis of a neuroblastoma is made from MRI and CT scanning (techniques that produce cross-sectional or three-dimensional images of internal body structures), blood tests, urine tests, and biopsy (removal of a small sample of tissue for analysis) of the bone marrow and any accessible tumours.

**TREATMENT AND OUTLOOK**
If possible, the tumour is surgically removed; this is not possible if it has grown around the large blood vessels in the abdomen, however. Treatment is primarily with anticancer drugs (chemotherapy). Radiotherapy and a bone marrow transplant are other treatments that may also be considered.

The outlook varies because neuroblastomas range from being relatively harmless to aggressively cancerous. Even if the tumour is widespread at the time of diagnosis, however, cure rates may still reach 30 per cent.

**neurocutaneous disorders**
A group of conditions characterized by abnormalities of the skin and of the nerves and/or the central nervous system.

The best known of the neurocutaneous disorders is neurofibromatosis, in which there are brown patches on the skin and numerous fibrous nodules on the skin and nerves. Another example is tuberous sclerosis, which is characterized by small skin-coloured swellings over the cheeks and the nose, mental deficiency, and epilepsy.

**neurodermatitis**
An itchy, eczema-like skin condition caused by repeated scratching. (See also lichen simplex.)

**neuroendocrinology**
The study of the interactions between the nervous system and the endocrine system that control internal body functions and the body’s response to the external environment.

**neurofibromatosis**
A genetic disorder that causes numerous soft, noncancerous growths, known as neurofibromas, to appear throughout the body. These tumours grow from nerve tissue and develop along nerve pathways. If the condition is severe, it can be very disfiguring.

**TYPES AND CAUSES**
There are two types of neurofibromatosis. The more common of the two, known as neurofibromatosis 1, is usually apparent in early childhood. The other type, neurofibromatosis 2, is extremely rare and the symptoms do not usually appear until adulthood.

Both types are caused by an abnormal gene that shows an autosomal dominant pattern of inheritance.

**SYMPTOMS**
In neurofibromatosis 1, numerous pale-brown, flat patches with irregular edges, which are known as café au lait spots, develop on the skin. The growths under the skin feel soft to the touch and range in size from hardly noticeable to large bumps. In addition there may be numerous freckles in the armpit and the groin areas.

Adults with neurofibromatosis 2 tend to develop tumours in the inner ear, which can affect hearing, but they rarely have tumours under the skin.

**COMPLICATIONS**
Complications may occur when the growing tumours press on surrounding organs or nerves. For example, vision may be affected if a tumour develops on the optic nerve, which connects the eye to the brain. Tumours can also cause curvature of the spine. Some children with neurofibromatosis may develop epilepsy or have learning problems. In rare cases, tumours become cancerous.

**TREATMENT**
There is no cure for neurofibromatosis, and its progression cannot be slowed. However, surgical removal of neurofibromas may be carried out if there are complications or if large, disfiguring tumours are causing distress. Anyone with this disorder, and parents of an affected child, may wish to seek genetic counselling when planning a pregnancy.

**OUTLOOK**
In mild cases, life expectancy is normal, but if the tumours are extensive and become cancerous, lifespan is reduced.

**neuroleptic drugs**
An alternative name for antipsychotic drugs.

**neurology**
The medical discipline concerned with the study of the nervous system and its disorders. Neurologists are trained to examine the nerves, reflexes, motor and sensory functions, and muscles to determine a disorder’s cause and extent. They are specialists in the treatment of conditions, such as migraine and Parkinson’s disease, that have a neurological basis, and in the care and support of patients with progressive disorders such as multiple sclerosis and muscular dystrophy. (See also neuropathology; neurosurgery.)

**neuroma**
A noncancerous tumour of nerve tissue. In most cases, the cause is unknown; rarely, a neuroma develops as a result of damage to a nerve.

A neuroma may affect any nerve in the body. Symptoms vary according to the nerve involved. In most cases, there is intermittent pain in the areas of the body supplied by the affected nerve. The same areas may also become numb and weak if the neuroma develops in a confined space and presses on the nerve.

If symptoms are troublesome, the tumour may be surgically removed. (See also acoustic neuroma.)

**neuron**
The medical term for a nerve cell.

**STRUCTURE**
A typical neuron consists of a cell body, several branching projections called dendrites, and a filamentous projection called an axon (also known as a nerve fibre). An axon branches at its end to form terminals through which nerve signals are transmitted to target cells.

Most axons are coated with a layered insulating myelin sheath, which speeds the transmission of nerve signals. The myelin sheath is punctuated along its length by gaps called nodes of Ranvier, which help this process. Because the myelin sheath is nonconductive, ion exchange (depolarization) only occurs at a node; signals leap from node to node along the length of the axon.

**FUNCTION**
The nervous system contains billions of neurons, of which there are three main types: sensory neurons, which carry signals from sense receptors into the central nervous system (CNS); motor neurons, which carry signals from the CNS to muscles or glands; and interneurons, which form all the complex electrical circuitry within the CNS itself.
When a neuron transmits (“fires”) a nerve impulse, a chemical called a neurotransmitter is released from the axon terminals, via which signals are transmitted to target cells, such as the dendrites of other neurons, muscle cells, or glands. Bundles of the axons of many neurons are known as nerves or, when they are located within the brain or spinal cord, as nerve tracts or pathways.

Different stimuli excite different types of neurons to fire. For example, physical stimuli such as cold, pressure, or light of a certain wavelength may excite sensory neurons. Most neurons’ activity is controlled by the effects of neurotransmitters released from adjacent neurons. Certain neurotransmitters generate a sudden change in the balance of electrical potential inside and outside the cell (an “action potential”), which occurs at one point on the cell’s membrane and flows at high speed along it. Others stabilize neuronal membranes, preventing an action potential. Thus, a neuron’s firing pattern depends on the balance of excitatory and inhibitory influences acting on it.

**LIFESPAN**

If the cell body of a neuron is damaged or degenerates, the cell dies and is never replaced. A baby is born with the maximum number of neurons, and this number decreases continuously throughout life. However, because people are born with a very large number of neurons, problems normally only arise when disease, injury, or persistent alcohol abuse affects the CNS, and dramatically increases the rate at which neurons are lost.

If a peripheral nerve is damaged, its individual nerve fibres have the ability to regenerate themselves (see nerve injury; neuropathy).
**neuropathic joint**

A joint that has been damaged by inflammation and a series of injuries, which pass unnoticed due to a loss of sensation in the joint resulting from *neuropathy* (nerve damage caused by disease). Neuropathic joints develop in a number of conditions, including *diabetes mellitus* and untreated *syphilis*.

**SYMPTOMS**

When sensation to pain is lost, abnormal stress and strain on a joint do not stimulate the protective reflex spasm of the surrounding muscles; this failure of the protective reflex allows exaggerated movement that can lead to damage within and around the joint. *Osteoarthritis*, swelling, and deformity are features of a neuropathic joint.

**TREATMENT AND OUTLOOK**

An orthopaedic *brace* or *caliper splint* may be necessary to restrict any abnormal movement of the joint. Occasionally, *arthrodesis* (a surgical operation to fuse a joint) is performed. The nerve damage is irreversible.

**neuropathology**

The branch of *pathology* that is concerned with the causes and effects of disorders of the *nervous system*. (See also *neurology*.)

**neuropathy**

Disease or inflammation of, or damage to, the peripheral *nerves*, which connect the *central nervous system* (the brain and the spinal cord), to the muscles, glands, sense organs, and internal organs. The term neuritis is now used more or less interchangeably with neuropathy.

**TYPES**

Most nerve cell axons (the conducting fibres that make up nerves) are insulated by a sheath of the fatty substance *myelin*. Most neuropathies arise from damage to, or irritation of, either the axons or their myelin sheaths. This may cause the passage of nerve signals to be slowed or blocked completely.

Various types of neuropathy are described according to the site and the distribution of the damage. For example, a distal neuropathy starts with damage at the far end of a nerve (the end farthest from the brain or spinal cord). A symmetrical neuropathy affects nerves at the same places on each side of the body. Some neuropathies are described according to the underlying cause of the condition, for example *diabetic neuropathy*, *entrapment neuropathy*, or alcoholic neuropathy.

Polyneuropathy (also known as *polyneuritis*) refers to damage to several nerves; mononeuropathy (or mononeuritis) indicates damage to a single nerve. The term *neuralgia* describes pain caused by irritation or inflammation of a particular nerve.

**CAUSES**

There are some cases of neuropathy that have no obvious cause. Among the many specific causes are *diabetes mellitus*, dietary deficiencies (particularly of the B vitamins), excessive alcohol consumption, and metabolic upsets such as *ureaemia*. Other causes include *Hansen’s disease* (leprosy), *lead poisoning*, or poisoning by drug overdose.

Nerves may become acutely inflamed after a viral infection, such as in *Guillain-Barré syndrome*. Neuropathies may also result from *autoimmune disorders* (disorders in which the immune system attacks the body’s own healthy tissues) such as *rheumatoid arthritis*, systemic *lupus erythematosus*, or *polymyositis nodosa*. In these disorders, there is often damage to the blood vessels supplying the nerves. Neuropathies may occur secondarily to cancerous tumours, such as lung cancer, or with *lymphomas* and *leukaemias*. There is also a group of inherited neuropathies, the most common being *peroneal muscular atrophy*.

**SYMPTOMS**

The symptoms of neuropathy depend on whether it affects mainly sensory nerve fibres or mainly motor nerve fibres. Damage to sensory nerve fibres may cause numbness, tingling, sensations of cold, and pain, which often starts in the hands and feet and spreads towards the centre of the body. Damage to motor fibres may cause muscle weakness and muscle wasting. Damage to nerves of the *autonomic nervous system* may lead to blurred vision, impaired or absent sweating, faintness, and disturbances of gastric, intestinal, bladder, and sexual functioning, including incontinence and impotence.

Some neuropathies are linked with particular symptoms; for example, diabetic neuropathy can cause severe pain.

**DIAGNOSIS**

In order to determine the extent of the damage, *nerve conduction studies* are carried out together with *EMG* tests, which record the electrical activity in muscles. Diagnostic tests such as *blood tests*, *MRI* scans (a technique that produces cross-sectional or three-dimensional images of body structures), and nerve or muscle *biopsy* (removal of a small sample of tissue for microscopic analysis) may also be required.

**TREATMENT AND OUTLOOK**

Treatment is aimed at the underlying cause. For example, vitamin injections may be given to correct a nutritional deficiency; blood sugar levels are carefully controlled to reduce the risk of further nerve damage and promote recovery in people with diabetes mellitus.

If the cell bodies of the damaged nerve cells have not been destroyed, full recovery from the neuropathy is possible. (See also *radiculopathy*.)

**neuropsychiatry**

The branch of medicine that deals with the relationship between psychiatric symptoms and neurological disorder (see *neurology*). This may include the effects of head injury and alcohol on the brain or specific disorders such as brain tumours, infections, inherited illnesses, and disorders causing brain damage in childhood. *Brain imaging* techniques are often used to demonstrate abnormalities of structure and function in disorders with psychiatric symptoms.

**neurosis**

An old term for a range of psychiatric disorders in which there was no loss of contact with reality (unlike *psychosis*). Disorders classed as neurotic included mild forms of *depression*, *anxiety*, *hypocondriasis*, and *dissociative disorders*.

**neurosurgery**

The specialty concerned with the surgical treatment of disorders of the *brain*, *spinal cord*, or other parts of the *nervous system*. Many generalized nervous system disorders do not respond to surgical treatment, but neurosurgery can deal with most conditions in which a localized structural change interferes with nerve function. Improvements in monitoring techniques and control of post-operative complications, such as swelling of the brain, have reduced the risk of serious problems developing.

Conditions treated by neurosurgery include *tumours* of the brain, spinal cord, or meninges (the membranes surrounding the brain and spinal cord); *brain abscesses*; trauma to parts of the nervous system, such as that caused by a penetrating wound; abnormalities of the blood vessels supplying the brain, such as an *aneurysm* (a balloon-like swelling at a weak point in an artery);
bleeding inside the skull (see extradural haemorrhage; intracerebral haemorrhage; subdural haemorrhage); a number of birth defects (such as neural tube defects and hydrocephalus); certain types of epilepsy; and nerve damage caused by illness or accidents. Neurosurgery may also be performed to relieve pain that would otherwise be untreatable.

**neurosyphilis**

Infection of the brain or spinal cord that occurs in untreated syphilis many years after initial infection.

Damage to the spinal cord due to neurosyphilis may cause tabes dorsalis, a condition characterized by poor coordination of leg movements when walking, urinary incontinence, and intermittent pains in the abdomen and limbs. Damage to the brain may cause dementia, muscle weakness, and, in rare cases, total paralysis of the limbs.

**neurotic**

Suffering from neurosis (any of a range of psychiatric disorders in which there is no loss of contact with reality).

**neurotoxin**

A chemical that damages nervous tissue. The principal effects of neurotoxic nerve damage are numbness, weakness, or paralysis of the part of the body supplied by the affected nerve.

Neurotoxins occur in the venom of certain snakes (see snake bites) and are released by some bacteria (such as those that cause tetanus and diphtheria). Some chemical poisons, such as arsenic and lead, are neurotoxic; certain drugs, such as nitrofurantoin, may cause neurodamage in high doses or in susceptible people.

**neurotransmitter**

A chemical released from a nerve ending that transmits impulses from one neuron (nerve cell) to another neuron or to a muscle cell.

**ACTION**

When a nerve impulse reaches a nerve ending, neurotransmitters are released from synaptic vesicles and cross a tiny gap (a synapse) to reach the target cell. Here, they cause channels in the target cell to open, letting through charged particles that stimulate an impulse in the cell. Alternatively, neurotransmitters may inhibit nerve impulses.

Scores of different chemicals fulfill this function in different parts of the nervous system. Many neurotransmitters also function as hormones, being released into the bloodstream to act on distant target cells.

**TYPES AND FUNCTIONS**

One of the most important neurotransmitters is acetylcholine, which causes skeletal muscles to contract when it is released by neurons connected to the muscles. Acetylcholine is also released by neurons that control the sweat glands and the heartbeat and transmits messages between neurons in the brain and neurons in the spinal cord. Interference with the action of acetylcholine on skeletal muscles is the cause of myasthenia gravis. It is thought that depletion of the nerve cells that release acetylcholine in the brain may be a factor in Alzheimer's disease.

Another chemical, noradrenaline (nor-epinephrine), aids the nervous control of heartbeat, blood flow, and the body's response to stress. This substance is made by the adrenal glands as well as being produced by neurons.

The neurotransmitter dopamine plays an important role in parts of the brain that control movement. A malfunction of the neurons that respond to dopamine is thought to underlie Parkinson's disease.

Serotonin is one of the main neurotransmitters found in the parts of the brain concerned with conscious processes.

Another group of neurotransmitters are called neuropeptides. This group includes the endorphins, which are used by the brain to control sensitivity to pain.

**neutropenia**

An abnormally low number of neutrophils (a type of white blood cell) in the blood, which results in an increased susceptibility to infection. Symptoms may include a sore throat and fever. Neutropenia can be due to aplastic anaemia (see anaemia, aplastic), agranulocytosis, acute leukaemia (see leukaemia, acute), or drugs such as anticancer drugs.

**neutrophil**

A type of phagocyte (a cell in the immune system). Neutrophils are a very important part in the immune system, and their role is to engulf and destroy invading bacteria.

**newborn**

A general term for an infant at birth and during the first few weeks of life.

**APPEARANCE OF A NEWBORN BABY**

A full-term newborn baby weighs, on average, 3.5 kg, measures 51 cm long, and is well prepared for survival. The newborn baby may have an oddly shaped skull or a swollen skull as a result of the transition from the uterus to the outside world. Such differences are normal, and they usually disappear relatively quickly.

In a newborn baby, other structures, such as the long bones in the legs, are not yet fully formed. The eyelids are puffy and vision is poor even when the eyes are wide open. The umbilical cord, which is cut at delivery, shrivels and falls off within about ten days to form the navel. The skin is often covered with vernix, a greasy substance that protects the skin in the uterus. Premature babies may have downy hair, called lanugo hair, all over the body; this hair disappears after about a month. Blisters, or small white bumps, can sometimes be seen on the lips of a newborn baby; these are due to vigorous sucking. The genitals may appear large in relation to the rest of the body.

At birth, there are changes in the structure of the heart that result in all the blood circulating through the lungs (see fetal circulation).

The baby has primitive reflexes, such as a grasp reflex, which were important to survival; although, these disappear with increasing age.

**MEDICAL EXAMINATION**

Immediately after birth, the newborn baby is usually given straight to the mother unless there is concern about its condition. Later, it is checked by the nurse, midwife, or doctor in attendance. This usually includes checking the heart rate with a stethoscope and establishing that breathing is normal.

The Apgar score and other tests are performed to confirm that the baby is in good health. The baby's sex, weight, length, and head circumference are noted and a check is made for any obvious birth defect. The vernix is wiped off and the baby is then usually given back to the mother to hold. If very small or sick, the baby may need to be monitored in a neonatal unit.

Within 24 hours of birth, the baby is given a complete medical examination. The skull, eyes, face, abdomen, heart, spine, hips, genitals, and limbs are checked, and the baby's posture, movements, behaviour, cry, reflexes, and responsiveness are noted. The doctor or midwife will confirm that the baby has passed urine and meconium (faeces). During the second week of life, blood...
HOW NEUROTRANSMITTERS WORK

When an electrical impulse travels down a nerve cell axon, it causes the release of a chemical neurotransmitter at the axon terminals. The chemical released is not the same in every case: acetylcholine, noradrenaline (norepinephrine), dopamine, and serotonin are all important examples.

1. The impulse travels down the neuronal axon (above), from the cell body towards the axon terminals; the neurotransmitter is released from tiny swellings, called synaptic knobs, at the axon terminals.

2. The neurotransmitter crosses the gap, or synapse, to the surface membrane of the target cell (right), where it binds to a protein called a receptor.

3. If sufficient target cell receptors are activated by neurotransmitter binding, an impulse is initiated and passes in turn down the target cell’s axon (below right).

Tests are performed to check for phenylketonuria (an inherited enzyme defect) and hypothyroidism (underactivity of the thyroid gland). Other tests may also be performed, depending on family history and the baby’s health.

CONDITIONS IN THE NEWBORN

Some babies suffer injury during birth (see birth injury), such as cephalhaematoma (a swelling of part of the head caused by bleeding between the scalp and the skull).

Jaundice (a yellowing of the skin and the whites of the eyes; see jaundice, neonatal) is an extremely common condition that occurs in newborn babies, especially if the baby is breast-fed. Usually appearing on the second or third day of life, the jaundice usually disappears over the next few days. In most cases, neonatal jaundice is harmless; however, the condition may be serious if it occurs during the first 24 hours, if it is severe (see kernicterus), or if it affects a premature infant.

Some newborn baby girls have slight vaginal bleeding or discharge, and babies of either sex may have enlarged breasts. These conditions are harmless and are the result of the mother’s circulating sex hormones that reach the fetus through the placenta. Any extra hormones leave the baby’s bloodstream and their effects soon disappear.

Infections of the umbilical cord stump sometimes occur, and antiseptic solution is usually applied to prevent this. A blotchy, red rash (see urticaria, neonatal) affecting the face, chest, arms, and thighs of the baby may occur around the second day after birth; this condition is harmless, of no known cause, and disappears without treatment. (See also prematurity; postmaturity.)

new variant CJD
One form of Creutzfeldt–Jakob disease.

NGU
An abbreviation for the condition nongonococcal urethritis.

niacin
See vitamin B complex.

nickel
A metallic element that is present in the body in minute amounts. Nickel is thought to activate certain enzymes (substances that promote biochemical reactions) and it may also play a part in stabilizing chromosomal material in the nuclei of cells.

Disease due to a deficiency of nickel is unknown. Exposure to nickel may cause dermatitis (inflammation of the skin). Lung cancer has been reported in workers in nickel refineries.

niclosamide
An anthelmintic drug used to treat tape-worm infestation. Niclosamide causes the tape-worm to loosen its grip on the inner wall of the intestine. The worm is then passed out of the body in the faeces. Side effects of niclosamide include abdominal pain, lightheadedness, and itching.

nicorandil
A potassium channel activator drug used in the prevention and long-term treatment of angina pectoris (chest pain due to inadequate blood supply to the heart). Side effects, which include flushing, nausea, vomiting, and dizziness, are mainly due to nicorandil’s vasodilation (widening of the blood vessels) effects and usually wear off with continued treatment. Rarely, mouth ulcers and muscle pain can occur.

nicotinamide
See vitamin B complex.

nicotinamide adenine dinucleotide
See NAD.

nicotine
A stimulant drug found in tobacco that is responsible for tobacco dependence. After inhalation, nicotine in tobacco smoke passes rapidly into the bloodstream. Nicotine in chewing tobacco is absorbed more slowly via the lining of the mouth. The drug stimulates the nervous system until it is broken down by the liver and excreted in the urine.
NICOTINE REPLACEMENT THERAPY

EFFECTS
Nicotine acts primarily on the autonomic nervous system, which controls involuntary body activities such as heart rate. The effects of the drug vary from one person to another and also depend on dosage and past usage. In someone who is not used to smoking, even a small amount of nicotine may slow the heart rate and cause nausea and vomiting. However, in habitual smokers, the drug increases the heart rate and narrows the blood vessels, the combined effect of which is to raise blood pressure. Nicotine also stimulates the central nervous system, thereby reducing fatigue, increasing alertness, and improving concentration.

Regular use of tobacco results in tolerance to nicotine, so that a higher intake is needed for the same effects.

WITHDRAWAL
Because most regular smokers are physically dependent on nicotine, the act of stopping smoking often causes withdrawal symptoms such as headaches, fatigue, drowsiness, and difficulty in concentrating. Nicotine replacement therapy, such as the use of nicotine skin patches and chewing gum, can be effective in aiding withdrawal from nicotine. (See also smoking.)

nicotine replacement therapy
Preparations containing nicotine that are used in place of cigarettes as an aid to stopping smoking. Nicotine products are available in the form of sublingual tablets (placed under the tongue), chewing gum, skin patches, nasal spray, or inhalers.

Side effects of such preparations may include nausea, headache, palpitations, cold- or flulike symptoms, hiccups, and vivid dreaming. Nicotine replacement therapy should be used as part of a complete package of measures, including the determination to succeed.

nicotinic acid
A form of niacin (see vitamin B complex). Apart from its use as a vitamin supplement, nicotinic acid is also prescribed as a lipid-lowering drug and as a vasodilator drug. High doses are used to treat certain types of hyperlipidaemia (a metabolic disorder in which there are high levels of fats in the blood). Nicotinic acid derivatives are used to improve circulation in disorders such as peripheral vascular disease.

Adverse effects of nicotinic acid are more common with high doses and include flushing, dizziness, nausea, palpitations, and itching.

NIDDM
The abbreviation for noninsulin-dependent diabetes mellitus (type 2 diabetes).

nifedipine
A calcium channel blocker drug used mainly to prevent and treat angina pectoris (chest pain due to inadequate blood supply to the heart). Nifedipine is also frequently used to treat hypertension (high blood pressure) and disorders affecting the circulation, such as Raynaud’s disease.

Possible side effects of nifedipine include swelling of the hands and feet as a result of oedema (accumulation of fluid in tissues), flushing of the skin, headache, and dizziness.

night blindness
The inability to see well in dim light. Many people with night blindness have no discernible eye disease. The condition may be an inherited functional defect of the retina (the light-sensitive inner layer at the back of the eye), an early sign of retinitis pigmentosa (degeneration of the light-sensitive cells of the retina), or a result of vitamin A deficiency.

nightmare
An unpleasant, vivid dream, sometimes accompanied by a sense of suffocation. Nightmares occur during REM (rapid eye movement) sleep in the middle and later parts of the night and they may be clearly remembered if the dreamer awakens completely during the course of the nightmare.

Nightmares are especially common in children aged between eight and ten and are particularly likely to occur when the child is unwell or anxious. In adults, nightmares may be a side effect of certain drugs, including beta-blocker drugs and benzodiazepine drugs. Repeated nightmares may be associated with traumatic experiences. However, there is no specific relationship with psychiatric illness.

Nightmares should not be confused with hypnagogic hallucinations, which occur while falling asleep, nor with night terror, which occurs in NREM (nonrapid eye movement) sleep and is not remembered on waking.

night terror
A disorder, occurring mainly in children, that consists of abrupt arousals from sleep in a terrified state. Night terror (or sleep terror) usually starts between the ages of four and seven, gradually disappearing in early adolescence. Episodes of night terror occur during NREM (nonrapid eye movement) sleep, usually half an hour to three and a half hours after falling asleep. Sufferers wake up screaming, in a semiconscious state, and remain frightened for some minutes. They do not recognize familiar faces or surroundings and usually cannot be comforted. Physical signs of agitation, such as sweating or an increased heart rate, are common. The sufferer gradually falls back to sleep and has no memory of the event the following day.

Though distressing to parents, night terror in children has no serious significance. However, in adults, it is likely to be associated with an anxiety disorder.

nipple
The small prominence at the tip of each breast. Women’s nipples contain tiny openings through which milk can pass. The nipple and the areola, the surrounding dark area, both increase in size during pregnancy. Involuntary muscle in the nipple allows it to become erect.

DISORDERS
Structural defects of the nipple are rare. One or both nipples may be absent or there may be additional nipples along a line extending from the armpit to the groin. An inverted nipple is usually a harmless abnormality of development, which can be corrected by drawing out the nipple between finger and thumb daily for several weeks. Nipple inversion that develops in older women is mostly due to aging, but mammography may be advisable to rule out the possibility of breast cancer.

Cracked nipples, common during breast-feeding, may lead to infective mastitis (inflammation of the breast tissue). Washing, drying, and moisturizing the nipple daily can help to prevent cracking.

Papilloma of the nipple is a noncancerous swelling attached to the skin by a stalk. Paget’s disease of the nipple appears initially as persistent eczema of the nipple and is due to a slow-growing cancer arising in a milk duct. Surgical treatment is required.

Discharge from the nipple occurs for various reasons. A clear, straw-coloured discharge may develop in early pregnancy; a milky discharge may occur after breast-feeding is over. Galactorrhoea (milk discharge in someone who is not pregnant or breast-feeding) may be due to a hormone imbalance or, rarely, a galactocele (cyst under the areola). A discharge containing pus indicates a breast abscess.
A bloodstained discharge may be due to a noncancerous breast disorder such as fibroadenosis (general lumpiness of the breast) or a cancerous tumour.

nitrate drugs

<table>
<thead>
<tr>
<th>COMMON DRUGS</th>
</tr>
</thead>
<tbody>
<tr>
<td>* Glyceril trinitrate * Isosorbide dinitrate * Isosorbide mononitrate</td>
</tr>
</tbody>
</table>

A group of vasodilator drugs used to treat or prevent attacks of angina pectoris (chest pain due to impaired blood supply to the heart) and to treat severe heart failure (reduced pumping efficiency).

Possible side effects of nitrate drugs include headaches, flushing of the skin, and dizziness. Tolerance (the need for greater amounts of a drug for it to have the same effect) may develop when some nitrate drugs are taken regularly. To avoid this, a change in dosage, frequency, or timing of the drug, or prescription of a different nitrate drug, may be required.

nitrazepam

A benzodiazepine drug used in the short-term treatment of insomnia. Nitrazepam is long-acting and may cause a hangover effect, with drowsiness and light-headedness, the following day. Regular use over several weeks can lead to reduced effectiveness as tolerance develops.

Nitrazepam can lead to drug dependence and to withdrawal symptoms, such as nervousness and restlessness.

nitric oxide (NO)

A gas that is produced both outside the body as a pollutant (for example, in car exhaust fumes) and inside the body, where it takes the form of a molecule that acts as a messenger between cells.

Nitric oxide causes blood vessels to dilate, affecting the flow of oxygenated blood and regulating blood pressure. Overproduction of nitric oxide is associated with various disorders, including toxic shock syndrome, and rheumatoid arthritis; underproduction may cause impotence and angina. The control of nitric oxide is an important element of many drug treatments.

nitrites

Salts of nitrous acid (a nitrogen-containing acid). To preserve meat, sodium nitrite is added in small amounts, together with potassium nitrate and salt, to inhibit the growth of potentially harmful bacteria. In large amounts, nitrites can cause dizziness, nausea, and vomiting.

nitrofurantoin

An antibiotic drug that is used in the treatment of urinary tract infection. Nitrofurantoin should be taken with food to reduce the risk of stomach irritation, which can cause abdominal pain and nausea. More serious side effects, such as breathing difficulty, numbness, and jaundice (yellowing of the skin and the whites of the eyes), occur rarely.

nitrogen

A colourless, odourless gas that makes up 78 per cent of the Earth’s atmosphere. Atmospheric nitrogen has no biological action.

Nitrogen gas cannot be utilized by the body, but compounds of nitrogen are essential to life. The most important of such compounds are amino acids, the building blocks of proteins, which represent the fundamental structural substances of all cells and tissues. Humans cannot make certain amino acids (called essential amino acids), which must be obtained from the diet in the form of animal and plant proteins. The proteins are then broken down by digestion into their constituent amino acids to be absorbed and reconstituted into the specific proteins needed by the body. These processes of protein breakdown and reconstitution produce a variety of nitrogen-containing waste products, primarily urea, which are excreted by the body in the urine. (See also nitrate drugs; nitrites.)

nitroglycerine

A former name for glyceryl trinitrate, a nitrate drug.

Nitrolingual Pumpspray

The brand name for an aerosol preparation of glyceryl trinitrate. This is sprayed under the tongue to treat angina pectoris (chest pain due to impaired blood supply to the heart muscle).

nitroprusside

An antihypertensive drug given as an infusion in the emergency treatment of hypertension (high blood pressure).

nitrous oxide

A colourless gas, also called laughing gas, that has a sweet smell and the chemical formula N₂O. Nitrous oxide is used with oxygen to provide analgesia (pain relief) and light anaesthesia (see anaesthesia, general) at the site of a serious accident or during childbirth, dental procedures, and minor surgery. For major surgery, which requires deeper anaesthesia, a nitrous oxide and oxygen mixture needs to be combined with other drugs.

The advantages of the combination of nitrous oxide and oxygen over other agents are its rapid action and nonflammability. Adverse effects of nitrous oxide may include nausea and vomiting during the recovery period.

nits

The eggs of lice. Both head lice and pubic lice produce eggs, which they stick to the base of hairs growing from their host’s head or pubic area. Nits are tiny, measuring only about 0.5 mm in diameter. They are light brown when newly laid and white when hatched. Hatching takes place within about eight days of being laid. Louse infestations are frequently identified by the presence of nits.

nocardiosis

An infection caused by a fungulike bacterium present in soil. The infection, which is acquired through inhalation, usually starts in the lung and spreads to the brain and tissues under the skin. Nocardiosis is rare, except in people with immunodeficiency disorders or those already suffering from a serious disease.

The resulting illness, similar to pneumonia with fever and cough, fails to respond to short-term antibiotic drug treatment, and progressive lung damage occurs. Brain abscesses may follow.
NOCTURIA

Nocardiosis is diagnosed by microscopic examination of sputum. Treatment, which may have to be continued over several months, is with sulphonamide drugs, often in conjunction with other antibiotic drugs, such as trimethoprim.

nocturia

The disturbance of sleep at night by the need to pass urine. In most people, a moderately full bladder does not usually disturb sleep, although light sleepers are more likely to wake with an urge to empty their bladders. Drinking alcohol in the evening stimulates urine production and may result in nocturia.

A common cause of nocturia in men is enlargement of the prostate gland (see prostate, enlarged), which obstructs the normal outflow of urine and causes the bladder to empty incompletely. In women, a common cause is cystitis (inflammation of the bladder), in which irritation of the bladder wall increases its sensitivity so that smaller volumes of urine trigger a desire to urinate. A common cause of nocturia in both sexes is heart failure (reduced pumping efficiency of the heart), leading to the retention of excess fluid in the legs during the day, which is absorbed into the bloodstream while lying down at night and is carried to the kidneys to make more urine.

Less common causes of nocturia include diabetes mellitus, in which greater volumes of urine are produced both during the day and night; chronic kidney failure, in which the normal ability of the kidney to produce a reduced quantity of more concentrated urine at night is lost; and diabetes insipidus, in which the kidneys fail to concentrate the urine due to the lack of a pituitary hormone.

nocturnal emission

Ejaculation that occurs during sleep, commonly called a “wet dream”. Nocturnal emission is normal in male adolescents and may also occur in adult men.

nocturnal enuresis

See enuresis, nocturnal.

nodal

Pertaining to a node (a small, rounded knot of tissue).

node

A small, rounded mass of tissue. The term commonly refers to a lymph node (a normal structure in the lymphatic system) or to the sinoatrial node or atrioventricular node within the conducting system of the heart. (See also Bouchard’s node; Heberden’s node; nodule; singer’s nodes.)

nodule

A small lump of tissue. A nodule may protrude from the skin’s surface or form deep under the skin. Nodules may be hard or soft. (See also rheumatoid nodules; surfer’s nodules.)

noise

Any sound, particularly one that is disordered and irregular, that is unwanted or interferes with the ability to hear. (See also noise-induced hearing loss.)

noise-induced hearing loss

Loss of hearing caused by prolonged exposure to excessive noise or by brief exposure to intensely loud noise.

Exposure to a sudden, extremely loud noise (above 130 decibels) can cause immediate and permanent hearing loss. Normally, muscles in the middle ear respond to loud noise by repositioning the ossicles (bones that pass vibrations to the inner ear) to damp down the noise. If these reflexes have no time to respond, the full force of the vibrations is carried to the inner ear, severely damaging delicate hair cells in the cochlea. Loud noises can even rupture the eardrum.

More commonly, noise damage occurs by prolonged exposure to lower levels of noise. Any noise above 85 to 90 decibels may cause gradual destruction of the cochlea’s hair cells, leading to permanent hearing loss. Prolonged exposure to loud noise leads initially to a loss of the ability to hear certain high tones. Later, deafness extends to all high frequencies, and speech perception is impaired. Eventually, lower tones are also affected.

Sounds at 85 to 90 decibels or above may initially cause pain and temporary deafness. Prolonged tinnitus (ringing or buzzing in the ears) occurring after a noise has ceased is an indication that some damage has probably occurred.

PREVENTION

People who cannot avoid exposure to loud noise (for example, workers using pneumatic drills) should wear ear protection and have their hearing monitored regularly (see hearing tests).

noma

Also called cancrum oris, noma is the death of tissue in the lips and cheeks due to bacterial infection. The condition is largely confined to young, severely malnourished children in developing countries. Noma can also occur in the last stages of leukaemia (cancer of the blood).

The first symptom is inflammation of the gums and the inner surface of the cheeks. Without treatment, this leads to severe ulceration (with a foul-smelling discharge), eventual destruction of the bones around the mouth, and loss of teeth. Healing occurs naturally after a time, but scarring may be severe.

Antibiotic drugs and improved nutrition halt the progress of the disease. Plastic surgery may be used to reconstruct damaged bones or to improve facial appearance.

nonaccidental injury

See child abuse.

nongonococcal urethritis

Inflammation of the urethra (the tube that carries urine from the bladder to be excreted) due to a cause other than gonorrhoea. Nongonococcal urethritis (NGU) was previously known as nonspecific urethritis (NSU). Worldwide, the condition is a very common type of sexually transmitted infection.

CAUSES

Almost half of all cases of nongonococcal urethritis are known to be caused by Chlamydia trachomatis (see chlamydial infections); others may be caused by the virus that causes herpes simplex, the protozoan trichomonas (see trichomoniasis), or other microorganisms. In some cases, the cause remains unknown.

SYMPTOMS

Symptoms generally appear one to five weeks after infection, usually in week two or three. In men, the infection may cause a urethral discharge, which may be accompanied by stinging on passing urine. There may be redness, crusting, and soreness at the urethral opening. However, often no symptoms are present.

The equivalent condition in women, sometimes called nonspecific genital infection, may not cause symptoms unless there are complications. However, a woman who has the infection can pass it on to her sexual partners.

DIAGNOSIS AND TREATMENT

Diagnosis is made from a swab taken from the urethra and a urine sample; both enable identification of the causative organism. Antibiotic drugs, such as doxycycline, are the usual treatment.

With treatment, the infection usually clears up in about a week. Follow-up visits may be advised after treatment as
the infection can recur. Sexual partners must be tested and treated if necessary in order to prevent reinfection.

COMPLICATIONS
In men, *epididymitis* (inflammation of the epididymis in the testes), *prostatitis* (inflammation of the prostate gland), and *urethral stricture* (narrowing of the urethra) can occur as complications of nongonococcal urethritis. *Reiter’s syndrome* (in which there is arthritis and conjunctivitis as well as the urethritis) occurs as a complication in some men who develop nongonococcal urethritis.

In women, *pelvic inflammatory disease* and infection in the *Bartholin’s glands* may occur. *Ophthalmia neonatorum*, a type of conjunctivitis, sometimes develops in babies born to women who have chlamydial cervicitis at delivery.

**non-Hodgkin’s lymphoma**

See lymphoma, non-Hodgkin’s.

**noninvasive**

A term used to describe any medical procedure that does not involve penetration of the skin or entry into the body through any natural opening. Examples of noninvasive procedures include *CT scanning* and *echocardiography*.

The term is sometimes also applied to noncancerous tumours that do not spread throughout body tissues.

**non-nucleoside reverse transcriptase inhibitors**

A type of *antiretroviral drug* that is used to delay the progression of *HIV* infection. (See also *AIDS*.)

**nonoxinol 9**

A *spermicide* used in contraceptive preparations such as gels, foams, and creams.

**nonspecific urethritis**

The former term for the condition *nongonococcal urethritis*.

**nonstarch polysaccharide (NSP)**

Another name for dietary fibre (see *fibre, dietary*).

**nonsteroidal anti-inflammatory drugs**

**COMMON DRUGS**

- COX-2 INHIBITORS: Celecoxib, Etodolac, Meloxicam, Rofecoxib
- OTHER NSAIDs: Acetaminophen, Aspirin, Benzydamine, Diclofenac, Diflunisal, Felbinac, Fenbufen, Fenoprofen
- Flurbiprofen, Ibuprofen, Indomethacin, Ketoprofen, Mefenamic acid, Nabumetone, Naproxen, Phenylbutazone, Piroxicam, Sulindac, Tenoxicam, Tiaprofenic acid

A group of drugs, also known as NSAIDs, that produce *analgesia* (pain relief) and reduce inflammation in joints and soft tissues such as muscles and ligaments.

**WHY THEY ARE USED**

Nonsteroidal anti-inflammatory drugs (NSAIDs) are widely used to relieve symptoms caused by types of arthritis, such as *rheumatoid arthritis*, *osteoarthritis*, and *gout*. They do not cure or halt the progress of disease but help to improve mobility of the affected joints and relieve pain and stiffness. NSAIDs are also used in the treatment of back pain, menstrual pain, headaches, pain following minor surgery, and injuries to soft tissue.

**HOW THEY WORK**

NSAIDs reduce pain and inflammation by blocking the action of the enzyme cyclooxygenase (COX), which is involved in the body’s production of *prostaglandins* (chemicals that cause inflammation and trigger transmission of pain signals to the brain, but that also protect the stomach lining). Most NSAIDs block both COX-2 (providing the anti-inflammatory effect) and COX-1 (leading to stomach irritation). COX-2 inhibitors were developed to block COX-2 alone, thereby reducing the risk of stomach irritation.

**POSSIBLE ADVERSE EFFECTS**

NSAIDs may cause a range of side effects, including nausea, indigestion, bleeding from the stomach, *fluid retention*, and, occasionally, *peptic ulcer*. They may also worsen *heart failure* or *kidney failure*. COX-2 inhibitors cause less gastrointestinal irritation than other NSAIDs.

**Noonan’s syndrome**

An inherited condition that shares many features with *Turner’s syndrome*, but in which there is a full complement of chromosomes. Noonan’s syndrome can affect both males and females. Features include congenital heart disease (see *heart disease, congenital*), *webbing* of the neck, *ptosis* (drooping eyelids), *myopia* (shortsightedness), feeding problems in infants, *short stature*, *hypotonia* (poor muscle tone), hearing difficulties, delayed speech development, delayed *puberty*, and undescended testes (see *testis, undescended*) in males.

In terms of inheritance, Noonan’s syndrome demonstrates an autosomal dominant pattern (see *genetic disorders*).

There is a family history of the condition in approximately half of all cases; the remainder are due to new *mutations*. There is no treatment for the condition as a whole, but many of its features (such as undescended testes and heart problems) may be treated successfully.

**noradrenaline**

Also known as norepinephrine, a *hormone* secreted by certain nerve endings (principally those of the *sympathetic nervous system*) and by the medulla (the central region) of the *adrenal glands*.

Noradrenaline’s primary function is to help maintain a constant blood pressure by stimulating certain blood vessels to constrict (narrow) when blood pressure falls. For this reason, it may sometimes be administered by injection in the emergency treatment of *shock* or severe bleeding. (See also *adrenaline*.)

**norepinephrine**

An alternative term for *noradrenaline*.

**noretisterone**

A progestogen drug used primarily as an ingredient of some *oral contraceptives* and HRT preparations. Noretisterone is sometimes prescribed to postpone menstruation. It is also used to treat *premenstrual syndrome*, menstrual disorders such as *menorrhagia* (heavy periods), *endometriosis*, and certain types of *breast cancer*. Noretisterone is given by injection as a long-acting contraceptive.

Possible side effects include swollen ankles, weight gain, depression and, rarely, *jaundice* (yellowing of the skin and the whites of the eyes).

**norfloxacin**

An *antibiotic drug* used in the treatment of *urinary tract infections*.

**norgestrel**

See *levonorgestrel*.

**Noriday**

A brand name for *noretisterone* tablets, which are progesterone-only oral contraceptives.

**normocytic anaemia**

Any form of *anaemia* in which the amount of *haemoglobin* (oxygen-carrying pigment) in the blood is reduced, due to a reduction in the total number of *red blood cells*, but the size and haemoglobin content of the individual cells is normal. Normocytic anaemia can develop as a
result of chronic diseases (such as renal failure or chronic inflammatory joint diseases such as rheumatoid arthritis), or as a result of a problem in the bone marrow itself. (See also microcytic anaemia.)

nose
The uppermost part of the respiratory tract and the organ of smell.

STRUCTURE
The nose is an air passage connecting the nostrils at its front to the nasopharynx (the upper part of the throat) at its rear. The nasal septum, which is made of cartilage at the front and bone at the rear, divides the passage into two chambers.

The bridge of the nose is formed from two small nasal bones and from cartilage. The roof of the nasal passage is formed by bones at the base of the skull; the walls by the maxilla (upper jaw); and the floor by the hard palate. Three conchae (thin, downward-curving plates of bone) covered with mucous membrane project from each wall.

Air-filled, mucous membrane-lined cavities (called paranasal sinuses) open into the nasal passage. There is an opening in each wall to the nasolacrimal duct, which drains away tears. Projecting into the roof of the nasal passage are the hairlike endings of the olfactory nerves, responsible for the sense of smell.

FUNCTION
One important function of the nose is to filter, warm, and moisten inhaled air before it passes into the rest of the respiratory tract. Just inside the nostrils, small hairs trap large dust particles and foreign bodies. Smaller dust particles are filtered from the inhaled air by the microscopic hairlike projections of the conchae. The mucus on the conchae flows inwards, carrying microorganisms and other foreign bodies back towards the nasopharynx to be swallowed and destroyed in the stomach.

The nose also detects smells by means of the olfactory nerve endings, which, when stimulated by inhaled vapours, transmit this information to the olfactory bulb in the brain. (See also nose disorders box.)

nosebleed
Loss of blood from the mucous membrane that lines the nose. Nosebleeds are common in children, but the bleeding is usually minor and stops by itself. Nosebleeds are also common, but in some cases serious, in people over the age of 50. In this age group, bleeding may come from the back of the nose and be hard to stop. If the blood is swallowed, bleeding may not be seen.

CAUSES
Nosebleeds often occur spontaneously. In dry environments or during the winter months, the membranes lining the nose may become dry and cracked, causing bleeding to occur. Nosebleeds may also occur if the lining of the nose is injured by a blow to the nose or by nose-picking or forceful nose-blowing. In children, nosebleeds often occur as a result of rough play.

A foreign body in the nose or an infection in the upper respiratory tract may also result in a nosebleed. In people over the age of 50, the small blood vessels in the nose may be more fragile and therefore more likely to rupture and cause bleeding.

Rarely, recurrent nosebleeds are a sign of an underlying disorder, such as hypertension (high blood pressure), a bleeding disorder such as thrombocytopenia, or a tumour of the nose or paranasal sinuses. Nosebleeds may also be caused by drugs that prevent blood clotting (see anticoagulant drugs).

TREATMENT
The vast majority of nosebleeds are short-lived and do not require specific treatment. A nosebleed can usually be stopped by pressing on the soft part of the nose (pressing both sides together) for about 15 minutes. If membranes in the nose are dry or cracked, rubbing water-based ointment on the area may help to prevent nosebleeds.

A nosebleed that persists for more than about an hour requires medical attention. Treatment for a serious nosebleed may involve nasal sponges placed into the nostrils to absorb the blood or the insertion and inflation of a balloon catheter to stop the bleeding. If the cause is not obvious, the nasal passages may be examined with a viewing instrument to look for ruptured blood vessels or a tumour (see endoscopy). Alternatively, imaging techniques such as X-rays or MRI (a technique that produces cross-sectional or three-dimensional images of body structures) may be used. Treatment will then be of the underlying cause. Occasionally, surgery is required to tie off leaking blood vessels.

nose, broken
Fracture of the nasal bones or dislocation of the cartilage that forms the bridge of the nose. A blow from the side may knock the bones or cartilage out of position or cause displacement of the nasal septum (the dividing partition inside the nose). A frontal blow tends to splay the bones of the nose outwards, depressing the bridge. The fracture is
DISORDERS OF THE NOSE

The nose is susceptible to a wide range of disorders. Infections and allergic conditions, leading to stuffiness or sneezing, are common. Due to its prominent position, the nose is also prone to injury.

Infection
The common cold (see cold, common), a viral infection, causes inflammation of the lining of the nasal passages and excessive production of mucus, leading to nasal congestion. Small boils (infected hair follicles) sometimes occur just within the nostril, where they may cause pain. Backward spread of infection from the nose may cause cavernous sinus thrombosis, a serious condition that, without antibiotic drugs, can be fatal.

Tumours
Noncancerous tumours of blood vessels, known as haemangiomas, may affect the nasal cavity in babies. Many disappear spontaneously before puberty. Basal cell carcinoma and squamous cell carcinoma (types of skin cancer) may occur in or around the nostril. The nose may also be invaded by cancers originating in the sinuses.

Injury
Because of its prominent position, the nose is also particularly prone to injury. Fracture of the nasal bones (see nose, broken) is a common sports injury that can lead to deformity and may require corrective surgery. Nosebleeds are also common, particularly in children; they may be caused by fragile blood vessels, infection of the lining of the nose, or a blow to the nose.

Drugs
Repeated sniffing of cocaine interferes with the blood supply to the mucous membrane lining the nose and can cause perforation of the nasal septum. Persistent taking of snuff can irritate or damage the nasal lining.

TREATMENT
Resetting is usually carried out either before the swelling has started or when it has subsided, usually about ten days after the injury. Occasionally, a displaced bridge can be carefully manipulated into position under a local anaesthetic (see anaesthesia, local). However, a general anaesthetic (see anaesthesia, general) is usually needed. A plaster splint is sometimes required during healing.

nose reshaping
See rhinoplasty.

nosocomial
A term that means associated with hospitals. A nosocomial infection, for example, is an infection acquired by a patient during a stay in hospital.

notifiable diseases
Medical conditions that must be report- ed to the local health authority. The notification of certain potentially harmful infectious diseases enables public health physicians to monitor and control the spread of infection and records to be kept of disease patterns.

Examples of notifiable infectious diseases are food poisoning, viral hepatitis, measles, malaria, pertussis (whooping cough), tetanus, tuberculosis, meningitis, mumps, and rubella (German measles). Similar information is also collected on cancers, occupational diseases, birth defects, and other noninfectious health problems. (See also prescribed diseases.)

NREM sleep
The abbreviation for nonrapid eye movement sleep, the period of sleep during which the brain is less active. NREM sleep occurs alternately with REM sleep throughout the night. An average cycle of sleep is made up of three-quarters NREM sleep and one-quarter REM sleep.

NSAID
The abbreviation for nonsteroidal anti-inflammatory drugs.

NSU
The abbreviation for nonspecific urethritis, the former term for gonococcal urethritis.

nuchal thickness scan
Ultrasound scanning performed in early pregnancy in order to identify fetuses at high risk of chromosomal abnormalities, such as Down's syndrome. The scan investigates the thickness of the nuchal fold, an area of skin at the back of the neck. Excessive thickness of the nuchal fold is an indication that there may be chromosomal abnormalities.

nuclear energy
The energy that is released as a result of changes in the nuclei (see nucleus) of atoms. Nuclear energy is also known as atomic energy and it is principally released in the form of heat, light, and ionizing radiation, such as gamma rays.

usually accompanied by severe swelling of overlying soft tissue. A fractured nose is painful and remains tender for about three weeks after the injury.

To inspect the inside of the nose, the doctor uses a speculum in order to open up the nostrils. If a fracture is suspected, X-rays are taken. If cancer is suspected, a nasal endoscopy and a biopsy are performed.

CT scan showing broken nose
In this three-dimensional image of the skull, a fracture of the nasal bone is clearly visible. The damaged bone is asymmetrical and has a V-shaped notch on the right-hand side.
NUCLEAR MAGNETIC RESONANCE

Nuclear energy is released in certain natural processes, examples of which include the spontaneous decay of radioactive substances, such as uranium ores, and the nuclear reactions that power the sun. Nuclear energy is also released in specifically designed devices, for example in nuclear reactors.

**nuclear magnetic resonance**
See MRI.

**nuclear medicine**
Techniques that use radioactive substances (see radioactivity) in the detection and treatment of disease.

Radioactive materials, which may be injected, inhaled, or swallowed, are taken up by body tissues or organs in different concentrations, and an instrument called a gamma camera is used to detect and map the distribution of radiation within the body (see radionuclide scanning). The technique uses only minuscule quantities of radiation.

In techniques for treatment, higher doses of radiation are used. Diseased tissues are destroyed by exposure to an external radioactive source or by insertion of a radioactive substance into a body cavity (see radiotherapy; interstitial radiotherapy; intracavitary therapy).

**nucleic acid**
A substance found in all living matter that has a fundamental role in the propagation of life. Nucleic acids provide the inherited coded instructions (or “blueprint”) for an organism’s development; they also provide apparatus by which these instructions are carried out.

**TYPES**
There are two types of nucleic acid: deoxyribonucleic acid (DNA) and ribonucleic acid (RNA). In all animal and plant cells, including human cells, DNA permanently holds the coded instructions, which are first translated and then implemented by RNA. DNA is the main constituent of chromosomes, which are carried in the nucleus of the cell.

**STRUCTURE**
DNA and RNA are similar in structure, both comprising long, chainlike molecules. However, DNA usually consists of two intertwined chains, whereas RNA is generally single-stranded.

The basic structure of DNA is like a rope ladder; the chains form the two sides, and interlinking structures in between form the rungs. The ladder twists into a spiral shape called a double helix.

Each DNA chain has a “backbone” consisting of a string of sugar and phosphate chemical groups. Attached to each sugar is a chemical called a base, which can be any of four types (adenine, thymine, guanine, and cytosine) and forms half a rung of the DNA ladder. The four bases can occur in any sequence along the chain. The sequence, often many millions of individual bases long, provides the code for the activities of the cell (see genetic code). Because the two bases that form each rung of the ladder conform to certain pairings, known as base pairs (adenine pairs with thymine; and guanine with cytosine) the sequence of bases on one chain determines the sequence on the other. This is of fundamental importance for the copying of DNA molecules when a cell divides.

DNA is like a single strand of DNA; the main difference is that the base thymine is replaced by another base, uracil, and the sugar and phosphate chain is chemically slightly different.

**FUNCTION**
DNA controls a cell’s activities by specifying and regulating the synthesis of enzymes (substances that promote biochemical reactions) and other proteins in the cell. Different genes (sections of DNA) regulate the production of different proteins. For a particular protein to be made, an appropriate section of DNA acts as a template for an RNA chain. This “messenger” RNA then passes out of the nucleus into the cell cytoplasm (a thick fluid that forms the bulk of the cell), where it is decoded to form proteins (see protein synthesis).

When a cell undergoes mitotic (see mitosis) division, identical copies of its DNA must go to each of the two daughter cells. The structure of DNA makes this process possible. Starting at one end of the molecule, the two chains “unzip”. As they do so, two more chains are formed (side by side with the original chains) by the linking of free, unlinked nucleotides that are present in cells. Because only certain base pairings are possible, the new double chains are identical to the original DNA molecule. Thus a dividing cell provides an exact copy of its DNA to its daughter cells. Each of a person’s cells carries the same DNA replica that was present in the fertilized ovum, thus the DNA message passes from one generation of cells to the next.

**nucleoside reverse transcriptase inhibitors**
An antiretroviral drug used to delay the progress of HIV infection. (See also AIDS.)

**nucleotide**
A compound that consists of a base, linked to a sugar and a phosphate group. The nucleic acids DNA and RNA are chains of linked nucleotides. There are four different bases in DNA, adenine, cytosine, guanine, and thymine, which...
always pair up, adenine with thymine and cytosine with guanine, to form the characteristic double helix of DNA. RNA is like a single strand of DNA but has uracil as a base instead of thymine. The sugar molecule in DNA is deoxyribose; in RNA it is ribose.

**nucleus**
The central core, structure, or focus of any of a variety of objects or structures.

**CELL NUCLEUS**
The nucleus of a living cell is a roughly spherical unit at the centre of the cell. It contains the *chromosomes* (composed mainly of *nucleic acid*), which are responsible for directing the cell’s activities, and is surrounded by a membrane. The membrane has small pores through which various substances can pass between the nucleus and the cytoplasm, a thick fluid that forms the bulk of the cell. Usually, the nucleus has one nucleolus, a smaller dense region with no membrane concerned with protein manufacture.

**NERVE NUCLEUS**
A nerve nucleus is a group of *neurons* (nerve cells) within the brain and the spinal cord that work together to perform a particular function.

**ATOMIC NUCLEUS**
The nucleus of an atom is composed of protons and neutrons and accounts for almost the total mass of the atom, but only a tiny proportion of its volume. *Nuclear energy* is produced through changes in atomic nuclei.

**nulliparous**
A term that refers to a woman who has never given birth to a live infant, including a woman who has never conceived. (See also *grand multipara; multiparous*.)

**numbness**
Loss of sensation in part of the body caused by interference with the passage of impulses along sensory nerves.

**CAUSES**
Numbness can occur naturally (such as when blood supply to a nerve in the leg is cut off temporarily by sitting cross-legged); it can be induced artificially (for example by a dentist anaesthetizing a nerve before filling a tooth); or it may be the result of a disorder of the nervous system or its blood supply.

*Multiple sclerosis* can cause loss of sensation in any part of the body through damage to nerve pathways in the central nervous system (CNS). In a *neuropathy*, the peripheral nerves (nerves outside the CNS) are damaged. In a *stroke*, pressure on, or reduced blood supply to, nerve pathways in the brain often causes loss of feeling on one side of the body.

Severe cold, as in *frostbite*, causes numbness by direct action on the nerves. Numbness is a symptom of *Raynaud’s disease*, a disorder of the blood vessels in which exposure to cold causes the small arteries supplying nerves in the fingers and toes to contract suddenly.

Numbness may indicate psychological disorders, such as *anxiety, panic attack*, or a hysterical *conversion disorder*.

**DIAGNOSIS AND TREATMENT**
Examination usually reveals an area of sensory loss or impairment corresponding to the skin distribution of a single peripheral nerve, several nerves, or a sensory area in the CNS. The distribution of the affected area may suggest the site and mechanism of the nerve damage. Treatment depends on the cause.

**nummular**
Round, flat, and disc-shaped. The term may also be used to describe a structure or condition that features round, flat, disc-shaped abnormalities. For example, nummular eczema is a skin disorder defined by the appearance of characteristic coin-shaped patches of itchy skin.

**nurse**
A person trained and experienced in the scientific basis of nursing. He or she is entrusted with the care of the sick and the carrying out of medical and surgical duties. Worldwide, nurses must meet certain prescribed standards of education and clinical competence. They must generally undergo a period of training in a hospital and pass a final examination in order to qualify in the profession.

The term nursing may also be used interchangeably with *breast-feeding*. (See also *doctor; midwifery*.)

**nutrient**
An essential dietary factor, such as carbohydrates, proteins, certain fats, vitamins, and minerals. (See *Essential nutrients* boxes, overleaf.)

**nutrition**
The scientific study of food and the processes of digestion and assimilation. Nutritionists look at the ways in which various types of food are used by the body, the chemical components of different foods, and the effects of eating certain foods on health. The knowledge gained by nutritionists from studying the effects of diet on health in different countries has led to the development of guidelines to ensure a healthy, balanced diet that can reduce the risk of ill health.

**A BALANCED DIET**
A good diet supplies adequate quantities of the main nutrients: *proteins, carbohydrates, fats and oils, vitamins, minerals*, dietary fibre (see *fibre, dietary*), and water. Each one of these elements makes an important contribution to health, but it is important that they are consumed in the correct proportions, with carbohydrates forming the bulk of the diet and fats only a relatively small proportion.

The daily diet should include foods from each of the five main food groups. Bread, potatoes, pasta, and other complex carbohydrates provide energy, plenty of dietary fibre, some minerals, and vitamins in the B group (see *vitamin B complex*). Milk and dairy foods provide protein and are a good source of *calcium* and certain vitamins, such as B₁₂, A, and D; low-fat versions are useful for reducing the overall fat intake in the diet. Meat, fish, and pulses provide protein, *iron*, B vitamins, and some minerals. A variety of fruit and vegetables should be eaten, ideally five portions each day. Fruit and vegetables provide fibre and carbohydrate and are rich in vitamins and minerals. Fatty and sugary foods (such as sweets, cakes, and chips), although providing *energy*, have little other nutritional value and should be limited in the diet. Consumption of saturated fats should be kept to an absolute minimum.

In addition to foods from the main groups, the diet should contain plenty of water, as much as eight glasses a day. The need for water is increased by diarrhoea, vomiting, and taking *diuretic drugs*. Drinks that contain sugar, caffeine, or alcohol should be consumed in moderation. Sugar contributes to tooth decay; carbonated drinks, even those low in sugar, can damage the teeth because they are acidic. Excessive intake of caffeine can cause palpitations and insomnia.

**ENERGY REQUIREMENTS**
The body needs a constant reserve of energy to function properly. Energy from food is measured in units called kilojoules (kJ) or kilocalories (kcal), which are usually referred to simply as calories.

The number of calories needed by an individual depends on how much energy their body uses. This depends partly on how efficiently the body’s cells use energy, which is genetically determined,
**ESSENTIAL NUTRIENTS**

<table>
<thead>
<tr>
<th>Nutrients</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Proteins</strong></td>
<td>The main structural component of tissues and organs. We need proteins for growth and repair of cells. Each protein contains hundreds and sometimes thousands of units called amino acids in specific combinations. In the body there are 20 different amino acids; 12 of these can be manufactured by the body itself and the remaining eight can only be obtained by eating a balanced diet. A vegetarian diet that contains eggs, milk, and cheese provides sufficient amounts of all the essential amino acids. A vegan diet, which also excludes dairy products, needs careful planning in order to prevent a deficient intake of protein (see Vegetarianism).</td>
</tr>
<tr>
<td><strong>Carbohydrates</strong></td>
<td>The two carbohydrate food groups, sugars (simple carbohydrates) and starches (complex carbohydrates), are the main energy sources that are required for metabolism (chemical processes that take place in cells). Complex carbohydrates should make up at least half of the diet. Complex carbohydrates found in cereals and fruit are rich in fibre and nutrients. Refined carbohydrates such as sugar and white flour should be kept to a minimum.</td>
</tr>
<tr>
<td><strong>Fats</strong></td>
<td>Fats provide energy for metabolism and are a structural component of cells. Most people in developed countries eat too much fat; fats should constitute no more than 30 per cent of total calorie intake. There are three types of dietary fats: saturated fats (found mostly in meat and dairy products), monounsaturated fats (found in olive oil and avocados), and polyunsaturated fats (found in fish and vegetable oils). Saturated fats tend to increase the amounts of unwanted types of cholesterol in the blood whereas polyunsaturated fats and monounsaturated fats have the opposite effect. Studies have indicated that a high level of low-density lipoprotein cholesterol in the blood is associated with coronary artery disease. Our bodies naturally produce enough cholesterol for our needs; excess is mostly due to eating too much saturated fat.</td>
</tr>
<tr>
<td><strong>Fibre</strong></td>
<td>This is the indigestible structural material that is found in plants. Although fibre passes through the intestine unchanged, it is an essential part of a healthy diet. A diet low in fibre may lead to constipation, diverticular disease, and other disorders. High-fibre diets (including plenty of fruit, raw vegetables, grains and cereals) provide bulk without excess calories. Low-fibre diets tend to be high in refined carbohydrates and fats, and thus increase the risk of developing obesity, heart disease, and some cancers.</td>
</tr>
<tr>
<td><strong>Water</strong></td>
<td>Our bodies are composed of about 60 per cent water. Water constitutes a high proportion of many foods, particularly fruit and vegetables, and is essential to maintain metabolism (chemical processes in cells) and normal kidney and bowel function. Water is also the major component of the volume of blood in the circulation.</td>
</tr>
<tr>
<td><strong>Vitamins</strong></td>
<td>Regulators of metabolism. Vitamins ensure the healthy functioning of the brain, nerves, muscles, skin, and bones. Although vitamins do not supply energy, some enable energy to be released from the food. A healthy, balanced diet contains enough vitamins for most people’s needs, and supplements are not usually necessary. Indeed, some vitamins that are stored in fats (A, D, E, and K) are dangerous if taken in excess. The body can store only relatively small amounts of water-soluble vitamins (B and C), but even on a very restricted diet, vitamin deficiency is usually rare until several months have elapsed.</td>
</tr>
<tr>
<td><strong>Minerals</strong></td>
<td>A balanced diet provides enough minerals for most people. Calcium is necessary for the maintenance of healthy teeth and bones. Other minerals, such as zinc and magnesium, are needed in minute amounts to control cell metabolism. The body can store only relatively small amounts of water-soluble vitamins (B and C), but even on a very restricted diet, vitamin deficiency is rare until several months have elapsed.</td>
</tr>

</table>

**NUTRITIONAL DISORDERS**

Nutritional disorders may be caused by a deficiency or excess of one or more nutrients, or by the presence of a toxin (poisonous element) in the diet.

**NUTRITIONAL DEFICIENCY**

A diet deficient in carbohydrates is usually also deficient in protein, leading to protein–calorie malnutrition, which most often occurs as a result of severe poverty and famine (see kwashiorkor; marasmus).

Inadequate intake of protein and calories may also occur in people who restrict their diet excessively to lose weight (see anorexia nervosa), hold mistaken beliefs about diet and health (see food fad), or lose interest in food due to alcohol dependence or drug dependence.

Deficiency of specific nutrients is commonly associated with a disorder of the digestive system, such as coeliac disease, Crohn’s disease, or pernicious anaemia (see anaemia, megaloblastic).

**NUTRITIONAL EXCESS**

Obesity results from taking in more energy from the diet than is used up by the body. It is a major threat to health and is associated with disorders such as coronary artery disease, hypertension (high blood pressure), and stroke (damage to part of the brain due to interruption to its blood supply). An excessive intake of saturated fat is thought to be a factor in cardiovascular disease and in certain cancers. Nutritional disorders may also result from excessive minerals and vitamins.

**TOXINS**

Naturally occurring toxins can interfere with the digestion, absorption, and/or utilization of nutrients or cause specific
disorders due to their toxic effects. For example, the ergot fungus on rye can cause ergotism, symptoms of which include gangrene (tissue death) of the toes and fingers, seizures, and mental disorders.

Industrial pollutants, pesticides, fertilizers, and various other chemicals may also contaminate food.

nymphomania
An outdated term for a condition in which a woman has an insatiable appetite for sexual activity with many partners. The equivalent behaviour in men is called satyriasis or Don Juanism. It was said to be caused by intense narcissism and feelings of inferiority.

nystagmus
A condition in which there is involuntary movement of the eyes. This movement is usually horizontal, but can be vertical or rotatory. In almost all cases, both eyes move together.

TYPES
In the most common type, jerky nystagmus, the eyes repeatedly move slowly in one direction and then rapidly in the other. This may also occur as a normal effect of attempting to follow a sequence of objects rapidly passing the eyes, such as when looking out of the window of a moving vehicle. This phenomenon is known as “optokinetic nystagmus”. Less commonly, nystagmus is “pendular”, with the eyes moving evenly up and down or from side to side.

CAUSES
Nystagmus may be congenital (present at birth), in which case the cause is unknown. Because a steady gaze is impossible, there is almost always a moderate to severe defect of visual acuity. The condition also occurs in albinism and as a result of any very severe defect of vision present at birth, such as congenital cataract.

Persistent nystagmus appearing later in life usually indicates a nervous system disorder (such as multiple sclerosis, a brain tumour, or an alcohol-related disorder), or a disorder of the balancing mechanism in the inner ear. Adult-onset nystagmus is occasionally seen as an occupational disorder in people who work in poor light, such as coal miners.

INVESTIGATION AND TREATMENT
Electronystagmography, which is a method of recording eye movements, may be used to differentiate between the different types of nystagmus. Treatment is of the underlying cause, if possible.

nystatin
An antifungal drug used in the treatment of candidiasis (thrush). Nystatin may be taken as a tablet, liquid, pessary, cream, or ointment and can be safely used during pregnancy. High doses taken orally may cause diarrhoea, nausea, vomiting, and abdominal pain.
OAT CELL CARCINOMA

oat cell carcinoma
A form of lung cancer, also known as small cell carcinoma.

obesity
An increasingly common condition in which a large amount of excess fat has accumulated in the body. An obese person is defined as having a body mass index (BMI) (calculated from height and weight) of over 30. A BMI of between 25 and 30 is overweight, but not obese.

CAUSES
Obesity is usually caused by the regular consumption of more food than is needed for energy. Energy requirements are determined partly by metabolic rate (see metabolism) and partly by level of physical activity. Genetic factors may play a significant part in obesity. However, environmental influences (such as eating and exercising patterns) are also important. In a small minority of cases, obesity is due to an underlying disorder, such as hypothyroidism (underactivity of the thyroid gland), Cushing’s syndrome, damage to the hypothalamus (the area of the brain responsible for controlling the appetite), or the effects of drug treatment (such as with corticosteroid drugs).

COMPLICATIONS
Obesity substantially increases the risk of serious illness. Hypertension (high blood pressure), stroke, and type 2 diabetes mellitus are much more likely to occur in obese people. Coronary artery disease is also more common in the obese, particularly in men under 40. Obesity is also associated with an increased risk of some cancers, including cancer of the colon, rectum, breast, and uterus. Extra weight may aggravate osteoarthritis due to strain on the joints.

TREATMENT
The first line of treatment is a weight-reducing diet (see weight reduction) plus regular exercise. Fad diets may cause a dramatic weight loss within a short period of time but, in almost all cases, the weight is quickly regained when normal eating habits are resumed.

Appetite suppressant drugs are rarely used because of their side effects. Orlistat, a drug that prevents absorption of fat from the intestine, is effective only while being taken. Side effects include diarrhoea and vitamin deficiencies.

Radical procedures are sometimes considered for severely obese people who have failed to lose weight using routine methods. Wiring of the jaws may be carried out to restrict food intake. An operation in which part of the stomach is stapled together to reduce its capacity may be performed. Intestinal bypass operations are occasionally performed to reduce the length of the digestive tract and allow less food to be absorbed. However, due to the risk of adverse effects, such procedures are only considered if obesity is seriously endangering a person’s health.

obsessive–compulsive disorder
A psychiatric condition, often known as OCD, in which an individual is dogged by persistent ideas (obsessions) that lead to repetitive, ritualized acts (compulsions). The disorder, which usually starts in adolescence, is rare. However, minor obsessional symptoms probably occur in about one sixth of the population, particularly at times of stress.

CAUSES
OCD may have a genetic element, but environmental factors also play a part. Personality traits of orderliness and cleanliness are thought to be related, as is a tendency to neurotic symptoms. Certain brain damage, especially that of the hypothalamus, can cause obsessional symptoms. Tests on people with OCD show overactivity in frontal areas of the brain.

SYMPTOMS
Obsessions are recurrent thoughts or feelings that come into the mind seemingly involuntarily. Although people who are affected regard such thoughts as senseless, they are unable to ignore or resist them. Thoughts of violence, fears of being infected by germs or dirt, and constant doubts (for example, whether the front door is shut or the oven turned off) are the most common obsessions. In obsessional ruminating, there is constant brooding over a word, phrase, or unanswerable problem.

Compulsions are repetitive, apparently purposeful acts that are carried out in a ritualized fashion. They are performed for the purpose of warding off fears or relieving anxiety. Handwashing, counting, and checking are the most common.

Compulsive acts may have to be performed so many times that they seriously disrupt work and social life.

The disorder is often accompanied by depression and anxiety. If severe, a person may become housebound.

TREATMENT
Many sufferers respond well to behaviour therapy, sometimes combined with anti-depressant drugs (see selective serotonin reuptake inhibitors). Most recover within a year, but symptoms may recur under stress. For the most severely affected, OCD can be a lifelong problem.

obstetrics
The branch of medicine concerned with pregnancy and antenatal care, childbirth, and postnatal care. Obstetrics also involves the study of the structure and function of the female reproductive system. (See also gynaecology.)

obstructive airways disease
See pulmonary disease, chronic obstructive.

obstructive jaundice
A type of jaundice (yellowing of the skin and the whites of the eyes) resulting from an obstruction to the flow of bile (an alkaline liquid that carries waste products away from the liver) between the liver and the small intestine. Causes include gallstones and cancer of the pancreas (see pancreas, cancer of).

obstructive sleep apnoea
A type of sleep apnoea due to obstruction of breathing by repeated blockage of the upper airway during sleep.

occipital lobe
One of the two areas of brain tissue that lie beneath the occipital bone at the back of the brain. The occipital lobe is primarily concerned with vision.

occiput
The lower back part of the head, where it merges with the neck.

occlusion
Blockage of a passage, canal, opening, or vessel in the body. Occlusion may be caused by disease (for example, a pulmonary embolism) or may be medically induced. The term also describes eye-patching for the treatment of amblyopia (a defect of visual acuity) in children.

In dentistry, occlusion is the relationship between the upper and lower teeth when the jaw is shut. In an ideal occlu-
sion: the upper incisors and canines (front teeth) slightly overlap the lower ones; the front two upper incisors are aligned centrally with the front two lower incisors; the remaining upper teeth are positioned in an alternating pattern relative to the equivalent lower teeth; and the outer ridges of the lower premolars and molars (back teeth) fit into the hollows in the corresponding upper teeth. Very few people have an ideal occlusion, but in the majority the arrangement of the teeth allows efficient biting and chewing of food. (See also malocclusion; retinal artery occlusion; retinal vein occlusion.)

occult
Hidden or obscure. For example, the term occult blood is often used to describe blood in a sample of faeces that is not visible to the naked eye but can be detected by chemical tests.

occult blood, faecal
The presence in the faeces of blood that cannot be seen by the naked eye, but can be detected by chemical tests (see faecal occult blood test).

Faecal occult blood tests are widely used in screening for cancer of the colon (see colon, cancer of). Finding faecal occult blood may also be a sign of various gastrointestinal disorders including oesophagitis (inflammation of the gullet); gastritis (inflammation of the stomach lining); stomach cancer; cancer of the intestine (see intestine, cancer of); rectal cancer (see rectum, cancer of); diverticular disease (in which pouches form in the wall of the intestine); polyps in the colon; ulcerative colitis (inflammation and ulceration of the lining of the colon and rectum); or irritation of the stomach or intestine by drugs such as aspirin. (See also rectal bleeding.)

occupational disease and injury
Illnesses, disorders, or injuries that are the result of exposure to chemicals or dust, or are caused by physical, psychological, or biological factors that occur in the workplace. Serious occupational diseases are far less common than formerly, but still make up an important group of conditions. They include the following main categories.

DUST DISEASES
The term pneumoconiosis is used to refer to fibrosis (formation of scar tissue) in the lung due to inhalation of industrial dusts, such as coal. Asbestosis is a lung condition associated with asbestos in industry. Allergic alveolitis (inflammation of the tiny air sacs in the lungs) is caused by inhalation of organic dusts (often containing fungal spores) (see farmer’s lung).

CHEMICAL POISONING
Industrial chemicals can damage the lungs if they are inhaled, or other major organs if they enter the bloodstream through the lungs or skin. Examples of harmful chemicals include fumes of cadmium, beryllium, lead, and benzene. Carbon tetrachloride and vinyl chloride are causes of liver disease. Many of these compounds can cause kidney damage.

OCCUPATIONAL SKIN DISEASE
Work-related skin disorders include contact dermatitis (skin inflammation), which results either from allergy or from direct irritation by chemicals in contact with the skin, and squamous cell carcinoma, which may be caused by exposure to tar.

INFECTIOUS DISEASES
Rare infectious diseases that are more common in certain jobs include brucellosis and Q fever (acquired from livestock), psittacosis (acquired from birds), and leptospirosis (caused by a bacterium excreted in rat’s urine). People who work with blood or blood products are at increased risk of viral hepatitis (see hepatitis, viral) and AIDS, as are healthcare professionals.

RADIATION HAZARDS
The nuclear industry and some healthcare professions use measures to reduce the danger from radiation hazards. Exposure to certain types of radiation increases the risk of cancer.

OTHER DISORDERS
Other occupational disorders include writer’s cramp, carpal tunnel syndrome, and singer’s nodes. Raynaud’s phenomenon is associated with the handling of vibrating tools. Deafness may be caused by exposure to excessive noise.

occupational medicine
A branch of medicine that deals with the effects of various occupations on health and with an individual’s capacity for particular types of work. It includes prevention of occupational disease and injury and the promotion of health in the working population.

Epidemiology is used to analyse patterns of sickness absence, injury, illness, and death. Clinical techniques are used to monitor the health of a particular workforce. Assessment of psychological stress and hazards of new technology are part of the remit.

Occupational health risks are reduced by dust control, appropriate waste disposal, use of safe work stations and practices, limiting exposure to harmful substances, and screening for evidence of occupational disorders.

occupational mortality
Death due to work-related disease or injuries. Annual death rates (deaths per million at risk) vary widely between occupations, ranging from very low levels in clothing and footwear manufacture to very high levels in industries such as the offshore oil and gas industries. The pattern of deaths varies over time as industrial standards change. Certain diseases that take many years to develop may reflect occupational practices that have since been improved.

occupational therapy
Treatment comprising individually tailored programmes of activities to help people who have been disabled by illness or accident to improve their function and ability to carry out everyday tasks. Occupational therapy also involves recommending aids and changes to the home that help to increase an individual’s independence.

octreotide
A somatostatin analogue, a hormone that acts on the pituitary gland. Given by injection, octreotide is used mainly in the treatment of acromegaly (a rare disorder that causes abnormal enlargement of certain body parts) and hormone-secreting intestinal tumours. Octreotide is also used to prevent complications following pancreatic surgery.

Side effects of octreotide may include various gastrointestinal disturbances such as nausea, vomiting, abdominal pain and bloating, flatulence, and diarrhoea.

ocular
Relating to or affecting the eye and its structures; also the eyepiece of an optical device, such as a microscope.

oculogyric crisis
A state in which the eyes are fixed, usually upwards, for minutes or hours. The crisis may occur with muscle spasm of the tongue, mouth, and neck, and is often triggered by stress. It may occur following encephalitis (inflammation of
the brain) and in parkinsonism (a movement disorder), or may be induced by drugs such as phenothiazine derivatives.

**oculomotor nerve**

The third cranial nerve, controlling most of the muscles that move the eye. The oculomotor nerve also supplies the muscle that constricts the pupil, that which raises the upper eyelid, and the ciliary muscle, which focuses the eye.

The oculomotor nerve may be damaged due to a fracture to the base of the skull or a tumour. Symptoms of damage to the oculomotor nerve include ptosis (drooping of the upper eyelid), squint, dilation of the pupil, inability to focus the eye, double vision, and a slight protrusion of the eyeball. (See also trochlear nerve; abducent nerve.)

**LOCATION OF THE OCULOMOTOR NERVE**

The oculomotor nerve originates high in the brainstem and passes forward through a slit in the bony eye socket to reach the muscles that move the eye and eyelids.

**oedema**

Abnormal fluid accumulation in body tissues that may be localized (as in swelling from an injury) or generalized (as in heart failure).

**WATER BALANCE IN THE BODY**

Water accounts for roughly three fifths of body weight and is constantly exchanged between blood and tissues. The pressure of blood being pumped around the body forces water out of the capillaries (tiny blood vessels) and into the tissues. By a reverse process, which depends on the water-drawing power of the proteins in the blood (see osmosis), water is reabsorbed into the capillaries and lymphatic vessels from the tissues. Normally, these two mechanisms are in balance, keeping the distribution of water between the blood and tissues more or less constant.

The action of the kidneys and hormones, including ADH, regulate the total amount of fluid in the body. Any excess is excreted from the body as urine.

**CAUSES OF OEDEMA**

Various disorders can disrupt these processes. Heart failure leads to congestion in the veins, which creates backward pressure in the capillaries. This overcomes osmotic pressure in the capillaries and causes more fluid than normal to be forced into the tissues. Backward pressure can also be created by a tumour pressing on veins, causing oedema in the area drained by the obstructed vein.

In nephrotic syndrome, an abnormal loss of protein from the blood reduces osmotic pressure and prevents enough fluid being drawn from the tissues into the blood. Kidney failure prevents salt being excreted from the body, allowing it to accumulate in the tissues and attract water to it.

Other disorders that can cause oedema include cirrhosis of the liver, which leads to blood congestion in the veins of the liver, lowers blood protein (and therefore osmotic pressure), and causes salt retention. A deficiency of protein in the diet, as may occur in alcoholics, can also reduce osmotic pressure.

Injury or inflammation may lead to oedema by causing capillaries to leak. The blockage of lymphatic vessels may result in lymphoedema.

Oedema may also be caused by certain drugs, such as corticosteroid drugs, that have an action on the kidneys, resulting in salt retention.

**SYMPTOMS**

Symptoms of generalized oedema, such as swelling around the base of the spine (in bedridden people) or in the ankles, occur when excess body fluid increases by more than 15 per cent. In severe cases, fluid accumulates in large body cavities, such as the peritoneal cavity of the abdomen in ascites or the pleural cavity of the lungs in pleural effusion. In pulmonary oedema, the air sacs of the lungs become waterlogged, causing breathlessness.

**TREATMENT**

The underlying cause of the oedema should be remedied. If this is not possible, symptoms can be relieved by excretion of the excess fluid. Output of urine by the kidneys is increased by restricting dietary salt and by the use of diuretic drugs.

**Oedipus complex**

A psychoanalytic term defined as the unconscious sexual attachment of a child for the parent of the opposite sex, which is manifested by the consequent jealousy of, and desire to eliminate, the parent of the same sex.

**oesophageal atresia**

A rare birth defect in which the oesophagus forms into two separate sections during embryonic development. A short section of the oesophagus is absent, the part of the oesophagus above the gap terminates in a pouch, and the lower part of the oesophagus, projecting upwards from the stomach, may also be blind-ended. In most cases, however, the upper or lower section of oesophagus connects with the trachea (windpipe) to form an abnormal channel, called a tracheoesophageal fistula.

The condition may be suspected before birth if the mother has polyhydramnios (excess amniotic fluid); this indicates that the fetus is unable to swallow the amniotic fluid as normal.
SYMPTOMS
The infant cannot swallow saliva or milk, and drools and regurgitates milk continually. If there is an upper tracheo-
oesophageal fistula, milk may be sucked into the lungs, provoking coughing fits and cyanosis (a bluish skin coloration).

TREATMENT AND OUTLOOK
Immediate surgery is needed in order to join the blind ends of the oesophagus and close the fistula. In some cases,
more than one operation may be necessary. If surgery is successful, the baby should develop normally.

oesophageal dilatation
A procedure to stretch the oesophagus when it has been narrowed by disease (see oesophageal stricture) and swallowing
is difficult.

Endoscopy is used to locate the obstruction. The narrowed area is then stretched by passing bougies (cylindri-
cal rods with olive-shaped tips) down the oesophagus, or by using a balloon catheter (a fine tube with an inflatable
balloon at the end).

oesophageal diverticulum
A saclike protrusion of part of the wall of the oesophagus. There are two types: a pharyngeal pouch (also known as a Zenker’s or pulsion diverticulum), and a mid-oesophageal diverticulum (also known as a traction diverticulum).

PHARYNGEAL POUCH
This type is located at the top of the oesophagus, at its entrance from the pharynx (throat). The pouch usually
projects backwards. The cause is a failure of the sphincter (circular muscle) at the entrance to the oesophagus to relax
during the act of swallowing, due to muscular incoordination. Instead, the sphincter resists the passage of food. As the
powerful throat muscles used for swallowing work against this resistance, part of the lining of the oesophagus is forced through the oesophageal wall, forming the diverticulum.

Once the diverticulum is formed, it gradually enlarges. Food and fluids become trapped in it and may spill into the
trachea (windpipe), causing coughing and recurrent chest infections. The condition is usually treated surgically.

MID-OESOPHAGEAL DIVERTICULUM
This disorder consists of a pouch that is formed further down the oesophagus. It rarely causes symptoms and may only
be discovered accidentally. It does not usually require treatment.

oesophageal spasm
Uncoordinated muscle contractions in the oesophagus, which cause intermittent swallowing difficulties and chest or
upper abdominal pain. The spasm may be due to reflux oesophagitis but often occurs for no apparent reason. Women
are more commonly affected than men.

A barium swallow (see barium X-ray examinations) and endoscopy may be used to rule out a more serious condition,
such as cancer. Treatment is of any underlying cause.

oesophageal speech
A technique for producing speech after surgical removal of the larynx (voice-box) (see laryngectomy). Air is trapped in the
oesophagus and is gradually expelled while the tongue, palate, and lips form distinguishable sounds.

oesophageal stricture
Narrowing of the oesophagus that may cause pain, swallowing difficulties, regurgitation of food, and weight loss.

CAUSES
Oesophageal stricture may be due to cancer of the oesophagus (see oesophagus, cancer of) or to any of numerous noncancerous causes. These include per-
sistent reflux oesophagitis, in which constant irritation from gastric acid causes inflammation and swelling fol-
lowing by the formation of fibrous scar tissue and narrowing. In Plummer–Vinson syndrome, a web of tissue forms in the
upper oesophagus in association with iron deficiency anaemia (see anaemia, iron deficiency). A Schatzki ring (a non-
cancerous fibrous ring found in the lower oesophagus) can also cause difficulty swallowing. Prolonged use of a
nasogastric tube may inflame the oesophagus, leading to a stricture, as may swallowing a corrosive liquid.

DIAGNOSIS AND TREATMENT
A barium swallow (see barium X-ray examinations) may help to confirm the diagnosis. Endoscopy (passage of a viewing
instrument down the oesophagus) is used to look at the narrowed area, and a biopsy (removal of a sample of tis-
sue for microscopic analysis) is carried out to exclude the possibility of cancer.

In some cases, the narrowed area can be stretched by oesophageal dilatation. In cases where the narrowing is caused by
cancer, or in very rare cases where there is severe narrowing over a long segment of oesophagus (usually due to the swal-
lowing of corrosives), the affected area may have to be removed surgically. The stomach can then be drawn up into the
chest or the missing oesophagus replaced with a section of colon.

oesophageal varices
Wide veins in the walls of the lower oesophagus and, sometimes, the upper part of the stomach.

CAUSE
Oesophageal varices develop as a consequence of portal hypertension (an increase in blood pressure in the portal vein
that is usually caused by liver disease). Blood in the portal vein, passing from the intestines to the liver, meets resistance due to liver disease, and is diverted into small veins in the walls of the oesophagus and stomach. The increased blood pressure causes the veins to balloon outwards.

SYMPTOMS
There are generally no symptoms until an episode of bleeding, which results in repeated episodes of haematemesis (vomiting of blood) and the passage of black faeces. There are usually other symptoms of chronic liver disease.

TREATMENT
To control acute bleeding, urgent endo-
scopic injection of a sclerosant to seal
OESOPHAGITIS

off the affected veins is required. Alternatively, banding (in which tight rubber bands are placed around the base of each enlarged vein) may be used. Replacement of lost blood and intravenous injection of drugs to constrict the blood vessels, such as octreotide and terlipressin, are also carried out. Creation of a shunt (a surgically created passage) to direct blood away from the varices may also be considered. Despite treatment, an episode of bleeding may still prove fatal.

oesophagitis

Inflammation of the oesophagus. There are two main types: corrosive oesophagitis, caused by accidental or intentional swallowing of caustic chemicals, and reflux oesophagitis, caused by regurgitation of the stomach’s contents.

CORROSIVE OESOPHAGITIS

Chemicals that are likely to cause severe corrosive oesophagitis include many cleaning and disinfecting products. The oesophagus may rupture, with fatal consequences; alternatively it may heal but may result in an oesophageal stricture (narrowing of the oesophagus).

REFLUX OESOPHAGITIS

Reflux oesophagitis is due to poor function of the muscles in the lower oesophagus, which permits the stomach’s acidic contents to rise back into the oesophagus (see acid reflux). The main symptom, heartburn, may be worsened by alcohol, smoking, and obesity. Poor function of the lower oesophagus may be linked with a hiatus hernia, in which the top part of the stomach slides back and forth through the muscular diaphragm between the chest and the abdomen.

COMPLICATIONS

Barrett’s oesophagus is a complication of reflux oesophagitis in which cells that normally line the stomach extend up into the oesophagus. It may lead to cancer. Severe, chronic oesophagitis can cause an oesophageal stricture.

TREATMENT

The treatment for most cases of persistent reflux oesophagitis is a change of diet and lifestyle: weight loss, avoiding heavy meals, limiting alcohol intake, and stopping smoking. Antacid drugs help to reduce acidity. Surgical treatment (such as minimally invasive surgery) may be necessary for a hiatus hernia.

oesophagogastroduodenoscopy

Examination of the upper digestive tract using an endoscope (see gastroscopy).

oesophagoscop

Examination of the oesophagus using an endoscope (see gastroscopy).

oesophagus

The muscular tube that carries food from the throat to the stomach. The oesophagus is part of the digestive tract (see digestive system).

STRUCTURE

The top end of the oesophagus is the narrowest section of the entire digestive tract. It is encircled by a sphincter (circular muscle) that is normally closed but can open to allow the passage of food. A similar sphincter operates where the oesophagus joins the stomach. The oesophageal walls consist of strong muscle fibres arranged in bundles: some circular, and others longitudinal. The inner lining of the oesophagus consists of smooth, squamous epithelium that is made up of flattened cells.

FUNCTION

Powerful waves of contractions (peristalsis) pass through the muscles in the oesophageal wall, propelling food and liquids down towards the stomach and intestines for digestion. Gravity plays little part in getting food into the stomach, making it possible to drink while upside down. (See also swallowing).

oesophagus, cancer of

A malignant tumour, most common in people over the age of 50, that mainly affects the middle or lower oesophagus and leads to swallowing difficulties. Smoking and heavy alcohol intake are risk factors; people with certain disorders of the oesophagus (such as Barrett’s oesophagus) are also at increased risk.

SYMPTOMS

The tumour is often present for some time before it begins to cause symptoms. Early symptoms may include pain on, and difficulty in, swallowing foods and/or liquids. The patient’s condition progressively worsens to a point where food is immediately regurgitated and there is rapid weight loss. Regurgitated fluid spilling into the trachea (windpipe) often causes respiratory infections.

DIAGNOSIS, TREATMENT, AND OUTLOOK

Diagnosis usually involves a barium swallow (see barium X-ray examinations) to detect an obstruction in the oesophagus and a biopsy (removal of a small sample of tissue for microscopic analysis) taken during endoscopy.

Treatment depends on whether or not the cancer has spread to surrounding structures. Removal of the oesophagus may be possible in some localized, and early diagnosed, cancer. Radiotherapy may cause regression of the cancer, relieve symptoms, and occasionally cure older patients who might not be suitable for major surgery. Permanent insertion of a rigid tube (a stent) through the tumour, or laser treatment to burn through it, can help temporarily to relieve symptoms and improve nutrition.

The outlook depends on whether the cancer has spread at the time of diagnosis. In cases in which there is no spread and surgery is carried out successfully, 50 per cent of patients survive for more than five years. If the cancer is more widespread, less than a quarter of patients survive longer than one year.

ANATOMY OF THE OESOPHAGUS

A muscular tube that propels food to the stomach from the throat. The upper and lower ends are bounded by sphincters – muscular valves that open to allow food to pass through.

OESOPHAGUS

A rigid tube that propels food to the stomach from the throat. The upper and lower ends are bounded by sphincters – muscular valves that open to allow food to pass through.
Conjugated oestrogens or to protect or Estropipate

• (thrush) spreading (narrowing of the inner bone of the forearm)
• antibiotic used to treat skin, infections. Side effects may include nausea, vomiting, diarrhea, and abdominal pain.

Diethylstilbestrol in both men and women, but oestrogens have no specific function in men. When levels are low, oestrogen hormones can be replaced with oestrogen drugs.

Oestrogen–progestogen pill

An alternative name for the combined pill (see oral contraceptives).

Oestrone
See oestradiol.

Oestradiol
See estradiol.

Oestriol
See oestriol.

Oestrogen drugs

COMMON DRUGS

• Conjugated oestrogens • Diethylstilbestrol • Estradiol • Estril • Estrone • Estropipate

A group of synthetically produced drugs that are used in oral contraceptives and additionally to supplement or replace the body’s own oestrogen hormones in hormone replacement therapy (HRT). Oestrogen drugs are often used with progestogen drugs.

Oestrogen drugs should not be taken during pregnancy because they may adversely affect the fetus.

Oestrogen hormones

A group of hormones that are essential for normal female sexual development and healthy functioning of the reproductive system. In women, they are produced mainly in the ovaries and also in the placenta in pregnancy. Small amounts are produced in the adrenal glands in both men and women, but oestrogens have no specific function in men. When levels are low, oestrogen hormones can be replaced with oestrogen drugs.

Oestrogen–progestogen pill

An alternative name for the combined pill (see oral contraceptives).

Oestrone
See oestradiol.

Oestradiol
See estradiol.

Oestriol
See oestriol.

Oestrogen drugs

COMMON DRUGS

• Conjugated oestrogens • Diethylstilbestrol • Estradiol • Estril • Estrone • Estropipate • Ethinylestradiol • Mestranol

A group of synthetically produced drugs that are used in oral contraceptives and additionally to supplement or replace the body’s own oestrogen hormones in hormone replacement therapy (HRT). Oestrogen drugs are often used with progestogen drugs.

Oestrogen drugs should not be taken during pregnancy because they may adversely affect the fetus.

Oestrogen hormones

A group of hormones that are essential for normal female sexual development and healthy functioning of the reproductive system. In women, they are produced mainly in the ovaries and also in the placenta in pregnancy. Small amounts are produced in the adrenal glands in both men and women, but oestrogens have no specific function in men. When levels are low, oestrogen hormones can be replaced with oestrogen drugs.

Oestrogen–progestogen pill

An alternative name for the combined pill (see oral contraceptives).

Oestrone
See oestradiol.

Oestradiol
See estradiol.

Oestriol
See oestriol.

Oestrogen drugs

COMMON DRUGS

• Conjugated oestrogens • Diethylstilbestrol • Estradiol • Estril • Estrone • Estropipate • Ethinylestradiol • Mestranol

A group of synthetically produced drugs that are used in oral contraceptives and additionally to supplement or replace the body’s own oestrogen hormones in hormone replacement therapy (HRT). Oestrogen drugs are often used with progestogen drugs.

Oestrogen drugs should not be taken during pregnancy because they may adversely affect the fetus.

Oestrogen hormones

A group of hormones that are essential for normal female sexual development and healthy functioning of the reproductive system. In women, they are produced mainly in the ovaries and also in the placenta in pregnancy. Small amounts are produced in the adrenal glands in both men and women, but oestrogens have no specific function in men. When levels are low, oestrogen hormones can be replaced with oestrogen drugs.

Oestrogen–progestogen pill

An alternative name for the combined pill (see oral contraceptives).

Oestrone
See oestradiol.

Oestradiol
See estradiol.

Oestriol
See oestriol.

Oestrogen drugs

COMMON DRUGS

• Conjugated oestrogens • Diethylstilbestrol • Estradiol • Estril • Estrone • Estropipate • Ethinylestradiol • Mestranol

A group of synthetically produced drugs that are used in oral contraceptives and additionally to supplement or replace the body’s own oestrogen hormones in hormone replacement therapy (HRT). Oestrogen drugs are often used with progestogen drugs.

Oestrogen drugs should not be taken during pregnancy because they may adversely affect the fetus.

Oestrogen hormones

A group of hormones that are essential for normal female sexual development and healthy functioning of the reproductive system. In women, they are produced mainly in the ovaries and also in the placenta in pregnancy. Small amounts are produced in the adrenal glands in both men and women, but oestrogens have no specific function in men. When levels are low, oestrogen hormones can be replaced with oestrogen drugs.

Oestrogen–progestogen pill

An alternative name for the combined pill (see oral contraceptives).

Oestrone
See oestradiol.

Oestradiol
See estradiol.

Oestriol
See oestriol.

Oestrogen drugs

COMMON DRUGS

• Conjugated oestrogens • Diethylstilbestrol • Estradiol • Estril • Estrone • Estropipate • Ethinylestradiol • Mestranol

A group of synthetically produced drugs that are used in oral contraceptives and additionally to supplement or replace the body’s own oestrogen hormones in hormone replacement therapy (HRT). Oestrogen drugs are often used with progestogen drugs.
olfactory bulb
The swelling at the end of each olfactory nerve that deals with the sense of smell. These bulbs lie on the brain’s lower surface, just above the roof of the nose.

olfactory nerve
The first cranial nerve, which conveys sensations of smell as nerve impulses from the nose to the brain. Each of the two olfactory nerves has receptors in the mucous membrane lining the nasal cavity. These receptors detect smells and send signals along nerve fibres, which pass through tiny holes in the roof of the nasal cavity and combine to form the olfactory bulbs. From here, nerve fibres come together to form the olfactory nerve, which leads to the olfactory centre in the brain. Sense of smell may be lost or impaired due to damage to the olfactory nerves, usually as a result of head injury.

oligo-
A prefix meaning few, scanty, or little, as in oligospermia (the presence of too few sperm in the semen).

oligodendrogloma
A rare and slow-growing type of primary brain tumour that originates in the oligodendroglial cells that support brain cells. Oligodendrogloma mainly affect young or middle-aged adults. Surgical removal of the tumour can, in some cases, lead to a total cure.

oligohydramnios
A condition in which an insufficient amount of amniotic fluid surrounds a fetus in the uterus.

CAUSES
Amniotic fluid is produced partly by the placenta, but mainly from the urine produced by the fetus. Oligohydramnios may occur if the placenta is not functioning properly, which can occur in severe pre-eclampsia, or if there is an abnormality of the kidneys or bladder of the fetus. Reduced quantities of amniotic fluid may also result from leakage due to a premature rupture of the amniotic membranes.

TREATMENT AND OUTLOOK
Oligohydramnios may be suspected if the woman’s uterus is smaller than expected; diagnosis is confirmed using ultrasound scanning.

In some cases, the underlying disorder can be treated, but this may not be possible (particularly if the fetus is not developing normally). If oligohydramnios occurs early in pregnancy, it usually results in miscarriage. In later pregnancy, the pressure of the uterus on the fetus may cause a deformity such as talipes (club-foot).

oligospermia
A temporary or permanent deficiency in the number of sperm in the semen. This condition is also known as oligo-azoospermia. It may be a cause of infertility, especially when other disorders of the sperm are also present.

CAUSES
Normally, there are more than 20 million sperm per millilitre of semen. A low sperm count can be due to various disorders, including hormonal disorders, orchitis (inflammation of a testis), undescended testis (see testis, undescended), and, infrequently, a varicocele (varicose vein in the scrotum). Smoking, alcohol abuse, and some drugs may also reduce the sperm count.

TREATMENT
Treatment of oligospermia is for the underlying cause. If the cause is a hormone deficiency, gonadotrophin hormones may be prescribed. If infertility is a problem, artificial insemination within the uterus or in vitro fertilization (IVF) with intracytoplasmic sperm injection may be successful. (See also azoospermia.)

oliguria
The production of low quantities of urine in proportion to the volume of fluid taken in. The condition may be caused by excessive sweating; in some cases, it is a sign of kidney failure.

olive oil
An oil, obtained from the fruit of the olive tree Uliva Europaea, that may be used to soften earwax or to treat cradle cap in babies. Olive oil is high in monounsaturated fat (see fats and oils); it is an important part of a Mediterranean diet.

Ollier’s disease
See dyschondroplasia.

-oma
A suffix denoting a tumour, which may be cancerous or noncancerous, as in lipoma and carcinoma.

omega-3 fatty acids
A group of polyunsaturated fatty acids that are found mainly in oily fish (such as mackerel, herring, and sardines). Omega-3 fatty acids are also found in certain vegetable oils (such as rapeseed oil and soya oil) and nuts such as walnuts and peanuts.

Omega-3 fatty acids have been found to lower raised levels of triglycerides (a type of fat) in the blood. Fish-oil preparations containing omega-3 fatty acids are used to treat severe hypertriglyceridaemia, in which levels of triglycerides in the blood are greatly elevated (see...
hyperlipidaemias). The principal side effects are nausea and belching, but these are uncommon.

**omentum**
A double fold of fatty membrane in the abdomen (peritoneum) hanging in front of the intestines that acts as a fat store.

**omeprazole**
A proton pump inhibitor drug used to treat peptic ulcer, reflux oesophagitis (inflammation of the gullet), and Zollinger-Ellison syndrome. Possible adverse effects include rashes, headache, nausea, diarrhoea, and constipation.

**omphalocele**
An alternative name for exomphalos.

**onchocerciasis**
A tropical disease, also called river blindness, caused by infestation with the worm *Onchocerca volvulus*. The disease, a type of *filariasis*, affects millions of people in some regions of Africa and Central and South America.

**CAUSES AND SYMPTOMS**
Onchocerciasis is transmitted from person to person by small, fiercely biting, black simulium flies. These flies, which breed in, and always remain near, fast-running streams, ingest microfilariae (tiny worms) and inject their larvae into human skin, where they multiply and spread around the body under the skin (see the illustrated box).

The dead larvae can cause an allergic reaction resulting in inflammation and the formation of fibrous tissue. When this occurs in the eye, the damage is permanent and leads to blindness. Symptoms of the condition include itchy, swollen patches; they usually arise about a year after infestation.

**TREATMENT AND PREVENTION**
Treatment involves taking *anthelmintic drugs*, which quickly kill the microfilariae. Such treatment needs to be repeated annually because the adult worms are not affected. Travellers to areas where the disease is prevalent should take measures to discourage insect bites.

**oncogenes**
Genes found in every cell of the body that control growth, repair, and replacement. Activation of an oncogene is a factor in the development of cancerous cells. Mutations (structural changes) in oncogenes, resulting from damage by carcinogens, can cause a cell to grow uncontrollably and infiltrate and destroy normal tissues (see cancer). Factors known to encourage oncogene mutation include ultraviolet light, radioactivity, tobacco smoke, alcohol, asbestos, and some chemicals. In addition, some viruses can activate oncogenes.

**oncology**
The study of the causes, development, characteristics, and treatment of tumours, particularly cancers (malignant tumours).

Because there are many different types of tumours, developing in virtually any tissue in the body, oncology encompasses a wide range of experimental techniques and investigative approaches. These include surveying the frequency and distribution of tumours, testing new treatments, investigating the biochemical processes involved in tumour formation, and studying abnormal genes that are associated with tumours. Doctors specializing in the study and treatment of cancer are known as oncologists.

**ondansetron**
A *serotonin antagonist* drug used to control the nausea and vomiting that occur following an operation or that are induced by *radiotherapy* or *anticancer drugs*. Ondansetron is taken in the form of tablets or suppositories or is given by injection. Side effects may include constipation, headache, and hiccups.

**onychogryphosis**
Abnormal thickening, hardening, and curving of the nails that occurs mainly in elderly people. It may be associated with *fungal infection* or poor circulation, or it may occur for no apparent reason.

**onycholysis**
Separation of the nail from its bed: a feature of many skin conditions, including *psoriasis* and dermatitis.

**oocyte**
One of the cells that are found in the *ovary* that, after undergoing *meiosis* (a type of cell division), form ova (egg cells; see ovum).

**oogenesis**
The process by which mature ova (egg cells; see ovum) are produced in the female’s ovary. At birth, a female has her entire lifetime’s complement of
ooogonia (cells that divide by meiosis to develop firstly into oocytes and eventually into mature ova).

**oophorectomy**

Removal of the ovaries, usually done to treat ovarian cysts or cancer (see ovary, cancer of). A partial oophorectomy may be performed to preserve ovarian function in premenopausal women. In a hysterectomy, both ovaries may be removed if disease has spread from the uterus, or as a preventive measure. The ovaries may be removed as part of the treatment for breast cancer if growth of the tumour depends on hormones produced by the ovary. If both ovaries are removed before the onset of the menopause, hormone replacement therapy (HRT) may be needed.

**-opathy**

A suffix denoting disease or disorder, as in neuropathy (a disorder of the nerves).

**open-angle glaucoma**

An alternative name for chronic simple glaucoma, a gradual buildup of excessive fluid pressure in the eye.

**open chest massage**

Rhythmic compression that is applied directly to the heart through an incision in the chest wall in order to restart arrested heart action (see cardiac arrest). Open chest massage, which is also known as internal cardiac massage, is an emergency measure for the purpose of maintaining the circulation. It is not commonly performed.

**open fracture**

A type of fracture, also known as a compound fracture, in which the broken bone penetrates the overlying skin. An open fracture carries a greater risk of infection than a closed fracture because the skin has been punctured.

**open heart surgery**

Any operation on the heart in which it is stopped temporarily and its function taken over by a mechanical pump (a heart–lung machine). The main forms of open heart surgery include the correction of congenital heart defects (see heart disease, congenital), surgery for the repair of narrowed or leaky heart valves (see heart-valve surgery), and coronary artery bypass surgery.

---

**OPERATING THEATRE**

The operating table can be raised, lowered, and titled in any direction to allow optimum access to the patient. For some operations, it is best for the surgeon to stand but, during delicate procedures, such as microsurgery, the surgeon usually sits. The operating lamp is designed to give brilliant focal illumination without causing any shadow. The anaesthetic apparatus can maintain breathing in patients who have been given a muscle-relaxant drug.
Once the heart–lung machine has been connected, the heart is isolated, and the defects repaired. Surgical hypothermia is used to keep the heart cool and help prevent damage to the heart muscle from lack of oxygen (see hypothermia, surgical). Various techniques that enable procedures to be performed on a beating heart without the need to use a heart–lung machine are now becoming available.

**Operable**
A term applied to a condition that is suitable for surgical treatment, such as an accessible noncancerous tumour. (See also inoperable.)

**Operating theatre**
A specialized room in which surgical procedures are performed. An operating theatre is one of a suite of rooms, attached to an anaesthetic room and a recovery area. The risk of infection of open wounds during surgery is reduced by a ventilation system that continually provides clean, filtered air, and surfaces that are easily washable. Surgeons, assistants, and nurses use sterile brushes and bactericidal soaps to scrub their hands and forearms before putting on sterile gowns and gloves.

The operating theatre has a range of equipment, including shadowless operating lights; lightboxes for viewing X-ray images or scans; anaesthetic machines (see anaesthesia, general); and a diathermy machine, which is used for the control of bleeding. A heart–lung machine may also be used.

**Operation**
A surgical procedure usually carried out with specialized instruments; but sometimes only the hands are used (as in the manipulation of a simple fracture).

**Ophryosis**
Spasm (involuntary contraction) of the muscles of the eyebrow.

**Ophthalmia**
An old term for ophthalmitis.

**Ophthalmia neonatorum**
A type of eye inflammation and a discharge (ophthalmitis) that occur in newborn infants, usually as a result of being infected with the sexually transmitted diseases gonorrhoea or chlamydia at birth. Treatment of ophthalmia neonatorum is with antibiotic drugs.

**Ophthalmitis**
A term that is used to describe any inflammatory eye disorder. Types of ophthalmitis include ophthalmia neonatorum and sympathetic ophthalmitis, a rare condition in which a penetrating injury to one eye is followed by severe uveitis (inflammation of the iris and choroid) that can lead to blindness in the other eye. Sympathetic ophthalmitis can be treated with corticosteroid drugs, but it is sometimes necessary to remove the injured eye in order to preserve the sight of the other.

**Ophthalmology**
The study of the eye and the diagnosis and treatment of the disorders that affect it. Ophthalmology covers assessment of vision, prescription of glasses or contact lenses, and surgery for eye disorders, such as cataracts and glaucoma. (See also eye, examination of; optician; optometry; orthoptics.)

**Ophthalmoplegia**
Partial or total paralysis of the muscles that move the eyes. Ophthalmoplegia may be caused by a disease that affects the eye muscles themselves, such as Graves’ disease, or by a condition that affects the brain or the nerves supplying the eye muscles, such as stroke, a brain tumour, encephalitis (inflammation of the brain), or multiple sclerosis.

**Ophthalmoplegic migraine**
A type of migraine (a severe headache that is often accompanied by visual disturbances) in which movement of an eye is affected. Movement of the pupil may or may not also be affected.

**Ophthalmoscope**
An instrument that is used to examine the inside of the eye. The ophthalmoscope contains a deflecting prism or a perforated angled mirror, which allows illumination and viewing of the entire area of the back of the eye, including the light-sensitive retina.

**Opiate**
Any drug derived from, or chemically similar to, opium.

**Opioid**
A type of analgesic drug (painkiller) used in the treatment of moderate to severe pain. Opioids, also known as narcotic drugs, may be abused for their euphoric effects; abuse may cause tolerance (the need for greater amounts of a drug to get the same effect), and physical and psychological drug dependence. Opioids in common use include codeine, diamorphine, morphine, and pethidine.

**Opisthotonus**
A form of spasm in which the head is bent backwards and the back is arched. Opisthotonus may occur in people with tetanus or meningitis or as a result of a severe brain injury.

**Opium**
A substance obtained from the unripe seed pods of the poppy plant *Papaver somniferum*. Opium has an analgesic (pain-relieving) effect and may also cause sleepiness and euphoria. Opium and its derivatives, such as codeine and diamorphine, are known as opiates or opioids.

**Opportunistic infection**
Infection by organisms that rarely have serious or widespread effects in people of normal health, but which can cause serious illness or widespread infection.

---

**OPHTHALMOSCOPE**
An ophthalmoscope allows viewing of the entire area of the back of the eye, including the retina.

- **Observer’s eyehole containing lens and light**
- **Lens selection ring**
- **Handle containing battery**
in a person whose immune system is impaired. Malfunction of the immune system can be caused by diseases such as AIDS and leukaemia or by chemotherapy.

Opportunistic infections include a variety of viral, bacterial, protozoal, and fungal infections, including tuberculosis, herpes simplex, pneumonia, cryptococcosis, and candidiasis (thrush). Treatment of the infection is with the appropriate antimicrobial drugs.

**oppositional defiant disorder**
A type of behavioural disorder that usually appears in childhood or early adolescence. Typically, an affected child shows hostile, argumentative behaviour that includes loss of temper, defiance of rules, and swearing. While to some extent such behaviour is a common feature of adolescence, when law-breaking or violence occur the condition is considered pathological.

**optic atrophy**
A shrinkage or wasting of the optic nerve fibres due to disease or injury to the optic nerve. The optic nerve is responsible for carrying electrical impulses from the light-sensitive layer of the eye, the retina, to the brain, where the information is processed to produce vision.

Damage to the fibres of the optic nerve leads to blurring of vision and may result in total visual loss. Damage to the optic nerve cannot be reversed. Optic atrophy may occur without prior signs of nerve disease.

Ischaemic optic atrophy is a type of optic atrophy in which damage to optic nerve fibres is caused by an impaired blood supply. Leber’s hereditary optic atrophy is a rare genetic disorder, most common in males, that causes degeneration of the optic nerve. The nerve degeneration first becomes apparent between 15 and 45 years of age.

Optic atrophy may be diagnosed by viewing the eye using an ophthalmoscope. The optic disc (the point where the optic nerve leaves the back of the eye) appears pale or white. Vision tests may also be performed.

If the underlying cause of the atrophy is identified and treated successfully, any further damage to the optic nerve can be prevented.

**optic disc**
The area on the retina (the light-sensitive layer at the back of the eye) where nerve fibres from the eyeball join the optic nerve. The optic disc is also known as the blind spot because of its lack of light-sensitive cells.

**optician**
A person who fits and sells glasses and contact lenses. An ophthalmic optician, or optometrist, examines the eyes for myopia (shortsightedness), hypermetropia (longsightedness), presbyopia (loss of focusing power with age), or astigmatism (uneven curvature of the cornea). Opticians also screen for eye disorders, such as glaucoma, and refer patients to ophthalmologists. (See also ophthalmology, optometry).

**optic nerve**
The second cranial nerve; the nerve of vision. The two optic nerves each consist of about one million nerve fibres that transmit impulses from the retina (the light-sensitive layer at the back of the eye) to the brain. The optic nerves converge behind the eyes, where fibres from the inner halves of the retina cross over. Nerve fibres from the right half of both retinas go to the right side of the occipital lobes in the brain; and those from the left halves of the retinas go to the left side.

Disease or injury occurring at a particular point on an optic nerve leads to loss of a specific part of the visual field.

Disorders of the optic nerve include optic atrophy, optic neuritis (nerve inflammation) and papilloedema (caused by pressure on the nerve from disease in the eye socket or by a brain tumour).

**optic neuritis**
Inflammation of the optic nerve, often causing sudden loss of part of the visual field. Attacks are sometimes accompanied by pain on moving the eyes. Vision usually improves within six weeks, but some optic nerve fibres will be damaged. Recurrent attacks usually lead to permanent loss of visual acuity.

Most cases are thought to be due to demyelination of the optic nerve fibres in multiple sclerosis. The condition may also result from inflammation or infection of tissues around the optic nerve. Corticosteroid drugs may help to restore vision, but have little effect on long-term outcome. (See also optic atrophy.)

**Opticrom**
A brand name for eye-drops containing sodium cromoglicate, an antiallergy drug used to treat allergic conjunctivitis.
optimum dose
The amount of an agent, such as a
drug, that will produce a desired effect
without causing unwanted side effects.

optometry
The practice of assessing vision to estab-
lish whether glasses or contact lenses are
needed to correct a visual defect, as carried
out by an optometrist. Disorders of the eye may require treatment
by an ophthalmologist. (See also op-
thalmology, optician.)

oral
Concerning the mouth.

oral contraceptives

<table>

<tr>
<td>PROGESTOGENS</td>
</tr>
<tr>
<td></td>
</tr>
<tr>
<td></td>
</tr>
</tbody>
</table>

A group of oral drug preparations con-
taining one or more synthetic female
sex hormones that are taken by women
in a monthly cycle to prevent pregnancy.

TYPES
“The pill” commonly refers to the com-
bined or the phased pill, which both contain an oestrogen drug and a proges-
togen drug, and the minipill (or proges-
teron-only pill), which contains only a progestogen. The combined pill is taken
for three weeks out of every four; the minipill is taken continuously.

EFFECTIVENESS
When oral contraceptives are taken cor-
rectly, the number of pregnancies among
women using them for one year is less
than 1 per cent. However, actual failure
rates may be up to four times higher,
particularly for the minipill, which has to be taken at the same time each day.
If vomiting or diarrhoea occurs after a pill has been taken, the woman should follow the drug manufacturer’s advice
for a missed pill. If a woman taking oral contraceptives has missed two consecu-
tive menstrual periods, she should have a pregnancy test.

HOW THEY WORK
Combined and phased pills increase
oestrogen and progesterone levels. This interferes with the production of two
hormones, luteinizing hormone (LH) and follicle-stimulating hormone (FSH), which in turn prevents ovulation. The minipill
works partly by making the mucus lin-
ing of the cervix (the neck of the womb)
too thick to be penetrated by sperm.

HOW ORAL CONTRACEPTIVES WORK

Combined pills (including phased pills) increase the levels of oestrogen and progesterone in the body, which interferes with the production by the pituitary gland of two gonadotrophin hormones called follicle-stimulating hormone (FSH) and luteinizing hormone (LH). This action in turn prevents ovulation.

The progesterone-only pill (the minipill) works partly by making the mucus that lines the inside of the cervix (neck of the uterus) so thick that it is impenetrable to sperm.

Possible adverse effects
Possible side effects of oestrogen-con-
taining (combined) pills include nausea, weight gain, depression, breast tender-
ness, increased appetite, reduced sex drive, leg cramps, abdominal cramps, headaches, and dizziness. They can also cause occasional spotting (slight blood
loss) in between periods, early in the cycle. More seriously, there is a small increase in the risk of thrombosis (an abnormal blood clot) occurring that may lead to a stroke or a pulmonary embolism. Oestrogen-containing pills may also aggravate heart disease, or they may cause gallstones, jaundice, and, very rarely, liver cancer. There is a small increase in the long-term risk of breast cancer occurring for women taking the combined pill.

CONTRAINDICATIONS

Oestrogen-containing pills are generally not recommended for use by women with liver disease, migraine, worsening otosclerosis (an ear disorder), or women at increased risk of thrombosis. They are not usually prescribed to a woman with a personal or family history of significant heart or circulatory disorders or to a woman who suffers from unexplained vaginal bleeding.

Combined or phased pills may interfere with milk production and should not be taken during breast-feeding.

Certain drugs, such as some antibiotic drugs or anticonvulsant drugs, may impair the effectiveness of oral contraceptives; a doctor should always be consulted. (See also contraception.)

oral hygiene

Measures that are used to keep the mouth and teeth clean and to reduce the risk of tooth decay (see caries, dental), gingivitis and other gum disorders, and halitosis (bad breath). Oral hygiene includes regular, thorough toothbrushing and flossing (see floss, dental) in order to remove plaque (a sticky coating that forms on the teeth and consists of saliva, bacteria, and food debris). Disclosing agents can be used to help to reveal areas of plaque build-up. Dentures are brushed on all surfaces and soaked in cleansing solution.

Professional treatment to remove calculus (a mineral deposit that forms on teeth) and stubborn plaque by scaling and polishing is usually carried out by a dentist or dental hygienist during a routine check-up. In periodontal disease, treatment may be needed more often.

oral phase

A term that is used in psychoanalytic theory to refer to the earliest stage of a person’s psychosexual development. The oral phase is thought to last from birth to about 18 months of age. (See also anal phase; genital phase.)
orf
A skin infection occasionally transmitted to humans from sheep. Caused by a pox virus, orf usually produces a single persistent, fluid-filled blister on the arm or hand. The antiviral drug idoxuridine may hasten recovery.

organ
A collection of various tissues integrated into a distinct structural unit to perform specific functions. For example, the brain consists of nerve tissue and support tissue that is organized to receive, process, and send out information.

organ donation
The agreement of a person (or of his or her family) to the surgical removal of one or more of the organs for use in transplant surgery.

Most organs that are commonly used for transplantation, such as the heart, lungs, liver, and kidneys, are removed immediately after death. Heart and lung function is sometimes maintained by machine after brain death has been certified until the organs have been removed. Living donors may be able to give a kidney, but usually only to a close relative (see tissue-typing).

Although it is not legal in the UK, in some countries, organ donors are paid for their organs. People can facilitate use of their organs after death by informing relatives and carrying a donor card. (See also corneal graft; heart–lung transplant; heart transplant; heart-valve surgery; kidney transplant; liver transplant.)

organelle
One of various specialized structures contained within a body cell.

organic
Related to a body organ; having organs or an organized structure; or related to organisms or to substances from them.

In medicine, the term indicates the presence of disease in the body.

In chemistry, the term refers to certain compounds that contain carbon. (See also inorganic.)

organic brain syndrome
See brain syndrome, organic.

organic disease
A term used to refer to any disorder that is associated with changes in the structure of an organ or tissues. (See also functional disorder.)

organism
A general term for an individual animal or plant. Bacteria and viruses are disease-causing microorganisms.

organ of Corti
A structure involved in hearing that is situated in the cochlea of the inner ear. Sensory hair cells in the organ of Corti vibrate in response to sounds and translate them into electrical impulses that travel via the cochlear nerve to the brain.

organomegaly
Abnormal enlargement of the body’s internal organs, such as hepatomegaly (enlargement of the liver).

organophosphates
Highly poisonous agricultural insecticides that are harmful when absorbed through the skin, by inhalation, or by swallowing. Among the many possible symptoms are nausea, vomiting, abdominal cramps, diarrhoea, blurred vision, excessive sweating, headache, confusion, and twitching. In cases of severe poisoning, breathing difficulty, palpitations, seizures, and unconsciousness may occur. If left untreated, death may result.

Treatment may include washing out the stomach (see lavage, gastric) or removing soiled clothing and washing contaminated skin. Injections of atropine may be administered, and oxygen therapy and/or artificial ventilation may be needed. With rapid treatment, people may survive doses that would otherwise have been fatal. Long-term effects of organophosphates in sheep dippers are thought to be responsible for debilitating illness with neural, muscular, and mental symptoms.

orgasm
Intense sensations produced by a series of muscular contractions at the peak of sexual excitement. Orgasm usually lasts for about three to ten seconds but can last up to a minute in women.

In men, contractions of the muscles of the inner pelvis massage semen into the urethra; the semen is then forcefully propelled through the urethral orifice (see ejaculation).

Orgasm in women is associated with irregular contractions of the voluntary muscles of the walls of the vagina and, in some women, of the uterus, followed by relief of congestion in the pelvic area. Some women experience multiple orgasms if stimulation is continued.

Orgasm is usually followed by a refractory phase during which there is no physical response to further sexual stimulation. Both men and women may experience problems with orgasm (see ejaculation, disorders of; orgasm, lack of).

orgasm, lack of
Inability to achieve orgasm during sexual activity. The problem is more common in women than men. In either sex, failure to achieve orgasm may be due to inhibited sexual desire (see sexual desire, inhibited) or inability to become aroused or maintain arousal (see frigidity, impotence). In men, there may be a problem achieving orgasm despite normal arousal (see ejaculation, disorders of).

In women, lack of orgasm is the most common sexual problem, affecting up to 50 per cent of women at some time in their lives. Some are unable to achieve orgasm under any circumstances, others experience orgasm only occasionally.

For both sexes, contributory factors include problems with sexual technique or a relationship, lack of familiarity with sexual responses, psychological problems (such as anxiety, early sexual trauma, or inhibitions), and the fear of becoming pregnant.

Sex therapy, relationship counselling, and psychotherapy may be helpful.

orifice
A term used in anatomy to refer to any opening in the body, especially an entrance or outlet of a body cavity. An example of an orifice is the mouth.

orlistat
An anti-obesity drug used with a slimming diet to treat severe obesity. Unlike appetite suppressants, orlistat acts on the gastrointestinal tract, preventing the digestion of fats by lipases (pancreatic enzymes). Instead of being absorbed, the fats pass out of the body in faeces.

Side effects are gastrointestinal in nature and can be minimized by reducing fat intake. Flatulence and faecal urgency are common. Deficiencies of fat-soluble vitamins may develop with prolonged use of orlistat.

ornithosis
A disease of birds, caused by the microorganism Chlamydia psittaci, that can cause psittacosis in humans.

oro-
A prefix pertaining to the mouth.
**Orphan Drugs**

Drugs that have been developed to treat rare conditions but are not manufactured generally.

**Orphenadrine**

A muscle-relaxant drug used to treat the movement disorder Parkinson’s disease. Side effects of orphenadrine include a dry mouth and blurred vision.

**ORT**

The abbreviation for oral rehydration therapy. (See also rehydration therapy.)

**Ortho-**

A prefix meaning normal, correct, or straight, as in orthopaedics, a branch of surgery concerned with correcting disorders of the bones and joints.

**Orthodontic Appliances**

Fixed or removable devices, commonly known as braces, worn to correct malocclusion (an abnormal relationship between the upper and lower teeth) or to reposition overcrowded or buck teeth. Usually fitted during childhood and adolescence, a brace moves teeth using sustained gentle pressure.

A fixed appliance has brackets attached to the teeth through which an arch wire is threaded and tightened to exert pressure. These are usually kept in place for about a year, after which time a retainer plate may be needed to hold the teeth in place until tooth and jaw growth has finished.

Removable appliances, which consist of a plastic plate with attachments that anchor over the back teeth, are used when only one or a few teeth need correcting. They apply force by means of springs, wire bows, screws, or rubber bands fitted to the plate.

**Orthodontics**

A branch of dentistry concerned with prevention and treatment of malocclusion (an abnormal relationship between the upper and lower teeth). The procedures are usually performed while teeth are developing and relatively manoeuvrable but may also be of benefit in adulthood.

An orthodontist may first make models of the teeth (see impression, dental) and take X-rays of the head and jaws. Certain teeth, often premolars, may be extracted to make room for the remaining teeth. Poorly positioned teeth are then moved by gentle pressure exerted by orthodontic appliances.

**Orthognathic Surgery**

Operations to correct deformities of the jaw and the severe malocclusion (abnormal relationship between the upper and lower teeth) that is associated with them.

Orthognathic surgery is performed under general anaesthesia. A jaw that projects too far can be shortened by removing a block of bone from each side and manoeuvring the front of the jaw backwards. A jaw that is too short can be reshaped by dividing the bone on each side, sliding the front of the jaw forwards, and inserting bone grafts (taken from elsewhere in the body) into the gaps. After repositioning, the jaw bones often require wiring together (see wiring of the jaws) until they have healed.

**Orthomyxovirus**

One of a family of viruses that includes the microorganisms responsible for respiratory tract diseases, especially influenza.
orthopaedics
The branch of surgery concerned with disorders of the bones and joints and their associated muscles, tendons, and ligaments. Orthopaedic procedures include setting broken bones and applying casts; treating slipped discs, dislocations, arthritis, and back problems; treating bone tumours and birth defects of the skeleton; and repairing or replacing hip, knee, or finger joints. (See also brace, orthopaedic; collar, orthopaedic.)

orthopnoea
Difficulty in breathing when lying flat. Orthopnoea is a symptom of heart failure (the heart is no longer pumping blood efficiently) and pulmonary oedema (an accumulation of fluid in the lungs), and also occurs with asthma and chronic obstructive pulmonary disease (see pulmonary disease, chronic obstructive).

orthoptics
Techniques used mainly in children to measure and evaluate squint, including eye exercises, assessment of monocular and binocular vision, and measures to combat amblyopia (lazy eye).

orthostatic hypotension
Also called postural hypotension, low blood pressure that occurs on standing. Orthostatic hypotension may be caused by treatment with antihypertensive drugs or the failure of nerves that control the diameter of the blood vessels, often as a result of diabetes mellitus.

orthotics
Use of appliances to support or correct weakened or deformed limbs, joints, or other parts of the body.

os
An anatomical term for a bone. Os also refers to an opening in the body, as in the cervical os (entrance to the uterus).

Osgood–Schlatter disease
Painful enlargement and tenderness of the tibial tuberosity, the bony prominence of the tibia (shin) just below the knee. The condition occurs most commonly in boys aged between 10 and 14 years of age. It may be the result of excessive, repetitive pulling of the quadriceps muscle at the front of the thigh due to repeated exercise. There is usually pain above and below the knee, which is worse during strenuous activity, and the tibial tuberosity is tender when touched. The disorder often clears up without treatment as long as sporting activity is restricted; severe pain may require physiotherapy or immobilization in a plaster cast.

Osler’s disease
A rare inherited condition in which capillaries (tiny blood vessels) in the skin and mucous membranes, such as those lining the mouth and nose, become dilated, forming red spots. The condition, which is also known as hereditary haemorrhagic telangiectasia, is an autosomal dominant genetic disorder.

The lesions may bleed easily. Nosebleeds are a common symptom and may begin in childhood. Lesions may also develop in the digestive tract, causing recurrent bleeding leading to anaemia; in the lungs, causing blood to be coughed up; or in the brain, causing tissue damage and seizures.

Anaemia can be countered with iron supplements. In some cases, laser treatment is used to seal the lesions.

osmosis
The passage of a solvent from a weaker solution to a more concentrated one through a semipermeable membrane. All body cells are surrounded by such membranes, which allow water, salts, simple sugars (such as glucose), and amino acids (but not proteins) to pass through. Therefore, osmosis plays an important part in regulating the distribution of water and other substances that are present in body tissues.

osmotic diuresis
An increased output of urine by the kidneys due to the presence of one or more substances in the urine that draw water from the blood into the urine. Excessive amounts of glucose in the urine, as a result of diabetes mellitus, can produce this effect; another possible cause is treatment with one of the osmotic diuretic drugs, such as mannitol.

osseous
Bony or bonelike. The term “osseous” is sometimes used to refer to the bony parts of the inner ear. (See also bone.)

ossicle
A small bone, especially any of the three tiny bones in the middle ear (malleus, incus, and stapes) that are involved in conducting sound from the eardrum to the inner ear.

ossification
The process by which bone is formed, renewed, and repaired, which starts in the embryo and continues throughout a person’s life. There are three main situations in which ossification occurs: bone growth, during which new bone forms at the epiphyses (ends) of bones; bone renewal as part of normal regeneration; and bone repair, which occurs following a fracture.

In newborn babies, the diaphysis (bone shaft) has begun to ossify and is composed mainly of bone tissue, while the epiphyses are made of cartilage that gradually hardens. In children, growth plates produce new cartilage to lengthen the bones and further bone forms at secondary ossification centres in the epiphyses. By the age of 18, the shafts, growth plates, and epiphyses have all ossified and fused into continuous bone, allowing no further growth.

Ossopan
A brand name for hydroxyapatite, a calcium supplement used in the treatment of osteoporosis (loss of bone tissue).

osteitis
Inflammation of bone. The most common cause is infection, usually by bacteria (see osteomyelitis). Other causes of osteitis include Paget’s disease and hyperparathyroidism (overactivity of the parathyroid glands).

osteitis deformans
An alternative term for Paget’s disease.
OSTEO-
A prefix that is used to denote a relationship to bone, as in osteoporosis, which is a condition that causes the bones to become thin and weaken.

osteoarthritis
A common joint disease, osteoarthritis is characterized by degeneration of the cartilage that lines the joints or by formation of osteophytes (bony outgrowths), leading to pain, stiffness, and occasionally loss of function. Osteoarthritis is the most common form of arthritis. Cervical osteoarthritis is a particular form of osteoarthritis that affects mainly the joints between the cervical vertebrae (the bones in the neck).

CAUSES AND SYMPTOMS
Osteoarthritis is due to inflammation and destruction of the cartilage that occurs at joint surfaces and changes to the bone beneath. This condition is most likely to occur in the weight-bearing joints as well as in any joints that have previously suffered some kind of damage. However, these are not the only causes. Genetic factors may be involved in cases in which osteoarthritis affects the joints.

Evidence of osteoarthritis can be seen on X-rays of almost everyone over the age of 60; however, not all of these people have symptoms. Factors that lead to the development of osteoarthritis at an earlier age include excessive wear of, or injury to, a joint; congenital deformity or misalignment of the bones in a joint; obesity; or inflammation from another disease such as gout. Severe osteoarthritis affects about three times as many women as men.

OSTEOARTHRITIS
Osteoarthritis differs from rheumatoid arthritis and has a better outlook. It is characterized by degeneration of cartilage or by formation of bony outgrowths (osteophytes). It results from excessive wear on joints or to slight deformity or misalignment of bones in a joint. Inflammation from a disease, such as osteoarthropathy, hypertrophic pulmonary

OSTEOARTHRITIS
A bone disorder almost always associated with lung cancer. Symptoms include pain and swelling of the wrists and ankles, accompanied by clubbing of the fingers. The condition will disappear if the underlying cancer is treated successfully. Symptoms can be partially relieved with nonsteroidal anti-inflammatory drugs.

osteoarthropathy, hypertrophic pulmonary
A painful, noncancerous bone tumour that is characterized by the formation of osteoid tissue and primitive bone. Osteoblastomas most commonly occur in the spine of a young person.

osteocondritis dissecans
Degeneration of a bone just under a joint surface, causing fragments of bone and cartilage to become separated; this may cause the joint to lock. The condition commonly affects the knee and usually starts in adolescence. Symptoms include aching discomfort and intermittent swelling of the affected joint.

If a fragment has not completely separated from the bone, the joint may be immobilized in a plaster cast to allow reattachment to occur. Loose bone or cartilage fragments in the knee are removed during arthroscopy. Disruption to the smoothness of the joint surface increases the risk of osteoarthritis.
osteocondritis juvenilis
Inflammation of an epiphysis (growing end of bone) occurring in children and adolescents. Osteochondritis juvenilis causes pain, tenderness, and restricted movement if the epiphysis forms part of a joint. The inflammation leads to softening of the bone, which may result in deformity. The condition may be due to disruption of the bone’s blood supply. There are several types of osteochondritis juvenilis: Perthes’ disease; Scheuermann’s disease, which affects several adjoining vertebrae; and other types that affect certain bones in the foot and wrist.

The affected bone may need to be immobilized in an orthopaedic brace or plaster cast. In Perthes’ disease, surgery may be required to prevent more deformity. The bone usually regenerates within three years and hardens, but deformity may be permanent and increases the risk of osteoarthritis in later life.

osteochondroma
A noncancerous bone tumour, which is formed from a stalk of bone capped with cartilage, and appears as a hard round swelling near a joint. An osteochondroma develops in late childhood and early adolescence, usually from the side of a long bone near the knee or shoulder. The tumour causes problems only if it interferes with the movement of tendons or the surrounding joint, in which case surgical removal may be necessary. Large osteochondromas can interfere with skeletal growth, and may cause deformity.

osteochondrosis
See osteochondritis juvenilis.

osteodystrophy
Any generalized bone defect caused by metabolic disorders. Types of osteodystrophy include rickets; osteomalacia; and bone cysts and bone mass reduction associated with chronic kidney failure or hyperparathyroidism (overactivity of the parathyroid glands). In adults, an osteodystrophy is usually reversible if the underlying cause is treated before bone deformity occurs.

osteogenesis imperfecta
A congenital characteristic by abnormally fragile bones that are unusually susceptible to fractures.

CAUSE AND SYMPTOMS
The condition is caused by an inherited defect in the connective tissue that forms the basic material of bone. Severely affected infants are born with multiple fractures and a soft skull and they do not usually survive. Other sufferers have many fractures during infancy and childhood, often as a result of normal handling and activities, and it may be difficult to distinguish the condition from child abuse.

A common sign of osteogenesis imperfecta is that the whites of the eyes are abnormally thin, making them appear blue. Sufferers may also be deaf as a result of otosclerosis. In very mild cases, osteogenesis imperfecta may not be detected until adolescence or later.

TREATMENT AND OUTLOOK
There is no specific treatment for the condition. Fractures are immobilized and usually heal quickly, but they may cause shortening and deformity of the limbs, resulting in abnormal, stunted growth. Skull fractures may cause brain damage or death. Parents may have genetic counselling to estimate the risk of the condition occurring in future children. Severe cases can be diagnosed prenatally by ultrasound scanning.

osteogenic sarcoma
See osteosarcoma.

osteoid osteoma
A bone disorder in which a tiny abnormal area of bone, usually in a long bone, causes deep pain, which is typically worse at night. The condition is cured by removing the area of bone. (See also osteoma.)

osteoma
A hard, noncancerous, usually small tumour that may occur on any bone in the body. Surgical removal of the osteoma may be necessary if it causes symptoms through pressing on surrounding structures.

osteomalacia
The softening, weakening, and demineralization (loss of essential minerals) of an adult’s bones as a result of a deficiency of vitamin D. Rickets is the equivalent disease in children.

The development and maintenance of healthy bone requires an adequate intake of calcium and phosphorus from the diet, but these minerals cannot be absorbed by the body without a sufficient amount of vitamin D. This vitamin is obtained from certain foods and from the action of sunlight on the skin.

CAUSES
Osteomalacia can be caused by a variety of factors, including: insufficient vitamin D in the diet (for example, due to lack of butter, fish, eggs, or fish-liver oils); insufficient exposure to sunlight; or inadequate absorption of vitamin D from the intestine (see malabsorption), caused by a disorder such as coeliac disease, or following intestinal surgery. Rare causes include kidney failure, acidosi (increased acidity of body fluids), and certain inherited metabolic disorders.

Osteomalacia is uncommon in developed countries, but it may affect people who have poor diets (especially dark-skinned people who have little exposure to sunlight).

SYMPTOMS
Osteomalacia causes bone pain, especially in the neck, legs, hips, and ribs. In addition, muscle weakness, particularly at the hips, can make it very difficult to stand up and to climb stairs. If the blood calcium level is very low, there may be tetany (muscle spasms) in the hands, feet, and throat. Weakened bones are vulnerable to distortion and fractures, which are often painless.

TREATMENT
Treatment is with a diet rich in vitamin D and regular supplements. Calcium supplements may also be given.

osteomyelitis
Infection, usually by bacteria, of bone and bone marrow. It is relatively rare in developed countries but is more common in children, most often affecting the long arm and leg bones and vertebrae; in adults, it usually affects the vertebrae. The condition may be either acute or chronic.

ACUTE OSTEOMYELITIS
In acute osteomyelitis, the infection (which is usually caused by the bacterium Staphylococcus aureus) enters the bloodstream via a skin wound or as a
result of infection elsewhere in the body. The infected bone and marrow become inflamed; pus forms, causing fever, severe pain and tenderness in the bone, and inflammation and swelling of the skin over the affected area.

Prompt treatment with high doses of antibiotic drugs, initially given intravenously and continued over several weeks or months, usually cures acute osteomyelitis. If the condition fails to respond, surgery has to be performed to remove infected and dead bone and drain away any pus.

**CHRONIC OSTEOMYELITIS**

Chronic osteomyelitis may develop if acute osteomyelitis is neglected or fails to respond to treatment; after a compound fracture; or due to infection of the bone with *Mycobacterium tuberculosis*, which causes tuberculosis.

The condition causes constant pain in the affected bone. Complications include persistent deformity and, in children, arrest of growth in the affected bone. Involvement of the spine can result in damage to the spinal cord if the condition is not treated. In the later stages of the disease, *amyloidosis* (abnormal deposits of a starchy substance in vital organs) may develop.

Chronic osteomyelitis requires surgical removal of all affected bone, sometimes followed by a bone graft; anti-biotic drugs are also prescribed.

**Osteopathy**

A system of diagnosis and treatment that recognizes the role of the musculo-skeletal system in the healthy functioning of the body. The basic principle of osteopathy is that all body systems operate in unison, and that disturbances in one system can alter the functions of some others. The osteopath uses manipulation, rhythmic stretching, and pressure to restore movement to the joints. He or she also uses traditional diagnostic and therapeutic procedures to diagnose and treat dysfunction.

**Osteopenia**

Any decrease in bone mass below the normal level. The term is used particularly to refer to a decrease in mass that occurs when the body makes too little new bone to compensate for normal bone lysis (breakdown or destruction). Osteopenia can occur throughout the skeleton or may be confined to a specific area, such as the bones adjacent to a diseased or damaged joint.

**Osteopetrosis**

A very rare inherited disorder in which bones harden and become denser. Deficiency of one of the two types of bone cell responsible for healthy bone growth results in a disruption of normal bone structure. In its mildest form, there may be no symptoms. More severe forms result in abnormally high susceptibility to fractures; stunted growth; deformity; and anaemia. Pressure on nerves may cause blindness, deafness, and facial paralysis.

Most treatments for osteopetrosis aim to reduce the severity of symptoms. Bone marrow transplants of cells from which healthy bone cells might develop are undertaken in some cases.

**Osteophyte**

An outgrowth of bone at the boundary of a joint. The formation of osteophytes is a characteristic feature of *osteoarthritis* that contributes to the deformity and restricted movement of affected joints.

**Osteoporosis**

A disease in which there is loss of bone tissue (and so loss of bone density), causing bones to become brittle and fracture easily.

**CAUSES**

Thinning of the bones is a natural part of the aging process. However, women are especially vulnerable to loss of bone density after the menopause, because their ovaries no longer produce *oestrogen* hormones, which help maintain bone mass.

Other causes of osteoporosis include premature removal of the ovaries; a diet that is deficient in calcium; certain hormonal disorders, such as an overactive thyroid gland (see *hyperthyroidism*); long-term treatment with corticosteroid drugs; and prolonged immobility. Osteoporosis is most common in heavy smokers and drinkers, and in very thin people.

**SYMPTOMS**

Osteoporosis may go undiagnosed for many years. The first sign is often a fracture, typically at the wrist or the top of the femur (thigh bone), after which there may have been a trivial injury. One or several vertebrae may fracture spontaneously and cause the bones to crumble, leading to progressive height loss and/or pain due to compression of spinal nerve roots.

**DIAGNOSIS AND TREATMENT**

Osteoporosis is confirmed by the use of bone densitometry. Bone loss can be minimized by adequate dietary calcium and regular, sustained exercise to build the bones and maintain their strength.

**Bisphosphonate drugs** may be used to prevent and treat bone loss following the menopause. Long-term *hormone replacement therapy* (HRT) is now usually only advised for women who cannot take other treatments or in whom other treatments have been unsuccessful. Women who have gone through a premature menopause before the age of 40 may be advised to have HRT until the age of 50 to protect them against osteoporosis; for these women, the health risks of HRT are thought to be less than normal.

**Osteosarcoma**

A cancerous tumour of the bone that can spread to the lungs and, less commonly, to other areas. An osteosarcoma usually develops in people between the ages of ten and 25, generally in a long bone of the arm or leg, often around the knee. Osteosarcomas may also be seen in elderly people as a rare complication of *Paget’s disease* or of previous treatment with *radiotherapy*. The tumour causes pain and swelling of the affected bone if it occurs near the surface.

In the past, amputation of the affected limb was inevitable. However, the outlook has improved due to a combination of *chemotherapy* and surgery in which the diseased bone is replaced with a custom-made *prosthesis*.

**Osteosclerosis**

Increased bone density, which is visible on X-rays as an area of extreme whiteness. Localized osteosclerosis may be caused by a severe injury that compresses the bone, the joint disorder *osteitis deformans*, chronic osteomyelitis (bone infection), or an osteoma (noncancerous bone tumour). Osteosclerosis occurs throughout the body in the inherited bone disorder *osteopetrosis*.

**Osteotomy**

Surgery to alter the alignment or length of a bone, by cutting it. Osteotomy is used to correct *hallux valgus* (a deformity of the big toe) that has caused a bunion; *coxa vara* (a deformity of the hip); or deformity caused by congenital hip dislocation (see *hip, congenital dislocation of*). Osteotomy is also used to straighten a long bone that has healed crookedly after a fracture, or to shorten the uninjured leg if a fractured leg has shortened during healing (see *leg, shortening of*).

**Ostium**

An anatomical term for an opening.
OTOACOUSTIC EMISSION

**OTOACOUSTIC EMISSION**

In osteoporosis, the density of bones decreases, and their brittleness increases, although there is no change in size or composition. Women past the menopause are the most commonly affected because their ovaries no longer produce oestrogen, which helps to maintain bone mass. The risk of the condition is greater in a woman who undergoes the menopause early, or whose mother had osteoporosis.

**Diagram:**
- **Normal bone cross-section:** Bone consists of fibres of collagen (a protein), which give elasticity, and calcium, which gives hardness.
- **Osteoporotic bone:** Thinning is mainly due to loss of collagen, which takes calcium with it. Both hard and spongy bone tissues are affected.

**-ostomy**
A term that is used to describe a surgical opening (for example, colostomy) or a junction of two hollow organs.

**otalgia**
The medical term for earache.

**OTC drug**
See over-the-counter drug.

**otitis externa**
Inflammation of the outer-ear canal, commonly due to infection (see Ear infections box, overleaf). It usually causes swelling, a discharge, and, in some people, eczema around the opening of the ear canal. The ear may be itchy and painful and blocked with pus, causing deafness.

**CAUSES**
Generalized infection of the canal, and sometimes of the pinna (external ear), may be due to a fungal or bacterial infection. The ear may also sometimes become inflamed as part of a generalized skin disorder such as atopic eczema or seborrhoeic dermatitis.

**TREATMENT**
Often, the only treatment required is to keep the ear clean and dry until the infection has cleared. Locally acting preparations that contain antibiotic drugs, antifungal drugs, or corticosteroid drugs may be used. Oral antibiotics may be given to treat bacterial infections if they are severe.

**otitis media**
Inflammation of the middle ear, the cavity between the eardrum and the inner ear, (see Ear infections box, overleaf).

**CAUSES**
This condition is due to a viral or bacterial infection that has usually travelled up the eustachian tube, the passage that runs from the back of the nose to the middle ear. The tube may become blocked by inflammation or enlarged adenoids, causing fluid and/or pus to accumulate in the middle ear rather than draining away through the tube. Children, particularly those under seven years, are especially susceptible to otitis media because of the shortness of their eustachian tubes; some children have recurrent attacks.

**SYMPTOMS**
Acute otitis media can cause sudden severe earache, a feeling of fullness in the ear, deafness, tinnitus (ringing or buzzing in the ear) and fever. The eardrum may burst, discharging pus and relieving pain, in which case healing usually occurs within a few weeks.

**DIAGNOSIS AND TREATMENT**
The condition is diagnosed by examination of the middle ear with an otoscope; the eardrum appears red and may bulge outwards. Treatment is with analgesic drugs (painkillers). Antibiotic drugs may be prescribed if the infection is bacterial.

**COMPLICATIONS**
A complication of otitis media is glue ear, in which a thick fluid builds up in the ear and affects hearing. Glue ear may follow severe or recurrent otitis media, which occurs mainly in children.

In rare cases, the infection spreads inwards to cause mastoiditis (inflammation of the mastoid bone in the skull).

**oto-**
Pertaining to the ear, as in otorrhoea (discharge from the ear).

**otoacoustic emission**
An echo emitted by the inner ear in response to sound. The emission is produced only by a normally functioning ear and is recorded in a test to detect impaired hearing.

---

**Bone loss with age**
The graph on the right shows how the percentage of bone lost increases in both sexes from age 50 onwards, with the losses particularly marked in women after the menopause. By age 80, up to half of all women have sustained at least one fracture due to osteoporosis, a much higher proportion than in men.

**Diagram:**
- **Bone tissue affected by osteoporosis:** When compared with normal bone tissue (left), the osteoporotic bone (right) is far less dense and appears thin and brittle.

Women | Men

**Diagram:**
- **Bone loss with age:** The graph on the right shows how the percentage of bone lost increases in both sexes from age 50 onwards, with the losses particularly marked in women after the menopause. By age 80, up to half of all women have sustained at least one fracture due to osteoporosis, a much higher proportion than in men.
Inflammation of the middle ear (otitis media) or ear canal (otitis externa) usually results from infection and may cause earache. Otitis media is more common in children and may be acute (with sudden onset of pain) or chronic (continuing over a long period).

Otitis media
This usually occurs through spread of infection from the back of the nose to the middle ear via the eustachian tube.

Otitis externa – infection spreads from outside
The ear canal is susceptible to infection if it is moist (after swimming) or damaged by attempts to remove earwax.

**OTOMYCOSIS**

A fungal ear infection that causes inflammation of the ear canal and the external ear (see *otitis externa*).

**Otoplasty**
Cosmetic surgery on the external ear, usually carried out to make protruding ears lie closer to the head. Otoplasty may also be performed to construct a missing ear in a child born with part or all of one missing, or to reconstruct a damaged ear.

**Otorhinolaryngology**
A surgical specialty, also known as ENT surgery, concerned with diseases of the ear, nose, and throat. ENT specialists treat sinus problems, *otitis media*, *tonsillitis*, minor hearing loss, *otosclerosis*, Ménière’s disease, airway problems in children, uncontrollable nosebleeds, and cancer of the *larynx* (voicebox) and *sinuses*.

**Otorrhoea**
A discharge of pus or other fluid from the ear (see *ear, discharge from*).

**Otosclerosis**
A disorder of the middle ear that causes progressive deafness. The condition usually develops in both ears.

Otosclerosis occurs when overgrowth of bone immobilizes the *stapes* (the innermost one of the three tiny bones in the middle ear). As a result, sound vibrations are prevented from passing along the bone to the inner ear. Otosclerosis frequently runs in families, and symptoms usually start to appear in early adulthood. The condition affects more women than men, and often develops during pregnancy.

**SYMPTOMS AND SIGNS**
To an affected person, sounds are muffled but can be distinguished more easily if there is background noise.

Hearing loss progresses slowly over 10 to 15 years and is often accompanied by *tinnitus* (ringing in the ears) and, more rarely, *vertigo* (a spinning sensation). A degree of sensorineural deafness may develop, making high tones difficult to hear and causing the sufferer to speak loudly.

**DIAGNOSIS AND TREATMENT**
The condition is diagnosed by *hearing tests*. It can be cured by *stapedectomy*, a surgical procedure in which the stapes is replaced by a tiny piston, which moves through a hole created in the inner ear. Because the piston can move freely, it can transmit sound vibrations to the inner ear. Alternatively, a *hearing-aid* can markedly improve hearing.

**Otoscope**
An instrument, also called an auroscope, for examining the outer-ear canal and the eardrum. An otoscope illuminates and magnifies the inside of the ear. Otoscopy (examination using an otoscope) is performed in order to detect physical abnormalities such as inflammation or pus in the outer-ear canal (see *otitis externa*) and distortion or rupture of the eardrum.

**Ototoxicity**
Toxic damage to the structures of the inner ear. High doses of certain drugs, such as *aminoglycoside* antibiotics, may cause this type of ear damage, resulting in impaired hearing and balance.

**Otrivine**
A brand name for *xylometazoline*, a *decongestant drug* that is used in the treatment of allergic *rhinitis* to relieve nasal congestion. Otrivine is available as a nasal spray or drops.

**Out-of-body experience**
A feeling of leaving one’s body and observing oneself from another dimension. The experience, which is thought to be due to disturbance of brain function, is reported by some patients following a general anaesthetic or a medical emergency.

**Outpatient treatment**
Medical care on a same-day basis in a hospital or clinic.
ovarian cyst
An abnormal, fluid-filled swelling in an ovary. Ovarian cysts are common and, in the majority of cases, noncancerous; however, the likelihood of a cyst being cancerous increases with age. In some cases, both of the ovaries have multiple cysts due to a hormonal disorder (see ovary, polycystic).

TYPES
The most common type, a follicular cyst, is one in which the egg-producing follicle enlarges and fills with fluid. Cysts may also occur in the corpus luteum, a mass of tissue that forms from the follicle after ovulation. Other types of cysts include dermoid cysts and mucous or serous cystadenomas (see adenoma), which can become very large. In some cases, an ovarian cyst may be due to ovarian cancer, particularly in postmenopausal women.

SYMPTOMS
Ovarian cysts often produce no symptoms, but some may cause abdominal swelling or discomfort, pain on intercourse, or irregularities of menstruation including amenorrhoea, menorrhagia, and dysmenorrhoea. Severe abdominal pain, nausea, and fever may develop if twisting or rupture of a cyst occurs. Surgery is required to treat these conditions.

DIAGNOSIS AND TREATMENT
An ovarian cyst may be discovered during the course of a routine pelvic examination and its position and size confirmed by ultrasound scanning. In many cases, simple ovarian cysts (thinned-walled or fluid-filled cysts) disappear without treatment. Complex cysts (such as dermoid cysts) usually require surgical removal. In some cases, aspiration (withdrawal by suction) of fluid under the guidance of ultrasound, or during laparoscopy, may be possible. If an ovarian cyst is particularly large, the ovary may need to be removed by surgery (see oophorectomy).

ovary, cancer of
A malignant growth of the ovary. The cancer may be primary (arising in the ovary) or secondary (due to the spread of cancer from another part of the body).

INCIDENCE AND CAUSES
Ovarian cancer can occur at any age but is most common in women over 50 and in those who have never had children. A family history of cancer of the ovary, breast, or colon, especially in close relatives under 50, is an important risk factor. Having taken oral contraceptives in the past substantially reduces the risk.

SYMPTOMS
In most cases, ovarian cancer causes no symptoms until it is widespread. The first symptoms may include vague discomfort and swelling in the abdomen; nausea and vomiting; and abnormal vaginal bleeding. The swelling may be due to the tumour itself or to ascites (excess fluid in the abdominal cavity).

DIAGNOSIS AND TREATMENT
Diagnosis of ovarian cancer involves a physical examination, ultrasound scanning, and blood tests to measure levels of a substance produced by the tumour. The tumour is usually surgically removed, along with the uterus (see hysterectomy) and the unaffected ovary. In younger women whose cancer is found early, it is sometimes possible to perform less radical surgery and preserve fertility. The extent of spread within the abdomen is assessed during surgery.

Surgery is followed by chemotherapy, unless the cancer was found at a very early stage. Platinum-based drugs, which are combined with paclitaxel, are usually given. Survival rates depend on the type of tumour and how advanced it is at the time of diagnosis; as the disease is often quite advanced, less than one in four women survive for more than five years.

ovary, disorders of
Diseases and abnormalities of the ovaries can occur for various reasons. Absence of ovaries, or their failure to develop normally, is rare and is usually due to a chromosomal abnormality (see Turner’s syndrome). Oophoritis (inflammation of an ovary) may result from infections such as gonorrhoea or pelvic inflammatory disease. Ovarian cysts are common and usually noncancerous. Polycystic ovary syndrome is due to an imbalance of sex hormones. Ovarian cancer (see ovary, cancer of) occurs mainly in women over 50. Ovarian failure causes premature menopause in about 5 per cent of women.

ovary, polycystic
An ovary with multiple ovarian cysts. Symptomless ovarian cysts are present in about a quarter of the female population. In some women, however, ovarian cysts are associated with menstrual disorders and/or other symptoms; in these cases the condition is known as polycystic ovary syndrome.

overbite
Overlapping of the lower front teeth by the upper ones. A slight degree of overbite is normal as the upper jaw is larger than the lower jaw. In malocclusion, overbite may be greater than normal or the lower teeth may project in front of the upper teeth (prognathism).
overbreathing
A common name for hyperventilation.

overcrowding, dental
Excessive crowding of the teeth so that they are unable to assume their normal positions in the jaw.

CAUSES
Dental overcrowding is commonly inherited and may occur because the teeth are too large for the jaw or the jaw is too small to accommodate the teeth. Overcrowding may also be caused, or aggravated, by premature loss of primary molar (back) teeth; this can cause the permanent teeth replacing them to move out of position and crowd the teeth further forward.

SYMPTOMS
Overcrowded teeth may lead to malocclusion (abnormal relationship between the upper and lower teeth) or may prevent certain teeth from erupting through the gum (see impaction, dental). The teeth can be difficult to clean, increasing the risk of dental decay (see caries, dental) and periodontal disease.

TREATMENT
Teeth may need to be extracted to allow room for others or for cosmetic reasons. Usually, an orthodontic appliance is fitted to the remaining teeth until they are positioned correctly.

Overcrowded teeth
The top and bottom front teeth are crowded together because the molars, just behind them, have grown too far forward.

overdose
See drug poisoning.

overflow incontinence
A type of incontinence (see incontinence, urinary) in which urine leaks from the bladder, or a type of faecal incontinence in which semi-liquid faeces leak out around impacted faeces in constipation (see incontinence, faecal). Overflow urinary incontinence most commonly occurs in cases of long-term urinary retention, which is caused by an obstruction at the outlet of the bladder. Treatment is generally of the underlying problem.

over-the-counter (OTC) drug
A drug that can be bought without a prescription at a pharmacy or other shop, such as a supermarket.

overuse injury
Also called repetitive strain injury, a term for any injury caused by repetitive movement of part of the body. Symptoms include pain and stiffness in the affected joints and muscles.
Examples include epicondylitis: painful inflammation of one of the bony prominences at the elbow, caused by the pull of the attached forearm muscles during strenuous activities (see golfer’s elbow, tennis elbow). Overuse injuries of the fingers, thumb, and wrist joints may affect assembly-line and keyboard workers, and musicians; injuries of the neck may affect violinists.
Rest usually relieves the symptoms. A change in the technique used during the activity may prevent recurrence.

overweight
Weighing more than the recommended weight for a particular height. (See also obesity.)

ovum
The egg cell (the female cell of reproduction). An ovum contains a nucleus suspended in cytoplasm (a gel-like substance) and it is surrounded by a protective layer that is known as the zona pellucida.

About one million immature ova are present in each ovary at birth, but only about 200 per ovary mature to be released at ovulation. A fertilized ovum develops into an embryo.

ovum, blighted
A zygote (a fertilized egg cell) in which development has stopped at an early stage. This condition results in the appearance of an empty sac in the uterus, with no fetus visible on ultrasound scanning; blighted ovum is a common cause of miscarriage.

Ovysmen
A brand-name oral contraceptive containing ethinylestradiol (a synthetic form of the female sex hormone estradiol) and levonorgestrel (a progestogen drug).

oxalate
A substance that is synthesized by the body as well as being derived from certain foods, such as spinach, rhubarb, and tea. When blood oxalate levels are raised, kidney stones (see calculus, urinary tract) may develop.

oxazepam
A benzodiazepine drug used as a short-term treatment for anxiety. Oxazepam may cause dependence if it is taken regularly for more than two weeks (see drug dependence).

oximeter
An instrument that measures the amount of oxygenated haemoglobin (see oxyhaemoglobin) in the blood. A pulse oximeter is a photoelectric sensor attached either to a finger or to an ear to measure oxygen saturation continuously. Oximetry is used to monitor a patient during certain procedures, and always during general anaesthesia; it is also used to help diagnose and monitor many lung diseases.

oxprenolol
A beta-blocker drug that is used in the treatment of hypertension (high blood pressure), angina (chest pain due to insufficient blood supply to the heart), and cardiac arrhythmias (irregular heart-
oxybutynin  
A drug used to treat frequent urination (see urination, frequent) and urge incontinence (see incontinence, urinary) by relaxing bladder muscle and increasing bladder capacity. Common side effects include dry mouth and blurred vision.

oxygen  
A colourless and odourless gas that makes up 21 per cent of the Earth’s atmosphere. Oxygen is essential for almost all forms of life, including humans, because it is necessary for the metabolic “burning” of foods to produce energy. This is a process that takes place in body cells and is known as aerobic metabolism.

Oxygen is absorbed through the lungs and into the blood, where it binds to the haemoglobin in red blood cells. As oxygen-rich blood circulates around the body, the oxygen is released from the red blood cells into the body tissues.

Additional supplies of oxygen are used to treat conditions such as severe hypoxia (inadequate oxygen in the body tissues) or bronchitis. High-pressure oxygen (see hyperbaric oxygen treatment) is sometimes used to treat decompression sickness or carbon monoxide poisoning. (See also ozone.)

oxygen concentrator  
An appliance used in oxygen therapy that separates oxygen from the air and mixes it back in at a greater concentration. This oxygen-enriched air is delivered through a tube for prolonged inhalation. The appliance is used by people who have persistent hypoxia (inadequate oxygen in body tissues) due to severe chronic obstructive pulmonary disease (see pulmonary disease, chronic obstructive). (See also hyperbaric oxygen treatment.)

oxygen therapy  
The process of supplying a person with oxygen-enriched air to relieve severe hypoxia (inadequate oxygen in body tissues). The oxygen is usually delivered through a face-mask or a nasal cannula (a length of narrow plastic tubing with two prongs that are inserted into the nostrils). The oxygen concentration of the air may be varied in accordance with the patient’s needs. Piped oxygen is used in hospitals; oxygen in cylinders can be used when the patient is moving from place to place. Long-term therapy for people with persistent hypoxia, which results from diseases such as chronic obstructive pulmonary disease (see pulmonary disease, chronic obstructive) or pulmonary fibrosis, may involve the use of an oxygen concentrator. (See also hyperbaric oxygen treatment.)

oxyhaemoglobin  
The substance formed when the iron in haem, the pigment in the haemoglobin of red blood cells, combines chemically with oxygen. Oxyhaemoglobin gives the blood in the arteries its bright red colour. This compound is the form in which oxygen is transported from the lungs to the tissues, where the oxygen is released (see respiration).

oxymetazoline  
A decongestant drug used in the treatment of allergic rhinitis (hay fever), sinusitis, and the common cold.

oxytetracycline  
A tetracycline antibiotic drug that is used to treat chlamydial infections such as nongonococcal urethritis. It is also used for a variety of other infective conditions, including bronchitis and pneumonia; the drug may also be used to treat severe acne.

Side effects may include nausea, vomiting, diarrhoea, skin rash, and increased sensitivity of the skin to sunlight. Oxytetracycline may discolour developing teeth and is not given to children under 12 or pregnant women.

oxytocin  
A hormone produced by the pituitary gland. Oxytocin causes uterine contractions during labour and stimulates milk-flow in breast-feeding women.

Synthetic oxytocin is used for induction of labour. It is given by intravenous infusion to produce uterine contractions. It is also often given with ergometrine as a single dose after delivery to prompt placental separation and expulsion, to reduce blood flow, or to empty the uterus after an incomplete miscarriage or a fetal death.

A possible adverse effect of synthetic oxytocin is abnormally strong, painful contractions. Rare side effects include nausea, vomiting, palpitations, and allergic reactions.

oxyuriasis  
An alternative name for enterobiasis or threadworm infestation.

ozena  
A severe and rare form of rhinitis, in which the mucus membrane in the nose wastes away and a thick nasal discharge dries to form crusts. Ozena often causes severe halitosis (bad breath).

ozone  
A form of oxygen, ozone (O₃), is a poisonous, faintly blue gas that is produced by the action of electrical discharges (such as lightning) on oxygen molecules (O₂) and by interactions between hydrocarbon pollutants and sunlight.

Ozone occurs naturally in the upper atmosphere, where it screens the Earth from most of the sun’s harmful ultraviolet radiation. The ozone layer is being depleted by atmospheric pollutants, allowing increasing amounts of ultraviolet radiation to reach the Earth’s surface. This increases the risk of affected populations developing higher rates of certain diseases and conditions, such as skin cancer and cataracts (see sunlight, adverse effects of). Increased levels of ozone near the ground are an indicator of poor air quality. In these circumstances, the raised levels make the breathing problems of people with allergic lung diseases increasingly likely to worsen, particularly if they exercise.
pacemaker
A small device that supplies electrical impulses to the heart in order to maintain a regular heartbeat.

WHY IT IS USED
A pacemaker is needed when the heart’s sinoatrial node malfunctions (see sick sinus syndrome), when the passage of the electrical impulses that stimulate heart contractions is impaired (see heart block), or when the heart rate is intermittently slow and fast or the rhythm is irregular.

TYPES
Pacemakers may be fitted externally, as a temporary measure until a permanent pacemaker can be fitted. They can also be internal (surgically implanted in the chest). Internal pacemakers can either discharge impulses at a steady (fixed) rate or discharge only at times when the heart rate slows or a beat is missed (demand); some types can increase the heart rate during exercise or change an abnormal rhythm into a normal one. Internal pacemakers are also either single-chambered or dual-chambered. Single-chamber pacemakers work by passing a single wire into the right atrium or right ventricle; dual-chamber pacemakers have two wires, one that passes into the right atrium, and the other into the right ventricle.

packed red blood cells
A blood product comprising blood from which 70 per cent of the plasma (the fluid that carries blood cells and other substances) has been removed to leave a high concentration of red blood cells. In blood transfusions, packed red blood cells are used much more commonly than “whole” blood (blood that has had nothing removed), especially to treat anaemia and haemolytic disease of the newborn; if a smaller volume of blood is transfused, there is less risk of overloading the circulation.

paclitaxel
An anticancer drug that is used to treat certain types of cancer, such as ovarian cancer (see ovary, cancer of) and breast cancer.

The possible side effects of paclitaxel include nausea, vomiting, anaemia, and increased susceptibility to infection.

paediatrics
The branch of medicine that concentrates on the development of children and with the diagnosis, treatment, and prevention of childhood diseases and other conditions.

paedophilia
Persistent sexual attraction to, often leading to abuse of, children. Paedophilia is most often seen in men. It is thought to result from a combination of psychological and social factors that affect sexuality. Paedophiles often show personality disorders such as antisocial personality disorder, and have little concern for the effect of their behaviour on the child.

Paedophilic activity is illegal; many affected people are only identified once they have been arrested. Treatments are designed to reduce the urge to have sexual relations with children; they include cognitive–behavioural therapy and drug treatment to reduce sexual urges. (See also child abuse; incest.)

Paget’s disease
A common disorder that occurs in middle-aged and elderly people that is characterized by the disruption of bone formation. The affected bones become weak, enlarged and thickened, and deformed. Paget’s disease is sometimes called osteitis deformans.

Paget’s disease usually affects the pelvis, skull, collarbone, vertebrae, and long bones of the leg. Normally, the maintenance of healthy bones involves a balance between the actions of cells that break down bone tissue and the activity of cells that create new tissue. In Paget’s disease, however, this balance is disturbed. The disorder is thought to be caused by a viral infection; it may run in families.

SYMPTOMS
There are often no symptoms. If symptoms do occur, the most common ones are bone pain and deformity, especially bowing of the legs. Affected bones are susceptible to fracture.
Skull changes may lead to leontiasis ossea (distortion of the facial bones producing a lionlike appearance) and cause damage to the inner-ear bones, sometimes resulting in deafness, tinnitus (ringing in the ears), vertigo (a spinning sensation), or headaches.

In the spine, enlarged vertebrae may press on the spinal cord, causing pain and sometimes paralysis of the legs. If the disease affects the pelvis, it may cause severe arthritis of the hip joints.

Occasionally, bone cancer may develop. In rare cases, when many bones are involved, increased blood flow through affected bones may cause heart failure.

**DIAGNOSIS AND TREATMENT**

Paget’s disease is diagnosed by X-rays, which show areas of porous and thickened bone, and blood tests, which reveal abnormal levels of the substances involved in bone formation and breakdown.

Most people do not need treatment, or need only analgesic drugs (painkillers). In more severe cases, treatment with drugs such as bisphosphonates or calcitonin may be prescribed to control the rates of bone breakdown and renewal. The drugs will not reverse any existing deformity, but will slow the progression of the disease. Surgery may be needed to correct deformities or treat arthritis.

**Paget’s disease of the nipple**

A rare type of breast cancer in which a tumour develops in the nipple. The disease resembles eczema and can cause itching and a burning feeling. A nonhealing sore may develop. Without treatment, the tumour may spread into the breast. Diagnosis is made with a biopsy (sample of tissue).

**pain**

A localized, unpleasant sensation that can range from a feeling of mild discomfort to an excruciating experience. Pain serves the function of alerting the body to possible causes of injury, or making an affected person (or animal) withdraw from a source of harm. It may be acute (in which it appears and disappears suddenly) or chronic (in which it persists for days, weeks, or even longer).

**MECHANISM OF PAIN**

Pain results from the stimulation of sensory nerve endings called nociceptors in the skin. Pain receptors are also present in other structures, such as the blood vessels and tendons. Some nociceptors respond only to severe stimulation, such as cutting, pricking, or extreme heat; others respond to warning stimuli such as firm pressure or stretching. Signals that arise from the nociceptors are transmitted via nerves to the brain. In addition, chemicals called prostaglandins trigger inflammation and swelling, and further stimulate the nerve endings.

Pain that may be felt at a point some distance from the cause is known as referred pain (see pain, referred).

**PSYCHOLOGICAL ASPECTS OF PAIN**

Pain is usually associated with distress and anxiety, and sometimes with fear. People vary tremendously in their pain thresholds (the level at which the pain is felt and the person feels compelled to act). The cause and circumstances of the pain may also affect the way it is perceived by the sufferer. The pain of cancer, because of fear of the disease, may seem much greater and cause more suffering than similar pain that results from persistent indigestion. Unexplained pain is often worse because of the anxiety it can cause; once a diagnosis is made and reassurance given, the pain may be perceived as less severe. In some cases, pain may be felt due to emotional reasons rather than any obvious physical cause (see pain, psychogenic).

The experience of pain may be reduced or blocked by arousal or strong emotion; for example, an injury sustained during competitive sport or on the battlefield may go unnoticed in the heat of the moment. Some people believe that mental preparation for pain, in advance of situations such as childbirth or in experiments to test pain, can greatly reduce the response.

A person’s response to pain is also greatly modified by past experience; the outcome of previous episodes of pain may affect the way in which the individual copes with subsequent pain. Factors such as insomnia, anxiety, and depression, which often accompany incapacitating chronic illness, lower tolerance to pain. Many hospitals now have specialist pain clinics, in which people with severe pain that has proved difficult to control may be assessed and treated. Such patients include those with advanced cancer and poorly understood conditions such as facial pain and various types of neuralgia.

**TREATMENT**

Treatment is for the underlying cause of the pain. It may involve analgesic drugs, electrical stimulation (TENS), surgery, or therapies such as acupuncture. (See also pain relief, endorphins.)

**painful arc syndrome**

A condition in which pain occurs when the arm is raised between 45 and 160 degrees from the side. The usual cause is an inflamed tendon or bursa in the shoulder joint that is being squeezed between the scapula (shoulderblade) and humerus (upper-arm bone). Treatment includes physiotherapy and injections of corticosteroid drugs. (See also subacromial bursitis.)

**painful heel**

See heel, painful.

**painkillers**

See analgesic drugs.

**painless haematuria**

A form of haematuria (blood in the urine) that is not associated with pain when urine is passed (see urination, painful). Common causes of painless haematuria include kidney tumours; tumours in the ureters; bladder tumours; or glomerulonephritis (inflammation in the tiny filtering units of the kidneys).

**pain, psychogenic**

Pain that occurs in response to a mental or emotional stimulus rather than having a physical cause. Persistent pain that has no obvious physical cause may be due to a psychological disorder (see somatization disorder).

**pain, referred**

Pain that is felt in a site other than the affected part of the body. This form of pain occurs when the brain cannot distinguish the correct source of the pain signals (see the illustrated box overleaf). Examples of referred pain are pain in the left shoulder or the arm, related to angina pectoris (chest pain due to insufficient blood supply to the heart muscle) and sciatica (pain that radiates along the sciatic nerve in the leg).

**pain relief**

The treatment of pain, usually with analgesic drugs. Paracetamol, aspirin and codeine are among the most widely used drugs in this group. Pain accompanied by inflammation is often alleviated by nonsteroidal anti-inflammatory drugs (NSAIDs). Severe pain may require treatment with opioids, such as morphine. Other types of drug may be used to treat nerve pain, such as trigeminal neuralgia or the burning sensation in the feet that may be a feature of diabetes mellitus. Examples are
PAIN RELIEF

PAIN

Pain mechanisms exist to provide a useful warning of possible injury or to caution against repeating an action that has led to injury. Certain diseases, such as arthritis and extensive cancer, may set off these same mechanisms, causing chronic pain that has no apparent function.

1 Receptors in the fingertip detect heat. Signals are sent along a sensory nerve to the spinal cord.

2 The signals arriving in the spinal cord pass instantaneously to a motor nerve that connects to a muscle in the arm. The signals received via the motor nerve cause the muscle in the arm to contract, moving the arm away from the source of danger (the flame).

Reflex action
The nerve pathways that warn of noxious stimuli (through the sensation of pain) may also initiate automatic, reflex actions that help prevent harm.

Perception of pain
When an injury occurs, signals pass along nerve pathways concerned with pain, first to the spinal cord and then to the thalamus in the brain; there the pain is perceived.

Signal transmission to brain
Within the brain and spinal cord, pain signals pass between nerve cells by means of chemicals that cross the gaps between the cells.

Initiation of pain signals
Pain signals are set off by stimulation of special nerve endings — by pressure, heat, or the release of chemicals, including prostaglandins, by cells that have been damaged.

REFERRED PAIN

A referred pain is one felt in a site other than an injured or diseased part. Sensory nerves from certain body areas converge before they enter the brain, causing confusion about the source of pain signals.

Tooth to ear region
A toothache may be felt in the ear, because the same sensory nerve supplies both parts.

Diaphragm to right shoulder
Inflammation of the diaphragm, often due to pneumonia, may be felt as a pain in the right shoulder.

Heart to left arm
Angina, a pain caused by reduced blood supply to the heart muscle, is often felt in the left shoulder or arm.

Hip to knee
Disorders that affect the hip, such as arthritis, may be felt as pain in the knee rather than in the hip.
tricyclic antidepressants (such as amitriptyline) and anticonvulsant drugs (such as carbamazepine or gabapentin).

Other methods of pain relief include massage, ice-packs, poultices, TENS, acupuncture, and hypnosis. Surgery to destroy pain-transmitting nerves (such as a sympathectomy) is occasionally performed in cases where all other appropriate treatments have failed.

**palate**
The roof of the mouth, which separates the mouth from the nasal cavity. The palate is covered with a mucous membrane. At the front is the hard palate, which is a plate of bone forming part of the maxilla (upper jaw). At the rear is the soft palate, which is a flap of muscle and fibrous tissue that projects into the pharynx (throat). During the process of swallowing, the soft palate presses against the rear wall of the pharynx, thereby preventing food from escaping into the nose. (See also cleft lip and palate.)

**palliative care**
Nursing or medical care that is given to relieve the symptoms of illness rather than to treat the cause. Palliative care is often given to people who are in the last stages of a terminal illness (see dying, care of the). In these cases, the aim is to minimize unpleasant symptoms and to provide a comfortable, reassuring environment for the last days or weeks of life. (See also palliative treatment.)

**palliative treatment**
Treatment that relieves the symptoms of a disorder but does not cure it. There is a wide variety of palliative treatments. Examples are pain relief; antiemetic drugs to relieve nausea and vomiting; sedative drugs to relieve insomnia; and other therapies, such as massage and counselling. (See also dying, care of the.)

**pallor**
Abnormal paleness of the skin and mucous membranes, particularly noticeable in the face. Pallor may have many possible causes and is not always a symptom of disease. Pallor may be caused by constriction of small blood vessels in the skin, which may occur in response to shock, severe pain, injury, heavy blood loss, or fainting. This restriction of blood flow to the skin ensures that the brain and other vital organs are adequately supplied with blood and that body heat is conserved (at least temporarily).

Less commonly, pallor may be due to a deficiency of the skin pigment melanin that may result from spending too little time in daylight. Abnormally pale skin is also a feature of albinism.

Disorders that cause pallor include anaemia, kidney failure, and hypothyroidism (underactivity of the thyroid gland). Lead poisoning is a rare cause.

**palmar erythema**
See liver palms.

**palpation**
A technique used in physical examination in which parts of the body are felt with the hands to assess the condition of the skin and underlying organs.

**palpitation**
An awareness or feeling in the chest of the heartbeat or a sensation of having a rapid and forceful heartbeat.

**CAUSES**
Palpitations are usually felt in tense or frightening situations, or following strenuous exercise. When experienced at rest or during a period of calm, they are usually due to ectopic heartbeats and are felt as fluttering or thumping in the chest. This condition is usually due to alcohol or caffeine consumption, or smoking, rather than disease. Palpitations may also be due to cardiac arrhythmias (irregularities of the heartbeat; see arrhythmia, cardiac); anaemia (a reduced level of the oxygen-carrying pigment haemoglobin in the blood); or hyperthyroidism (overactivity of the thyroid gland), which speeds up the heartbeat.

**LOCATION OF THE PALATE**
The palate forms the floor of the nasal cavity and the roof of the mouth, providing a surface against which the tongue can push during chewing and swallowing.

**panaceae**
A remedy that is claimed to cure all diseases. No such remedy is known.

**Panadol**
A brand name for the analgesic (pain-killing) drug paracetamol.

**Pancoast’s syndrome**
A collection of symptoms that occurs when a growth presses on the brachial plexus (the group of major nerves controlling the arm and hand). These symptoms include pain and paralysis in the arm or hand, as well as Horner’s syndrome if the growth presses on the sympathetic cervical (neck) nerves. Pancoast’s syndrome is commonly due to a tumour called Pancoast’s tumour, which develops in the upper part of the lung in people with lung cancer.

**pancreas**
A tapered gland that lies across the back of the abdomen, behind the stomach. The broadest part (which is called the head) is on the right-hand side, in the loop of the duodenum (the first part of the small intestine). The main part (which is called the body) tapers from the head and extends horizontally. The narrowest part (the tail) extends backwards, towards the spleen.

**structure and function**
The major part of the pancreas is made up of exocrine tissue, which release chemicals through ducts. Embedded within these tissues are “nests” of
LOCATION OF THE PANCREAS

This organ lies behind and under the stomach, except for its head, which lies within the curve of the duodenum.

endocrine cells (known as the islets of Langerhans), which secrete hormones into the bloodstream.

The exocrine cells secrete digestive enzymes into a network of ducts that meet to form the main pancreatic duct. This duct joins the common bile duct (which carries bile from the gallbladder) to form a small chamber, the ampulla of Vater, which opens into the duodenum. Also secreted is sodium bicarbonate, which neutralizes stomach acid entering the duodenum.

The islets of Langerhans are surrounded by many blood vessels, into which they secrete the hormones insulin, glucagon, and somatostatin. These hormones regulate the level of glucose in the blood. (See also Disorders of the pancreas box.)

pancreas, cancer of

A malignant tumour of the pancreas. Pancreatic tumours usually arise in the exocrine tissue, which is responsible for producing digestive juices. They may also occasionally arise from parts of the endocrine system or from the ampulla of Vater (the junction of the common bile duct and the pancreatic duct). The cause of cancer of the pancreas is unknown, but smoking, chronic pancreatitis, and a high alcohol intake may contribute.

SYMPTOMS

Symptoms and signs of pancreatic cancer include upper abdominal pain that radiates to the back; loss of appetite; weight loss; jaundice (yellowing of the skin) if the tumour obstructs the bile ducts; and possibly even diabetes mellitus. There may also be indigestion, nausea, vomiting, diarrhoea, and tiredness. In many cases, symptoms do not appear until the cancer has spread (typically to the liver and the lymph nodes in the abdomen).

DIAGNOSIS AND TREATMENT

Diagnosis usually requires ultrasound scanning, CT scanning or MRI of the upper abdomen, or ERCP (endoscopic examination of the pancreatic ducts).

In the early stages, Whipple’s operation (surgical removal of cancerous tissue), radiotherapy, and anticancer drugs may provide a cure. In the later stages, little can be done apart from provision of palliative treatment, such as pain relief, a bypass operation to treat obstruction of the duodenum, or insertion of a stent (rigid tube) to relieve jaundice. Most people with advanced pancreatic cancer survive for less than one year.

pancreatectomy

Removal of all or part of the pancreas, which may be performed as treatment for pancreatitis (inflammation of the pancreas). In rare cases, pancreatectomy is performed as a treatment for insulinomas (insulin-producing tumours).

Pancreatectomy may cause a deficiency of pancreatic hormones and digestive enzymes. This situation may lead to diabetes mellitus, which needs to receive treatment with insulin therapy, and malabsorption, which requires oral supplements of pancreatin.

pancreatin

An oral preparation of pancreatic enzymes required for digestion. It is used to prevent malabsorption, and it may be needed after pancreatectomy or by people who have disorders affecting the pancreas, such as chronic pancreatitis, cancer (see pancreas, cancer of), or cystic fibrosis.

pancreatitis

Inflammation of the pancreas, a condition that may be acute or chronic. In acute pancreatitis, the pancreas suddenly becomes inflamed, causing severe abdominal pain. This condition can be life-threatening if left untreated. In chronic pancreatitis, the pancreas is persistently inflamed; this condition leads to a progressive loss of function.

CAUSES

The main causes of acute pancreatitis are alcohol abuse, typically a bout of heavy drinking, and gallstones. Less common causes are injury (such as a violent blow to the abdomen), viral infections (such as mumps), surgery on the biliary system, or certain drugs, such as immunosuppressants and thiazide diuretic drugs.

Chronic pancreatitis is usually due to long-term alcohol abuse. Less common causes include hyperlipidaemia (a high level of fat in the blood), cystic fibrosis, haemochromatosis (a condition in which there is excess iron in the body), and severe acute pancreatitis.

SYMPTOMS

An attack of acute pancreatitis usually lasts about 48 hours. Symptoms are a sudden attack of severe upper abdominal pain, which may spread to the back, often accompanied by vomiting. Movement often makes the pain worse, but sitting may help to relieve it. In severe cases, inflammation may affect the whole abdomen (see peritonitis); there is also a risk of shock (failure of blood circulation), which may be life-threatening.

Chronic pancreatitis usually develops over several years, and may be symptomless in the early stages. When symptoms do appear they are usually the same as those of acute pancreatitis, although the pain may last from a few hours to several days, and attacks may become more frequent over time. If there is no pain, the principal signs may be of malabsorption or diabetes mellitus due to reduced levels of pancreatic enzymes and insulin, respectively.

COMPLICATIONS

Acute pancreatitis may recur repeatedly. Severe acute pancreatitis may damage the pancreas and lead to hypotension (low blood pressure), heart failure, kidney failure, respiratory failure, pancreatic cysts, and ascites (accumulation of fluid in the abdomen).

Chronic pancreatitis leads to permanent damage to the gland; the tissue is damaged and gradually replaced by scar tissue, and normal function is progressively impaired. Other possible complications include the development of ascites and cysts, as well as bile duct obstruction.

DIAGNOSIS AND TREATMENT

A diagnosis may be made using abdominal X-rays, ultrasound scanning, or CT scanning or MRI (techniques that produce cross-sectional or three-dimensional images of body structures). In addition, blood tests may be used in cases of suspected acute pancreatitis, to detect pancreatic enzymes that have leaked directly into the blood.
DISORDERS OF THE PANCREAS

Serious disruption of pancreatic function occurs only when the secretory tissue of the gland has been damaged or destroyed in advanced disease. The most common pancreatic disorder is diabetes mellitus, in which the insulin-producing cells in the gland are destroyed.

Congenital and genetic disorders
About 85 per cent of people with the genetic disorder cystic fibrosis produce totally inadequate quantities of pancreatic digestive enzymes, which results in malabsorption of fats and proteins. This, in turn, may produce steatorrhoea (excess fat in the faeces) and muscle wasting.

Genetic factors are thought to play some part in diabetes mellitus, although they are not the primary cause of the disease.

Chronic pancreatitis (inflammation of the pancreas) may, in rare cases, be hereditary; chronic pancreatitis often causes diabetes.

Infection
Acute pancreatitis may result from certain viral infections, especially with the mumps or hepatitis viruses. Other viruses, such as coxsackievirus, may also cause pancreatitis. In some cases, coxsackievirus infection may contribute to the development of diabetes.

Tumour
Pancreatic cancer is one of the fairly common cancers (see pancreas, cancer of). It is difficult to diagnose and, in most cases, has spread extensively by the time it is detected.

Trauma
Injury to the pancreas – as a result of a blow to the abdomen, for example – may cause acute pancreatitis. The mechanism by which this occurs is not fully established, but it is believed that pancreatic enzymes (most of which are inactive until they reach the intestine) are released within the gland and then activated, with the result that they digest the pancreas.

Poisons and drugs
Excessive alcohol intake is a common cause of pancreatitis. It can also be caused by various drugs, such as sulphonamides, oestrogen drugs (including oestrogen-containing contraceptive pills), and thiazide diuretic drugs; corticosteroid drugs may also cause pancreatitis.

Autoimmune disorders
The cause of the damage to the pancreas in diabetes mellitus remains controversial. However, there is increasing evidence that, possibly in response to a viral infection, the body’s immune system produces antibodies (proteins made by the immune system) that inappropriately attack and destroy the pancreatic cells.

Infection
Congenital and genetic disorders
Acute pancreatitis is treated with intravenous infusion of fluids and salts and opioid analgesic drugs (painkillers). In some cases, the abdominal cavity may be washed out with sterile fluid; ERCP (an endoscopic X-ray procedure) may be used to find and remove gallstones; or a pancreatectomy (surgical removal of damaged tissue) may be performed.

Treatment for the chronic form is with painkillers, insulin, pancreatin, and, in some cases, pancreatectomy.

pancreatography
Imaging of the pancreas or its ducts using CT scanning, MRI, ultrasound scanning, X-ray (after a radiopaque contrast medium is injected into the ducts during exploratory surgery), or with ERCP (an endoscopic X-ray procedure).

pancreatin
A simultaneous and severe reduction in the numbers of red blood cells (causing anaemia); white blood cells (a condition called leucopenia); and platelets, involved in clotting (thrombocytopenia). This condition may be a result of damage to the bone marrow, where blood cells are made; such damage may be due to cancer in the marrow, or to destruction of the marrow by radiotherapy or anticancer drugs. Pancytopenia may also be due to hypersplenism (over-activity of the spleen), in which the spleen destroys excessive numbers of blood cells. (See also aplastic anaemia; Fanconi’s anaemia.)

pandemic
A medical term that is applied to a disease that occurs over a large geographical area and that affects a high proportion of the population; a widespread epidemic.

panencephalitis
See subacute sclerosing panencephalitis.

panic attack
A brief period of acute anxiety, often dominated by an intense fear of dying or losing one’s reason. Although unpleasant and frightening, panic attacks usually last for only a few minutes, cause no physical harm, and are rarely associated with any serious physical illness.

Panic attacks are generally a feature of an anxiety disorder, agoraphobia, or other phobias. In some cases, however, such attacks are associated with a somatization disorder or schizophrenia.

Attacks are unpredictable at first, but tend to become associated with specific situations, such as being in a cramped lift. Symptoms begin suddenly. They include a sense of breathing difficulty, chest pains, palpitations, feeling light-headed, dizziness, sweating, trembling, and faintness. Hyperventilation often also occurs. This condition results in carbon dioxide levels in the blood becoming abnormally low, which leads to a pins-and-needles sensation and feelings of depersonalization and derealization. The attacks end quickly.

The symptoms of hyperventilation may be relieved quickly by covering the mouth and nose with a small paper bag and breathing into the bag for a few minutes; this measure restores carbon dioxide levels in the blood.
dioxide levels to normal. In the longer term, cognitive–behavioural therapy and relaxation exercises may be used to help affected people control their anxiety.

**panic disorder**
A type of anxiety disorder characterized by recurrent panic attacks that are of intense anxiety and accompanied by distressing physical symptoms.

**panniculitis**
Inflammation occurring in subcutaneous fat (the layer of fatty tissue just beneath the skin). The inflamed fatty tissue forms multiple tender nodules under the skin. One form of this condition is erythema nodosum, in which swellings develop on the legs.

**pantothenic acid**
A vitamin of the vitamin B complex.

**papain**
A naturally occurring mixture of enzymes, including chymopapain, which is found in pawpaws. Papain breaks down proteins and has been used to remove clotted blood and dead tissue from wounds and ulcers.

**papilla**
Any small, nipple-shaped projection from a tissue’s surface, such as the mammary papilla (the breast nipple).

**papilloma**
A noncancerous growth of the epithelium (the cell layer that forms the surface of the skin and mucous membranes) that resembles a wart and most commonly affects the skin, tongue, larynx, and urinary and digestive tracts. If it does not disappear spontaneously it can be surgically removed.

**Papillon–Lefevre syndrome**
A rare genetic disorder affecting the skin and gums. Papillon–Lefevre syndrome results in areas of thinned, cracked skin. In addition, it makes the gums prone to infection from very early in life. Severe gum disease (see periodontal disease) causes the milk teeth to be lost prematurely, and may cause all the adult teeth to be lost by age 20.

**papovavirus**
A family of viruses that includes papillomaviruses (see human papillomavirus).

**pap smear**
See cervical smear test.

**papule**
A small, solid, slightly raised area of skin. Papules are usually less than 5 mm in diameter. They may be raised or flat; rough or smooth; and pigmented or the colour of the surrounding skin.

**par-**/para-
Prefixes that have several meanings. They may mean “beside or beyond”, as in the parathyroid glands (which lie behind the thyroid); “closely resembling or related to”, as in paratyphoid fever (a disease that is very similar to typhoid fever); or “faulty or abnormal”, as in paraesthesia (abnormal sensation).

**para-aminobenzoic acid (PABA)**
A biochemical that used to be the active ingredient of many sunscreen preparations, but is now rarely used.

**paracentesis**
A procedure in which a body cavity is punctured with a needle to remove fluid for analysis, to relieve pressure from excess fluid, or to instil drugs.

**paracetamol**
An analgesic drug that is used to treat mild pain and to reduce fever. Paracetamol may, in rare cases, cause nausea or a rash. An overdose may cause liver damage and can be fatal. An antidote is available, but must be given early.

**paraesthesia**
Altered sensation in the skin without any stimulus (see pins-and-needles).

**paraffinoma**
A tumourlike swelling under the skin caused by prolonged exposure to paraffin. Paraffinomas may form in the lungs if paraffin is inhaled.

**paraffin, white soft**
See petroleum jelly.

**paraldehyde**
A sedative drug used to stop prolonged epileptic seizures. Paraldehyde can be administered as an enema or by injection into a muscle.

**paralysis**
Complete or partial loss of controlled movement caused by the inability to contract one or more muscles. Paralysis may be temporary or permanent, and can affect areas of varying sizes, from a small facial muscle to many of the major muscles in the body. There may also be loss of feeling in affected areas. Paralysis is also known as palsy.

**TYPES**
The types of paralysis are classified by the areas of the body that are affected and by the effect on the muscles. Paralysis of one half of the body is called hemiplegia. If corresponding areas on both sides of the body (such as the legs) are affected, it is known as diplegia. If all four limbs and the trunk are affected, the paralysis is called quadriplegia or tetraplegia. Paraplegia is the paralysis of both legs and sometimes part of the trunk. In addition, paralysis may be classified as flaccid, causing flaccidness, or spastic, causing rigidity.

**CAUSES**
The muscles that control body movements are stimulated to contract by impulses originating in the motor cortex of the brain. These impulses travel via the spinal cord and peripheral nerves to reach the muscles. Paralysis may be caused by any form of injury or disorder anywhere along this nerve pathway. Alternatively, it may result from a disorder in the muscle.

**Brain disorders**
A common cause of paralysis is a stroke, in which brain tissue is damaged by bleeding from a ruptured blood vessel, or an area of the brain is starved of oxygen due to a clot in the blood vessel supplying that region. The paralysis will occur on the
opposite side of the body to the site of the brain damage because the motor nerves cross over in the brainstem.

Hemiplegia may be caused by any brain disorder in which the portion of the brain that controls movement is damaged. Examples of such disorders include a brain tumour, brain abscess, or brain haemorrhage.

Some types of paralysis are caused by damage to parts of the nervous system concerned with fine movement control, such as the cerebellum and the basal ganglia. Parkinson’s disease is caused by a lack of dopamine in the basal ganglia.

Cranial nerve damage may affect a variety of muscles and functions. For example, damage to the facial nerve (the seventh cranial nerve) causes weakness of the facial muscles (see facial palsy) and loss of taste.

Spinal cord disorders If the spinal cord becomes damaged or diseased, paralysis will develop in muscles that are supplied by nerves below the affected area. Damage to, or pressure on, the spinal cord may result from fracture of one or more vertebrae (which may result from severe injury, as in a road traffic accident) or disc prolapse (slipped disc). Diseases affecting the spinal cord include multiple sclerosis and poliomyelitis.

Peripheral nerve disorders Certain nerve disorders, called neuropathies, affect the peripheral nerves and may cause varying degrees of paralysis. Neuropathies may be caused by a variety of conditions, such as diabetes mellitus (see diabetic neuropathy), vitamin deficiency, liver disease, cancer, and the toxic effects of some drugs or metals (such as lead).

Muscle disorders Certain disorders arising in the muscles, such as muscular dystrophy, may cause paralysis. Temporary paralysis sometimes occurs in myasthenia gravis.

TREATMENT
The underlying cause is treated, if possible. Physiotherapy is given for both temporary and permanent paralysis, to prevent joints from becoming locked in awkward positions. In addition, it re-trains and strengthens the muscles and joints in people with temporary paralysis, so that some degree of mobility will be possible after recovery.

For paralysed people who are confined to a bed or a wheelchair, nursing care is essential to avoid the complications that can result from prolonged immobility, such as bedsores, deep vein thrombosis, urinary tract infections, constipation, and limb deformities.

paralysis, periodic
A rare, inherited condition that causes intermittent phases of muscle weakness, often associated with raised or lowered blood levels of potassium. The disorder shows an autosomal dominant pattern of inheritance (see genetic disorder).

Periodic paralysis affects young people, with attacks usually beginning in childhood or adolescence. Episodes of muscle weakness vary in frequency from daily to once every few years and last from a few minutes to a few hours.

Lowered potassium levels may occur after a high-carbohydrate meal or during a period of rest following physical exertion. The diuretic drug acetazolamide may be used to prevent attacks; potassium is often given orally to restore muscle strength when an attack occurs.

In other cases, potassium levels are raised; triggers include being cold, having a rest after physical exertion, and pregnancy. Diuretic drugs may be given as preventive treatment; a sugary drink may help to relieve an attack.

The condition often clears up without treatment by the age of 40.

paralytic ileus
See ileus, paralytic.

paramedic
A term for any health-care worker who is trained to work in an auxiliary capacity to medical professionals such as doctors and nurses. The term usually refers to ambulance staff who attend accidents or medical emergencies.

paramyxovirus
One of a family of viruses that includes the microorganisms responsible for croup, mumps, measles, and parainfluenza (a mild form of influenza).

paranoia
A condition in which the central feature is the delusion that people or events are especially connected to oneself. The term “paranoia” may also be used to describe feelings of persecution. A paranoid person builds up an elaborate set of beliefs based on the interpretation of chance remarks or events. Typical themes are persecution, jealousy (see jealousy, morbid), love, and grandeur (belief in one’s own superior position and powers).

TYPES AND CAUSES
Paranoia may be chronic or acute. Chronic paranoia may be caused by brain damage, abuse of alcohol or amphetamine, manic-depressive illness, or schizophrenia. It is also a feature of paranoid personality disorder, which is a psychological condition that causes people to be constantly suspicious of the motives of other people.

Acute paranoia, lasting for less than six months, may occur in people who have experienced radical life changes, such as refugees. In shared paranoia (see folie à deux), delusion develops because of a close relationship with someone else who has a delusion.

SYMPTOMS
There are usually no other symptoms of mental illness apart from occasional hallucinations. In time, however, the anger, suspicion, and social isolation may become severe.

TREATMENT AND OUTLOOK
If acute illness is treated early with antipsychotic drugs, the outlook is good. In long-standing cases of paranoia, however, the delusions are usually firmly entrenched, but antipsychotic drugs may make them less debilitating.

paraparesis
Partial paralysis or weakness of both legs and sometimes part of the trunk.

paraphimosis
Constriction of the penis behind the glans (head) by an extremely tight foreskin that has been pulled back, causing swelling and pain. Paraphimosis often occurs as a complication of an abnormally tight foreskin (see phimosis).

The problem can often be remedied manually by applying an ice-pack to reduce swelling and then squeezing the glans to return the foreskin to its normal position. Otherwise, an injection or an operation to cut the foreskin may be necessary. Circumcision (surgical removal of the foreskin) may be performed to prevent recurrence.

paraplegia
Weakness or paralysis of both legs and sometimes part of the trunk, often accompanied by loss of feeling and by loss of urinary control. Paraplegia is a result of nerve damage in the brain or spinal cord.

parapsychology
The branch of psychology dealing with experiences and events that cannot be explained by scientific knowledge. Such phenomena include extrasensory perception (ESP), telepathy (communication
of thoughts), telekinesis (movement of objects with the mind), and precognition (being able to see into the future).

Many “paranormal” experiences can probably be explained by mental disturbances; others are probably due to coincidence, self-deception, or fraud.

paraquat
A weedkiller, available in high concentrations for agricultural use, which can be fatal if swallowed, inhaled, or absorbed through the skin. Paraquat poisoning requires urgent medical attention. Symptoms may include breathing difficulty, mouth ulcers, nosebleeds, diarrhoea, and later, respiratory and kidney failure.

Treatments include eating activated charcoal or Fuller’s earth. Haemodialysis (removal of toxic substances from the blood) may also be used.

parasite
Any organism living in or on another living creature (the host) and deriving advantage from it, while causing the host disadvantage. In contrast, some organisms live on other creatures but have a symbiotic, or mutually beneficial, relationship with their host (see commensal).

Parasites obtain nourishment from the host’s blood, tissues, or ingested food. The organisms may spend only part of their life-cycle with the host or remain there permanently. Some cause few symptoms, while others cause disease or even death.

Animal parasites of humans include protozoa, worms, flukes, leeches, lice, ticks, and mites. Viruses and disease-causing fungi and bacteria are also parasites.

parasitology
The scientific study of parasites. Although viruses and many types of bacteria and fungi are parasites, their study is conducted under the title of microbiology.

parasicide
See suicide, attempted.

parasympathetic nervous system
One of the two divisions of the autonomic nervous system, which controls the automatic activities of organs, glands, blood vessels, and other tissues throughout the body. In contrast to the function of the sympathetic system, which prepares the body for action, the parasympathetic system controls everyday functions such as breathing, digestion, and excretion of waste products.

parathyroidectomy
Surgical removal of abnormal tissue from the parathyroid glands. Parathyroidectomy may be performed to treat hyperparathyroidism (excess secretion of parathyroid hormones). Less commonly, it may be used to treat parathyroid cancer.

If hyperparathyroidism is caused by an adenoma (a small, benign tumour), usually only one of the parathyroid glands is involved and needs to be removed. If all the glands are enlarged and overactive, more parathyroid tissue may be removed.

parathyroid glands
Two pairs of oval, pea-sized glands that lie behind the thyroid gland in the neck. The glands produce parathyroid hormone (PTH), which helps to regulate the level of calcium in the blood.

Blood calcium levels are monitored continuously by the body because even small variations can impair muscle and nerve function. If the calcium levels drop too low, the parathyroid glands...
release more PTH (see feedback). This response causes the bones to release more calcium into the blood, the intestines to absorb more from food, and the kidneys to conserve calcium; as a result, calcium levels rise rapidly. If the blood level of calcium is too high, the glands reduce their output of PTH. Some people have only one parathyroid gland or have extra glands in the neck or chest. Rarely, the parathyroid glands may become overactive (a condition called hyperparathyroidism), which causes erosion of the bones and stones in the kidneys, ureters, or bladder (see calculus, urinary tract). Alternatively, the glands may become underactive (see hypoparathyroidism), resulting in tetany (painful muscle spasms) or seizures.

parathyroid tumour
A growth within a parathyroid gland. The tumour may cause excess secretion of parathyroid hormone (PTH), leading to hyperparathyroidism. Parathyroid cancers are very rare; most parathyroid tumours are noncancerous adenomas. An adenoma that causes hyperparathyroidism will be surgically removed (see parathyroidectomy). This usually provides a cure.

paratyphoid fever
An illness identical in most respects to typhoid fever, except that it is caused by a different bacterium, Salmonella Paratyphi, and is usually less severe.

paraumbilical hernia
A hernia occurring near the navel. Paraumbilical hernias may occur in obese women who have had several children.

parenchyma
The functional (as opposed to supporting) tissue of an organ.

parenteral
The administration of drugs or other substances by any route other than via the gastrointestinal tract (for example, by injection into a blood vessel).

parenteral nutrition
Intravenous feeding (see feeding, artificial).

paresis
Partial paralysis or weakness affecting one or more muscles.

parietal
A medical term that is used to refer to the wall of a part of the body.

parity
A term used to indicate the number of pregnancies a woman has undergone that have resulted in the birth of a baby capable of survival.

parkinsonism
Any neurological disorder that is characterized by tremor (typically, this is a “pill-rolling” tremor, which occurs when the thumb is rubbed over the index finger); slow movements; and rigidity. The other characteristic features of the disorder of parkinsonism result from the slowness of movement. These features include a masklike face, a festinating gait (a shuffling, unbalanced style of walking), a monotonous style of speech, and reduced blinking. The most common type of parkinsonism is known as Parkinson’s disease.

The known causes of parkinsonism include cerebrovascular disease (problems involving the blood vessels in the brain); the use of antipsychotic drugs, or the abuse of certain designer drugs; carbon monoxide poisoning; and, rarely, the infection encephalitis lethargica.

CAUSE OF PARKINSON’S DISEASE
This disorder results from damage, of unknown origin, to the basal ganglia (nerve cell clusters in the brain). The difference between the healthy state and that of Parkinson’s disease is shown in the diagrams below.

Healthy state
During movement, signals pass from the brain’s cortex, via the reticular formation and spinal cord (pathway A), to muscles, which contract. Other signals pass, by pathway B, to the basal ganglia; these damp the signals in pathway A, reducing muscle tone so that movement is not jerky. Dopamine, a nerve transmitter made in the basal ganglia, is needed for this damping effect. Another transmitter, acetylcholine, inhibits the damping effect.

Parkinson’s disease
In Parkinson’s disease, degeneration of parts of the basal ganglia causes a lack of dopamine within this part of the brain. The basal ganglia are thus prevented from modifying the nerve pathways that control muscle contraction. As a result, the muscles are too tense, causing tremor, joint rigidity, and slow movement. Most drug treatments increase the level of dopamine in the brain or oppose the action of acetylcholine.

PARKINSONISM

589
PARKINSON’S DISEASE

Parkinson’s disease
A neurological disorder that is the most common cause of parkinsonism.

CAUSES AND INCIDENCE
Parkinson’s disease is caused by degeneration of, or damage to, cells in the basal ganglia of the brain. As a result, there is a deficiency of the neurotransmitter dopamine (which is needed for the control of movement). The condition occurs mainly in elderly people and is more common in men.

For further information on the processes leading to Parkinson’s disease, see the illustrated box, previous page.

SYMPTOMS AND SIGNS
The main symptoms develop gradually, over several months or even years. The disease usually begins as a slight tremor of one hand, arm, or leg, which is worse when the hand or limb is at rest.

Later, both sides of the body are affected, causing stiffness, weakness, and trembling of the muscles. Symptoms include a stiff, shuffling walk that may break into uncontrolled, tiny running steps; constant hand tremors, sometimes accompanied by shaking of the head; a permanent rigid stoop; and an unblinking, fixed expression. Everyday activities such as eating, washing, and dressing become very difficult.

The intellect is unaffected until late in the disease, although the affected person’s speech may become slow and hesitant, and the handwriting usually becomes very small. Depression is a common complication.

TREATMENT
There is no cure, but drug treatment, physiotherapy, and, rarely, surgery can help to relieve symptoms. In the early stages of Parkinson’s disease, exercises, special aids in the home (see disability), and support can improve the affected person’s morale and mobility. Drug treatment is used to minimize symptoms in later stages. These treatments cannot halt the degeneration of brain cells, but can minimize the symptoms by helping to correct the chemical imbalances in the brain.

In some cases, an anticholinergic drug such as trihexyphenidyl (benzhexol) may initially be given to reduce tremor. Anticholinergic drugs can be effective for several years, but may cause side effects such as dry mouth, blurred vision, and difficulty in passing urine.

Levodopa, which the body converts into dopamine, is usually the most effective drug. It may, however, cause side effects such as nausea and vomiting; therefore, the dose is increased gradually, and the drug may be given in combination with benserazide or carbidopa. Levodopa is usually effective for several years, but the effects gradually wear off. Drugs that may be used in conjunction with it, or as substitutes for it, include amantadine and bromocriptine.

Surgical operations on the brain are occasionally performed, if the affected person is young and otherwise in good health. New therapies that are still being assessed include replacement of damaged tissue with transplanted brain cells, and deep brain stimulation with electrical impulses to reduce tremor.

OUTLOOK
If left untreated, the disease progresses over 10 to 15 years, leading to severe weakness and incapacity. Some sufferers eventually develop dementia. Modern drug treatments, however, can provide considerable relief from the symptoms and give affected people a much-improved quality of life.

paronychia
An infection of the skin fold at the base of the nail. The affected area becomes swollen and painful, and there may be a buildup of pus.

Paronychia may be acute (caused by bacteria) or chronic (usually caused by Candida albicans). The condition is most common in women, particularly those with poor circulation and whose work involves frequent contact with water. It also affects people with skin disease involving the nail fold.

Treatment is with antifungal drugs or antibiotic drugs. If pus has collected in the area, it may need to be drained surgically. To prevent the occurrence of paronychia, gloves should be worn for all tasks that involve putting the hands in water, and the hands should be dried thoroughly after washing.

parotid glands
The largest of the three pairs of salivary glands. The parotid glands are situated on each side of the face, just above the angle of the jaw and in front of the ear. They secrete saliva into the mouth through a duct that opens into the inner cheek, level with the second molar tooth.

The parotid glands may develop various disorders that can affect all of the salivary glands, such as infections, abscesses (collections of pus), or calculi (stones). One disorder that specifically affects these glands is mumps, which causes inflammation of one or both glands. Another is a form of noncancerous tumour, pleomorphic adenoma, which is slow-growing and painless but may rarely become cancerous.

parotitis
Inflammation of the parotid glands, which is often due to infection with the mumps virus.

paroxetine
A selective serotonin reuptake inhibitor antidepressant drug. Possible side effects of paroxetine include nausea, indigestion, and appetite loss.

paroxysm
A sudden attack, worsening, or recurrence of symptoms or of a disease; a spasm or seizure.

paroxysmal nocturnal dyspnoea
Acute breathing difficulty that occurs suddenly at night, usually wakening the person from sleep. The condition most commonly affects people suffering from congestive heart failure with pulmonary oedema (a buildup of fluid in the lungs); in these cases, it is caused by fluid leaking out of the blood vessels into the air spaces of the lungs once the person is lying down. It may also occur in people with chronic lung diseases.

paroxysmal tachycardia
A form of tachycardia (abnormally rapid heartbeat) that usually comes on abruptly and stops just as suddenly. It
may be due to irregular muscle contractions in one of the chambers of the heart (see arrhythmia, cardiac).

parrot fever
The common name for psittacosis.

parturition
See childbirth.

parovirus
The former name for erythrovirus.

passive movement
Movement of a person’s limbs or body by another person. Passive movement is used in physiotherapy to exercise the body if a person has nerve or muscle disorders that prevent voluntary movements.

passive smoking
Involuntary inhalation of tobacco smoke by people who do not smoke. Passive smoking has been shown to increase risks of chest and ear infections in children and of tobacco-induced cancers in adults.

passivity
In psychology, a persistent unwillingness or inability to take responsibility for oneself and one’s everyday life. Passivity may be a feature of disorders such as depression or dependent personality disorder. The term has a specific meaning when used in reference to schizophrenia: it describes a patient’s belief that his or her thoughts, feelings, or actions are controlled by others.

pasteurization
The process of heating foods to destroy disease-causing microorganisms, and to reduce numbers of microorganisms that cause fermentation and putrefaction.

Patau’s syndrome
A chromosomal abnormality in which there are three copies of chromosome 13 rather than the normal two. Patau’s syndrome is a congenital condition (one that is present from birth). It causes low birth weight and a range of deformities including cleft palate or hare lip; eye deformities; micrognathia (undersized jaw); low-set ears; extra digits (see polydactyly); and malformation of the genitalia. There may also be serious deformities of the internal organs, such as heart defects, meningocele (see neural tube defects), and exomphalos (in which part or all of the intestines protrude through the navel). Most children with Patau’s syndrome die before two years of age, and those that survive have learning difficulties. Sometimes, affected children may have a mixture of normal and abnormal cells (see mosaicism), and they may have milder forms of the condition.

The condition may be diagnosed at an early stage of pregnancy by a test such as chorionic villus sampling or amniocentesis. In addition, genetic counselling may be offered.

patch test
A method that is used to diagnose the substances that are responsible for the skin disorder allergic contact dermatitis. A selection of possible allergens are put on a patch and taped to the skin. A skin reaction indicates that there is a sensitivity to a particular allergen.

patella
The kneecap (see knee).

patent
A term meaning “open” or “unobstructed” (such as in patent ductus arteriosus). The term “patent medicine” is sometimes used to refer to proprietary drugs protected by a patent.

patent ductus arteriosus
A defect of the heart in which the ductus arteriosus (a channel between the pulmonary artery and the aorta in the fetus) fails to close at birth.

cause
In the fetus, blood that is pumped by the right side of the heart flows through the ductus arteriosus and bypasses the lungs (see fetal circulation). Normally, the ductus arteriosus closes at or shortly after birth, and blood passes from the right ventricle (lower chamber) of the heart to the lungs. In some babies this closure may fail to happen, producing a patent ductus arteriosus. In this condition, some of the blood that is pumped by the left side of the heart, and which should go to the rest of the body, is directed via the ductus to the lungs. As a result, the heart has to work harder than normal to pump sufficient blood to the body.

symptoms
Patent ductus arteriosus usually causes no symptoms, unless a large amount of blood is misdirected, in which case the baby fails to gain weight, becomes short of breath on exertion, and may have frequent chest infections. Eventually, heart failure may develop.

diagnosis and treatment
Diagnosis is made from hearing a heart murmur, from chest x-rays, and from an ECG and echocardiography. The drug indometacin or surgery may be used to close the duct.

paternity testing
The use of tests, including DNA tests and blood tests, to help decide whether a particular man is the father of a certain child. This procedure may be requested, or ordered by a court, in legal situations in which the paternity of a child is disputed. Blood samples or buccal swabs (cell samples taken from rubbing the inside of the cheek) are taken from the child, from the man who is believed to be the father, and from the mother. There are various methods of testing for paternity: blood samples may be tested for blood groups, histocompatibility antigens (proteins that normally exist within body tissues, and whose form is inherited from the parents), and/or short lengths of DNA (a technique known as genetic fingerprinting); buccal swabs may only be used for DNA tests. Genetic fingerprinting is the most conclusive method of paternity testing. Particular regions of DNA are examined for structures called genetic markers. If certain markers are present in the child’s blood but not in the mother’s blood, it follows that they must be determined by genes inherited from the child’s biological father. If the man being tested shows the markers in his blood, there is a high probability that he is the biological father; if he does not, he can be excluded from the paternity of the child. No form of paternity testing is 100 per cent accurate in confirming or excluding someone as the father of a child.

patho-
A prefix denoting a relationship to disease.

pathogen
Any agent, but particularly a microorganism, that causes disease.

pathogenesis
The processes by which a disorder originates and develops.

pathognomonic
A medical term applied to a sign or symptom that is characteristic of a disease or disorder and is therefore sufficient by itself to make a diagnosis.
**Paternity Testing Using DNA Analysis**

DNA analysis (commonly referred to as genetic fingerprinting) is replacing older techniques of paternity testing because it gives a decisive result in more cases. Blood samples are taken from the mother, child, and possible father, and some DNA (hereditary material) from each is specially processed.

<table>
<thead>

<tbody>
<tr>
<td>DNA bands from the biological parents. First the bands from the mother are identified.</td>
<td>DNA bands from the biological parents. First the bands from the mother are identified.</td>
<td>DNA bands from the biological parents. First the bands from the mother are identified.</td>
</tr>
</tbody>
</table>

1. Each person’s DNA has a unique banding pattern, or “fingerprint”, detectable by X-rays after the processing.
2. A child’s DNA bands come from the biological parents. First the bands from the mother are identified.
3. The other bands are compared with the suspected father’s bands. Here they match, proving paternity.

<table>
<thead>

<td>The mother’s, the child’s, and the suspected father’s DNA have different banding patterns, shown above.</td>
</tr>
</tbody>
</table>

1. The mother’s, the child’s, and the suspected father’s DNA have different banding patterns, shown above.
2. Half the child’s DNA bands can be seen to have come from the mother, as in the example above.
3. The other bands are not shared by the suspected father, meaning he is not the biological father.

Key: M = Mother  C = Child  F = Father

**Pathological**

Relating to disease or to its study (see *pathology*).

**Pathological Diagnosis**

A method of *diagnosis* in which diseases are identified through examination of cells (see *cytopathology*), tissues (see *histopathology*), or body fluids. A clinical diagnosis, based on a patient’s symptoms and a physical examination, is also undertaken.

**Pathological Fracture**

*A fracture* of a bone weakened by disease, such as by certain forms of *cancer*, *osteoporosis*, and *Paget’s disease*.

**Pathology**

The study of disease, and specifically its causes, mechanisms, and effects on the body. The study of disease-induced changes in cells is called *cytopathology*; the study of such changes in body tissues is called *histopathology*. A doctor who specializes in these subjects is called a pathologist.

Pathologists carry out laboratory studies of cells and tissues that help other doctors to reach accurate diagnoses, and they also supervise other laboratory personnel in the testing and microscopic examination of blood and other body fluids. In addition, pathologists conduct *autopsies* (physical examinations of dead people) to determine causes of death and to determine the effects that a disease or a treatment has had on the body.

**Pathology, Cellular**

Also called *cytopathology*, the branch of *cytology* concerned with the effects of disease on cells.

**Pathology, Chemical**

Another name for *clinical biochemistry*, which is the study of abnormalities that occur in the chemistry of diseased body tissues and fluids.

**Pathophysiology**

The study of the effects of disease on body functions.

**-pathy**

A suffix that is used to denote a disease or disorder.

**Paul–Bunnell Test**

A type of blood test, also called the heterophil agglutination test, that is used to detect infection with the Epstein–Barr virus, which causes glandular fever (see *mononucleosis, infectious*). The Paul–Bunnell test involves detecting particular *antibodies* (proteins produced by the immune system to combat the virus) in a sample of blood.

**PCR**

The abbreviation for *polymerase chain reaction*.

**Peak-Flow Meter**

A piece of equipment that measures the maximum speed at which air can flow out of the lungs. A peak-flow meter is useful in assessing the severity of *bronchospasm* (constriction of the airways in the lungs), because narrowed airways slow the rate at which air can be expelled from the lungs. A peak-flow meter is most commonly used to diagnose *asthma*. In people who already have the disorder, it is used to monitor their condition and assess how they respond to treatment.

The peak flow is measured by taking in a deep breath and breathing out with the maximum force possible through the mouthpiece. The meter has a pointer and a scale on the side; the expelled breath moves the pointer to give a reading on the scale — the higher the reading, the greater the speed at which the air is travelling.
peau d’orange
A condition in which the skin is a normal colour but looks like orange peel. The skin’s dimpled appearance is due to fluid retention in the nearby lymph vessels. Peau d’orange is not necessarily a sign of disease, although it is, for example, one of the features of breast cancer.

pectoral
A medical term that means “relating to the chest”, as in the pectoral muscles on either side of the chest. The pectoralis major is a large muscle covering much of the upper front of the chest. The smaller pectoralis minor lies beneath it.

pectin
A form of polysaccharide found in apples and in the rinds of citrus fruits. Preparations containing pectins may be used to relieve diarrhoea.

pectoral muscles

The major pectoral draws the arm across the body. The minor, which lies beneath it, moves the shoulder and raises some ribs.

pelvic abscess
An abscess (a collection of pus formed after infection with microorganisms) that develops in one of the structures within the pelvis. Pelvic abscesses may be due to peritonitis (inflammation of the membrane lining the abdominal cavity) or to localized inflammation resulting from disorders such as pelvic inflammatory disease.

pelvic examination
Examination of a woman’s external and internal genitalia. After examination of the external genitalia, a speculum is inserted into the vagina to allow a clear view of the cervix. A cervical smear test may be performed. The doctor also carries out a bimanual examination: he or she inserts two fingers into the vagina, feeling the abdomen with the other hand to evaluate the position and size of the uterus and the ovaries and to detect any tenderness or swelling (see Procedure for a pelvic examination box, overleaf).

pelvic infection
An infection that affects the female reproductive system. Severe or recurrent pelvic infection is referred to as pelvic inflammatory disease (PID).

pelvic inflammatory disease
Inflammation of the internal female reproductive organs. Pelvic inflammatory disease (PID) is usually due to an infection. It is most common in young, sexually active women. PID is a common cause of lower abdominal pain in women. In some cases, however, there are no obvious symptoms, and affected women may be unaware that they have had the condition until they undergo an examination to assess their fertility.

Causes
Pelvic inflammatory disease may not have any obvious cause, but it usually occurs as a result of a sexually transmitted infection, such as a chlamydial infection. It may also occur after a miscarriage, abortion (see abortion, induced), or childbirth. Use of an IUD increases the risk of infection, particularly soon after insertion of the device.

Symptoms and complications
Common symptoms of PID include pain and tenderness in the lower abdomen, fever, and irregular menstrual periods.
There may also be a profuse vaginal discharge consisting of blood and/or pus. Pain often occurs after menstruation and may be worse during sexual intercourse (see intercourse, painful). There may also be malaise, vomiting, or backache. PID may be acute or chronic.

**DIAGNOSIS AND TREATMENT**

A diagnosis is usually made by an internal pelvic examination and examination of swabs from the vagina or cervix to look for infectious organisms. Laparoscopy (examination of the abdominal cavity using a viewing instrument) can confirm the diagnosis.

Antibiotic drugs are prescribed to clear the infection, and sometimes analgesic drugs (painkillers) may be given. If an IUD is the suspected cause of PID, the device may need to be removed.

**OUTLOOK**

If PID is detected and treated early, the patient should recover fully. Some affected women, however, have repeated attacks with or without reinfection. A pelvic abscess may develop as a complication of the condition. PID may cause infertility or increase the risk of ectopic pregnancy; this is primarily due to scarring of the fallopian tubes, which prevents eggs from travelling down the tubes to the uterus.

**pelvic pain**

See abdominal pain.

**pelvimetry**

Assessment of the shape and dimensions of a woman’s pelvis. Pelvimetry may be carried out a couple of weeks before childbirth, to determine whether a woman is likely to have difficulty in delivering a baby vaginally. The procedure may also be performed after a vaginal delivery has been unsuccessful and a caesarean section has been carried out, to assist in planning a future pregnancy and delivery.

Medical staff can obtain a rough indication of the size of the pelvic outlet by manually checking the distance between the ischial tuberosities (the prominent bones in the lower pelvis) during a pelvic examination. More precise information may be obtained by taking an X-ray of the pelvis and then making measurements from the resulting image. However, excessive exposure to X-rays in pregnancy may increase the risk of subsequent leukaemia or other cancers in the unborn child, and therefore this procedure is carried out only in rare circumstances.

**pelvis**

The ring of bones in the lower trunk that supports the trunk, protects the lower abdominal organs, and forms part of the hip joints. Attached to the pelvis are the muscles of the abdominal wall, the buttocks, the lower back, and the insides and backs of the thighs.

**STRUCTURE**

The pelvis consists of two innominate bones (hip-bones). At the back, the hip-bones are joined by rigid joints (the sacroiliac joints) to the sacrum (the triangular spinal bone below the lumbar vertebrae). At the front, they curve forwards to join at a central point known as the pubic symphysis.

Each innominate bone consists of three fused bones: the ilium, ischium, and pubis. The ilium, the largest and uppermost of these bones, consists of a wide, flattened plate with a long, curved ridge (the iliac crest) along its upper border. The ischium is the bone that bears much of the body weight when sitting. The pubis is the smallest of the pelvic bones; from the ischium it extends forwards and round to the pubic symphysis, where it is joined to the other pubis bone by tough fibrous tissue. All three bones meet in the acetabulum, the cup-shaped cavity that forms the socket of the hip joint.

In women, the pelvis is generally shallow and broad, and the pubic symphysis joint is less rigid than a man’s. These differences facilitate childbirth. In men, the greater body weight needs a larger and more heavily built pelvis for support.
The tube that develops on the skin in a rare brain and liver disorder is frequently accompanied by damage to internal organs (mainly affecting elderly people), in which the disease, there may be severe skin loss, which can lead to bacterial infection and, sometimes, death.

Diagnosis is made with a skin biopsy. Treatment of the disease is usually with a long-term course of corticosteroid or immunosuppressant drugs.

A rare, serious skin disease in which numerous blisters develop on the skin and in the mouth. Pemphigoid primarily affects people aged between 40 and 60. The blisters usually develop in the mouth, then appear on the skin. They rupture to form raw areas that may become infected and later crust over. Skin that appears unaffected may also blister after gentle pressure is applied. If a large area of the body is affected by the disease, there may be severe skin loss, which can lead to bacterial infection and, sometimes, death.

The diagnosis is confirmed by skin biopsy. Treatment of pemphigus is with a long-term course of corticosteroid drugs and, in some cases, with immunosuppressants. Antibiotics may also be prescribed.

A group of antibiotic drugs. Natural penicillins are derived from the mould *Penicillium*; others are synthetic preparations. Penicillins are used to treat many infective conditions, including tonsillitis, bronchitis, bacterial endocarditis, syphilis, and pneumonia. They are also given to prevent rheumatic fever from recurring. Penicillins destroy bacteria by preventing them from forming normal cell walls.

**POSSIBLE ADVERSE EFFECTS**

Diarrhoea is a common adverse effect of penicillin drugs. Penicillins may also provoke an allergic reaction (see allergy) in susceptible individuals. Allergic symptoms appear immediately after the drug is taken and include urticaria (nettle rash),
wheezing, and angioedema (swelling of body tissues, occurring especially around the mouth and eyes). In rare cases, penicillins may cause the life-threatening allergic reaction anaphylactic shock. Reaction to a penicillin drug requires immediate discontinuation of the drug; urgent medical advice should be sought.

penile implant
A prosthesis inserted into the penis to help a man suffering from permanent impotence to achieve sexual intercourse. The various types include a silicone splint inserted in the tissues of the upper surface of the penis, and an inflatable prosthesis that is inflated by squeezing a small bulb in the scrotum.

penile warts
See warts, genital.

penis
The male sex organ, through which urine and semen pass.

STRUCTURE AND FUNCTION
The penis consists of three cylindrical bodies of erectile tissue (spongy tissue full of blood vessels) that run along its length. Two of these bodies, the corpora cavernosa, lie side by side along the upper part of the penis. The third body, the corpus spongiosum, lies centrally beneath them and expands at the end to form the glans. Around the erectile tissue is a sheath consisting of fibrous connective tissue that is enclosed by skin. Over the glans, the skin forms a fold called the foreskin.

Through the centre of the corpus spongiosum runs the urethra, which is a narrow tube that carries urine and semen out of the body through an opening at the tip of the glans.

The principal functions of the penis are the excretion of urine and the discharge of semen during sexual intercourse (see erection; ejaculation).

DISORDERS
One common problem is impotence (failure to attain or maintain an erection). This condition affects most men at some point in their lives, and is usually psychological in origin. However, persistent impotence may be caused by nerve damage associated with diabetes mellitus, alcohol dependence, atherosclerosis, or spinal cord injury.

Balantitis (inflammation of the glans and foreskin) is usually caused by candidiasis, although other organisms, including those that cause gonorrhoea and syphilis, may cause inflammation. Balanitis may lead to phimosis, in which the foreskin is abnormally tight, or paraphimosis, in which the foreskin retracts at erection but is too tight to move back over the glans.

Penile warts (see warts, genital) are caused by a sexually transmitted virus. Cancer of the penis (see penis, cancer of) is a rare disorder; the incidence is higher in men who have not been circumcised than in those who have.

The most common congenital abnormality of the penis is hypospadias, a condition in which the opening to the urethra is located on the underside of the penis. In male pseudohermaphroditism, which is also congenital, the penis is very small and there is usually also hypospadias.

Other disorders of the penis include priapism, in which an erection is painful and abnormally prolonged, and a condition called Peyronie’s disease, in which the erect penis bends.

penis, cancer of
A rare type of cancerous tumour that is more common in uncircumcised men with poor personal hygiene. Viral infection and smoking have both been shown to be additional risk factors. The tumour usually starts on the glans or on the foreskin as a painless, wartlike lump or a painful ulcer, and develops into a cauliflower-like mass. The growth usually spreads slowly, but in some cases it can spread to the lymph nodes in the groin within a few months.

Diagnosis is made by a biopsy (tissue sample). If the tumour is detected early, surgical removal is usually successful. Otherwise, removal of part or all of the penis may be necessary. Radiotherapy and chemotherapy may also be used.

pentamidine
An antiprotozoal drug (see protozoa) administered by intravenous infusion or nebulizer to prevent and treat pneumocystis pneumonia in immunosuppressed people. Pentamidine is also used to treat the tropical disease leishmaniasis. Side effects of the drug may include nausea and vomiting, dizziness, flushing, rash, and taste disturbances.

pentazocine
An opioid analgesic drug used to relieve moderate or severe pain caused by injury, surgery, cancer, or childbirth. It is rarely used because of its adverse affects, which include dizziness, drowsiness, nausea, vomiting, and, rarely, hallucinations. Drug dependence may develop if high doses are taken for prolonged periods.

peppermint oil
An oil obtained from the peppermint plant Mentha Piperita. It is prescribed to relieve abdominal colic but may cause heartburn. Peppermint oil is also used as a flavouring in some drug preparations.

peptic ulcer
A raw area that develops in the gastrointestinal tract due to erosion by acidic gastric juice. A peptic ulcer most commonly occurs in the stomach, where it is known as a gastric ulcer, or the duodenum (the first part of the small intestine), where it is known as a duodenal ulcer.

CAUSES
The lining of the stomach and duodenum is usually protected from the acid gastric juice by a layer of mucus. If this layer is damaged, the acid can come into contact with the tissues, causing inflammation and erosion. Ulcers can also form in the oesophagus, when acid juice from the stomach enters it (see acid reflux).

The major cause of peptic ulcers is infection with Helicobacter pylori bacteria, which can damage the lining of the stomach and duodenum, allowing the acid stomach contents to attack it. The long-
term use of nonsteroidal anti-inflammatory drugs (NSAIDs), smoking, alcohol consumption, and excess acid production can also damage the stomach lining. A stress ulcer is a peptic ulcer caused by severe physiological stress, such as that due to neurosurgery or to burns (for example, a Curling’s ulcer). Psychological stress is thought to aggravate an existing ulcer.

For further information on how an ulcer forms and the sites where ulcers may develop, see the illustrated box.

For further information on how an ulcer forms and the sites where ulcers may develop, see the illustrated box.

**SYMPTOMS**

There may be no symptoms, or there may be burning or gnawing pain in the upper abdomen when the stomach is empty. The pain of a duodenal ulcer is often relieved by eating, but usually recurs a few hours later. The pain of a gastric ulcer may be worsened by food. Other possible symptoms of a peptic ulcer include a loss of appetite, a bloated or full feeling in the abdomen, nausea, and, sometimes, vomiting.

**COMPLICATIONS**

The most common complication of a peptic ulcer is bleeding as the ulcer penetrates deeper and damages blood vessels. If severe, bleeding may result in haematemesis (vomiting of blood) and melaena (black faeces) and is a medical emergency. Chronic bleeding may cause iron-deficiency anaemia. Rarely, an ulcer may perforate the wall of the digestive tract and lead to peritonitis (inflammation of the abdominal cavity’s lining).

**SITES AND CAUSES OF PEPTIC ULCER**

A peptic ulcer develops in about one in eight people in the UK at some time in their lives. Some of the mechanisms that are involved in causing ulcers are shown below. A peptic ulcer is investigated using endoscopy, which involves passing a gastroscope (a type of endoscope) through the mouth to view the stomach and duodenum. A sample of the stomach lining may be taken at the same time to look for evidence of Helicobacter pylori infection, the major cause of peptic ulcers; blood tests (to check for antibodies against Helicobacter pylori) and breath tests are also used to confirm its presence.

**HOW AN ULCER IS FORMED**

1. Gastric glands in the lining of the stomach secrete acid and the enzyme pepsin, which help to break down food. The acid and pepsin would quickly eat away the stomach and duodenum if other cells in the lining did not secrete a protective mucus.

2. Most peptic ulcers are due to bacterial infection of the stomach lining, which damages its mucous layer (making it vulnerable to acid) and the cells that control excess acid production. Ulcers can also be caused by NSAIDs or excess alcohol combined with excess production of acid. Smoking is another important irritant factor.

3. If damaging influences overcome the protective factors in the stomach or duodenal lining, the mucous layer and mucus-secreting cells are eroded and an ulcer forms. Stress is probably not a prime cause of ulcers but it is possible it may aggravate an existing ulcer.
Another rare complication is scarring of the tissues that occurs as a result of chronic ulcers. Scar tissue around the pyloric sphincter (the outlet where the stomach opens into the duodenum) may cause narrowing of the outlet. This condition, which is called pyloric stenosis, may obstruct the passage of food from the stomach to the duodenum, resulting in vomiting and weight loss.

**DIAGNOSIS AND TREATMENT**

An ulcer is usually diagnosed by endoscopy of the stomach and duodenum, or, less commonly, a barium meal (see *barium X-ray examination*). Tests are carried out to see whether the individual is infected with the *Helicobacter* bacteria. If so, a combination of antibiotics and an ulcer-healing drug will be given as treatment. A further test may be carried out to check that the treatment has been successful. If *Helicobacter* is not detected, however, (for example, in cases where the ulcer was due to the use of NSAIDs), the NSAIDs will be stopped and treatment with *proton pump inhibitors* or *H₂-blockers* will be given.

Surgery is now rarely needed for peptic ulcers, except to treat complications such as bleeding or perforation.

**peptide**

A protein fragment consisting of two or more *amino acids*. Peptides that consist of very many linked amino acids are called polypeptides; chains of polypeptides are called *proteins*. In the body, peptides occur in forms such as *hormones* and *endorphins*.

**percutaneous**

A term meaning “through the skin”.

**perforation**

A hole made in an organ or tissue by disease or injury.

**pergolide**

A drug used to treat *parkinsonism*, a type of neurological disorder resulting from a lack of *dopamine*. It acts by stimulating the *receptors* for dopamine in the brain.

**peri-**

A prefix meaning “around”, as in pericardium, the membranous sac that surrounds the heart.

**perianal haematoma**

A *haematoma* (collection of blood) under the skin around the anus. A perianal haematoma is painful and of sudden onset. It usually disappears with no treatment, but minor surgery may be required to drain the blood.

**periapical abscess**

See *abcess, dental*.

**pericarditis**

Inflammation of the *pericardium* (the double-layered membrane surrounding the heart). This disorder often leads to chest pain and fever. There may also be an increased amount of fluid (see *effusion*) in the pericardial space, which separates the two smooth layers of the pericardium. The excess fluid may compress the heart and restrict its action.

Long-term inflammation can cause a condition called constrictive pericarditis, in which the pericardium becomes scarred, thickened, and contracts, and as a result impedes the heart’s action.

**CAUSES**

Causes of pericarditis include infection; *myocardial infarction* (heart attack); cancer spreading from another site; and injury to the pericardium. The disorder may accompany the autoimmune conditions *rheumatoid arthritis* and *systemic lupus erythematosus*, or kidney failure.

**SYMPTOMS**

Pain, behind the sternum (breastbone) and sometimes in the neck and shoulders, may be more severe if the person takes a deep breath, changes position, or swallows. Pain may be relieved by sitting up and leaning forward. There may also be fever. Constrictive pericarditis causes *oedema* (fluid swelling) of the legs and abdomen.

**DIAGNOSIS AND TREATMENT**

Diagnosis is made from a *physical examination*, from an ECG (which records the electrical activity in the heart) and chest X-rays or echocardiography, which will show any excess fluid around the heart.

If possible, treatment is aimed at the cause. *Analgesic drugs* (painkillers) or *anti-inflammatory drugs* may be given. If there is an effusion, the excess fluid may be drawn off through a needle. In severe constrictive pericarditis, the thickened part of the pericardium may be surgically removed so that the heart can pump freely.

**pericardium**

The membranous bag that surrounds the *heart* and the roots of the major blood vessels that emerge from it.

The pericardium is made up of two layers. The outer layer is tough, inelastic, and fibrous. It is attached to the diaphragm below and to the sternum (breastbone) in front. The inner layer is separated into two sheets; the innermost one is firmly attached to the heart, and the outer one is attached to the fibrous layer. The smooth inner surfaces of these sheets are separated by a space called the pericardial space, which contains a small amount of fluid that lubricates the heart.

**perimenopause**

The period immediately preceding the *menopause* (when the ovaries stop producing eggs and menstruation ceases). During the perimenopause, levels of *oestrogen* begin to fall. Fluctuations in hormone levels cause menstrual periods to become irregular and results in symptoms such as hot flushes.

**perimetry**

A visual field test to determine the extent of peripheral vision. (See *eye, examination of*).

**perinatal**

Relating to the period that extends from just before the birth of a baby to just after. The perinatal period is often defined as the period from the 24th week of pregnancy to the end of the first week after birth.

**perinatology**

A branch of *obstetrics* and *paediatrics* concerned with the study and care of the mother and baby during pregnancy and just after birth.
Perinatologists are specialists in the management of high-risk pregnancies and births, and in the investigation and treatment of prenatal conditions that might endanger the life or health of the fetus, such as Rhesus incompatibility, spina bifida, or biochemical disorders. These doctors are also skilled in assessing the function of the placenta and maintaining the health of an expectant mother who may herself be at risk of health problems.

**Perindopril**
One of a class of drugs called ACE inhibitors, which act by widening the blood vessels and thereby ease the workload on the heart. Perindopril may be used to relieve hypertension (high blood pressure) or congestive heart failure.

The drug may have side effects related to widening of the blood vessels, such as hypotension (low blood pressure), leading to dizziness or fainting; flushed skin; and headaches.

**Perineum**
The area that is bounded internally by the bony structures that surround the pelvic floor (the muscles that support the pelvis). Internally, the perineum extends from the coccyx at the back to the pubic symphysis at the front of the body and incorporates the lower parts of the genitourinary and gastrointestinal tracts. Outside the body, the perineum is the area that extends from the genitals to the anus.

**Periodic fever**
An inherited condition that causes recurrent bouts of fever (see familial Mediterranean fever).

**Periodic paralysis**
See paralysis, periodic.

**Period, menstrual**
See menstruation.

**Periodontal abscess**
See abscess, dental.

**Periodontal disease**
Any disorder of the periodontium (the tissues that surround and support the teeth). The most common type of periodontal disease is gingivitis (gum inflammation). Gingivitis can lead to marginal periodontitis, which often causes the development of a periodontal abscess (see abscess, dental).

In marginal periodontitis there are signs of gingivitis, such as red, soft, shiny, tender gums that bleed easily. There is also an unpleasant taste in the mouth and bad breath. The deepening pockets in the gums gradually expose the sensitive dentine in the roots of the teeth, causing the teeth to ache when hot, cold, or sweet foods or liquids are consumed. Occasionally, there is a discharge of pus from the gums, or a periodontal abscess develops.

**Diagnosis and Treatment**
The diagnosis of periodontitis is by a dental examination to find any pockets and assess their size and depth, and dental X-rays to check for bone loss.

Periapical periodontitis is treated by draining the pus and filling the tooth or alternatively by root-canal treatment, in which decayed pulp is removed from a tooth and its root and the cavity is then filled. If the tooth cannot be saved, however, extraction is performed.

In the early stages of marginal periodontal disease, regular, scrupulous teeth cleaning can prevent further plaque and calculus formation and thus halt destruction of the tissues surrounding the teeth. For more severe periodontitis, the dentist will remove existing plaque and calculus by scaling and root planing (smoothing the surface of an exposed root). In some cases, gingivectomy (surgical trimming of the gums) may be performed to reduce the size of gum pockets. Surgery may also be carried out in order to remove the diseased lining from the pocket (see curettage, dental), so that healthy underlying tissue will reattach itself to the tooth; and the damaged, irregular bone is smoothed. Loose teeth can sometimes be anchored to firmer ones by a method called splinting (see splinting, dental).

**Period pain**
See dysmenorrhea.

**Periostem**
The layer of connective tissue that coats all of the bones in the body except the joint surfaces. The periosteum contains small blood vessels and nerves. It produces new bone in the initial stages of healing following a fracture.

**Periostitis**
Inflammation of the periosteum (connective tissue covering bone). The usual cause is a blow that presses directly on to bone. Symptoms include pain, tenderness, and swelling over the affected area.
**peripheral nerves**

Nerves that run between the central nervous system (CNS, the brain and spinal cord) and particular body tissues. Of these, 12 pairs are cranial nerves and 31 pairs are spinal nerves. Some peripheral nerves are sensory, carrying messages from sensory organs and nerve endings (see receptor) towards the brain and spinal cord; others are motor nerves, carrying signals away from the CNS to stimulate responses in the tissues.

**peripheral nervous system**

The system of peripheral nerves, which fan out from the central nervous system (the brain and spinal cord) to the muscles, skin, internal organs, and glands.

**peripheral vascular disease**

Narrowing of arteries in the legs, and sometimes in the arms, which restricts blood flow and causes pain. In severe cases, gangrene (death of tissue due to lack of blood supply) develops, initially appearing in the toes and then spreading up the leg.

**CAUSES**

In most affected people, peripheral vascular disease is caused by atherosclerosis, in which fatty deposits form on the inner walls of arteries. The greatest risk factor for developing atherosclerosis is smoking. Other risk factors include hypertension (high blood pressure), a high-fat diet, and poorly controlled diabetes mellitus.

Diseases of the peripheral arteries that are not caused by atherosclerosis include Buerger’s disease and Raynaud’s disease.

**SYMPTOMS AND COMPLICATIONS**

The first symptom of narrowed arteries due to atherosclerosis is usually an aching feeling in the leg muscles (usually in the calf) when walking. The pain may be relieved by resting for a few minutes, but recurs after the same amount of walking as before. Prolonged use of the arms may also cause pain.

Symptoms then become worse until, eventually, pain is present even when the person is at rest. The pain may be severe and continuous, even disrupting sleep. By this stage, the blood supply to the affected leg is dangerously low. The affected limb is cold and numb, with dry, scaly skin, and leg ulcers may develop after even minor injuries. In the final stage, gangrene (tissue death) develops, initially appearing in the toes and then spreading up the leg.

Sudden arterial blockage sometimes occurs, causing acute ischaemia (insufficient blood supply to an organ or tissue). This arterial blockage may be due to the rapid development of a clot on top of a plaque of atherosclerosis, by a dissecting aneurysm (splitting of an arterial wall), or by an embolism arising from a clot formed in the heart and carried to a peripheral artery. It causes sudden, severe pain. The affected limb becomes cold and pale or blue, with no pulse. Movement and feeling in the limb are lost.

**DIAGNOSIS AND TREATMENT**

A diagnosis is often based on the results of Doppler ultrasonography, which shows the flow of blood through the affected vessels, or angiography, which will reveal signs of narrowing or other structural abnormalities.

Exercise and giving up smoking are important aspects of treatment. For peripheral vascular disease of the legs, the affected person needs to take scrupulous care of the feet in order to prevent infection and minimize the risk of gangrene. Arterial reconstructive surgery, bypass surgery, or balloon angioplasty may be needed to widen or bypass the affected blood vessels. Amputation is necessary if gangrene has developed.

**peristalsis**

Wavelike movement caused by the rhythmic contraction and relaxation of the smooth muscles in the walls of the digestive tract and the ureters. Peristalsis is responsible for the movement of food and waste products through the digestive system and for transporting urine from the kidneys to the bladder.

In the digestive system, peristalsis in the oesophagus (gullet) moves food towards the stomach, even if the body is...
turned upside down. In the stomach, similar muscle movements help to mix food with gastric juices and move the partly digested food into the duodenum (the first part of the small intestine). The muscles of the small intestine move in a slow, back-and-forth churning motion that allows more time for the intestine to absorb nutrients. In the large intestine, peristaltic contractions occur only about once every 30 minutes. Two or three times a day, however, usually following a meal, a strong, sustained wave of peristalsis in the colon forces the contents into the rectum, and may prompt the urge to defaecate. (See also the illustrated box.)

**peritoneal dialysis**

See dialysis.

**peritoneum**

The two-layered membrane that forms a lining in the abdominal cavity and covers and supports the abdominal organs. The peritoneum contains blood vessels, lymph vessels, and nerves. The surface area of the peritoneum is equal to that of the entire skin.

The peritoneum produces a lubricating fluid that allows the abdominal organs to glide smoothly over each other. It also protects the organs against infection. In addition, the membrane absorbs fluid and acts as a natural filtering system; this function is utilized in one form of dialysis. The peritoneum may become inflamed as a complication of an abdominal disorder (see peritonitis).

**peritonitis**

Inflammation of the peritoneum (the membrane lining the abdominal wall and covering the abdominal organs). Peritonitis is a serious condition.

**CAUSES**
The inflammation is almost always due to irritation and bacterial infection caused by another abdominal disorder. The most common cause is perforation of the stomach or intestine wall, which allows bacteria and digestive juices to move into the abdominal cavity. Perforation is usually the result of a peptic ulcer, appendicitis (acute inflammation of the appendix), or diverticulitis (inflammation of abnormal pouches in the wall of the intestine).

Peritonitis may also be associated with acute salpingitis (inflammation of a fallopian tube), cholecystitis (inflammation of the gallbladder), or septicaemia (blood poisoning).

**SYMPTOMS**

There is usually severe abdominal pain over part or all of the abdomen. After a few hours, the abdomen feels hard, and peristalsis (wavelike contractions of the intestinal muscles) stops (see ileus, paralytic). Other symptoms are fever, bloating, nausea, and vomiting. Dehydration and shock may occur.

**DIAGNOSIS AND TREATMENT**

Diagnosis is made from a physical examination. The affected person will need to be admitted to hospital without delay. Surgery may be necessary to deal with the cause. If the cause is unknown, a laparoscopy or an exploratory laparotomy may be performed. Antibiotic drugs are often given to destroy bacteria, and intravenous infusions of fluid may be given to treat dehydration.

**OUTLOOK**

In most cases, a full recovery is made. Rarely, however, intestinal obstruction, caused by adhesions (bands of scar tissue between loops of intestine), may occur at a later stage.

**peritonsillar abscess**

An abscess (collection of pus) in the soft tissue around the tonsils that occurs as a complication of tonsillitis. A peritonsillar abscess, also known as quinsy, causes pain, swallowing difficulties, and jaw stiffness. The tonsils appear asymmetrical. Antibiotic drugs and analgesic drugs (painkillers) are usually given to help relieve the symptoms, and, in some cases, a small surgical incision may be made to drain the abscess.

**permanent teeth**

The second set of teeth, which usually start to replace the primary teeth at about the age of six. There are 32 permanent teeth: 16 in each jaw. Each set of 16 consists of four incisors, two canines, four premolars and six molars. (See also eruption of teeth.)

**permethrin**

A drug included in preparations used to treat lice and scabies.

**pernicious anaemia**

A type of anaemia (reduced blood levels of the oxygen-carrying pigment haemoglobin) caused by the stomach lining failing to produce intrinsic factor – necessary for vitamin B₁₂ absorption. Deficiency of vitamin B₁₂ prevents bone marrow from producing normal red blood cells (see anaemia, megaloblastic).

**peroneal muscular atrophy**

A rare, inherited disorder characterized by muscle wasting in the feet and calves and then in the hands and forearms. The condition, which is also known as Charcot–Marie–Tooth disease, is caused by degeneration of some peripheral nerves. It usually appears in late childhood or adolescence.

Muscle wasting stops halfway up the arms and legs, making them look like inverted bottles; sensation may be lost. There is no treatment for the disorder, but it is rare for the sufferer to become totally incapacitated because the disease usually progresses at a very slow rate. Life expectancy is normal.

**perphenazine**

A phenothiazine-type antipsychotic drug that is used to relieve symptoms in psychiatric disorders, such as schizophrenia, to sedate agitated or anxious patients; and sometimes for the relief of severe nausea and vomiting. Possible adverse effects include abnormal movements of the face and limbs, drowsiness, blurred vision, stuffy nose, and headache. Long-term use of the drug may cause the movement disorder parkinsonism.

**Persantin**

A brand name for dipyridamole, an antiplatelet drug. Persantin prevents abnormal blood clotting by inhibiting the activity of platelets (tiny blood cells that aid clotting). The drug is used to prevent recurrence of a stroke or transient ischaemic attack or to prevent the development of blood clots in people with prosthetic heart valves.

**persistent vegetative state**

A term used to describe a type of indefinite, deep coma (unconsciousness and unresponsiveness to stimuli). The condition is caused by damage to areas of the brain that control higher mental functions. Although the eyes may open and close and there may be random movements of the head and limbs, there is no response to stimuli such as pain. Only basic functions, such as breathing and heartbeat, are maintained due to functioning of the brainstem. There is no treatment to reverse the situation; with good nursing care, survival for several years is possible.
personality
A term that is used to describe the sum of a person’s traits, habits, and experiences. Temperament, intelligence, emotion, and motivation are important aspects. The development of personality seems to depend on the interaction of heredity and environment.

personality disorders
A group of conditions characterized by a failure to learn from experience or to adapt appropriately to changes, resulting in distress, impaired social functioning, and, in some cases, occupational problems. Personality disorders are patterns of abnormal behaviour that may become especially obvious during periods of stress. They are usually first recognizable in adolescence and may continue throughout life, often leading to depression or anxiety. Personality disorders are not the result of another psychiatric disorder or a result of substance abuse.

TYPES
Specific types of personality disorders are divided into three groups, but there is often overlap between them.

The first group is characterized by eccentric behaviour. Paranoid people show suspicion and mistrust of others; schizoid people are cold emotionally; and schizotypal personalities have behavioural oddities similar to, but less severe than, those of schizophrenia.

In the second group, behaviour tends to be dramatic. Histrionic people are excitable and constantly crave stimulation. Narcissists have an exaggerated sense of self-importance (see narcissism). People with antisocial personality disorder (formerly called psychopaths) disregard accepted standards of behaviour and show no concern for other people’s feelings and rights. As a result, they often come into contact with the police. People with borderline personality disorder behave very impulsively; their self-image, relationships, and emotions are unstable.

People in the third group show anxiety and fear. Dependent personalities lack the self-confidence to function in an independent way (see dependence). People who have avoidant personalities are hypersensitive to criticism and rejection and cautious about new experiences. Those with obsessive-compulsive personalities are very rigid in their habits (see obsessive-compulsive disorder).

TREATMENT
Personality disorders are generally difficult to treat. Treatment options include counselling, psychotherapy, and behaviour therapy. The treatment may need to be prolonged, however, and affected people may not always comply with guidance from doctors or therapists.

personality tests
Questionnaires designed to define various personality traits or types. Tests may be used to detect psychiatric symptoms, various underlying traits, how outgoing or reserved a person is, and predisposition to developing neurotic illness.

perspiration
The production and excretion of sweat from the sweat glands. Perspiration is another name for sweat.

Perthes’ disease
Inflammation of an epiphysis (growing area) of the head of the femur (thigh bone). The disease is a type of osteochondritis juvenilis, thought to be due to disrupted blood supply to the bone.

The condition is most common in boys aged between five and ten years, and usually affects one hip. Symptoms include pain in the thigh and groin, and a limp on the affected side. Movement of the hip is restricted and painful.

Diagnosis is made with X-rays, which may show flattening, fragmentation, and (in later stages) shrinking of the head of the femur. Treatment of the disease may be rest for a few weeks, followed by splinting of the hip, or surgery to fit the head of the femur more securely into the pelvis. The disease usually clears up by itself within three years, but the hip may be permanently deformed.

pertussis
A highly contagious infectious disease, also called whooping cough. It mainly affects infants and young children and is most dangerous in newborn babies. The main features are bouts of coughing, often followed by a “whoop” as air is drawn back into the lungs.

CAUSE
The main cause is infection with Bordetella pertussis bacteria, which are spread in airborne droplets. In affluent countries such as the UK, however, the incidence of pertussis has been greatly reduced by immunization.

SYMPTOMS
After an incubation period of seven to ten days, the illness starts with a mild cough, sneezing, nasal discharge, fever, and sore eyes. After a few days, the cough becomes worse. Whooping occurs in most cases. Sometimes the cough can cause vomiting. In infants, there is a risk of temporary apnoea (cessation of breathing) following a coughing spasm. The illness may last anything from a few weeks up to three months, although the child is usually only infectious for about three weeks.

COMPLICATIONS
Coughing may cause nosebleeds and bleeding from ruptured blood vessels on the surface of the eyes or petechiae (red, flat, pinhead spots) on the face. Other possible complications include dehydration from repeated vomiting; pneumonia; pneumothorax (a form of collapsed lung); bronchiectasis (permanent widening of the airways); and seizures. Untreated, pertussis may prove fatal.

DIAGNOSIS AND TREATMENT
Pertussis is usually diagnosed from the symptoms. In the early stages of the illness, the antibiotic erythromycin is often given to reduce the child’s infectivity. Treatment consists of keeping the child warm, giving small, frequent meals and plenty to drink, and protecting him or her from stimuli, such as smoke, that can provoke coughing. If the child becomes blue or persistently vomits after coughing, he or she must be admitted to hospital.

PREVENTION
In the UK, vaccination against pertussis is usually given at two, three, and four months of age, with a booster dose at three to five years.

Possible complications of vaccination include mild fever and fretfulness. Very rarely, an infant may react severely, with high-pitched screaming or seizures.

Communities need to maintain a high level of immunity, through immunization, to protect infants. It should be remembered that the risks from the disease itself are far greater than any risk from the pertussis vaccine.

perversion
See deviation, sexual.

pes cavus
See claw-foot.

pessary
Any of a variety of devices placed in the vagina. Some types are used to correct the position of the uterus (see uterus, prolapse of); others are used as contraceptive devices. The term “pessary” is also used to refer to a dose of medication, in solid form, that is inserted into the vagina, where it dissolves to release the drug.
pesticides
Poisonous chemicals used to eradicate pests. Different types of pesticide include herbicides, insecticides, and fungicides. Pesticide poisoning, particularly in children, may result from swallowing an insecticide or a garden herbicide (see chlorate poisoning). Poisoning may also occur in agricultural workers, often as a result of inhalation or of absorption of the chemical through the skin. Exposure to pesticides can also occur indirectly, through eating food in which chemicals have accumulated as a result of crop spraying. (See also DDT; defoliant poisoning; lindane; paraquat; parathion.)

petechiae
Red or purple, flat, pinhead-sized spots that occur in the skin or mucous membranes. They do not blanch (go pale) when pressure is applied to them. Petechiae are caused by a localized haemorrhage (leakage of blood) from small blood vessels. They occur in purpura (a group of bleeding disorders) and, sometimes, in bacterial endocarditis (infection of the inner lining of the heart). Petechiae may also arise after periods of excessive straining; in conditions such as pertussis (whooping cough), for example.

pethidine
A synthetic opioid analgesic drug similar to, but less powerful than, morphine. Pethidine is used as a premedication and to relieve severe pain after operations or during childbirth. The drug may cause nausea and vomiting, so it is usually given with an antiemetic drug. Pethidine can be addictive, making it unsuitable for treating continuing pain.

petit mal
A type of generalized seizure that occurs in epilepsy. Petit mal attacks affect children and adolescents but rarely persist into adulthood. Attacks may take place many times a day, and they may sometimes last as long as 30 seconds each. The signs include a momentary loss of awareness, occasionally with drooping eyelids. Treatment for petit mal attacks is with an anticonvulsant drug.

petroleum jelly
A greasy substance, also known as petrolatum or soft paraffin, that is obtained from petroleum. The jelly is commonly used as an ointment base, a protective dressing, and an emollient.

PET scanning
The abbreviation for positron emission tomography. This imaging procedure is a diagnostic technique that is based on the detection of positrons (a type of subatomic particle) emitted by radioactively labelled substances introduced into the body. PET scanning produces images of the metabolic and chemical activity of tissues.

HOW IT WORKS
Certain substances used in biochemical processes in the body, such as glucose or oxygen, are labelled with radioisotopes and then injected into the bloodstream. They are taken up in greater concentrations by tissues that are more active or overactive metabolically. The substances emit positrons, which release photons that are detected by the scanner. A computer then converts this information into images, which are colour-coded to show different levels of tissue activity.

WHY IT IS DONE
PET scans are used to detect brain tumours, locate epileptic activity within the brain, and examine brain function in Alzheimer's disease and in mental illnesses such as depression.

petechiae
Red or purple, flat, pinhead-sized spots that occur in the skin or mucous membranes. They do not blanch (go pale) when pressure is applied to them. Petechiae are caused by a localized haemorrhage (leakage of blood) from small blood vessels. They occur in purpura (a group of bleeding disorders) and, sometimes, in bacterial endocarditis (infection of the inner lining of the heart). Petechiae may also arise after periods of excessive straining; in conditions such as pertussis (whooping cough), for example.

pethidine
A synthetic opioid analgesic drug similar to, but less powerful than, morphine. Pethidine is used as a premedication and to relieve severe pain after operations or during childbirth. The drug may cause nausea and vomiting, so it is usually given with an antiemetic drug. Pethidine can be addictive, making it unsuitable for treating continuing pain.

petit mal
A type of generalized seizure that occurs in epilepsy. Petit mal attacks affect children and adolescents but rarely persist into adulthood. Attacks may take place many times a day, and they may sometimes last as long as 30 seconds each. The signs include a momentary loss of awareness, occasionally with drooping eyelids. Treatment for petit mal attacks is with an anticonvulsant drug.

petroleum jelly
A greasy substance, also known as petrolatum or soft paraffin, that is obtained from petroleum. The jelly is commonly used as an ointment base, a protective dressing, and an emollient.

PET scanning
The abbreviation for positron emission tomography. This imaging procedure is a diagnostic technique that is based on the detection of positrons (a type of subatomic particle) emitted by radioactively labelled substances introduced into the body. PET scanning produces images of the metabolic and chemical activity of tissues.

HOW IT WORKS
Certain substances used in biochemical processes in the body, such as glucose or oxygen, are labelled with radioisotopes and then injected into the bloodstream. They are taken up in greater concentrations by tissues that are more active or overactive metabolically. The substances emit positrons, which release photons that are detected by the scanner. A computer then converts this information into images, which are colour-coded to show different levels of tissue activity.

WHY IT IS DONE
PET scans are used to detect brain tumours, locate epileptic activity within the brain, and examine brain function in Alzheimer's disease and in mental illnesses such as depression.

petechiae
Red or purple, flat, pinhead-sized spots that occur in the skin or mucous membranes. They do not blanch (go pale) when pressure is applied to them. Petechiae are caused by a localized haemorrhage (leakage of blood) from small blood vessels. They occur in purpura (a group of bleeding disorders) and, sometimes, in bacterial endocarditis (infection of the inner lining of the heart). Petechiae may also arise after periods of excessive straining; in conditions such as pertussis (whooping cough), for example.

pethidine
A synthetic opioid analgesic drug similar to, but less powerful than, morphine. Pethidine is used as a premedication and to relieve severe pain after operations or during childbirth. The drug may cause nausea and vomiting, so it is usually given with an antiemetic drug. Pethidine can be addictive, making it unsuitable for treating continuing pain.

petit mal
A type of generalized seizure that occurs in epilepsy. Petit mal attacks affect children and adolescents but rarely persist into adulthood. Attacks may take place many times a day, and they may sometimes last as long as 30 seconds each. The signs include a momentary loss of awareness, occasionally with drooping eyelids. Treatment for petit mal attacks is with an anticonvulsant drug.

petroleum jelly
A greasy substance, also known as petrolatum or soft paraffin, that is obtained from petroleum. The jelly is commonly used as an ointment base, a protective dressing, and an emollient.

PET scanning
The abbreviation for positron emission tomography. This imaging procedure is a diagnostic technique that is based on the detection of positrons (a type of subatomic particle) emitted by radioactively labelled substances introduced into the body. PET scanning produces images of the metabolic and chemical activity of tissues.

HOW IT WORKS
Certain substances used in biochemical processes in the body, such as glucose or oxygen, are labelled with radioisotopes and then injected into the bloodstream. They are taken up in greater concentrations by tissues that are more active or overactive metabolically. The substances emit positrons, which release photons that are detected by the scanner. A computer then converts this information into images, which are colour-coded to show different levels of tissue activity.

WHY IT IS DONE
PET scans are used to detect brain tumours, locate epileptic activity within the brain, and examine brain function in Alzheimer's disease and in mental illnesses such as depression.

petechiae
Red or purple, flat, pinhead-sized spots that occur in the skin or mucous membranes. They do not blanch (go pale) when pressure is applied to them. Petechiae are caused by a localized haemorrhage (leakage of blood) from small blood vessels. They occur in purpura (a group of bleeding disorders) and, sometimes, in bacterial endocarditis (infection of the inner lining of the heart). Petechiae may also arise after periods of excessive straining; in conditions such as pertussis (whooping cough), for example.

pethidine
A synthetic opioid analgesic drug similar to, but less powerful than, morphine. Pethidine is used as a premedication and to relieve severe pain after operations or during childbirth. The drug may cause nausea and vomiting, so it is usually given with an antiemetic drug. Pethidine can be addictive, making it unsuitable for treating continuing pain.

petit mal
A type of generalized seizure that occurs in epilepsy. Petit mal attacks affect children and adolescents but rarely persist into adulthood. Attacks may take place many times a day, and they may sometimes last as long as 30 seconds each. The signs include a momentary loss of awareness, occasionally with drooping eyelids. Treatment for petit mal attacks is with an anticonvulsant drug.

petroleum jelly
A greasy substance, also known as petrolatum or soft paraffin, that is obtained from petroleum. The jelly is commonly used as an ointment base, a protective dressing, and an emollient.

PET scanning
The abbreviation for positron emission tomography. This imaging procedure is a diagnostic technique that is based on the detection of positrons (a type of subatomic particle) emitted by radioactively labelled substances introduced into the body. PET scanning produces images of the metabolic and chemical activity of tissues.

HOW IT WORKS
Certain substances used in biochemical processes in the body, such as glucose or oxygen, are labelled with radioisotopes and then injected into the bloodstream. They are taken up in greater concentrations by tissues that are more active or overactive metabolically. The substances emit positrons, which release photons that are detected by the scanner. A computer then converts this information into images, which are colour-coded to show different levels of tissue activity.

WHY IT IS DONE
PET scans are used to detect brain tumours, locate epileptic activity within the brain, and examine brain function in Alzheimer's disease and in mental illnesses such as depression.

petechiae
Red or purple, flat, pinhead-sized spots that occur in the skin or mucous membranes. They do not blanch (go pale) when pressure is applied to them. Petechiae are caused by a localized haemorrhage (leakage of blood) from small blood vessels. They occur in purpura (a group of bleeding disorders) and, sometimes, in bacterial endocarditis (infection of the inner lining of the heart). Petechiae may also arise after periods of excessive straining; in conditions such as pertussis (whooping cough), for example.

pethidine
A synthetic opioid analgesic drug similar to, but less powerful than, morphine. Pethidine is used as a premedication and to relieve severe pain after operations or during childbirth. The drug may cause nausea and vomiting, so it is usually given with an antiemetic drug. Pethidine can be addictive, making it unsuitable for treating continuing pain.

petit mal
A type of generalized seizure that occurs in epilepsy. Petit mal attacks affect children and adolescents but rarely persist into adulthood. Attacks may take place many times a day, and they may sometimes last as long as 30 seconds each. The signs include a momentary loss of awareness, occasionally with drooping eyelids. Treatment for petit mal attacks is with an anticonvulsant drug.

petroleum jelly
A greasy substance, also known as petrolatum or soft paraffin, that is obtained from petroleum. The jelly is commonly used as an ointment base, a protective dressing, and an emollient.

PET scanning
The abbreviation for positron emission tomography. This imaging procedure is a diagnostic technique that is based on the detection of positrons (a type of subatomic particle) emitted by radioactively labelled substances introduced into the body. PET scanning produces images of the metabolic and chemical activity of tissues.

HOW IT WORKS
Certain substances used in biochemical processes in the body, such as glucose or oxygen, are labelled with radioisotopes and then injected into the bloodstream. They are taken up in greater concentrations by tissues that are more active or overactive metabolically. The substances emit positrons, which release photons that are detected by the scanner. A computer then converts this information into images, which are colour-coded to show different levels of tissue activity.

WHY IT IS DONE
PET scans are used to detect brain tumours, locate epileptic activity within the brain, and examine brain function in Alzheimer's disease and in mental illnesses such as depression.
SYMPTOMS AND SIGNS
Hypertension is usually the only sign. However, certain conditions or situations (such as pressure on the tumour, emotional upset, change in posture, or taking beta-blocker drugs) can cause a surge of hormones. This surge brings on a sudden rise in blood pressure, palpitations, headache, nausea, vomiting, facial flushing, sweating, and, sometimes, a feeling of impending death.

DIAGNOSIS AND TREATMENT
Blood tests and urinalysis are used to detect excessive levels of epinephrine and norepinephrine and thus make a diagnosis. CT scanning, MRI, and radioisotope scanning may be used to locate the tumours, and they are then usually removed surgically. Follow-up medical checks are required because the condition occasionally recurs.

phagocyte
A cell in the immune system that can surround, engulf, and digest microorganisms, foreign particles, and cellular debris. Phagocytes are found in the blood, spleen, lymph nodes, and alveoli (small air sacs) within the lungs. Some types of white blood cell, especially granulocytes and some monocytes, are “free” phagocytes, which are able to migrate through the tissues and engulf harmful organisms and debris.

phalanges
The small bones that make up the fingers, thumb, and toes. The thumb and big toe have two phalanges; all the other fingers and toes have three.

phalanx
A term for any of the bones in the fingers or the toes.

phallus
Any object that may symbolize the penis.

phantom limb pain
The perception that a limb is still present after it has been amputated. The sensation occurs because impulses from the nerves in the stump are interpreted by the brain as coming from the limb.

phantom pregnancy
See pregnancy, false.

pharmaceutical
Any medicinal drug. The term is also used with reference to the manufacture and sale of drugs.

pharmacognosy
The study or knowledge of the pharmacologically active ingredients of plants.

pharmacokinetics
The term that is used to describe how the body deals with a drug. It covers the way in which the drug is absorbed into the bloodstream, how the drug is distributed to different body tissues, and how the drug is broken down for excretion from the body.

pharmacology
The branch of science that is concerned with the discovery and development of drugs; their chemical composition; their actions; their uses; and their toxicity. Pharmacodynamics involves the study of the drugs’ interactions with, and effects on, living organisms.

pharmacopeia
Any book that lists and describes most medicinal drugs, especially an official publication. One such example is the British Pharmacopoeia (BP).

A pharmacopoeia provides a description of the sources, preparations, and doses of drugs. There may also be information on how drugs work and on possible adverse effects.

pharmacy
The practice of preparing drugs, and making up and dispensing prescriptions. The term is also used to describe the place, in a hospital for example, where these activities are carried out.

pharyngeal diverticulum
An alternative term for a pharyngeal pouch (see oesophageal diverticulum).

pharyngeal pouch
See oesophageal diverticulum.

pharyngitis
Acute or chronic inflammation of the pharynx (the part of the throat that is situated between the tonsils and the voicebox), causing a sore throat.

CAUSES
The most common cause is a viral infection. Pharyngitis often occurs as part of a cold (see cold, common) or influenza. It may also be an early feature of glandular fever (see mononucleosis, infectious) or scarlet fever. Sometimes, the condition is due to a bacterial infection, such as streptococcal infection; a rare but serious bacterial cause is diphtheria.

Swallowing substances that can scald, corrode, or scratch the lining of the throat, smoking, and excessive consumption of alcohol may also be the causes of pharyngitis.

SYMPTOMS
As well as a sore throat, there may be discomfort when swallowing, slight fever, earache, and swollen lymph nodes in the neck. In severe cases of pharyngitis, there may be a high fever, and the soft palate and throat may swell so much that breathing and swallowing can become difficult.

TREATMENT
Gargling with warm salt water and taking analgesic drugs (painkillers) is usually the only treatment needed. If the sore throat is severe or prolonged, a doctor may take a throat swab and prescribe antibiotic drugs.

pharynx
The passage that connects the back of the mouth and nose to the oesophagus. The upper part of the passage, or nasopharynx, connects the nasal cavity to the area situated behind the soft palate. The middle part, the oropharynx, runs from the nasopharynx to below the tongue. The lower part, called the laryngopharynx, lies behind and to each side of the larynx (voicebox).

LOCATION OF THE PHARYNX
The pharynx, or throat, plays an essential part in breathing and eating and can change shape to help form vowel sounds in speech. It has a mucous membrane lining.
DISORDERS
The most common disorder affecting the pharynx is acute pharyngitis (inflammation of the pharynx), which causes a sore throat. Another common problem is choking due to the presence of a foreign body, such as a fish-bone, that has become lodged in the pharynx.

A rare disorder is oesophageal diverticulum. In this condition, a small sac (a pharyngeal pouch) develops in the rear wall of the laryngopharynx.

Cancerous tumours (see nasopharynx, cancer of; pharynx, cancer of) are relatively rare in Western countries, but more common in the Far East. Some forms of cancer have been linked with smoking and excessive drinking.

pharynx, cancer of
A cancerous tumour of the pharynx (the part of the throat between the tonsils and the voicebox). Pharyngeal cancer usually develops in the mucous membrane lining the throat.

CAUSES AND INCIDENCE
In the West, almost all cases of pharyngeal cancer are related to smoking and alcohol. The disorder is more common in men, and incidence rises with age.

Tumours of the nasopharynx (see nasopharynx, cancer of) have different causes and symptoms from those that arise lower in the pharynx.

SYMPTOMS
Cancerous tumours of the oropharynx (the middle section of the pharynx) usually cause difficulty in swallowing, often accompanied by a sore throat and earache. Blood-stained sputum may be coughed up. Sometimes, there is only the feeling of a lump in the throat or a visibly enlarged lymph node in the neck.

Cancer of the laryngopharynx (the lowermost part of the pharynx) initially produces a sensation of incomplete swallowing; symptoms that develop in the later stages include a muffled voice, hoarseness, and also an increased difficulty in swallowing.

DIAGNOSIS AND TREATMENT
Diagnosis is made by biopsy, which is often performed in conjunction with laryngoscopy, bronchoscopy, or oesophagoscopy. The growth may be removed surgically or treated with radiotherapy. Anticancer drugs may also be given.

phenelzine
A monoamine oxidase inhibitor antidepressant drug usually given when other antidepressant drugs have been found to be ineffective. Possible side effects include dizziness, drowsiness, and rash. When taken with some other drugs or certain foods, such as mature cheese, broad beans, and yeast extract, phenelzine can cause a dangerous rise in blood pressure.

Phenergan
A brand name for the antihistamine drug promethazine.

phenobarbital
A barbiturate drug that is used mainly as an anticonvulsant. Phenobarbital may be used with phenytoin in the treatment of epilepsy. Possible side effects of the drug include drowsiness, clumsiness, dizziness, excitement, and confusion.

phenol
A strong antiseptic, also called carbolic acid. Liquids or ointments that contain phenolic compounds are used to cleanse wounds and inflamed skin, while phenol in an oil base can be injected into haemorrhoids in order to shrink them. Phenol is also found in chemical substances such as disinfectants; in this form, it is highly toxic.

phenothiazine drugs
COMMON DRUGS
- Chlorpromazine
- Fluphenazine
- Methotrimeprazine
- Perphenazine
- Pipotiazine
- Thoridizaine
- Trifluoperazine

A group of drugs that are used in the treatment of psychotic illnesses (see antipsychotic drugs) some of which are also used to relieve severe nausea and vomiting (see antiemetic drugs).

phenotype
The physical appearance, form, and biochemical make-up of an individual. (In contrast, the genotype is an individual’s genetic make-up.) The phenotype is influenced by the genes that a person possesses and by environmental factors (such as diet).

phenoxy methylpenicillin
A synthetic penicillin drug used to treat bacterial infections, such as pharyngitis, tonsillitis, and dental abscesses.

Possible adverse effects include rash and nausea. A few people may develop a serious allergic reaction, as can occur with other penicillin drugs.

phenylbutazone
A nonsteroidal anti-inflammatory drug (NSAID) used to relieve the symptoms of the inflammatory condition ankylosing spondylitis. Phenylbutazone may cause nausea, fluid retention, rash, and peptic ulcer. It may also increase the risk of certain blood disorders, such as agranulocytosis (a deficiency in granulocytes, a type of white blood cell). The drug is prescribed only under hospital supervision, and only if other drugs are ineffective.

phenylephrine
A decongestant drug used to relieve the symptoms of seasonal allergic rhinitis (hay fever; see rhinitis, allergic) and the common cold. As eye-drops, it is used to dilate the pupils for eye examinations. High doses or prolonged use of the nasal preparations may cause headache and blurred vision; if a person stops taking the drug suddenly, this may make nasal congestion worse. Use of phenylephrine for longer than a week is not, therefore, recommended.

phenylketonuria
An inherited disorder in which the enzyme that converts the amino acid phenylalanine into tyrosine (another amino acid) is defective. Unless phenylalanine is excluded from the diet, they develop an abnormality, but, if phenylalanine is not excluded from the diet, it may become phenylketonuria.

Affected babies show few signs of abnormality, but, if phenylalanine is not excluded from the diet, they develop neurological disturbances including
epilepsy. The babies tend to have blonde hair and blue eyes, and their urine may have a musty odour. Many have the skin condition eczema.

TREATMENT AND PREVENTION
Phenylalanine is found in most foods that contain protein, and also in artificial sweeteners. A specially modified diet is generally recommended throughout life, and sticking to this diet is especially important during pregnancy, because high levels of phenylalanine in the mother can damage the fetus.

phenytoin
An anticonvulsant drug used in the treatment of epilepsy. Side effects may include nausea, dizziness, tremor, and overgrown and tender gums.

pheromone
A substance with a particular odour that, when released in minute quantities by an animal, affects the behaviour or development of other individuals of the same species.

Philadelphia chromosome
A chromosomal abnormality that is associated with one form of leukaemia (see leukaemia, chronic myeloid). In this abnormality, one copy of chromosome 22 has been missing; this portion has become detached and then reattached to a copy of chromosome 9. (See also chromosome; karyotype.)

phimosis
Tightness of the foreskin, preventing it from being drawn back over the glans (head) of the penis. In uncircumcised babies, some degree of phimosis is normal, but it usually improves by age three or four. In some boys, the condition persists and may cause the foreskin to balloon out on urination. Attempts to retract a tight foreskin may make the condition worse.

Phimosis may also develop in adult men, causing painful erection and it may lead to paraphimosis (constriction of the penis behind the glans). Proper cleaning of the glans may not be possible, so balanitis (infection of the glans) may develop.

The treatment for both adults and children is circumcision.

phlebitis
Inflammation of a vein. A clot often develops, in which case the condition is termed thrombophlebitis.

phlebography
The obtaining of X-ray images of veins that have been injected with a radiopaque substance. An alternative name is venography.

phlebotomy
Puncture of a vein to remove blood (see venepuncture; venesection).

phlegm
See sputum.

phobia
A persistent, irrational fear of a certain object or situation. Many people have minor phobias, which may cause distress but do not affect everyday life. A phobia is considered a psychiatric disorder when it interferes with normal social functioning.

TYPES
Simple phobias (specific phobias) are the most common. These problems may involve fear of particular animals or situations, such as enclosed spaces (claustrophobia). Animal phobias usually start in childhood, but other types of phobia can develop at any time.

More severe, pervasive fears are called complex phobias. One form is agoraphobia, which often causes severe impairment. The disorder usually starts in the late teens or early 20s. Another complex phobia is social phobia – fear of being exposed to scrutiny, such as a fear of eating or speaking in public. The onset of this disorder usually occurs in late childhood or early adolescence.

CAUSES
The causes of phobias are unknown. Simple phobias are thought by some to be a form of conditioning. For example, a person with a fear of dogs may have been frightened by a dog in childhood.

SYMPTOMS AND COMPLICATIONS
Exposure to the feared object or situation causes intense anxiety and, in some cases, may lead to a panic attack. The person may start to avoid any situation that might involve contact with the trigger for the fear, and this may adversely affect his or her lifestyle. Phobias may also be associated with depression or with obsessive–compulsive behaviour. In addition, the person may attempt to relieve the fear by using drugs or drinking alcohol to excess.

TREATMENT
Treatment depends on the severity of the condition and the wishes of the individual. For simple phobias, no treatment may be necessary unless the feared object is so common that it cannot easily be avoided (for example, if a person lives in the city but has a fear of lifts). Treatment is more commonly sought for complex phobias. It may involve cognitive–behavioural therapy and sometimes antidepressant drugs.

phocomelia
A limb defect in which the feet and/or the hands are joined to the trunk by short stumps. The condition is extremely rare, but used to occur as a side effect of women taking the drug thalidomide in early pregnancy.

pholcodine
A cough suppressant.

phosphates
Salts containing phosphorus and oxygen. Phosphates are an essential part of the diet and are present in many foods, including cereals, dairy products, eggs, and meat.

FUNCTION
Most of the phosphorus in the body is combined with calcium to form the structure of bones and teeth. The remainder is present in small amounts in most of the body’s tissues, and plays a part in maintaining the acid–base balance of the blood, urine, saliva, and other body fluids. ATP (adenosine triphosphate) is a phosphate compound that stores the energy for chemical reactions in cells.

DISORDERS
In most people, the kidneys maintain a constant level of phosphates in the body by regulating the amount that is excreted in the urine. They can compensate for a slight deficiency of phosphates in the diet by reducing the amount lost in the urine. Hypophosphataemia (an abnormally low level of phosphates in the blood) may occur in some forms of kidney disease, hyperparathyroidism, long-term treatment with diuretic drugs, malabsorption, or prolonged starvation. It causes bone pain, weakness, seizures, and, in severe cases, coma and death.

DRUG THERAPY
Phosphates may be taken by mouth in the form of drug preparations or milk to treat hypophosphataemia. They are also used to treat hypercalcaemia (abnormally high levels of calcium in the blood). Diarrhoea is a possible side effect of phosphate drugs.

phospholipid
A compound formed from one or more lipids (fats), phosphate, and, usually, glycerol. They are manufactured in the liver and small intestine. Examples of phospholipids include lecithins.
Phospholipids are important constituents of cell membranes and nerve tissues, particularly in the brain. In addition, those existing on the surfaces of blood platelets play a part in blood clotting. In an autoimmune disorder called Hughes’ syndrome, the immune system may form antibodies to phospholipids and thus disrupt the clotting process, causing abnormal clot formation.

**phosphorus**
An essential mineral present in many foods, including cereals, dairy products, and meat. In the body, phosphorus is combined with calcium to form the bones and teeth. (See also phosphates.)

**photocoagulation**
The destructive heating of tissue by intense light focused to a fine point, as in laser treatment.

**photophobia**
An uncomfortable sensitivity or intolerance to light. It occurs with certain eye disorders, such as corneal abrasion, and is a feature of meningitis (inflammation of the membranes that surround the brain and spinal cord).

**photorefractive keratectomy**
A surgical treatment for astigmatism (a vision disorder resulting from uneven curvature of the front of the eye), myopia (shortsightedness), and hypermetropia (longsightedness) in which areas of the cornea are shaved away by laser.

**photosensitivity**
An abnormal reaction to light. Photosensitivity usually causes a rash on skin exposed to sunlight or artificial ultraviolet light. This often occurs because a photosensitizer (a substance such as a particular drug, dye, chemical in perfume or soap, or a plant such as mustard) has been ingested or applied to the skin. Photosensitivity is also a feature of disorders such as systemic lupus erythematosus.

People who are susceptible to photosensitivity reactions should avoid being exposed to sunlight and known photosensitizers and should use sunscreens.

**phototherapy**
Treatment that uses light, including sunlight, ultraviolet light, and blue light. Moderate exposure to sunlight is the most basic form and is often helpful in treating the skin disorder psoriasis. PUVA is another form of phototherapy. Phototherapy may also be used to treat seasonal affective disorder.

**PUVA**
This therapy combines the use of long-wave ultraviolet light with a psoralen drug, which sensitizes the skin to light. The procedure is used to treat psoriasis and certain other skin diseases, such as vitiligo. Psoriasis may also be treated using short-wave ultraviolet light, sometimes combined with the application of coal tar.

**BLUE LIGHT**
Visible blue light is used to treat neonatal jaundice (see jaundice, neonatal), which is due to high levels of the pigment bilirubin in the blood. The light is thought to cause the conversion of bilirubin into a harmless substance that can be excreted. To maximize exposure, the baby is undressed and placed under the lights in an incubator (with his or her eyes shielded).

**phrenic nerve**
One of the pair of main nerves that supply the diaphragm. The phrenic nerves branch from the third, fourth, and fifth cervical nerves in the neck (see spinal nerves) and then pass down through the chest to each side of the diaphragm. Each of the phrenic nerves carries motor impulses to one half of the diaphragm and plays a part in the control of breathing. Damage that occurs to either one of the nerves, including invasion by a tumour (such as lung cancer), results in paralysis of that half of the diaphragm.

**physical examination**
See examination, physical.

**physiological saline**
An isotonic solution of 0.9% sodium chloride in water, also called normal saline, used to replace body fluids and rehydrate tissues. Physiological saline is given by intravenous infusion.

**physiology**
The study of body functions, including physical and chemical processes of cells, tissues, organs, and systems, and their various interactions.

**physiotherapy**
Treatment with physical methods, such as exercise or physical agents. Physiotherapy can prevent or reduce joint stiffness and restore muscle strength in arthritis, or after a fracture has healed. It is also used to reduce pain, inflammation, and muscle spasm, and retrain joints and muscles, after stroke or nerve injury. Methods include active exercises and passive movement, heat treatment, massage, ice-packs, hydrotherapy, and TENS (therapeutic use of electrical currents).

Physiotherapy is also used to maintain breathing in people with impaired lung function, and to prevent and treat pulmonary complications after surgery. Techniques for doing this include postural drainage, breathing exercises, and administration of oxygen, drugs, or moisture through a nebulizer.

**phyto-**
A prefix meaning of plant origin.

**phytomenadione**
A form of vitamin K.

**phyto-oestrogens**
Oestrogens that occur naturally in plants.

**pia mater**
The innermost of the three membranes of the meninges, lying next to the brain.

**pica**
A craving to eat non-food substances such as earth or coal. Pica is common in early childhood and may occur during pregnancy. It may also occur in nutritional or iron-deficiency disorders, and in severe psychiatric disorders.
Pickwickian syndrome
An uncommon disorder characterized by extreme obesity, shallow breathing, excessive sleepiness, and obstructive sleep apnoea. Pickwickian syndrome is of unknown cause. The symptoms usually improve with weight loss; specific treatment for sleep apnoea may be required.

PID
The abbreviation for pelvic inflammatory disease.

Piebaldism
A rare genetic disorder in which a patchy absence of the dark pigment melanin results in areas of skin and sometimes hair that lack pigmentation. In many cases, there is a white panel in the centre of the face, which may include the hair and eyebrows as well as the skin. Piebaldism shows an autosomal dominant pattern of inheritance.

Piercing
See ear piercing.

Pierre Robin’s syndrome
A disorder causing abnormalities of the lower jaw and throat. The condition may occur by itself, or may be associated with other problems. It is congenital (present at birth).

The main structural malformations are micrognathia (an abnormally small lower jaw) and cleft palate (or an unusually arched palate). Functional defects include a tendency for the tongue to fall backwards into the throat, causing breathing difficulty and a tendency to choke.

Affected babies may have difficulty in feeding. Micrognathia may disappear as the child grows, but cleft palate and airway obstruction may require surgery.

Pigeon toes
A minor abnormality in which the leg or foot is rotated, forcing the foot and toes to point inwards. Although the condition occurs commonly in toddlers, it has usually corrected itself by the time the child is seven years old.

Pigmentation
Coloration of the skin, hair, and iris of the eyes by melanin, a brown or black pigment produced by cells called melanocytes. The more melanin, the darker the coloration (the amount produced is determined by heredity and exposure to sunlight). Blood pigments can also colour skin (as in a bruise).

Pilocarpine
A drug used in the form of eye-drops to treat glaucoma (raised pressure in the eyeball). Pilocarpine may initially cause blurred vision, headache, and eye irritation. In tablet form, the drug is used to treat dry mouth due to Sjogren’s syndrome or radiotherapy to the head and neck.

Pilonidal sinus
A pit in the skin, often containing hairs, in the upper part of the buttock cleft. The cause is probably hair fragments growing inwards. Although the condition is usually harmless, infection may occur, causing recurrent, painful abscesses.

If a pilonidal sinus is infected, the sinus and a wide area around it will be surgically removed. The resulting wound will usually be left open to allow slow healing from the skin layers below. Recurrence of infection is common, and plastic surgery is sometimes required.

Pimozide
An antipsychotic drug also used to treat Gilles de la Tourette’s syndrome. Pimozide may cause sedation, dry mouth, constipation, and blurred vision.

Pimple
A small pustule or papule.

Pindolol
A beta-blocker drug used to treat angina pectoris (chest pain due to inadequate blood supply to the heart) and hypertension (high blood pressure). Possible side effects are typical of other beta-blocker drugs, except that pindolol is less likely than some others to cause bradycardia (abnormally slow heartbeat).

Pineal gland
A tiny, cone-shaped structure deep within the brain. The pineal gland is situated just below the back of the corpus callosum, the band of nerve fibres that connects the two halves of the cerebrum (the topmost, and largest, area of the brain).

The sole function of the gland appears to be the secretion of the hormone melatonin in response to changes in light. The amount of melatonin secreted varies over a 24-hour cycle, being greatest at night. Hormone secretion is thought to be controlled through nerve pathways from the retina in the eye; a high light level seems to inhibit secretion. The exact function of melatonin is not understood, but it may help to synchronize circadian (24-hour) and other biorhythms.
pinguecula
A small, noncancerous, yellowish spot that occurs on the conjunctiva over the white of the eye. These spots are common in elderly people and may be removed purely for cosmetic reasons. If a pinguecula encroaches on the cornea, it may lead to pterygium.

pink-eye
A common name for conjunctivitis.

pinna
The fleshy part of the outer ear, consisting of a flap of cartilage and skin. It is also called the auricle.

pins-and-needles
A tingling or prickly feeling in an area of skin that is usually associated with numbness and, sometimes, a burning feeling. The medical term for this phenomenon is paraesthesia. Transient pins-and-needles is due to a temporary disturbance in the conduction of nerve signals from the skin to the brain. Persistent pins-and-needles may be caused by a nerve disorder, or neuropathy.

pinta
A bacterial skin infection, caused by Treponema carateum, occurring in remote tropical America. A large spot surrounded by smaller ones appears on the face, neck, buttocks, hands, or feet. After one to twelve months, it is followed by red skin patches that turn blue, then brown, and finally white. A penicillin drug or tetracycline clears up the infection, but the skin may be permanently disfigured.

pinworm infestation
An alternative name for threadworm infestation.

pioglitazone
An oral hypoglycaemic drug (see hypoglycaemics, oral) that is used in combination with other oral hypoglycaemics (either metformin or a sulphonylurea) in the treatment of type 2 diabetes mellitus. Pioglitazone acts by reducing resistance to insulin in the body tissues. Side effects may include gastrointestinal disturbances, weight gain, and anaemia.

piperazine
An anthelminthic drug used to treat infestation by roundworms and threadworms. Possible side effects include abdominal pain, nausea, vomiting, and diarrhoea.

Piriton
A brand name for the antihistamine drug chlorphenamine.

piroxicam
A type of nonsteroidal anti-inflammatory drug (NSAID) that is used to relieve the symptoms of types of arthritis, and to relieve pain in bursitis, tendinitis, and after minor surgery. Possible adverse effects of the drug include nausea, indigestion, abdominal pain, swollen ankles, peptic ulcer, and liver problems.

pituitary gland
Sometimes referred to as the master gland, the pituitary is the most important of the endocrine glands (glands that release hormones directly into the bloodstream).
PITUITARY TUMOURS

**DISORDERS OF THE PITUITARY GLAND**

Any abnormality of the pituitary gland usually means that it produces either too much or too little of one or more hormones, causing changes elsewhere in the body. Locally, serious effects may be caused by enlargement of the gland; for example, it may press on the nearby optic nerves and cause visual defects.

**Congenital and genetic disorders**
Deficiency of *growth hormone* may be a genetic disorder, or it may be due to congenital absence or undergrowth of the pituitary or to damage to the gland sustained during birth. Whatever the cause, deficiency of growth hormone leads to *short stature*.

Congenital growth hormone deficiency may also be associated with deficiency of other pituitary hormones, notably *ACTH* (adrenocorticotrophic hormone), *gonadotrophin hormones*, and thyroid-stimulating hormone (TSH).

**Tumours**
*Pituitary tumours* are usually noncancerous but may cause either overproduction of pituitary hormones (*hyperpituitarism*) or underproduction (*hypopituitarism*), as well as headaches and loss of the visual field.

**Injury**
Birth injury may cause loss of pituitary function, as may head injuries at any age.

**Impaired blood supply**
Rarely, the pituitary may suffer deprivation of its blood supply as a result of pressure exerted on its blood vessels from a growing tumour. This may cause a sudden loss of pituitary function, which may be fatal, or a more gradual loss, which produces signs of general underactivity of the gland.

A similar deprivation of blood supply may occur as a complication of massive blood loss associated with childbirth (Sheehan’s syndrome). This may lead to failure of milk production, and a wide range of secondary effects due to the resultant underactivity of other endocrine glands. Impaired blood supply may also occur due to *vasculitis* or pressure on the gland from an *aneurysm* of a nearby artery.

**Radiation**
Radiotherapy for a pituitary tumour may cause general underactivity of the gland.

**INVESTIGATION**

Techniques include analysis of pituitary hormones in the blood or urine, and of hormones from other endocrine glands under pituitary control; pituitary X-rays, CT scanning, or MRI; angiography, to show blood-vessel displacement by a pituitary tumour; and, possibly, a visual field test (see vision tests).

---

It regulates the activities of other endocrine glands and many body processes (see endocrine system).

For information on disorders that can affect the pituitary gland, see the pituitary gland disorders box.

**STRUCTURE**
The pituitary gland is a pea-sized structure attached by a stalk of nerve fibres to the hypothalamus, a region of the brain just above the gland. The hypothalamus controls pituitary function by nervous stimulation and by secreting substances called hormone-releasing factors.

The pituitary gland consists of three lobes: the anterior, the intermediate, and the posterior.

**FUNCTIONS**
The three lobes of the pituitary produce a range of hormones. For further information on the individual pituitary hormones and their effects, see the illustrated box, overleaf.

The anterior lobe produces most of the pituitary hormones including *growth hormone*, prolactin, ACTH (adrenocorticotrophic hormone), TSH (thyroid-stimulating hormone), and the *gonadotrophins* FSH (follicle-stimulating hormone) and LH (luteinizing hormone). The intermediate lobe secretes melanocyte-stimulating hormone (MSH). The secretion of these hormones is triggered by hormone-releasing factors from the hypothalamus.

The posterior pituitary lobe secretes ADH and *oxytocin*. These hormones are actually produced in the hypothalamus, and pass down nerve fibres to be stored in the posterior lobe until they are needed.

**pitu**atory tumours

Growths in the pituitary gland. Pituitary tumours are rare, and usually noncancerous, but they can put pressure on the optic nerves, causing visual defects.

**CAUSES AND SYMPTOMS**
The causes of pituitary tumours are unknown. One type, called an endocrine inactive tumour, causes the destruction of some of the hormone-secreting cells in the pituitary gland. This leads to inadequate hormone production, causing problems such as tiredness, loss of appetite, symptoms of hypothyroidism (underactivity of the thyroid gland), and cessation of menstrual periods or reduced sperm production.

Tumours may also cause the gland to produce excessive amounts of certain hormones. Tumours of the anterior lobe can cause various disorders. Overproduction of growth hormone causes *gigantism* or *acromegaly*. Excess thyroid-stimulating hormone (TSH) can lead to *hyperthyroidism*. Excess adrenocorticotrophic hormone (ACTH) can cause Cushing’s disease (see Cushing’s syndrome). An increase in prolactin can cause *galactorrhoea* (abnormal milk production), *amenorrhoea* (absence of menstrual periods), and *infertility* in women. In men, it can cause *impotence*, infertility, feminization, and galactorrhoea.

Tumours that affect the posterior pituitary may disrupt the production of antiuretic hormone (ADH) and lead to *diabetes insipidus*.

Pressure from tumour enlargement may cause headaches, cranial nerve paralysis, and defects of vision.

**DIAGNOSIS AND TREATMENT**
Diagnosis is made using blood tests to measure hormone levels; X-rays; MRI of the pituitary; and, often, vision tests.

Treatment may consist of surgical removal of the tumour, radiotherapy, hormone replacement, or a combination of these techniques. The drug bromocriptine may be used; it can reduce production of certain hormones and shrink some tumours.

**pityriasis alba**

A common skin condition occurring in childhood and adolescence, particularly in dark-skinned children, that is caused by mild eczema. Irregular, fine, scaly, pale patches appear on the face; the patches may be more noticeable after exposure to the sun, because they tan poorly. The condition can usually be cleared up with emollients.
pityriasis rosea
A common, mild skin disorder in which a rash of flat, scaly-edged, pink spots or patches appears on the trunk and upper arms. It is not contagious and mainly affects children and young adults. Its cause is unknown, but may be associated with a viral infection.

The first sign is a large, round spot, called a herald patch, on the trunk. The rash appears about a week later. It lasts for four to eight weeks, may cause itching, and usually clears up without treatment. Calamine lotion or antihistamine drugs may relieve any itching.

pityriasis versicolor
A common skin condition, also known as tinea versicolor, in which patches of white, brown, or salmon-coloured flaking skin appear on the trunk and neck. The patches are more noticeable on sun-tanned skin; they may be either paler or darker than the surrounding skin. Pityriasis versicolor mainly affects young and middle-aged adults. It is caused by Pityrosporum, a fungus that exists on most people's skin and normally produces no symptoms. The condition is not contagious.

Treatment is with selenium sulphate shampoo, used as a lotion, or with antifungal drugs in the form of a cream or lotion. The whole of the affected area must be treated thoroughly, to prevent the infection from recurring. With careful treatment, the infection will clear up in two to three weeks, but the spots may take months to disappear. Antifungal tablets may be needed if the rash does not improve or is very widespread.

pityrosporum
A group of fungi that normally live on the skin or the scalp, but which may sometimes cause pityriasis versicolor or may multiply excessively resulting in a condition called folliculitis (inflammation of the hair follicles). This overgrowth of fungi may occur in people with lowered resistance to infection; people taking antibiotic drugs, corticosteroids, or oral contraceptives; those with diabetes mellitus; and those under emotional stress. It may also be associated with a predisposition to severe dandruff or seborrhoeic dermatitis.

Treatment includes addressing any underlying cause and using solutions or creams containing antifungal drugs.

pivmecillinam
A type of penicillin drug.

pivot joint
A form of joint that allows only rotation, such as the joint between the top of the spine and the skull.

pizotifen
An antihistamine drug used to prevent migraine in people with frequent, disabling attacks. Adverse effects of taking the drug can include nausea, dizziness, drowsiness, dry mouth, and muscle pains. Prolonged use can in some cases cause weight gain.

PKU test
See Guthrie test.

placebo
A chemically inert substance given instead of a drug. Benefit may be gained from a placebo because the person taking it believes it will have a positive effect. As the effectiveness of any drug may be partly due to this “placebo effect”, many new drugs are tested against a placebo preparation.

placenta
The organ that develops inside the uterus during pregnancy and that is the link between the blood supplies of the mother and the baby.

FUNCTION OF THE PLACENTA
The mother’s and baby’s blood do not mix in the placenta, but are separated from each other by such a thin layer of cells that exchange of nutrients and oxygen (from mother to baby) and waste products (from baby to mother) can occur between the two blood circulations.

structure
The placenta develops from the chorion (the outermost layer of cells that develops from the fertilized egg). It is attached to the uterus lining and connected to the baby by the umbilical cord. The placenta, and the other uterine tissues, which are all expelled at birth, are collectively known as the afterbirth.

FUNCTION
The placenta transfers oxygen, nutrients, and protective antibodies from the mother’s circulation to the fetus’s circulation and removes waste products from the fetal blood into the mother’s blood for excretion by her lungs and kidneys.

The organ also produces hormones such as oestrogen, progesterone, and human chorionic gonadotrophin (HCG). These hormones enter the mother’s blood to help her body adapt to the conditions of pregnancy; they also prepare the breasts for breast-feeding. High levels of HCG appear in the woman’s urine during early pregnancy, and detection of them in the urine forms the basis of pregnancy tests.

placental abruption
Separation of all or part of the placenta from the wall of the uterus before the baby is delivered.
PLACENTA PRAEVIA

CAUSES
The exact cause of placental abruption is not known, but it is more common in women who have long-term hypertension (high blood pressure) and in those who have previously had the condition or who have had several pregnancies. Smoking and high alcohol intake may also contribute to the risk of placental abruption.

SYMPTOMS
Symptoms usually occur suddenly and depend on how much of the placenta has separated from the wall of the uterus. They include vaginal bleeding, which can be severe haemorrhaging in complete separation; abdominal cramps or backache; severe, constant abdominal pain; and reduced fetal movements.

TREATMENT
If the bleeding does not stop, or if it starts again, it may be necessary to induce labour (see induction of labour). A small placental abruption is usually treated with bed-rest in hospital. In more severe cases of placental abruption, an emergency caesarean section is often necessary to save the the life of the fetus. A blood transfusion is also sometimes required.

placenta praevia
Implantation of the placenta in the lower part of the uterus, near or over the cervix. The condition varies in severity from marginal placenta praevia, when the placenta reaches the edge of the cervical opening, to complete placental praevia, when the entire opening of the cervix is covered.

SYMPTOMS
Marginal placenta praevia may have no adverse effect. More severe cases often cause painless vaginal bleeding in late pregnancy, as placental tissue separates from the wall of the uterus.

TREATMENT
If the bleeding is slight and the pregnancy still has several weeks to run, bed rest in hospital may be all that is necessary. The baby will probably be delivered by caesarean section at the 38th week. If the bleeding is heavy or if the pregnancy is near term, an immediate delivery is carried out.

placenta, tumours of
See choriocarcinoma; hydatidiform mole.

plagiocephaly
Any asymmetry or distortion in the shape of the head. Plagiocephaly is usually due to irregularity in the closure of the sutures (fixed joints) between the skull bones.

plague
A serious infectious disease caused by the bacterium *Yersinia pestis*. It mainly affects rodents but can be transmitted to humans by flea bites. Plague caused one of the largest pandemics (world-wide epidemics) in history; the “Black Death” of the 14th century, which killed 25 million people in Europe alone. Today, human plague occurs sporadically in parts of the world, but not in Europe.

CAUSES, TYPES, AND SYMPTOMS
There are two main types: bubonic and pneumonic. Bubonic plague is caused by a bite from an infected flea. Pneumonic plague can be a complication of bubonic plague or can be transmitted in infected droplets expelled in coughing.

Bubonic plague is characterized by swollen lymph nodes (which are called “buboes”). Symptoms usually start two to five days after infection, with fever, shivering, and severe headache. Soon, the smooth, red, painful buboes appear, usually in the groin. There may be bleeding into the skin around the buboes, causing dark patches. The victim may have seizures. Without prompt treatment, the person may die. Occasionally, septicemia (blood poisoning) may cause death before buboes appear.

Pneumonic plague affects the lungs. The symptoms are severe coughing that produces a bloody, frothy sputum and laboured breathing. Without early treatment, death is almost inevitable.

DIAGNOSIS AND TREATMENT
A sample of fluid from a bubo, or a sputum sample, is taken to establish the presence of plague bacteria and confirm the diagnosis. Possible treatments are streptomycin and tetracycline drugs.

plantar fascitis
*Fasciitis* (inflammation of a layer of connective tissue) affecting the sole of the foot, especially the heel.

plantar wart
See wart, plantar.

plants, poisonous
Several species of plant, including foxglove, holly, deadly nightshade, and laburnum, are poisonous or can cause severe allergic reactions.

Paradoxically, many poisonous plants are also sources of useful drugs. Examples include deadly nightshade, from which atropine is made, and foxglove, from which digitalis drugs are created.

CAUSES AND SYMPTOMS OF POISONING
Toxins from plants can cause poisoning either through contact with the skin, if a person touches or handles the plants, or internally, if a person (usually a child) ingests them.

Skin contact
Nettles, hagweed, poison ivy, and primula cause skin reactions, including rash, itching, and blisters, on contact. In some people, these reactions can be extremely severe.

Internal poisoning
Plants that are poisonous to eat include foxglove,aconite, hemlock, laburnum seeds, and holly and deadly nightshade berries. Internal poisoning most commonly affects young children who have consumed colourful berries. Symptoms of poisoning vary according to the plant but may include abdominal pain, vomiting, flushing, breathing difficulty, delirium, and coma. Urgent medical attention is required.

TREATMENT
Skin reactions can be treated by washing the area affected (and any clothes that have come into contact with the plant), and applications of alcohol or calamine lotion. Corticosteroid drugs may be prescribed for severe reactions.

Internal poisoning usually requires gastric lavage. Fatal poisoning is rare. (See also mushroom poisoning.)

plaque
The term given to an area of atherosclerosis (fatty deposits within arteries). The plaques are symptomless until they
are large enough to reduce blood flow or until the surface of a plaque is disturbed, causing thrombosis (clotting of blood). Plaques in coronary arteries, which supply blood to the heart, cause coronary artery disease.

**plaque, dental**
A rough, sticky coating on the teeth consisting of saliva, bacteria, and food debris. It is the chief cause of tooth decay (see caries, dental) and gingivitis (gum disease), and forms the basis of a hard deposit (see calculus, dental).

Some of the microorganisms found in plaque, particularly the bacterium *Streptococcus mutans*, break down sugar in the remains of carbohydrate food that sticks to the mucus, creating an acid that can erode tooth enamel.

**plasma**
The fluid part of blood that remains if the blood cells are removed. Plasma is a solution that contains many nutrients, salts, and proteins.

**plasma D-dimers**
Substances formed in the body by the breakdown of blood clots (see blood clotting); for example, when the body clears blocked blood vessels. Tests that can detect plasma D-dimers can be helpful in monitoring conditions such as disseminated intravascular coagulation or in deciding whether someone may have had a pulmonary embolism or deep vein thrombosis (see thrombosis, deep vein). These tests are not used to make or confirm a diagnosis, but the possibility of pulmonary embolism or deep vein thrombosis may be ruled out if plasma D-dimers are not present.

**plasminogen activator**
See tissue plasminogen activator.

**Plasmodium**
A group of protozoa (single-celled organisms) including the microorganisms that are responsible for malaria. Once they are introduced into the body, usually via a mosquito bite, plasmodia live in liver cells, red blood cells, and in the bloodstream.

**plaster cast**
See cast.

**plaster of Paris**
A white powder that is made of a calcium compound that, when mixed with water, produces a paste that can be shaped before it sets. Plaster of Paris is used for constructing casts and making dental models (see impression, dental).

**plastic surgery**
Any operation carried out to repair or reconstruct skin and tissue that has been damaged or lost, is malformed, or has changed with aging. (Any procedures that are performed mainly to improve the appearance of a healthy person are described as cosmetic surgery.)

Plastic surgery is often performed to repair damage caused by severe burns or injuries, cancer, or some operations, such as mastectomy (removal of breast tissue). Some congenital conditions may also require plastic surgery; these include cleft lip and palate, hypospadias (a defect in the penis), and imperforate anus (see anus, imperforate).

Techniques that are used in plastic surgery include skin grafts, skin flaps, and Z-plasty; these may be combined with implants or a bone graft.

**-plasty**
A suffix meaning “shaping by surgery”. The term is usually used to describe various procedures in plastic surgery, such as rhinoplasty (surgery on the nose) and mammoplasty (reshaping or reconstruction of the breast).

**platelet**
The smallest type of blood cell; also called a thrombocyte. Platelets play a major role in blood clotting. When they are activated, for example by contact with damaged blood-vessel walls, they clump together at injury sites, releasing chemicals that constrict the damaged blood vessels and trigger the process of
pleural effusion
An accumulation of fluid between the layers of the pleura (the membrane lining the lungs and chest cavity). Pleural effusion may be caused by lung infections such as pneumonia or tuberculosis, or other lung disorders such as pulmonary embolism, or mesothelioma (a tumour of the pleura). It may also result from heart failure or cancer. Pleural effusion may affect one or both sides of the chest. The excess fluid puts pressure on the lung beneath, gradually making breathing difficult.

Diagnosis is confirmed by chest X-ray. Some fluid may be removed with a needle and syringe and examined to find the cause of the condition. A biopsy (tissue sample) of the pleura may also be needed. The underlying cause is treated; fluid may also be drained off to relieve breathing problems.

pleurisy
Inflammation of the pleura (the membrane lining the lungs and chest cavity). Causes include lung infections, such as pneumonia, or, more rarely, pulmonary embolism, lung cancer, or rheumatoid arthritis. Pleurisy causes a sharp chest pain, which is worse when breathing in; this pain is due to the inflamed layers of the membrane rubbing together. Treatment of the condition is aimed at the underlying cause, and analgesic drugs (painkillers) are also given.

pleurodynia
Pain in the chest, also known as Bornholm disease. Pleurodynia is caused by coxsackie virus B infection. It often occurs in epidemics and usually affects children.

There is sudden severe pain in the lower chest or upper abdomen, with fever, sore throat, headache, and malaise. The disease usually settles in three to four days without treatment.

plexus
A network of interwoven nerves or blood vessels. Examples include the solar plexus (the large network of nerves just behind the stomach) and the brachial plexus (a network of nerves in the neck and upper arm).

plethysmography
A way of estimating the blood flow in vessels by measuring changes in the size of a body part. Plethysmography of the penis is sometimes used to investigate impotence in men by establishing whether or not a man has erections while sleeping.

plethora
A florid, bright-red, flushed complexion. It may be caused by dilation of blood vessels, or, less commonly, by polycythaemia (excessive numbers of red blood cells).

play therapy
A method used in the psychoanalysis of young children, based on the principle that all play has some symbolic significance. Watching a child at play helps a therapist diagnose the source of the child’s problems; the child can then be helped to “act out” thoughts and feelings that are causing anxiety.

pneumococcus
A common name for the bacterium Streptococcus pneumoniae (see Streptococcal infections).

pneumothorax
air in the pleural cavity may result in collapse of a lung; the condition may occur spontaneously or may result from a penetrating injury. Cancerous tumours (see mesothelioma) may also develop in the pleura.

pneumonia
A lung infection (also called bronchitis). It often occurs as a complication of other infections such as influenza. Signs include fever, cough (usually with phlegm), and sometimes chest pain. It is usually treated with antibiotics.

Pneumoconiosis
Any of a group of lung diseases that are caused by the inhalation of certain mineral dusts. Dust particles of less than 0.005 mm across can reach the air sacs in the lungs (see alveolus, pulmonary); they may accumulate and cause thickening and scarring. As a result, the lungs may become less efficient at supplying oxygen to the blood.

Plummer–Vinson syndrome
Difficulty in swallowing due to webs of tissue forming across the upper oesophagus. The syndrome often occurs along with severe iron-deficiency anaemia and affects middle-aged women.

plutonium
A radioactive metallic element which occurs naturally only in uranium ores; it is produced artificially in breeder reactors. It is used as a fuel in nuclear reactors and nuclear weapons. The element is highly toxic if it enters the body, because it emits high levels of radiation and is absorbed into the bone marrow, where it may remain for many years.

PMS
The abbreviation often used for premenstrual syndrome.

PMT
The abbreviation for premenstrual tension, an alternative name for premenstrual syndrome.

pneumaturia
The presence of gas, including air, in the urine. Pneumaturia usually indicates that a fistula (abnormal channel) has developed between the bladder and the intestine.

pleural effusion
An accumulation of fluid between the layers of the pleura (the membrane lining the lungs and chest cavity). Pleural effusion may be caused by lung infections such as pneumonia or tuberculosis, or other lung disorders such as pulmonary embolism, or mesothelioma (a tumour of the pleura). It may also result from heart failure or cancer. Pleural effusion may affect one or both sides of the chest. The excess fluid puts pressure on the lung beneath, gradually making breathing difficult.

Diagnosis is confirmed by chest X-ray. Some fluid may be removed with a needle and syringe and examined to find the cause of the condition. A biopsy (tissue sample) of the pleura may also be needed. The underlying cause is treated; fluid may also be drained off to relieve breathing problems.

pleurisy
Inflammation of the pleura (the membrane lining the lungs and chest cavity). Causes include lung infections, such as pneumonia, or, more rarely, pulmonary embolism, lung cancer, or rheumatoid arthritis. Pleurisy causes a sharp chest pain, which is worse when breathing in; this pain is due to the inflamed layers of the membrane rubbing together. Treatment of the condition is aimed at the underlying cause, and analgesic drugs (painkillers) are also given.

pleurodynia
Pain in the chest, also known as Bornholm disease. Pleurodynia is caused by coxsackievirus B infection. It often occurs in epidemics and usually affects children.

There is sudden severe pain in the lower chest or upper abdomen, with fever, sore throat, headache, and malaise. The disease usually settles in three to four days without treatment.

plexus
A network of interwoven nerves or blood vessels. Examples include the solar plexus (the large network of nerves just behind the stomach) and the brachial plexus (a network of nerves in the neck and upper arm).

pneumococcus
A common name for the bacterium Streptococcus pneumoniae (see Streptococcal infections).

pneumoconiosis
Any of a group of lung diseases that are caused by the inhalation of certain mineral dusts. Dust particles of less than 0.005 mm across can reach the air sacs in the lungs (see alveolus, pulmonary); they may accumulate and cause thickening and scarring. As a result, the lungs may become less efficient at supplying oxygen to the blood.

TYPES AND CAUSES
The main types of pneumoconiosis are asbestosis (see asbestos-related diseases), coal workers’ pneumoconiosis,
and silicosis, caused by silica dust. These diseases primarily affect workers over 50 years of age. However, the incidence is falling due to better preventive measures.

**SYMPTOMS AND COMPLICATIONS**
The main symptom of pneumoconiosis is shortness of breath. In severe cases, *cor pulmonale* (right-sided heart failure due to lung damage) or *emphysema* (destruction of the air sacs in the lungs) may develop. The risk of *tuberculosis* is increased in coal workers’ pneumoconiosis and silicosis; the risk of *lung cancer* is increased in asbestosis. Smoking further increases the risk.

**DIAGNOSIS AND TREATMENT**
Pneumoconiosis is often detected by a *chest X-ray* before symptoms develop. Diagnosis is also based on a history of exposure to dusts, medical examination, and *pulmonary function tests*.

There is no treatment for the condition apart from treating any complications. Further exposure to any dust must be avoided.

**pneumocystis pneumonia**
A lung infection caused by *Pneumocystis carinii*, a type of *protozoan*. Pneumocystis pneumonia is an *opportunistic infection*, which is dangerous only to people with impaired resistance to infection. It is particularly common in those with *AIDS*. Symptoms include fever, dry cough, and shortness of breath, and may last for several weeks or months.

Diagnosis is made by examination of sputum or a lung *biopsy* (tissue sample). High doses of *antibiotic drugs* (commonly co-trimoxazole) may eradicate the infection; lower doses are used in the long term to prevent infection in people at increased risk.

**pneumonectomy**
Surgery carried out to remove a *lung*.

**pneumonia**
Inflammation of the lungs usually due to infection. There are two main types: lobar pneumonia and bronchopneumonia. Lobar pneumonia first affects one lobe of a lung. In the condition bronchopneumonia, inflammation initially starts in the bronchi and bronchioles (airways), then spreads to affect patches of tissue in one or both lungs.

**CAUSES**
Pneumonia is usually caused by various types of infection. Most cases are due either to viruses, such as adenovirus or respiratory syncytial virus, or to bacteria, such as *Streptococcus pneumoniae*, *Haemophilus influenzae*, *Staphylococcus aureus*, and *Mycoplasma pneumoniae*.

Another form is aspiration pneumonia, due to accidental inhalation of vomit. Aspiration pneumonia usually occurs in people whose cough reflex is not functioning, such as those who have drunk excessive amounts of alcohol or taken certain illegal drugs, or people who have suffered a head injury.

**SYMPTOMS AND COMPLICATIONS**
Symptoms usually include fever, chills, shortness of breath, a sharp chest pain, and a cough that produces yellow-green *sputum* and occasionally blood.

Potential complications include *pleurisy* (inflammation of the membrane lining the lungs and chest cavity), a lung *abscess* (collection of pus), and *septicaemia* (blood poisoning).

**DIAGNOSIS AND TREATMENT**
Diagnosis is made by physical examination, *chest X-ray*, and examining sputum and blood for microorganisms. Treatment depends on the cause, and usually includes *antibiotic drugs*. Aspirin or *paracetamol* may be given to reduce fever, and, in severe cases, *oxygen therapy* and artificial *ventilation* may be needed.

In most cases, recovery usually occurs within two weeks.

**pneumonitis**
Inflammation of the lungs that may cause coughing, breathing difficulty, and wheezing. Causes include an allergic reaction to dust containing animal or plant material (see *alveolitis*) and exposure to radiation (see *radiation hazards*). Pneumonitis may also occur as a side effect of drugs, such as *aminophylline* and *azathioprine*.

**pneumothorax**
A condition in which air enters the pleural cavity (the space between the layers of membrane lining the lung), causing partial or total collapse of the lung. The air may enter the lungs from the airways or from outside the body.

**CAUSES**
The most common cause is the spontaneous rupture of an enlarged alveolus (air sac). This occurrence is much more common in men than in women; it usually affects tall, thin young men who have no underlying lung disease. Other possible causes include a penetrating
chest wound that allows air into the pleural cavity, or a fractured rib that tears the lung beneath it.

**SYMPTOMS**  
The main symptoms of pneumothorax are chest pain or shortness of breath, which varies depending on the size of the pneumothorax. If air continues to leak, the pneumothorax may grow to produce a tension pneumothorax. This condition may be life-threatening. It causes an area of high pressure that compresses the lung and heart tissues, preventing the passage of oxygen-rich blood from the lungs to the heart.

**DIAGNOSIS AND TREATMENT**  
Diagnosis is confirmed by chest X-ray. A small pneumothorax may disappear in a few days without treatment. A larger one, or one associated with underlying lung disease, may need hospital treatment. This involves removing the air through a tube with a one-way valve, known as a chest drain, to allow the lung to reinflate fully.

**pocket, gingival**  
A feature of marginal periodontitis.

**podiatry**  
Another name for chiropody, a paramedical speciality concerned with the feet.

**podophyllin**  
A drug used to treat genital warts (see warts, genital). Podophyllin may cause irritation of the treated area and severe toxicity on excessive application.

**poison**  
A substance that, in small amounts, disrupts the structure and/or function of cells. (See also drug poisoning; poisoning.)

**poisoning**  
Poisons may be swallowed, inhaled, absorbed through the skin, or injected under the skin (as with an insect sting). They may also originate within the body, for example when bacteria produce endotoxins, or when metabolic disorders produce poisonous substances or allow them to accumulate. Poisoning may be acute, if a large amount of poison enters the body in a short time, or chronic, resulting from a gradual accumulation of poison that is not quickly eliminated from the body.

Unintentional poisoning occurs most commonly in young children. Adults may be poisoned by mistaking the dosage of a prescribed drug (see drug poisoning), by taking very high doses of vitamin or mineral supplements, by exposure to poisonous substances in industry, or by drug abuse. Poisoning may also be a deliberate attempt to commit suicide. Antidotes may be available to counteract the effects of the poison.

**polio**  
An abbreviation for poliomyelitis.

**poliomyelitis**  
Also called polio, a highly infectious disease caused by the polio virus. It is usually mild, but in serious cases, it attacks the brain and spinal cord, sometimes causing paralysis or death.

**CAUSE AND INCIDENCE**  
The virus is spread from the faeces of infected people to food. Airborne transmission also occurs. In countries with poor hygiene and sanitation, most children develop immunity through being infected early in life, when the infection rarely causes serious illness. In countries with better sanitation, this does not occur and, if children are not vaccinated, epidemics can occur. In the UK, however, polio is now very rare due to a vaccination programme.

**SYMPTOMS**  
Most infected children have no symptoms at all. In others, however, there is usually an incubation period of seven to 14 days, after which a slight fever, sore throat, headache, and vomiting occur. Most children recover completely after a few days. In some, however, inflammation of the meninges (membranes surrounding the brain and spinal cord) may develop. This condition causes fever, severe headache, stiff neck and back, and aching muscles, sometimes with widespread twitching. In a few cases, extensive paralysis, usually of the legs and lower trunk, then develops within a few days. If the infection spreads to the brainstem, the affected person may find it difficult or impossible to breathe and swallow.

**DIAGNOSIS**  
Diagnosis is made from a sample of cerebrospinal fluid (see lumbar puncture), a throat swab, a faeces sample, or blood tests for antibodies to the virus. Paralysis occurring with an acute feverish illness is characteristic of severe polio, and an immediate diagnosis can often be made.

**TREATMENT**  
There is no effective drug treatment for polio. Nonparalytic patients usually need bed rest and analgesic drugs (painkillers). If the person is paralysed, physiotherapy and, in some cases, catheterization, tracheostomy (surgical creation of an opening in the windpipe for a breathing tube), and artificial ventilation are needed.

**OUTLOOK**  
Recovery from nonparalytic polio is complete. More than half of those with paralysis make a full recovery, fewer than a quarter are left with severe disability, and fewer than 1 in 10 dies.

**PREVENTION**  
In the UK, vaccination against polio is given at approximately two, three, and four months, with a booster dose given between the ages of three and five, and again on leaving school (see immunization). Parents and carers should also keep their immunization up-to-date.

**pollen**  
Dustlike grains produced by the male sexual organs of plants for fertilizing the female organs. Pollens from flowers, grasses, and some other plants may produce allergic reactions (see allergy) in humans and cause disorders such as hay fever (see rhinitis, allergic).

**pollution**  
Contamination of the environment by poisons, radioactive substances, microorganisms, or other wastes.

**poly-**  
A prefix meaning “many” or “much.”

**polyarteritis nodosa**  
Also called periarthritis nodosa, an uncommon form of vasculitis (inflammation of blood vessels), affecting medium-sized arteries. Areas of arterial wall become inflamed, weakened, and liable to aneurysms (ballooned-out segments). The severity of the condition depends on the arteries that are affected and how much they are weakened.

**CAUSE AND INCIDENCE**  
The cause seems to be an immune system disturbance, sometimes triggered by exposure to the hepatitis B virus. It is most common in adults and affects men more than women.

**SYMPTOMS**  
Early symptoms of polyarteritis nodosa include fever, aching muscles and joints, general malaise, loss of appetite and weight, and, sometimes, nerve pain. There may also be hypertension (high blood pressure), skin ulceration, and gangrene (localized tissue death). If the coronary arteries are affected, myocardial infarction (heart attack) may occur. Many patients suffer abdominal
pain, nausea, vomiting, diarrhoea, and blood in the faeces. The condition may occasionally lead to kidney failure.

**DIAGNOSIS, TREATMENT, AND OUTLOOK**

Diagnosis is made by biopsy (tissue sampling) and angiography. Large doses of corticosteroids, and in some cases immunosuppressants, may allow survival for at least five years. Without treatment, few patients survive for this length of time.

**polyarthritides**

Any form of arthritis (joint inflammation) that affects several joints at once. It may be a complication of infections such as rubella, gastroenteritis, or sexually transmitted infections (see reactive arthritis). Other arthritic conditions that can cause polyarthritis include rheumatoid arthritis, osteoarthritis, and juvenile chronic arthritis.

**polycystic kidney**

See kidney, polycystic.

**polycystic ovary syndrome**

A condition, previously known as Stein–Leventhal syndrome, that is characterized by multiple ovarian cysts together with oligomenorrhea (scanty periods) or amenorrhea (absence of periods), reduced fertility, hirsutism (excessive hairiness), and obesity. Most women with the syndrome begin menstruation at a normal age, but between the ages of 15 and 30 periods become irregular and then cease. Hirsutism and obesity occur in about half of all cases.

**CAUSES**

The condition is now thought to result from insulin resistance, which leads to the overproduction of insulin. This situation is associated with increased levels of androgen hormones, giving rise to symptoms. Polycystic ovary syndrome may also have a genetic element.

**DIAGNOSIS AND TREATMENT**

A diagnosis of polycystic ovary syndrome is based on the patient’s history, measurement of hormone levels, and ultrasound scanning of the ovaries. Treatment depends on which aspect of the condition most concerns the patient. Weight reduction often brings about an improvement in all other symptoms and the return of regular periods. Metformin, an oral hypoglycaemic drug, may be used to reduce insulin resistance and as an aid to weight loss; hirsutism may respond to treatment with an antiandrogen drug, such as cyproterone; fertility treatment with the anti-oestrogen drug clomifene is often successful.

**OUTLOOK**

In the long term, women with polycystic ovary syndrome are at an increased risk of developing diabetes mellitus during pregnancy and in later life. Obesity leads to a greater risk of atherosclerosis and hypertension (high blood pressure). High levels of oestrogen may also increase the risk of developing endometrial cancer (see uterus, cancer of).

**polycythaemia**

A condition in which an increased production of red blood cells leads to an unusually large number of them in the blood. This disorder is usually caused by another disorder or by hypoxia (reduced oxygen in the blood and body tissues), in which cases it is called secondary polycythaemia. If the increase in red blood cells occurs for no apparent reason, it is called polycythaemia vera or primary polycythaemia.

**SECONDARY POLYCYTHAEMIA**

Secondary polycythaemia occurs naturally at high altitudes due to the reduced oxygen level. It can also result from a disorder that impairs the oxygen supply to the blood, such as chronic bronchitis (see pulmonary disease, chronic obstructive). In these cases, the low level of oxygen in the blood stimulates the kidneys to produce a hormone called erythropoietin, which in turn stimulates the bone marrow to produce more red cells and thus compensate for the lack of oxygen. Secondary polycythaemia may also be secondary to liver cancer, some kidney disorders, or heavy smoking.

Descending to sea level, or effective treatment of an underlying disorder, returns the blood to normal.

**POLYCYTHAEMIA VERA**

Polycythaemia vera is a rare disorder that mainly affects people over the age of 40. The large number of red blood cells causes increased volume and thickening of the blood, which may lead to headaches, blurred vision, and hypertension (high blood pressure). There may also be flushed skin, dizziness, night sweats, and widespread itching. The spleen is often enlarged.

Possible complications include a tendency to bleed easily or for the blood to clot; stroke; and disorders affecting the bone marrow, such as myelofibrosis or acute leukaemia (see leukaemia, acute).

Diagnosis is made from a physical examination and blood tests and by ruling out other possible causes of polycythemia. Treatment is by venesection (bloodletting) sometimes in combination with anticancer drugs or with radioactive phosphorus. This enables most patients to survive for 10 to 15 years.

**polydactyly**

A birth defect in which there is an excessive number of fingers or toes. The extra digits may be fully formed or they may be fleshy stumps. Polydactyly often runs in otherwise normal families; however, it may also occur as part of Laurence–Biedl–Moon syndrome or some other congenital syndromes.

**polydipsia**

Persistent excessive thirst (see thirst, excessive). Examples of conditions that can cause polydipsia include diabetes mellitus and diabetes insipidus.

**polyhydramnios**

Excess amniotic fluid surrounding the fetus during pregnancy.

**CAUSES**

The condition often has no known cause. It sometimes occurs if the fetus has a malformation that makes normal swallowing impossible, or if the pregnant woman has diabetes mellitus.

**SYMPTOMS**

The excess amniotic fluid usually accumulates during the second half of pregnancy, producing symptoms from about week 32. The main symptom is abdominal discomfort. Other possible symptoms are breathlessness and swelling of the legs (see oedema). The uterus is larger than expected.

Occasionally, acute polyhydramnios occurs. Fluid collects rapidly, causing abdominal pain, breathlessness, nausea, vomiting, and leg swelling. The abdomen becomes tense, and the skin is shiny. Premature labour may occur.
polymerase chain reaction (PCR)
A method of rapidly copying DNA sequences so that they can be analysed.

polymorphic light eruption (PLE)
A common skin condition that occurs in people who are sensitive to light (see photosensitivity) and results from exposure to ultraviolet light rays in sunlight. PLE is thought to be a form of delayed allergy, but the cause is unknown.

Light causes an itchy rash of papules (raised bumps) to develop on exposed areas of the skin. The rash may last for several days. Sunblock should be used as a preventative measure. A mild case of PLE may be treated by applying a topical corticosteroid drug. In severe cases, a short course of oral steroids can be used to prevent or treat an attack. Controlled exposure to ultraviolet light (see phototherapy) may reduce the symptoms in resistant cases.

polymyositis
A rare disease in which the muscles are inflamed and weak.

polymyxoxy
A group of antibiotic drugs derived from the bacterium Bacillus polymyxa. Polymyxoxy, which include the drug colistin, are given to treat eye and skin infections.

polypeptide
A compound made up of many peptides.

polypharmacy
The practice of prescribing several drugs to one person at the same time. Combinations of drugs may be more effective than single drugs and may reduce the risk of drug resistance. However, polypharmacy increases the risk of drug interactions and, as a result, the risk of adverse effects.

polyposis, familial adenomatous
A rare, inherited disorder, also known as polyposis coli, in which many polyps are present throughout the large intestine, but mainly in the colon. If familial adenomatous polyposis (FAP) is not treated, cancer of the colon (see colon, cancer of) is almost certain to develop.

The polyps may appear from the age of ten. They may cause bleeding and diarrhoea; however, there are often no symptoms until cancer has developed. The polyps are detected by colonoscopy (examining the interior of the colon with a viewing instrument).

There is a 50 per cent chance that a child of an affected person will inherit the disease, so medical surveillance is necessary from about the age of 12. Individual polyps may be heat-treated (see cauterization). Since there is a high risk of developing cancer; a colectomy and ileostomy are often performed.

polysaccharide
A carbohydrate that is formed from many monosaccharides (simple sugar molecules) joined together. Examples of polysaccharides include glycogen (the main form in which carbohydrates are stored in the body); starch, a form of carbohydrate obtained from fruits, vegetables, and cereals; and cellulose, an indigestible material found in plant-based foods (see fibre, dietary).

polysaccharide
A carbohydrate that is formed from many monosaccharides (simple sugar molecules) joined together. Examples of polysaccharides include glycogen (the main form in which carbohydrates are stored in the body); starch, a form of carbohydrate obtained from fruits, vegetables, and cereals; and cellulose, an indigestible material found in plant-based foods (see fibre, dietary).

polysaccharide
A carbohydrate that is formed from many monosaccharides (simple sugar molecules) joined together. Examples of polysaccharides include glycogen (the main form in which carbohydrates are stored in the body); starch, a form of carbohydrate obtained from fruits, vegetables, and cereals; and cellulose, an indigestible material found in plant-based foods (see fibre, dietary).

polyunsaturated fats
Fats (see fats and oils) with relatively few hydrogen atoms in their chemical structure. Polyunsaturated fats tend to protect against cardiovascular disease.

polyuria
See urination, excessive.

PoM
The abbreviation for prescription-only medicine.

pompholyx
An acute form of eczema in which itchy blisters form on the palms and/or soles. The condition, also called dyshydrotic eczema, is sometimes due to an allergic response. Rarely, it is associated with fungal infections of the skin. Treatment is with an emollient and topical application of a corticosteroid drug.

pons
The middle part of the brainstem.

Ponstan
A brand name for the nonsteroidal anti-inflammatory drug mefenamic acid.

POP
An abbreviation for “progestogen-only pill” (see oral contraceptives) and for “plaster of Paris” cast.

popliteal cyst
A fluid-filled sac that develops at the back of the knee. The cysts may occur in both adults and children, but for different reasons.

In children, the condition may be due to a swollen bursa (fluid-filled pad) behind the knee; the cause is unknown, but not related to any knee problem. These cysts usually cause no symptoms and disappear spontaneously.

In adults, the cysts usually result from conditions that cause chronic swelling or an accumulation of fluid in the knee joint. One possible cause is osteoarthritis; others include injuries to the meniscus (cartilage inside the knee) or to the ligaments, which allow synovial fluid (which lubricates joints) to escape from the joint capsule.

Most popliteal cysts disappear without treatment, although some may rupture, resembling a deep vein thrombosis (DVT). A diagnosis of DVT must be excluded before treatment with rest and analgesic drugs. In some cases, the cyst may need to be removed surgically.
Pore
A tiny opening, usually in the skin.

Porphyria
Any of a group of rare, often inherited disorders caused by the accumulation of substances called porphyrins.

CAUSES
Porphyrins are chemicals formed in the body during the manufacture of haem (a component of haemoglobin, the oxygen-carrying pigment in red blood cells). A block in this process causes a buildup of porphyrins, which can act as a poison. Such blocks may result from various genetic enzyme deficiencies. Porphyria may also be due to poisoning.

TYPES AND SYMPTOMS
There are six types of porphyria, each of which has different symptoms. Sufferers often have a rash or blistering brought on by sunlight, and may have abdominal pain and nervous system disturbances due to the effects of certain drugs or alcohol.

Acute intermittent porphyria
This form usually appears in early adulthood, causing abdominal pain, and often limb cramps, muscle weakness, and psychiatric disturbances. The patient’s urine turns red when left to stand. Barbital drugs, phenytoin, oral contraceptives, and certain other drugs precipitate attacks.

Variegate porphyria
This condition has similar effects to acute intermittent porphyria, and may be caused by the same drugs. An additional symptom is blistering on skin that is exposed to sunlight.

Hereditary coproporphyria
This form also has similar effects to acute intermittent porphyria, and may cause additional skin symptoms.

Protoporphyria
In this form of porphyria, mild skin symptoms appear after exposure to sunlight.

Porphyria cutanea tarda
This condition causes blistering of skin that is exposed to the sun, but with no disturbances of the digestive or nervous systems. Wounds are slow to heal, and urine is sometimes pink or brown. Many cases are precipitated by liver disease.

Congenital erythropoietic porphyria
This is the rarest and most serious form of porphyria. It causes red discoloration of urine and teeth, excessive hair growth, severe skin blistering and ulceration, and haemolytic anaemia. Death may occur in childhood.

DIAGNOSIS AND TREATMENT
Diagnosis is made from abnormal levels of porphyrins in the urine and faeces. Treatment of porphyria is difficult.

Avoiding sunlight and/or precipitating drugs is the most important measure. Acute intermittent porphyria, hereditary coproporphyria and variegate porphyria may be helped by the administration of glucose or hemin (a substance that is chemically related to haem). Cases of porphyria cutanea tarda may sometimes be helped by venesection (withdrawing blood from a vein).

Portal hypertension
Increased blood pressure in the portal vein, which carries blood from the stomach, intestines, and spleen to the liver. The pressure causes oesophageal varices (widen ed veins in the oesophagus), which may rupture and cause internal bleeding. In addition, fluid is forced out of the overloaded portal vein, resulting in ascites (accumulation of fluid in the abdomen).

CAUSES
The most common cause of portal hypertension is cirrhosis of the liver, in which areas of scar tissue in the liver obstruct the portal vein. Another possible cause is thrombosis (abnormal blood clotting) due to narrowing of the portal vein. The narrowing may be congenital (present from birth), appear shortly after birth, or develop later in life (due to compression of the vein by enlarged lymph nodes, or to inflammation resulting from an infection). In tropical areas, a common cause is disease that causes the spleen to enlarge and results in an increased blood flow from the spleen through the portal vein.

A rare cause of portal hypertension is an abnormal connection that occurs between the portal vein and an artery (see arteriovenous fistula); this type is usually the result of injury.

SYMPTOMS
Symptoms may only appear once complications have developed. Ruptured oesophageal varices lead to massive, recurrent vomiting of blood and produce black faeces (melaena). Ascites results in abdominal swelling and discomfort, and sometimes difficulty in breathing. In addition, the veins that are situated just under the skin of the abdomen may be visibly swollen.

DIAGNOSIS
Diagnosis is usually made from the symptoms and signs. Doppler ultrasound scanning may be used to assess the pressure in the portal vein.

TREATMENT
Various treatments may be used to reduce blood pressure and to stop bleeding or prevent further bleeding. For example, ruptured blood vessels may be treated by sclerotherapy, in which a chemical is
injected into the veins to block them. A shunt is sometimes carried out to prevent further bleeding. Ascites is controlled by restriction of salt and with diuretic drugs.

port-wine stain
A purple-red birthmark that is a permanent, non-raised type of haemangiomia. Port-wine stains are a feature of Sturge–Weber syndrome.

positron emission tomography
See PET scanning.

possetting
A term for the regurgitation of small quantities of milk by infants after they have been fed. Possetting is common and harmless.

postcoital contraception
See contraception, emergency.

posterior
Relating to the back of the body, or referring to the rear part.

postherpetetic neuralgia
Burning pain due to nerve irritation (see neuralgia) occurring at the site of a previous attack of herpes zoster (shingles).

postmaturity
A condition in which a pregnancy persists for longer than 42 weeks; the average length of a normal pregnancy is 40 weeks (see gestation). Postmaturity may be associated with a family tendency to prolonged pregnancy. Postmaturity is associated with a prolonged labour and an increased risk of a difficult delivery; this is because a postmature fetus is larger than average, and the skull bones are harder and mould less readily to fit through the birth canal. The risk of fetal death increases after 42 weeks because the placenta becomes less efficient, causing the fetus to be starved of oxygen and nutrients. Postmature infants tend to have dry skin and may be more susceptible to infection. Many obstetricians attempt to prevent postmaturity by induction of labour as the pregnancy nears 42 weeks.

postmenopausal bleeding
Abnormal vaginal bleeding in women who have already gone through the menopause (the time when ovulation and menstruation cease). The bleeding may be a symptom of various disorders of the reproductive organs. The most common, and least serious, is irritation of the genital tissues (see vulvovaginitis). Other causes include cervical erosion; cervical cancer (see cervix, cancer of); growths in the uterus (see uterus, cancer of; polyp); or, rarely, cancer of the vulva or the vagina. All postmenopausal bleeding must be investigated in order to exclude the possibility of cancer.

postmenopausal osteoporosis
Osteoporosis (loss of bone density) in women who have gone through the menopause (the time when ovulation and menstruation cease). In postmenopausal women, thinning of the bones is due to the sharp decrease in levels of oestrogen hormones, which normally help to maintain bone mass.

postmenopause
The period of a woman’s life following the menopause (the time when ovulation and menstruation cease).

postmortem examination
An alternative term for an autopsy.

postmyocardial infarction syndrome
Another name for Dressler’s syndrome.

postnasal drip
A watery or sticky discharge from the back of the nose into the nasopharynx (the uppermost part of the throat, behind the nose), particularly at night when a person is lying down. The fluid may cause a cough, hoarseness, or the feeling of a foreign body. The usual causes are allergic rhinitis (inflammation of the mucous membrane in the nose) and the common cold. Another cause, in young children, is enlarged adenoids.

postnatal care
Care of the mother after childbirth until about six weeks later. After delivery, the mother’s temperature, pulse, and blood pressure are monitored, especially after a caesarean section or if there have been complications, such as pre-eclampsia or bleeding. The length of the stay in hospital depends on whether or not there have been any complications. Women used to remain in hospital for up to a week after delivery, but nowadays the length of stay after a straightforward delivery may be only 48 hours or even less. During the hospital stay, a daily check is made for any signs of puerperal sepsis (infection of the genital tract after childbirth), including inspection of the lochia (vaginal discharge after childbirth). If the woman has had an episiotomy or if she has torn tissue around the vagina, the wounds are checked daily.

The woman is encouraged to walk as soon as possible after the delivery to reduce the risk of thrombosis (abnormal blood clotting). If necessary, help is given with feeding techniques (see bottle-feeding; breast-feeding). There may also be instruction on various abdominal exercises and pelvic floor exercises, which can help to restore muscle tone.

A final postnatal check-up usually takes place about six weeks after delivery. The obstetrician or GP may check the woman’s blood pressure, weight, breasts, haemoglobin levels, and emotional state; may examine the uterus and bladder to make sure they are in the correct positions; may check for urinary incontinence (see incontinence, urinary); may take a smear; and ensures that any wounds are healing properly. Advice on contraception may also be given.

postnatal depression
Depression in a woman after childbirth. The cause is probably a combination of sudden hormonal changes and psychological and environmental factors. The depression ranges from an extremely common and mild, short-lived episode (“baby blues”) to a rare, severe depressive illness: puerperal psychosis.

MILD DEPRESSION
Most mothers first get the “blues” four to five days after childbirth and may feel miserable, irritable, and tearful. The feeling is caused by hormonal changes, perhaps coupled with a sense of anticlimax after the birth or an overwhelming sense of responsibility for the baby. With reassurance and support, the depression usually passes in two to three days.

MORE SEVERE DEPRESSION
In some women, postnatal depression lasts for several weeks and causes a constant feeling of tiredness, difficulty in sleeping, loss of appetite, and restlessness. The condition usually clears up of its own accord or is treated with antidepressant drugs and emotional support.

PUERPERAL PSYCHOSIS
This condition causes severe mental confusion, feelings of worthlessness, threats of suicide or harm to the baby, and sometimes delusions. Admission to hospital, ideally with the baby, and antidepressant drugs are often needed.
postpartum depression
See postnatal depression.

postpartum haemorrhage
Excessive blood loss after childbirth. It is more common after a long labour or after a multiple birth.

CAUSES AND SYMPTOMS
Most cases of postpartum haemorrhage occur immediately after delivery (primary postpartum haemorrhage) and are due to excessive bleeding from the site where the placenta was attached to the uterus. Normally, once the placenta is delivered, contractions of the uterus constrict the blood vessels at the site, and stop the bleeding. Excessive bleeding may be caused by failure of the uterus to contract efficiently after delivery. It may also be due to the retention of placental tissue within the uterus.

Haemorrhaging immediately after delivery may also be caused by tears anywhere along the birth canal. Tearing is more likely to occur during a forceps delivery or a breech delivery. In some cases, however, postpartum haemorrhage occurs because the mother has a bleeding disorder.

Occasionally, haemorrhage occurs with pain and fever between five and 10 days after delivery (secondary postpartum haemorrhage). In these cases of haemorrhage, the cause is usually infection of a retained fragment of placenta.

TREATMENT
A blood transfusion may be given to replace lost blood, and emergency treatment may be needed for shock (a severe drop in blood pressure, which may be due to heavy blood loss). Other treatment depends on the cause of the haemorrhage. Any retained placental tissue may need to be removed; an injection of a drug such as ergometrine may be given to stimulate uterine contractions; and any lacerations that have been made in the vagina or on the cervix are sutured (stitched). Antibiotic drugs are used to treat infection and iron supplements may be needed to counteract iron deficiency due to blood loss.

post-traumatic stress disorder
A form of anxiety that develops after a stressful or frightening event. Common causes include natural disasters, violence, rape, torture, serious physical injury, and military combat.

Symptoms may develop immediately after the event or may not appear for many months or years afterwards. They include flashbacks (recurring memories or dreams of the event), a sense of personal isolation, and disturbed sleep and concentration. There may be a deadening of feelings, or irritability and feelings of guilt, sometimes building up to depression. The symptoms may be worsened by any reminder of the trauma.

Most people recover, in time, with emotional support and counselling. However, prolonged physical and emotional trauma (such as that experienced in a concentration camp) may scar a person psychologically for life, altering his or her personality.

postural drainage
A technique that enables sputum (phlegm) or other secretions to drain from a person’s lungs in order to clear the lungs and so ease breathing.

Postural drainage is used in the treatment of cystic fibrosis and bronchiectasis, a lung disorder. The person lies on his or her front or side, with the head lower than the chest. This position allows the secretions to drain by gravity, into the trachea (windpipe), from where they can be coughed up. Tapping the person’s chest with cupped hands can help to loosen sticky secretions.

postural hypotension
See hypotension.

posture
The relative positions of different parts of the body when a person is at rest or during movement. Good posture consists of balancing the body weight around the body’s centre of gravity, which is in the lower spine and pelvis. Maintaining good posture helps prevent neck pain and back pain.

post-viral fatigue syndrome
See chronic fatigue syndrome.

potassium
A metallic mineral needed to help maintain normal heart rhythm, regulate the body’s water balance, conduct nerve impulses, and contract muscles.

Many foods contain potassium; particularly rich dietary sources include lean meat, whole grains, green leafy vegetables, beans, and various fruits, such as apricots, dates, and peaches.

Potassium deficiency When there is a low level of potassium in the blood, the condition is known as hypokalaemia. This condition usually results from loss of fluids through diarrhoea and/or vomiting, and causes fatigue, drowsiness, dizziness, and muscle weakness. Children are particularly susceptible to this form of potassium loss. In more severe cases of hypokalaemia, there may be abnormal heart rhythms and muscle paralysis.

Other potential causes of hypokalaemia include any prolonged treatment that involves taking diuretic drugs or corticosteroid drugs; overuse of laxative drugs; diabetes mellitus; Cushing’s syndrome (overproduction of corticosteroid hormones by the adrenal glands); aldosteronism (overproduction of the hormone aldosterone by the adrenal glands); certain kidney diseases; excessively high intake of coffee or alcohol; and extremely profuse sweating.

POTASSIUM EXCESS
Excess potassium in the blood is known as hyperkalaemia and is much less common than hypokalaemia. It may be due to excessive intake of potassium supplements, severe kidney failure, Addison’s disease, or prolonged treatment with potassium-sparing diuretics. The effects of high potassium levels in the blood can include numbness and tingling, disturbances of the heart rhythm, and muscle paralysis. In severe cases, there may be heart failure.

potassium channel activators
A class of drugs that are used in the prevention and long-term treatment of angina (chest pain due to inadequate blood supply to the heart). Nicorandil is a potassium channel activator that acts in a similar way to nitrates, and widens both arteries and veins. Possible side effects of taking potassium channel activators include flushing, nausea, vomiting, and dizziness.

potassium citrate
A substance used to relieve discomfort in mild urinary tract infections by making the urine less acid.

potassium permanganate
A drug that has an antiseptic and astrin-gent effect and is used to treat dermatitis. Potassium permanganate can occasionally cause irritation and can also stain skin and clothing.

potency
The ability of a man to perform sexual intercourse; or the ability of a drug to cause desired effects.
POTT’S FRACTURE

Pott’s fracture
A combined fracture and dislocation of the ankle caused by excessive or violent twisting. The fibula (the outer of the two bones of the lower leg) breaks just above the ankle; in addition, the tibia (shin) breaks or the ligaments tear, resulting in dislocation.

poultice
A warm pack consisting of a soft, moist substance (such as kaolin) that is spread between layers of soft fabric. Poultices are applied to the skin. They were once widely used for the reduction of localized pain or inflammation, bringing boils to a head, and improving circulation in a specific area.

pox
Any of various infectious diseases characterized by blistered skin eruptions (for example chickenpox). Pox is sometimes used as a slang word for syphilis.

Prader–Willi syndrome
A rare genetic disorder that is believed to result from a chromosomal abnormality affecting chromosome 15. The condition is congenital (present at birth).

The physical features of this condition include short stature; hypogonadism (underdeveloped testes or ovaries); a small penis, in males; very small hands and feet; almond-shaped eyes; and squint. Mental characteristics include specific learning difficulties.

Affected babies have hypotonia (floppy muscles), feeding difficulties, and are abnormally sleepy; these problems lessen after about six months. Young children may be slow learning to walk and talk (see developmental delay).

Affected children develop an uncontrollable hunger and an obsession with eating. If their food intake is not controlled, they will eat continually. This can lead to obesity, which may in turn cause other disorders, such as diabetes mellitus and heart failure. The desire for food may cause behavioural problems if a child is prevented from eating; in addition, he or she may suffer from anxiety and show harmful behaviour, such as picking at the skin. In most other aspects, children with Prader–Willi syndrome are generally good-natured, although their problems may cause them to be socially isolated.

Treatment is for the symptoms. Parents, teachers, and carers must ensure that the child does not eat too much.

Underdevelopment of sexual organs, especially in boys, may be corrected by treatment with sex hormones. Growth hormone may be given for short stature. Learning difficulties are treated with appropriate education or therapy.

pravastatin
A lipid-lowering drug.

praziquantel
An anthelmintic drug used to treat tapeworm infestation and schistosomiasis. Side effects may include dizziness, drowsiness, and abdominal pain.

prazosin
A vasodilator drug used to treat hypertension (high blood pressure), heart failure, Raynaud’s disease, and urinary symptoms resulting from an enlarged prostate gland (see prostate, enlarged). Side effects include dizziness and fainting, nausea, headache, and dry mouth.

precancerous
A term applied to any condition in which there is a tendency for cancer to develop. Such conditions are characterized by abnormal changes in cells; the affected areas may need to be removed in order to prevent cancer.

Examples of precancerous conditions are cervical intraepithelial neoplasia, the pre-invasive stage of cervical cancer (see cervix, cancer of); leukoplakia of the mouth, vulva, or penis, which can develop into squamous cell carcinoma; and familial adenomatous polyposis (growth of multiple polyps within the intestine; see polyposis, familial adenomatous), which may also become cancerous.

Certain other disorders carry a risk of cancerous changes, but such changes are less inevitable than with precancerous conditions. These disorders may require monitoring, but do not always need treatment. Examples are ulcerative colitis (chronic inflammation and ulceration of the lining of the colon and rectum), carrying an increased risk of tumours in the colon and rectum, and atrophic gastritis (inflammation of the stomach lining).

precocious puberty
The development of secondary sexual characteristics that occurs before age eight in girls and nine in boys.

CAUSES
Precocious puberty is uncommon. It may be due to various disorders that can cause the production of sex hormones at an abnormally early age. Some possible underlying causes include a brain tumour or other brain abnormalities; abnormality of the adrenal glands (for example, congenital adrenal hyperplasia); ovarian cysts, and tumours, or a tumour in the testes. In some cases, no underlying cause can be identified.

SYMPTOMS
The hormones may cause a premature growth spurt followed by early fusion of the bones. As a result, affected children may initially be tall but, if untreated, final height is often greatly reduced.

INVESTIGATION AND TREATMENT
The child’s pattern of pubertal development is assessed by a doctor. Blood tests are performed in order to measure hormone levels. Ultrasound scanning of the ovaries and testes, and CT scanning of the adrenal glands or brain, may also be carried out, depending on the underlying cause that is suspected.

Treatment is of the underlying cause, and hormone drugs may be given to delay puberty and increase final height.

predisposing factors
Factors that lead to increased susceptibility to a disease.

prednisolone
A corticosteroid drug used in the treatment of a wide variety of disorders.

pre-eclampsia
A serious condition that can arise from 20 weeks of pregnancy. Features of pre-eclampsia include hypertension (high blood pressure), oedema (accumulation of fluid in tissues), and proteinuria (protein in the urine). If severe, symptoms may include headache, nausea and vomiting, abdominal pain, and visual disturbances. The cause is not fully understood.

The condition, which is sometimes called pre-eclamptic toxaemia or PET, is more common in first pregnancies and if the mother suffers from diabetes mellitus, hypertension, or kidney disease. Pre-eclampsia may cause liver, kidney, or blood clotting problems. Untreated pre-eclampsia may lead to eclampsia, which can cause seizures in the mother and even death of the mother and/or fetus.

For some cases, treatment is with bedrest and antihypertensive drugs. The health of the fetus and functioning of the placenta must be carefully monitored. In late pregnancy, or if severe, induction of labour or caesarean section...
may be necessary. The condition can be prevented by frequent blood pressure checks and urinalysis (to look for protein in the urine) as part of antenatal care.

**pregnancy**

The period from conception to birth. Pregnancy begins with fertilization of an ovum (egg) and its implantation. The egg develops into the embryo, which becomes the fetus, and the placenta, the organ that nourishes the embryo and then the fetus.

Most eggs implant into the uterus. Very occasionally, an egg implants into an abnormal site, such as a fallopian tube, resulting in an ectopic pregnancy.

**STAGES AND FEATURES OF PREGNANCY**

Pregnancy is traditionally dated from the first day of a woman’s last menstrual period (LMP), although conception would not have taken place until two weeks after this. A normal pregnancy is considered to last between 37 and 42 weeks; it is divided into three stages (trimesters) of three months each. For the first eight weeks of pregnancy, the developing baby is called an embryo; thereafter it is called a fetus.

In the first trimester the breasts start to swell and may become tender. Morning sickness is common. The baby’s major organs have developed by the end of this stage. During the second trimester, the mother’s nipples enlarge and darken and weight rises rapidly. The baby is usually felt moving by 16–22 weeks. During the third trimester, stretch marks and colostrum (nipple secretions) may appear, and Braxton Hicks’ contractions may be felt. The baby’s head engages at about 36 weeks.

For details on the physical features and changes of pregnancy, see the illustrated box below. For information on the hormones involved in sustaining pregnancy, see the box overleaf.

**PROBLEMS IN PREGNANCY**

In addition to the expected features of pregnancy, such as experiencing nausea...
and tiredness, some women experience certain common, minor health problems. Although these conditions may be uncomfortable or troublesome, they usually disappear after delivery.

During pregnancy, food passes through the intestine more slowly than normal. This enables more nutrients to be absorbed for the baby, but also tends to cause constipation. Pica (craving to eat substances other than foods) is another common condition. In late pregnancy, the growing fetus puts pressure on the internal organs; this pressure may result in haemorrhoids, heartburn (due to acid reflux), swollen ankles, and varicose veins. Other common disorders during pregnancy include urinary tract infections, stress incontinence (see incontinence, urinary), and vaginal candidiasis.

Complications of pregnancy and disorders that affect it include antepartum haemorrhage; diabetic pregnancy; miscarriage; polyhydramnios; pre-eclampsia; pre-maturity; and Rhesus incompatibility. (See also childbirth; fetal heart monitoring; pregnancy, multiple.)

### pregnancy, drugs in

Certain drugs taken during pregnancy, such as thalidomide and isotretinoin, may pass from the mother to the fetus through the placenta. They may interfere with fetal development, leading to birth defects. Relatively few drugs have been proved to cause harm to a developing baby, but no drug should be considered completely safe, especially in early pregnancy. Pregnant women should seek medical advice before taking any drug, including over-the-counter preparations. However, if the benefits of a drug to the mother outweigh the risks to the fetus, the drug may be recommended.

Problems may also be caused in a developing baby if a pregnant woman drinks alcohol, smokes tobacco (see smoking), or takes drugs of abuse. The babies of women who use heroin during pregnancy tend to have a low birthweight and a higher death rate than normally expected during the first few weeks of life. Babies of women who abuse drugs intravenously are at high risk of HIV infection.

### pregnancy, false

An uncommon psychological disorder, which is also known as pseudocyesis. In false pregnancy, a woman has many of the physical signs of pregnancy, including morning sickness, amenorrhoea (absence of periods), enlarged breasts, and abdominal swelling, but is not pregnant. The woman is convinced that she is pregnant, more ova (eggs; see ovum) are fertilized at the same time or if a single egg divides early in development.

### pregnancy, multiple

More than one fetus in the uterus. Multiple pregnancy can occur if two or more ova (eggs; see ovum) are fertilized at the same time or if a single egg divides early in development.

### Causes and incidence

Twins are the most common type of multiple pregnancy and occur in about 1 in 80 pregnancies; triplets occur in about 1 in 8,000, and quadruplets in about 1 in 500,000. Multiple pregnancies are more common in women who are treated with fertility drugs, or if a number of fertilized ova are implanted in the uterus during in vitro fertilization.
SYMPTOMS AND COMPLICATIONS
The common problems that are associated with normal pregnancy may be more severe in a multiple pregnancy. There is also an increased risk of severe morning sickness, anaemia, and ante-partum haemorrhage (high blood pressure), polyhydramnios (an excess of amniotic fluid), postpartum haemorrhage, and malpresentation (abnormal positioning of a fetus just before birth) all occur more frequently in a multiple pregnancy. Prematurity is a common complication, and the weight of each baby is usually less than the weight of a single baby. Caesarean section is required more frequently than for single pregnancies.

DIAGNOSIS AND TREATMENT
During the woman’s antenatal examination, the doctor or midwife may be able to feel more than one fetus, and may find that the abdomen is larger than expected for the stage of gestation. The doctor or midwife may also be able to hear more than one fetal heartbeat when listening through a stethoscope. Ultrasound scanning may be used to confirm the diagnosis.

The woman is advised to take more rest during pregnancy and to increase her intake of protein. Supplements of iron and folic acid are also recommended in order to prevent iron-deficiency anaemia in the mother and neural tube defects in the fetuses, respectively.

PREGNANCY TEST KIT
The pregnancy test shown here is one of a variety that are available over the counter at chemist’s shops, allowing pregnancy testing to be carried out at home. All of the kits test for the presence of the hormone human chorionic gonadotrophin (HCG) in a sample of urine. HCG is normally produced only by a developing placenta, which makes the tests very accurate, even if they are carried out early in a pregnancy.

1 The indicator stick is dipped into a container of urine (as shown here). Alternatively, the user can place it directly into the urine flow while passing urine normally.

2 The first line that becomes visible in the result window shows that the test is working. If HCG is present, this line is quickly followed by a second, different coloured line, which signifies pregnancy. A result can be obtained within a few minutes.

PREGNANCY TESTS
Tests on urine or blood performed to determine whether a woman is pregnant. Pregnancy testing kits are available over the counter from pharmacies.

All kits are designed to test for the presence of human chorionic gonadotrophin (HCG) in a sample of urine. This hormone is normally produced only by a developing placenta; the tests are extremely accurate (about 97 per cent accurate for a positive result and 80 per cent accurate for a negative result) and can be reliably used from the first day of a missed period. The test can, however, misdiagnose pregnancy in cases of hydatidiform mole, due to very high HCG levels.

Different brands of test vary, but all involve introducing a sample of urine to a test stick that has been treated with a chemical that reacts with HCG. Blood tests for detecting pregnancy can be used from 9 to 12 days after conception (even before a period is missed).

PREMATURE MENOPAUSE
Menopause (cessation of ovulation and menstruation) that occurs before the age of 40. Premature menopause can be caused by any disorder or treatment in which the ovaries are destroyed or removed or ovarian functions are permanently disrupted (radiotherapy of the pelvic region, for example). Hormone replacement therapy can relieve symptoms and reduce the risk of osteoporosis (loss of bone tissue). For women who want to conceive, in vitro fertilization (IVF) is possible, using donor eggs.

MULTIPLE PREGNANCY
About one pregnancy in 80 is multiple (e.g. twins or triplets). The rate is highest among women in their 30s. Problems arise more often in multiple pregnancies than in single pregnancies. For example, twins are much more likely than single babies to be born prematurely.
premature sexual maturation

See: precocious puberty.

prematurity

The birth of a baby that occurs before 37 weeks’ gestation. The premature infant may not be sufficiently developed to cope with independent life and needs special care.

CAUSES

Nearly 50 per cent of premature deliveries occur for no known reason. The remainder are due to conditions such as pre-eclampsia, hypertension, diabetes mellitus, long-standing kidney disease, and heart disease. Other causes are antepartum haemorrhage, intrauterine infection, or premature rupture of the membranes. A common cause of premature birth is multiple pregnancy (see pregnancy, multiple).

FEATURES AND COMPLICATIONS

A premature infant is smaller than a full-term baby. He or she lacks subcutaneous fat, is covered with downy hair (lanugo), and has very thin skin.

The baby’s internal organs are also immature. The major complication is respiratory distress syndrome, which may occur because the lungs are insufficiently developed. There are also increased risks of brain haemorrhage, jaundice, and hypoglycaemia (low blood sugar). The baby has a limited ability to suck and to maintain a normal body temperature, and he or she is also prone to infection due to a poorly developed immune system. The earlier a baby is born, the more likely it is that he or she will have such problems.

TREATMENT AND OUTLOOK

Premature infants are usually nursed in a special baby unit that provides intensive care. The baby is placed in an incubator. He or she may have artificial ventilation to assist breathing, artificial feeding through a stomach tube or into a vein, and treatment with antibiotic drugs and iron and vitamin supplements. The baby is usually kept in hospital until he or she has reached a weight of at least 2.25 kg, is growing sufficiently, and is feeding well.

With the modern techniques that are now generally available, some infants survive even if they are born as early as 24 weeks’ gestation. Most babies that are born after 28 weeks, and given specialist care, survive. The majority of premature babies catch up with full-term babies, in terms of their development, before the end of their first year.

premedication

The term applied to drugs that are given, usually by injection, one to two hours before an operation in order to prepare a person for surgery. The premedication injection usually contains an opioid analgesic drug (painkiller), and often an anticholinergic drug (which reduces the secretions in the airways and protects the heart).

premenstrual syndrome

The combination of physical and emotional symptoms that occurs in many women in the week or so running up to menstruation. Premenstrual syndrome (commonly known as PMS) begins at or after ovulation (the mid-point of the menstrual cycle, when an egg is released from an ovary) and continues up until the onset of menstruation. In
some women, the condition may be so severe that work and social relationships are seriously disrupted.

**CAUSES**
Theories for the cause of PMS include hormonal changes and vitamin or mineral deficiencies, but none of these has been confirmed.

**SYMPTOMS**
The most common emotional symptoms are fatigue, irritability, tension, aggression, tearfulness, and depression. Physical symptoms include breast tenderness, fluid retention, headache, backache, and lower abdominal pain.

**TREATMENT**
No single treatment has proved completely successful. Remedies for specific symptoms include dietary changes, relaxation techniques, and regular physical exercise. Pyridoxine (vitamin B₆) may help to relieve some symptoms in some women. Oral contraceptives can relieve symptoms by suppressing the normal menstrual cycle. Progesterone supplements may sometimes be used but are not always effective. The antidepressant drug fluoxetine is now licensed to treat PMS.

**premenstrual tension**
See premenstrual syndrome.

**premolar**
One of eight permanent grinding teeth, two in the upper and two in the lower jaw on each side of the mouth, located between the canines and molars. (See also permanent teeth; eruption of teeth.)

**Prempak-C**
A brand-name drug used in hormone replacement therapy to relieve symptoms of the menopause and to prevent osteoporosis. Prempak-C contains conjugated oestrogens (see oestrogen drugs) and norgestrel (a progestogen drug).

**prenatal**
A term referring to the period of pregnancy; often a synonym for antenatal.

**prepuce**
See foreskin.

**presbyacusis**
The progressive loss of hearing that occurs with age. Presbyacusis is a form of sensorineural deafness (degeneration of the hair cells and nerve fibres in the inner ear), which makes sounds less clear and tones less audible.

**SYMPTOMS AND CAUSES**
The symptoms of presbyacusis develop gradually. People with the condition often find it difficult to understand speech and cannot hear well when there is background noise. The severity and progression of the disorder vary considerably from person to person.

Presbyacusis may be exacerbated by exposure to high noise levels, diminished blood supply to the inner ear due to atherosclerosis (the buildup of fatty deposits on artery walls), and damage to the inner ear from drugs such as aminoglycoside drugs.

**DIAGNOSIS AND TREATMENT**
Diagnosis is by physical examination using an otoscope, and by various hearing tests to determine the type and degree of hearing loss. Hearing-aids help most affected people.

**presbyopia**
The progressive loss of the power of adjusting the eye (see accommodation) for near vision. The focusing power of the eyes weakens with age. Presbyopia is usually noticed around the age of 45 when the eyes cannot accommodate to read small print at a normal distance. Reading glasses with convex lenses are used to correct presbyopia.

**prescribed diseases**
A group of industrial diseases that give sufferers legal entitlement to financial benefit. To be eligible, a claimant has to have worked in an occupation that is recognized to increase the risk of developing a particular disease.

Examples include conditions due to physical agents (such as occupational deafness), biological agents (for example, anthrax), or chemical agents (such as lead poisoning); pneumoconiosis; and byssinosis. (See also notifiable diseases; occupational disease and injury.)

**prescription**
An instruction written by a doctor that directs a pharmacist to dispense a particular drug in a specific dose. A prescription details how often the drug must be taken, how much is to be dispensed, and other relevant facts.

**prescription-only medicine (PoM)**
Drugs and medicines that are not available over the counter and can only be obtained by prescription. PoMs are those whose safe use is hard to ensure without medical supervision. Some are subsequently reclassified to over-the-counter (OTC) drugs once their efficacy and safety have been established.

**presenile dementia**
A type of dementia (a deterioration in brain function) that occurs in a person under 65. (Most dementia affects those over 65.) Possible causes of presenile dementia include damage to brain tissue resulting from AIDS or alcohol dependence; severe vitamin deficiencies, as in Wernicke–Korsakoff syndrome or pernicious anaemia; a serious head injury; or Alzheimer’s disease.

The underlying cause of presenile dementia is treated, if possible. Damage to brain tissue is irreversible, however, but drug treatment may help to relieve any associated symptoms such as depression.

**presentation**
A term describing the position of the fetus before childbirth. The presentation is classified by the part of the fetus that is closest to the cervix and will emerge first. The cephalic (head) presentation is normal. Forms such as the breech presentation (in which the buttocks lie over the cervix) and the shoulder presentation may cause problems during delivery (see also breech delivery). The term presentation is also used to describe how an illness or condition manifests itself.

**preservative**
A substance that inhibits the growth of bacteria, yeasts, and moulds and therefore protects foods from putrefying and fermenting. Examples include sulphur dioxide, benzoic acid, salt, sugar, and nitrates. (See also food additives.)

**pressure points**
Places on the body where pressure can be applied by hand to limit severe arterial bleeding (in which bright red blood is pumped out in regular spurts with the heartbeat). At these points, arteries lie near the surface of the body and can easily be compressed against a bone to stop the blood flow.

Major pressure points of the body include the brachial pressure point in the middle part of the upper arm and the carotid pressure point at the side of the neck, below the jaw.

**pressure sore**
See bedsore.
**prevalence**
The total number of cases of a disease in existence at any one time in a defined population. Prevalence is often expressed as the number of cases per 100,000 people. (See also incidence.)

**preventive dentistry**
An aspect of dentistry concerned with the prevention of tooth decay and gum disease. It consists of the encouragement of good oral hygiene, fluoride treatment, and scaling.

**preventive medicine**
The branch of medicine that deals with disease prevention. It involves public health measures, such as the provision of pure water supplies and sanitation; health education and promotion; specific preventive measures, such as immunization against infectious diseases; and screening programmes to detect diseases before they cause symptoms.

In affluent countries, the main objective of preventive medicine is to educate the adult population to adopt a healthier lifestyle. In the UK, many of the deaths that occur in adults before the age of 65 are preventable, being due to accidents and/or linked to such factors as smoking, an unhealthy diet, excessive alcohol consumption, and insufficient exercise. Adoption of a healthier lifestyle, the wider use of screening for various cancers, and measures to reduce accidents could all lead to substantial improvements in health.

**priapism**
Persistent, painful erection of the penis that occurs without sexual arousal. This is a dangerous condition that requires emergency treatment.

Priapism occurs when the penis has become erect but blood cannot drain from the spongy tissue, and as a result the erection cannot subside. Possible causes include a blockage in the penile blood vessels due to a blood disorder such as sickle cell anaemia; damage to nerves supplying the penis; or, rarely, the effects of treatment for impotence.

Urgent treatment is needed to avoid permanent damage to the tissues of the penis. Blood may be withdrawn from the penis with a needle.

**prickly heat**
An irritating skin rash that is associated with profuse sweating. The medical name is miliaria rubra. Multiple tiny, red, itchy spots cover the affected areas of skin and are accompanied by prickling sensations. The irritation tends to affect areas where sweat collecting, such as the armpits.

The cause is not fully known, but unevaporated sweat is an important contributory factor; the ducts from sweat glands become blocked with debris and leak sweat into the skin. Frequent cool showers and sponging of the affected areas relieve the itching.

**primaquine**
A drug used to treat vivax and ovale malaria. It is given after treatment with chloroquine. Side effects include nausea, vomiting, and abdominal pain. In people with G6PD deficiency, primaquine may cause haemolytic anaemia (see anaemia, haemolytic).

**primary**
A term that is used to describe a disease that has originated within the affected organ or tissue and is not derived from any other cause or source; an example is primary cancer. The term “primary” is also applied to the first of several diseases that may affect a tissue or organ. The preventive measures that are taken before an illness has manifested itself are known as primary prevention; secondary prevention is used to prevent a recurrence of the disease.

**primary biliary cirrhosis**
See biliary cirrhosis.

**primary care**
Health care that is provided by a general practitioner (GP) or other healthcare professional who is the first point of contact for a patient who is seeking medical treatment.

**primary central nervous system lymphoma (PCNSL)**
A form of non-Hodgkin’s lymphoma (see lymphoma, non-Hodgkin’s) affecting the brain or spinal cord. The cancer occurs most commonly in immunocompromised people (those with lowered resistance to infection), such as people with AIDS and those who are taking immunosuppressant drugs.

**primary teeth**
The first teeth to erupt (also known as milk teeth), which usually start to appear around the age of six months. The primary teeth are replaced by the permanent teeth from about the age of six years. There are 20 primary teeth in total, ten of which are in the upper jaw and ten in the lower jaw. (See also teeth; eruption of teeth; teething.)

**primidone**
An anticonvulsant drug that is used to treat epilepsy and, occasionally, tremor. It is usually prescribed with another anticonvulsant. Adverse effects of the drug may include drowsiness, clumsiness, and dizziness.

**primitive reflex**
See reflex, primitive.

**Prinzmetal’s angina**
See variant angina.

**prion**
A tiny, protein-based infectious particle. Prions transmit diseases that cause degeneration of the central nervous system, including Creutzfeldt–Jakob disease in humans and bovine spongiform encephalopathy (BSE) in cattle.

Prions do not contain nucleic acids, unlike viruses, and are difficult to destroy because they are highly resistant to heat and disinfectants. There is currently no treatment available for prion diseases. (See also slow virus diseases; spongiform encephalopathy.)

**Pripsen**
A brand name for the anthelmintic (worm-killing) drug piperazine.

**PRK**
The abbreviation for photorefractive keratectomy.

**probenecid**
A drug that was formerly used in the long-term treatment of gout. Probenecid is used to prevent kidney damage in AIDS patients who are taking the drug cidofovir for the treatment of cytomegalovirus retinitis. Probenecid may cause nausea and vomiting. Other possible side effects of probenecid include flushing and dizziness.

**probiotic bacteria**
Species of microorganisms that inhabit the digestive tract, guarding it against harmful microorganisms such as bacteria, yeasts, and viruses. Some drinks are manufactured using probiotic bacteria; they are thought to protect the health of the digestive system.
PROGESTOGEN DRUGS

**COMMON DRUGS**
- Desogestrel + Dydrogesterone
- Levonorgestrel + Medroxyprogesterone
- Norethisterone + Norgestimate = Norgestrel
- Progesterone

A group of drugs that are similar to progesterone hormone. They include both natural progesterone and synthetic progestosterone derivatives.

Progesterone drugs are used in oral contraceptives. They may be used on their own in, for example, the progesterone-only pill, as contraceptive implants, or as contraceptive injections (see contraceptives, injectable), or in combination with oestrogen drugs in the combined pill. Progestogens work by making the cervical mucus impenetrable to sperm; reducing the production of gonadotrophin hormones, which may prevent eggs from ripening in the ovaries; and altering the lining of the uterus in order to prevent the implantation of fertilized eggs. They also reduce the movement of an egg along the fallopian tube, which may lead to an increased risk of an ectopic pregnancy.

Another use for progestogens is in hormone replacement therapy (HRT). A progestogen drug is used in combination with an oestrogen drug to reduce the risk of uterine cancer (see uterus, cancer of), which may occur if oestrogens alone are taken over a long period of time. The progestogens induce a monthly shedding of the uterine lining, if taken cyclically (for the last 10–13 days of the cycle).

Progestogen drugs are also prescribed as a treatment for various menstrual problems (see menstruation, disorders of). In addition, they are used to treat premenstrual syndrome, endometriosis (a condition in which fragments of uterine lining are found elsewhere in the pelvic cavity), and are sometimes used as an anticoncancer drugs.

Adverse effects of taking progestogen drugs are weight gain, oedema (accumulation of fluid in body tissues), headache, dizziness, rash, irregular

---

**procarbazine**
An antiproliferative drug used most often in Hodgkin’s disease. Side effects are typical of anticancer drugs.

**prochlorperazine**
A phenothiazine-type antipsychotic drug used to relieve symptoms of certain psychiatric disorders, such as schizophrenia and mania. Prochlorperazine is also used in small doses as an antiemetic drug. It may in some cases cause involuntary movements of the face and limbs, lethargy, dry mouth, blurred vision, and dizziness.

**procidentia**
A medical term for severe prolapse, usually of the uterus.

**proctalgia fugax**
A severe cramping pain in the rectum unconnected with any disease. It may be due to muscle spasm. The pain is usually of short duration and subsides without any treatment.

**proctitis**
Inflammation of the rectum, causing soreness and bleeding, sometimes with a mucus and pus discharge. Proctitis commonly occurs as a feature of certain diseases including ulcerative colitis, Crohn’s disease, or dysentery. In cases where inflammation is confined to the rectum, the cause is often unknown. Proctitis is sometimes due to gonorrhoea or another sexually transmitted infection, especially in male homosexuals. Rare causes of proctitis include tuberculosis, amoebiasis, and schistosomiasis.

Diagnosis is made by proctoscopy (examination of the rectum with a viewing instrument). A biopsy (collection of a tissue sample) is sometimes carried out at the same time. Treatment of the underlying condition usually clears the problem. Corticosteroid drugs may relieve symptoms.

**proctoscopy**
Examination of the anus and rectum using a proctoscope (a rigid viewing instrument).

**procyclidine**
An anticholinergic drug that is used to treat Parkinson’s disease. It is also used to minimize the side effects of some antipsychotic drugs. The possible adverse effects of procyclidine include a dry mouth and blurred vision.

**progeria**
Premature aging. There are two forms of progeria, and both are very rare.

In Hutchinson-Gilford syndrome, premature aging starts at about four years old, and many features of old age, including grey hair, balding, sagging skin, and atherosclerosis (buildup of fatty deposits on artery walls), have developed by the age of ten to twelve. Death usually occurs at puberty. Wernicke’s syndrome (adult progeria) starts in adolescence or early adulthood and follows the same course.

The cause of Hutchinson-Gilford syndrome is a gene mutation. The cause of progeria is unknown.

**progestosterone hormone**
A female sex hormone essential for the functioning of the female reproductive system. Progesterone is made in the ovaries during the second half of the menstrual cycle (see menstruation), and by the placenta during pregnancy. Small amounts are also produced by the adrenal glands and, in men, by the testes.

During the menstrual cycle, increasing progesterone levels after ovulation (the release of an egg from an ovary) cause the endometrium (uterine lining) to thicken in preparation for receiving a fertilized egg. If fertilization does not occur, the production of progesterone and oestrogen hormones falls to a level that results in a menstrual period, during which the uterine lining is expelled from the body.

If pregnancy occurs, progesterone is produced by the placenta. It causes a number of changes in the mother’s body, one of which is enlargement of the breasts. A fall in the mother’s progesterone level in late pregnancy helps to initiate labour (see childbirth).

Other effects of progesterone in women include increased fat deposition and increased sebum production by glands in the skin.
PROGESTOGEN-ONLY PILL

periods, breast tenderness, and, less commonly, ovarian cysts. (See also contraception, hormonal methods of.)

progestogen-only pill
See oral contraceptives.

prognathism
Abnormal protrusion of the lower jaw or both jaws.

prognosis
An assessment of the probable course and outcome of a disease.

progressive
A term that is used to describe a condition that becomes more severe and/or extensive over time.

progressive muscular atrophy
A type of motor neuron disease in which the muscles of the hands, arms, and legs become weak and wasted and twitch involuntarily. As the muscular atrophy advances, it eventually spreads to other muscles.

proguanil
An antimalarial drug that is used in the prevention of malaria. Side effects of the drug are rare. Indigestion, nausea, or vomiting may occur but usually disappear as treatment continues.

prolactin
A hormone produced by the pituitary gland. Prolactin helps to stimulate the development of the mammary glands (see breast), and to initiate and maintain milk production for breast-feeding. (See also prolactinoma.)

prolactinoma
A noncancerous tumour of the pituitary gland that causes overproduction of the hormone prolactin. In women, this may result in galactorrhoea (breast secretion at any time other than during breast-feeding), amenorrhoea (absence of menstrual periods), or infertility. In men, it may lead to impotence and gynaecomastia (development of breasts). In either sex, it may cause headaches, diabetes insipidus, and, if the tumour presses on the optic nerves, loss of the outer visual field.

Diagnosis of the condition is made from blood tests and CT scanning or from MRI of the brain. Treatment of prolactinoma may involve removal of the tumour, radiotherapy, or prescribing the drug bromocriptine.

prolapse
The displacement of part or all of an organ or tissue from its normal position in the body (see disc prolapse; mitral valve prolapse; rectal prolapse; uterovaginal prolapse; uterus, prolapse of).

promazine
A phenothiazine-type antipsychotic drug that is used as a sedative drug. Possible adverse effects include abnormal movements of the face and limbs, drowsiness, lethargy, constipation, dry mouth, and blurred vision. Long-term treatment may cause parkinsonism.

promethazine
An antihistamine drug used to relieve itching in a variety of skin conditions, such as eczema. It is also used as an antiemetic drug, and sometimes as a premedication. Possible adverse effects of promethazine include a dry mouth, blurred vision, and drowsiness.

pronation
The act of turning the body to a prone (face-down) position, or the hand to a palm-backwards position.

propantheline
An antispasmodic drug. Possible adverse effects of propantheline include a dry mouth, blurred vision, and retention of urine.

propylthiouracil
A beta-blocker drug used to treat hyperthyroidism (high blood pressure), angina pectoris (chest pain due to inadequate blood supply to the heart), and cardiac arrhythmias (irregular heartbeats). It may also be used to reduce the risk of further heart damage after myocardial infarction (heart attack). In addition, it relieves symptoms of hyperthyroidism (overactivity of the thyroid gland) and anxiety, and can prevent migraine attacks.

Possible adverse effects of propylthiouracil are typical of most beta-blocker drugs; they include fatigue, nausea, and cold hands and feet.

proprietary
A term for a drug patented for production by one company.

proprioception
The body's internal system for collecting information about its position and the state of contraction of its muscles.

Information originating from proprioceptors (sensory nerve endings in the muscles, tendons, joints, and inner ear) passes to the brain and spinal cord. The information is used to make adjustments to maintain posture and balance. During movement, there is a constant feedback of information from the proprioceptors and the eyes to the brain. This helps the brain to ensure that actions are smooth and coordinated.

proptosis
A term meaning protrusion, especially of the eyeballs (see exophthalmus).

propylthiouracil
A drug used to treat hyperthyroidism (overactivity of the thyroid gland) or to control its symptoms before a thyroidectomy (surgical removal of thyroid tissue). Possible side effects are itching, headache, rash, joint pain, and decreased production of white blood cells.

prostaglandin
One of a group of fatty acids that is made naturally in the body and acts in a similar way to hormones. Prostaglandins

Pro Plus
A brand name for caffeine in the form of over-the-counter tablets.

propranolol
A beta-blocker drug used to treat hypertension (high blood pressure), angina pectoris (chest pain due to inadequate blood supply to the heart), and cardiac arrhythmias (irregular heartbeats). It may also be used to reduce the risk of further heart damage after myocardial infarction (heart attack). In addition, it relieves symptoms of hyperthyroidism (overactivity of the thyroid gland) and anxiety, and can prevent migraine attacks.

Possible adverse effects of propranolol are typical of most beta-blocker drugs; they include fatigue, nausea, and cold hands and feet.

proprietary
A term for a drug patented for production by one company.

proprioception
The body's internal system for collecting information about its position and the state of contraction of its muscles.

Information originating from proprioceptors (sensory nerve endings in the muscles, tendons, joints, and inner ear) passes to the brain and spinal cord. The information is used to make adjustments to maintain posture and balance. During movement, there is a constant feedback of information from the proprioceptors and the eyes to the brain. This helps the brain to ensure that actions are smooth and coordinated.

proptosis
A term meaning protrusion, especially of the eyeballs (see exophthalmus).

propylthiouracil
A drug used to treat hyperthyroidism (overactivity of the thyroid gland) or to control its symptoms before a thyroidectomy (surgical removal of thyroid tissue). Possible side effects are itching, headache, rash, joint pain, and decreased production of white blood cells.

prostaglandin
One of a group of fatty acids that is made naturally in the body and acts in a similar way to hormones. Prostaglandins
were first discovered in semen but are now known to occur in many different body tissues, including the uterus, brain, and kidneys. Prostaglandins are divided into broad groups according to their chemical structure.

Prostaglandins produce a wide range of effects on the body. These actions include causing pain and inflammation in damaged tissue; protecting the lining of the stomach and duodenum against ulceration; lowering blood pressure; and stimulating contractions in labour. (These effects may also be achieved by the use of prostaglandin drugs.) For further information describing the effects of various prostaglandins, see the box below.

Certain drugs counteract the effects of prostaglandin in the body. Examples of these drugs are aspirin, nonsteroidal anti-inflammatory drugs (NSAIDs), and corticosteroids, which relieve pain and inflammation by reducing prostaglandin production in the tissues. If taken for a long period, however, NSAIDs and aspirin may increase the risk of a peptic ulcer, in part by reducing the production of the prostaglandins that protect the stomach lining.

**prostaglandin drugs**

Syntetically produced prostaglandins. Dinoprostone is used with synthetic oxytocin for induction of labour. Mifepris-tone may be taken orally to induce an abortion; this is followed by insertion of a gemeprost suppository, which softens and helps to dilate the cervix. Alprostadil is used to treat newborn infants who are awaiting surgery for certain congenital heart diseases.

**prostate, cancer of**

A cancerous growth in the prostate gland that is one of the most common types of cancer in men. The cause of the cancer is unknown, but the male sex hormone testosterone has been found to influence the growth rate and spread of the tumour. Men who have a family history of prostate cancer are at an increased risk of developing cancer of the prostate and the condition most commonly affects elderly men.

**SYMPTOMS**

An enlarged prostate (see prostate, enlarged) may cause symptoms that include difficulty in starting to pass urine, poor urine flow, and increased frequency of urination. If a tumour blocks the urethra (the passage from the bladder to the outside of the body) or the cancer spreads to the ureters (the tubes linking each kidney to the bladder), urine flow may eventually cease altogether (see urinary retention).

In some cases, there are no urinary symptoms and the first signs may only appear once secondary cancers have arisen. Such signs may include pain in the bones, enlarged lymph nodes, shortness of breath (due to tumours in the lungs), and weight loss.

**SCREENING AND DIAGNOSIS**

Some older men and men suspected of having prostate cancer may be screened for the disorder. This procedure involves tests to detect blood levels of a protein called prostate-specific antigen (PSA), as well as a rectal examination. If blood levels of PSA are above a certain level, this may be an early sign of prostate cancer; rectal examination allows a doctor to assess the size and hardness of the gland.

Transrectal ultrasound (a procedure in which an ultrasound probe is inserted into the rectum) and a biopsy (removal of a tissue sample for analysis) are used to confirm a diagnosis. Blood tests and a bone scan (see radionuclide scanning) may also be carried out.

**TREATMENT**

Medical opinions vary regarding the appropriate treatment for localized prostate cancer. If the man is elderly and has a small prostate cancer that has not spread, no treatment may be recommended; the man’s condition will be monitored. For younger men, prostatectomy (removal of the prostate gland) or radiotherapy may be performed.

In many cases, widespread disease is controllable for some years with the use of drugs or with orchidectomy (removal of part or all of the testes).

**prostatectomy**

The surgical removal of part or all of the prostate gland. Prostatectomy is performed to treat enlargement of the prostate (see prostate, enlarged), in cases where the enlarged prostate is obstructing the flow of urine, and cancer (see prostate, cancer of).

The most common method is transurethral prostatectomy, in which the prostate is accessed via the urethra (the channel in the penis through which urine is excreted), thereby avoiding open surgery. If the prostate gland is very enlarged, retropubic prostatectomy may be performed: an incision is made to expose the prostate and the tissue is removed. These techniques are shown in the illustrated box overleaf.

Prostatectomy may affect potency or sexual sensation, though this is not common. The operation usually causes sterility due to a condition called retrograde ejaculation, in which semen is expelled backwards into the bladder rather than out of the penis. This condition, though abnormal, is not harmful.

**prostate, enlarged**

Increased size of the inner zone of the prostate gland, caused by benign prostatic hypertrophy (see prostatic hypertrophy, benign), prostate cancer, or prostatitis (inflammation of the prostate gland). Enlargement of the prostate can cause obstruction to the flow of urine from the bladder to the urethra, leading to prostatism and urinary retention (the inability to pass urine). The size of the gland can be assessed by a rectal examination.

**Prostate gland**

A solid, chestnut-shaped organ that surrounds the first part of the male urethra. The prostate gland is situated just underneath the bladder. It produces secretions that form part of the seminal fluid during ejaculation.

The prostate gland consists of two distinct zones: an inner zone, which produces secretions that keep the lining of the urethra moist, and an outer zone, which produces seminal secretions. Two ejaculatory ducts pass from the seminal vesicles through the prostate gland to enter the urethra; the ducts carry fluid and nutrients from the vesicles to be added to the semen. The prostate gland weighs only a few grams at birth. At puberty, androgen hormones cause the gland to enlarge, and it reaches adult size at around age 20. In most men, the prostate begins to enlarge further after the age of 50.

There are a number of disorders that affect the prostate gland. These include benign prostatic hypertrophy (see prostate, cancer of, and prostatitis (inflammation of the prostate gland).

**Prostate-specific antigen (PSA)**

An enzyme that is normally produced by the prostate gland. If the enzyme is produced in excess, it may indicate the presence of prostate cancer; tests to detect blood levels of PSA are therefore used as a screening test for prostate cancer. However, PSA levels may also be raised in other conditions such as...
benign prostatic hypertrophy (see prostatic hypertrophy, benign) and prostatitis (inflammation of the prostate).

**prostatic hypertrophy, benign**

An increase in size of the prostate gland, which is most common in men over the age of 50. The cause is unknown.

**SYMPTOMS**

The enlarging prostate compresses and distorts the flow of urine from the bladder (known as outflow obstruction). This causes symptoms of prostatism, such as frequent urination and dribbling at the end of the urine stream. There may also be incontinence (see incontinence, urinary). Eventually the bladder is unable to expel all the urine (see urinary retention) and becomes distended, causing swelling, which may be painful. The bladder’s inability to empty completely each time urine is passed may lead to urinary tract infections. Kidney failure may occur as a complication of outflow obstruction.

**DIAGNOSIS AND TREATMENT**

Prostate enlargement is detected by a rectal examination. Tests may include blood tests, ultrasound scanning, and recording the strength of urine flow. Tests to exclude prostate cancer as a cause of enlargement may be needed.

Mild cases do not require treatment, but severe abdominal pain due to blockage of the urine flow needs immediate treatment. Men with a severely enlarged prostate usually require prostatectomy (surgical removal of the prostate gland). Alternatively, alpha-blocker drugs may be given to improve the flow of urine or antiandrogen drugs may be used to counteract the effects of testosterone.

**prostatism**

Symptoms that arise from the enlargement of the prostate gland (see prostate, enlarged) due to its compression and distortion of the urethra, which impedes the flow of urine from the bladder (outflow obstruction). Symptoms of prostatism often include frequent urination (see urination, frequent), getting up at night to urinate, delay before the urine stream starts, dribbling at the end of the stream, and incontinence (see incontinence, urinary).

**prostatitis**

Inflammation of the prostate gland, usually affecting men aged between 30 and 50. It is often caused by a bacterial infection that has spread from the urethra. The presence of a urinary catheter increases the risk of prostatitis.

The main symptoms of prostatitis are fever, flu-like symptoms, and pain in the lower back. There may also be pain around the rectum, which is particularly troublesome on passing faeces. Diagnosis is made by rectal examination and tests on urine samples. Treatment is with antibiotic drugs. The condition may be slow to clear up and tends to recur.

**prosthesis**

An artificial replacement for a missing or diseased part of the body; for example, artificial limbs (see limb, artificial), heart valves (see heart-valve surgery), or glass eyes (see eye, artificial).

**prosthetics, dental**

The branch of dentistry concerned with the replacement of missing teeth and their supporting structures. It includes dentures, overdentures (semipermanent fittings over existing teeth), crowns (see crown, dental), and bridges (see bridge, dental).

**protease inhibitors**

A type of antiretroviral drug that is used to delay the progression of HIV infection. (See also AIDS.)

**proteins**

Large molecules consisting of hundreds or thousands of amino acids linked into long chains. Proteins may be combined with sugars (glycoproteins) and lipids (lipoproteins).

There are two main types of proteins. The first type, fibrous proteins, are insoluble and form the structural basis of many body tissues. The second type, globular proteins, are soluble and include all enzymes, many hormones, and some blood proteins, such as haemoglobin. In addition, the chromosomes in cell nuclei are formed from proteins linked with nucleic acids, and cell walls are formed in part from proteins linked with lipids (see cell).

Dietary proteins are needed mainly in order to supply the body with amino acids. Ingested proteins are broken down in the digestive system to form amino acids, which are then absorbed and rebuilt into new body proteins (see protein synthesis).
PROTEINURIA

Proteins consist of one or more subunits, which are called polypeptides. These are formed, within cells, from building blocks called amino acids, which are provided to each cell as raw materials. The instructions for making polypeptides are encoded in the DNA that is present within the cell nucleus.

1. To make a specific protein or polypeptide, DNA separates into two strands and acts as a template to make a strand of a substance called messenger RNA. Like DNA, this consists of a string of substances called nucleotide bases.

2. The messenger RNA passes out of the cell nucleus into the cytoplasm, where it is latched on to by several decoding particles called ribosomes. Starting at one end, the ribosomes travel along the RNA strand.

3. As it moves along the RNA, each ribosome connects a chain of amino acids, using special chemical “keys” (called transfer RNAs) within the cell. The correct order of the amino acids is coded by the sequence of bases in the messenger RNA.

4. At the end of the messenger RNA strand, the ribosome parts from the amino acid chain, which folds up to form the finished polypeptide or protein.

proteins

The presence of protein in the urine. It may result from kidney disorders, such as glomerulonephritis and urinary tract infection. Proteinuria may also occur because of a generalized disorder that causes increased protein in the blood. It is diagnosed by urinalysis.

Prothiaden

A brand name for the antidepressant drug dosulepin.

prothrombin time

A form of blood-clotting test. The conversion of prothrombin to thrombin is one of the chemical reactions that takes place during the process of blood clotting. This reaction depends on the presence of clotting factors together with calcium and a substance called thromboplastin. If calcium and thromboplastin are added to a sample of blood, it should clot within a certain time. A clotting time that is abnormally slow indicates a deficiency of clotting factors, as occurs in some liver diseases and in vitamin K deficiency. Tests to measure prothrombin time are used to monitor people undergoing treatment with warfarin (an anticoagulant drug). (See also International Normalized Ratio.)

proton pump inhibitors

A type of ulcer-healing drug, for example omeprazole, that is used in the treatment of peptic ulcers.

protoplasm

A term for the entire contents of a cell.

protozoa

The simplest, most primitive type of animal, consisting of a single cell. Protozoa are bigger than bacteria but still microscopic. About 30 types are human parasites, including those responsible for malaria, amoebiasis, giardiasis, sleeping sickness, trichomoniasis, toxoplasmosis, and leishmaniasis.

proximal

A term describing a part of the body nearer to a central point of reference, such as the trunk. (See also distal.)

Prozac

A brand name for the antidepressant drug fluoxetine.

prurigo

Thickening and itching of the skin due to repeated scratching.
pruritus
The medical term for itching.

pruritus ani
Itching of the anus. Causes of pruritus ani may include an anal fissure, haemorrhoids, or threadworm infestation.

PSA
The abbreviation for prostate specific antigen.

pseud-/pseudo-
Prefixes meaning false.

pseudarthrosis
A term meaning “false joint”, which is used to describe an operation in which the ends of the two opposing bones in a joint are removed and a piece of tissue is fixed in the gap as a cushion. The term also describes a rare childhood condition in which congenital abnormality of the lower half of the tibia leads to spontaneous fracture.

pseudoacanthosis nigricans
The most common form of acanthosis nigricans, in a condition in which dark patches of thickened skin appear in the body’s various skin folds.

pseudocyesis
See pregnancy, false.

pseudodementia
Severe depression in elderly people that mimics dementia. Symptoms of pseudodementia include intellectual impairment and loss of memory.

pseudoephedrine
A decongestant drug used to relieve nasal congestion. High doses may cause anxiety, nausea, and dizziness. Occasionally, hypertension, headache, and palpitations occur. Pseudoephedrine nasal drops should not be taken for longer than a week because this may cause a sudden increase in congestion on stopping the drug.

pseudoepidemic
An outbreak of an illness in a community or in an institution that is thought to be due to a form of hysteria. Typical symptoms are headache and a general feeling of sickness.

pseudogout
A form of arthritis that results from the deposition of calcium pyrophosphate crystals in a joint. The underlying cause is unknown; in rare cases, it is a complication of diabetes mellitus, hyperparathyroidism, and haemochromatosis. Symptoms are similar to gout. Diagnosis is from a sample of joint fluid. Treatment is with nonsteroidal anti-inflammatory drugs (NSAIDs).

pseudohermaphroditism
A congenital abnormality in which the external genitalia resemble those of the opposite sex, but ovarian or testicular tissue is present as normal. A female with pseudohermaphroditism may have an enlarged clitoris that resembles a penis and enlarged labia resembling a scrotum. A male may have a very small penis that may resemble a clitoris and a divided scrotum resembling labia. (See also hermaphroditism, sex determination.)

pseudomonas
Species of rodlike bacteria that are inhabitants of soil and some decomposing matter. PSEUDOMONAS AERUGINOSA is capable of causing disease in humans and is present in pus from wounds.

psilocybin
An alkaloid that is present in certain types of mushrooms. It is a hallucinogenic drug possessing properties that are similar to those of LSD.

psittacosis
A rare illness resembling influenza that is caused by the microorganism CHLAMYDIA PSITTACI. The disease is contracted by inhaling dust containing the droppings of infected birds, such as pigeons or poultry. Most cases occur among poultry farmers, pigeon owners, and people working in pet shops. Common symptoms are severe headache, fever, and cough, developing a week or more after infection. Other symptoms may include muscle pains, sore throat, nosebleed, lethargy, depression. In some cases, breathing difficulty may also occur.

A diagnosis of psittacosis is made by confirmation of the presence of antibodies against CHLAMYDIA PSITTACI in the blood. Treatment of the disease is with tetracycline antibiotic drugs. If no treatment is given, death may result.

psoralen drugs
Drugs containing chemicals called psoralens, which occur in some plants and are present in some perfumes. When absorbed into the skin, psoralens react with ultraviolet light to cause skin darkening or inflammation. Psoralen drugs may be used in conjunction with ultraviolet light (a combination called PUVA) to treat psoriasis and vitiligo.

Overexposure to ultraviolet light during treatment, or to too high a dose of a psoralen drug, may cause redness and blistering of the skin. Psoralens in perfumes may cause photosensitivity.

psoriasis
A common skin disease characterized by thickened patches of red, inflamed skin, often covered by silvery scales. The disease usually appears between the ages of 10 and 30, tends to run in families, and affects both men and women. The exact cause of the disease is unknown, although one form (guttate psoriasis) may be caused by a streptococcal infection, such as tonsilitis.

SYMPTOMS AND TYPES
In psoriasis, new skin cells are made about ten times faster than normal. The excess cells accumulate, forming thickened patches covered with dead, flaking skin. Sometimes, there is also a painful swelling and stiffness of the joints (see arthritis). Psoriasis tends to recur in
attacks, which may be triggered by factors such as emotional stress, skin damage, and physical illness.

There are different forms of the disease, and the most common of which is discoid, or plaque, psoriasis, in which patches appear on the trunk, limbs, and scalp. Another type, guttate psoriasis, occurs most often in children, and consists of many small patches that develop over a wide area of skin. Pustular psoriasis is characterized by small pustules over part or all of the body.

TREATMENT
In most cases of psoriasis, the condition can be improved with topical treatments, such as those containing corticosteroid drugs, coal tar, calcipotriol and other vitamin D analogues. Other treatments include dithranol ointment, PUVA, and drugs such as methotrexate. Psoriasis is usually a long-term condition.

prefix meaning mental processes or activities, as in psychology.

psyche
A term meaning mind. (See also psychoanalytic theory.)

psychiatry
The branch of medicine concerned with the study, prevention, and treatment of mental illness and emotional and behavioural problems. Psychiatrists conduct examinations of physical and mental state and trace the patient’s personal and family history. Treatment may include medication, counselling, psychotherapy, psychoanalysis, cognitive-behavioural therapy, or ECT.

psychoanalysis
A treatment that is based on psychoanalytic theory that is used to help people who have neuroses and personality disorders. A modified approach may also be used in the treatment of psychosis. Psychoanalysis aims to help the patient to understand his or her emotional development and to make adjustments in particular situations. Interpretation of the patient’s dreams is another aspect of the treatment (see dream analysis).

psychoanalytic theory
A system of ideas developed by Sigmund Freud that explains personality and behaviour in terms of unconscious wishes and conflicts. The main emphasis was on sexuality. Freud believed that a child passes through three stages in the first few years of life: oral, anal, and genital. After this, the child develops a sexual attraction to the parent of the opposite sex and wants to eliminate the other parent (Oedipus complex). Sexual feelings become latent around the age of five but re-emerge at puberty. Psychological problems may develop if fixation occurs at a primitive stage.

MODERN DEVELOPMENTS
Modern psychoanalysis has progressed from these early ideas and is generally based on the observation that the majority of emotional problems are caused by childhood experiences. The aim of psychoanalysis is to free the individual from the past, thereby helping him or her to adjust to the present.

psychodrama
An aid to treatment with psychotherapy in which the patient acts out certain roles or incidents. Psychodrama is often carried out with a partner or in a group; music, dance, and mime are often used as part of psychodrama.

psychogenetic
A term used to describe a symptom or disorder that is caused by psychological or emotional problems.

psychology
The scientific study of mental processes. Psychology deals with all internal aspects of the mind, such as memory, feelings, thought, and perception, as well as external manifestations, such as speech and behaviour. In addition, psychology is concerned with intelligence, learning, and personality development.

psychometry
The measurement of psychological functions with the use of intelligence tests, personality tests, and tests for specific aptitudes, such as memory, logic, concentration, and speed of response.

psychoneurosis
A term that can be used interchangeably with neurosis.

psychopathology
The study of abnormal mental processes. There are two main approaches: the descriptive, which aims to record symptoms that make up a diagnosis of mental illness; and the psychoanalytic, which is concerned with a person’s unconscious feelings and motives.

psychopathy
An outdated term for an antisocial personality disorder.

psychopharmacology
The study of drugs that affect mental states, such as antipsychotic drugs, antidepressant drugs, and anti-anxiety drugs.

psychosexual disorders
A range of disorders related to sexual function. Psychosexual disorders include transsexualism, psychosexual dysfunction, and sexual deviation.

psychosexual dysfunction
A disorder in which there is interference with the sexual response for no physical cause. (See also sex therapy.)

psychosis
A severe mental disorder in which the individual loses contact with reality and develops a distorted view of life. Unlike neurotic people, who know they have a problem, those with psychoses may be unaware they are ill. The cause is most
likely to be a disorder of brain function. Drug abuse may also precipitate psychosis, which can be acute or chronic.

Psychosis is divided into three main categories, namely schizophrenia, manic-depressive illness, and organic brain syndrome (see brain syndrome, organic). Paranoia may be considered to constitute a fourth category. Symptoms of psychosis include delusions, hallucinations, and change in affect (mood), including mania and depression.

Episodes of acute psychosis may improve with or without drug treatment. Antipsychotic drugs are usually effective in controlling the symptoms. Long-term treatment, rehabilitation, and support are often needed. (See also puerperal psychosis.)

**psychosomatic**
A term that describes physical disorders that seem to be caused, or made worse, by psychological factors. Common examples of conditions that may be psychosomatic are headache, breathlessness, nausea, asthma, irritable bowel syndrome, dyspepsia, and some types of eczema. (See also somatization disorder.)

**psychosurgery**
Any operation on the brain that is carried out as a treatment for serious mental illness. It is performed only as a last resort when other treatments have failed. Prefrontal lobotomy has now been largely replaced by types of stereotaxic surgery.

**psychotherapy**
Treatment of mental and emotional problems by the use of psychological methods. Patients talk to a therapist about their symptoms and problems, with the aim of learning about themselves, developing insights into their relationships, and, ultimately, changing their behaviour patterns.

**psychotropic drugs**
Drugs that have an effect on the mind, including hallucinogenic drugs, sedative drugs, sleeping drugs, tranquilizer drugs, and antipsychotic drugs.

**pterygium**
A wing-shaped thickening of the conjunctiva that extends from either side of the eye towards the centre. Pterygium is attributed to prolonged exposure to bright sunlight and is common in tropical areas. It is surgically removed if it threatens vision or causes discomfort.

---

**ptosis**
Drooping of the upper eyelid. It may be congenital, occur spontaneously, or be due to injury or disease, such as myasthenia gravis. It may be due to weakness of the levator muscle of the eyelid or interference with nerve supply. Severe congenital ptosis is corrected surgically.

**ptyalism**
See salivation, excessive.

**puberty**
The period during which adult body features (see sexual characteristics, secondary) develop and sexual organs mature, making reproduction possible.

---

**CHANGES OF PUBERTY**
There is considerable variation in the age of onset of puberty, but girls, on average, undergo puberty at an earlier age than boys. The entire process takes about three to four years to reach completion. In addition to the changes specific to each sex, height and weight of both girls and boys increase rapidly.

**Girls**
Puberty most often starts between the ages of 10 and 12 in girls. Major changes include growth of breasts and pubic hair, widening of the hips, enlargement of the uterus, and the onset of menstruation.

**Boys**
The main changes are enlargement of the sex organs, widening of the shoulders, deepening of the voice, and the growth of facial and pubic hair. The onset is usually between the ages of 12 and 14.
Puberty usually occurs between the ages of 10 and 15. It is initiated by the pituitary gland producing gonadotrophin hormones, which in turn stimulate the ovaries to increase secretion of oestrogen hormones and in boys the testes to increase secretion of testosterone.

Puberty is accompanied by a significant growth spurt. Body weight may double during this period, primarily due to muscle growth in boys and increased fat in girls. The growth spurt occurs later in boys.

**PUBERTY IN GIRLS**

The first sign of puberty in girls is usually breast budding, which occurs around the age of 11; in about one third of girls, pubic hair appears first. The breasts may grow at unequal rates, but any difference usually disappears by the time full maturity is reached. Other secondary sexual characteristics, such as the wider pelvis, the female distribution of fat, and the growth of pubic and underarm hair, develop progressively during this period.

The first menstrual period (see menstruation) usually occurs a year or more after the start of puberty. The process of puberty is considered complete when periods occur at regular, predictable intervals. The age at which menstruation starts has decreased during the past century, probably because of an improvement generally in nutrition and living standards, but is now stable. Strenuous sports or other hard physical activity (such as ballet), and debilitating disease, can also delay the onset of menstrual periods.

**PUBERTY IN BOYS**

In boys, puberty is heralded by a sudden increase in the growth of the testes and scrotum, followed by the appearance of pubic and facial hair. The penis begins to grow around the age of 13 and reaches its adult size about two years later; however, there is a wide variation, so that, at the age of 14, some boys may be fully grown while others still have immature genitals.

Semen production and semen production and semen production and semen production causes the prostate gland and seminal vesicles to mature. It leads to the development of the typical male distribution of hair on the face, chest, and abdomen. The larynx enlarges and the vocal cords become longer and thicker, causing the pitch of the voice to drop. (See also delayed puberty, precocious puberty.)

**pubic bone**

The front part of each of the two hip bones (see pelvis). The two pubic bones meet at the pubic symphysis, which is situated at the front of the pelvis.

**pubic lice**

Small, wingless insects (Phthirius pubis), also called crab lice or crabs, that live in the pubic hair and feed on blood. A louse has a flattened body, up to 2 mm across. Female lice lay eggs (nits) on the hair, where they hatch about eight days later. On men, the lice may also be found in hair around the anus, on the legs, on the trunk, and on the face. The bites sometimes cause itching.

The lice are usually spread from person to person by sexual contact. Children can become infested by transmission from parents, and the lice may live on the eyelids. An insecticide lotion will kill the lice and eggs. In addition, anyone in contact with the infested person should be treated, and clothes and bedding should be washed in water hotter than 60°C before use.

**public health**

The branch of medicine that is concerned with prevention of disease through measures such as health education, provision of clean water supplies, sewage disposal, safer working conditions, methods of infection control, immunizations, and care of pregnant women and young children. Public health functions are covered by many people and agencies, such as Environmental Health Officers, Medical Officers of Environmental Health, and the Public Health Laboratory Service.

**pudenda**

The external genitalia.

**pudendal block**

A type of nerve block used to provide pain relief for a forceps delivery. A local anaesthetic (see anaesthesia, local) is injected into either side of the vagina near the pudendal nerve.

**puerperal psychosis**

A severe mental illness that follows childbirth. Symptoms of psychosis usually develop within two weeks of delivery of the baby and include confusion and mood swings, together with disordered thinking and behaviour, for example believing that the baby is abnormal. Hallucinations and delusions also occur. There may be very severe depression, including thoughts of suicide and/or of harming the baby. Many women who suffer from puerperal psychosis have a family history of psychotic illness or have had such an illness themselves.

Puerperal psychosis requires urgent psychiatric assessment and hospitalization, ideally in a mother and baby psychiatric unit. Treatment of the condition is with antipsychotic drugs and antidepressant drugs.

**puerperal sepsis**

An infection that originates in the genital tract within the first ten days after childbirth, miscarriage, or abortion. Formerly a common cause of death, puerperal sepsis is now easily treated with antibiotic drugs.

**puerperium**

The period of time after childbirth during which the uterus and genitals return to their pre-pregnancy state.

**pulmonary**

Relating to the lungs.

**pulmonary disease, chronic obstructive**

A combination of the two lung conditions chronic bronchitis and emphysema. Chronic obstructive pulmonary disease (COPD) severely restricts air flow into or out of the lungs. Bronchitis causes inflammation and narrowing of the airways, while emphysema results in damage to the alveoli (tiny air sacs) in the lungs, making them much less effective at transferring oxygen from the lungs to the bloodstream.

The major cause of COPD is smoking. Atmospheric pollution is a contributory factor, and occupational exposure to dusts and certain other irritants can worsen pre-existing COPD.

**SYMPTOMS**

Some affected people (so-called “pink puffers”) maintain adequate oxygen in their bloodstream through an increase in their breathing rate; however, they suffer from almost constant shortness of breath. Others (“blue bloaters”) have cyanosis (a bluish discoloration of the skin and mucous membranes), and sometimes oedema (accumulation of fluid in tissues), mainly due to heart failure resulting from the lung damage.

**DIAGNOSIS AND TREATMENT**

COPD may be diagnosed from the symptoms and a physical examination.
The diagnosis of COPD is confirmed by procedures such as pulmonary function tests, chest X-rays and CT scans.

Lung damage that is pre-existing is irreversible, but the affected person must stop smoking immediately in order to prevent further damage. Also, exposure to smoke, pollution, dust, damp, and cold should be minimized.

Drug treatment for COPD may include bronchodilator drugs to widen the airways, diuretic drugs to remove excess fluid, and antibiotic drugs for chest infections. Some people may need oxygen therapy for the relief of severe shortness of breath.

**pulmonary embolism**

Obstruction that affects the pulmonary artery or one of its branches in the lung by an embolus, usually a blood clot that has formed as a result of deep vein thrombosis (see thrombosis, deep vein). In cases in which the embolus is large enough to block the main pulmonary artery or if there are many clots, it may lead to cardiac arrest and require emergency resuscitation (see cardiopulmonary resuscitation).

**CAUSES AND SYMPTOMS**

Pulmonary embolism is more likely after recent surgery, pregnancy, oestrogen treatment – for example with the combined pill (see contraceptives, oral) or hormone replacement therapy (HRT) – and immobility, including long-haul flights. It may also be linked to thrombophilia (a genetic tendency for blood to clot too readily). A massive embolus can cause sudden death. Smaller emboli may cause severe shortness of breath, rapid pulse, dizziness, chest pain that is made worse by breathing, and coughing up of blood. Tiny emboli may not produce any symptoms, but, if recurrent, they may eventually lead to pulmonary hypertension (high blood pressure in the arteries that supply the lungs). After having a first embolism, the risk of developing further emboli is significantly increased.

**DIAGNOSIS**

A diagnosis may be made using procedures including chest X-rays, radionuclide scanning, and pulmonary angiography. An ECG and analysis of arterial blood gases may also be performed.

**TREATMENT**

Treatment depends on the size and severity of the embolus. A small clot gradually dissolves; thrombolytic drugs may be given to speed up this process. Surgery may be needed to remove larger clots. Anticoagulant drugs reduce the chance of developing further clots. If the condition recurs, however, tests are needed to investigate the possibility of blood clotting disorders. Affected females should stop using combined oral contraceptives and HRT.

**pulmonary fibrosis**

Scarring and thickening of lung tissue, usually as a result of previous lung inflammation. It may be confined to an area of the lung affected by a condition such as pneumonia or tuberculosis, or it may be widespread through the lungs (see fibrosing alveolitis). Shortness of breath is a common symptom.

Diagnosis is confirmed by chest X-ray. Treatment depends on the cause, but in most cases the fibrosis is irreversible and treatment aims to prevent the condition from progressing.

**pulmonary function tests**

A group of procedures that are used to evaluate lung function, to confirm the presence of lung disorders, or to ensure that surgery on the lungs will not disable the patient. Pulmonary function tests include an assessment of the degree of bronchospasm (narrowing of the airways due to muscle contraction) with a peak-flow meter, spirometry, measurement of lung volume, a test of blood gases, and measurement of the exchange of gases across the alveoli (the tiny air sacs in the lungs).

**pulmonary hypertension**

A disorder in which the blood pressure in the arteries supplying the lungs is abnormally high, which develops in response to increased resistance to blood flow through the lungs. In order to maintain an adequate blood flow, the right-hand side of the heart needs to contract more vigorously than previously. As a consequence of this extra work for the heart, right-sided heart failure may later develop.

**CAUSES**

Causes of pulmonary hypertension may include chronic obstructive pulmonary disease (COPD) (see pulmonary disease, chronic obstructive), a pulmonary embolism, pulmonary fibrosis, and some congenital heart diseases (see heart disease, congenital), but it can also develop without an obvious cause.

**SYMPTOMS**

Symptoms, which include enlarged veins in the neck, enlargement of the liver, and generalized oedema, only develop when heart failure occurs.

**TREATMENT**

Treatment is aimed at the underlying disorder (if this is known) and the relief of the heart failure. Diuretic drugs or other drugs may be given, and oxygen therapy may also be necessary.
**PULMONARY INCOMPETENCE**

A rare defect of the pulmonary valve at the exit of the heart's right ventricle (lower chamber). The valve fails to close properly, allowing blood to leak back into the heart. The usual causes of pulmonary incompetence are rheumatic fever, endocarditis (inflammation of the inner lining of the heart), or severe pulmonary hypertension.

**pulmonary oedema**

Accumulation of fluid in the lungs, which is usually due to left-sided heart failure. The build-up of fluid may also be due to a chest infection, to inhalation of irritant gases, or to any of the problems that cause generalized oedema (fluid accumulation in tissues).

The main symptom of pulmonary oedema is breathlessness, which is usually worse when the person is lying flat and may disturb sleep (see paroxysmal nocturnal dyspnœa). There may also be a cough that produces frothy sputum, which is sometimes pink coloured. In some cases breathing may sound bubbly or possibly wheezy.

A diagnosis of pulmonary oedema is made by a physical examination and by a chest X-ray. Treatment of the condition may include morphine, diuretic drugs, aminophylline, and oxygen therapy; artificial ventilation may also be given.

**pulmonary stenosis**

A heart condition in which the outflow of blood from the right ventricle (lower heart chamber) is obstructed, causing the heart to work harder in order to pump blood to the lungs.

**CAUSES**
The obstruction may be caused by narrowing of the pulmonary valve at the exit of the ventricle; by narrowing of the pulmonary artery, which carries blood to the lungs; or by narrowing of the upper part of the ventricle.

**SYMPTOMS**
Pulmonary stenosis is usually congenital, and it may occur on its own or with a set of heart defects that collectively are called the tetralogy of Fallot. In rare cases, the stenosis develops later in life, after rheumatic fever, and it may cause symptoms of heart failure.

**DIAGNOSIS AND TREATMENT**
Diagnosis of pulmonary stenosis is made by a chest X-ray, ECG, echocardiography, and Doppler ultrasound scanning. A balloon catheter may relieve the narrowing. In more serious cases, heart-valve surgery or other types of open heart surgery are often very successful.

**pulp, dental**
The soft tissue containing blood vessels and nerves that is situated in the middle of each tooth (see teeth).

**pulpectomy**
The removal of the tooth pulp. Pulpectomy is part of the procedure called root-canal treatment.

**pulpitis**
Inflammation of the dental pulp, which most commonly occurs as a result of dental caries. Pulpitis can lead to periapical periodontitis and a periapical abscess (see abscess, dental).

**pulpectomy**
Removal of the coronal part of the pulp of a tooth after it has become inflamed, usually by infection. Infection of the pulp is most often caused by extensive tooth decay (see caries, dental) or to dental fractures (see fracture, dental). Now, pulpectomy is performed only on primary teeth. The technique prevents further degeneration of the pulp.

**pulse**
The rhythmic expansion and contraction of an artery as blood is forced through it, pumped by the heart. The pulse can be felt at various points on the exterior of the body where arteries lie just below the skin's surface. Examples of such pulse points are the inside of the wrist, the side of the neck, and the top of the thigh.

**pump, infusion**
A machine that is used in order to administer a continuous and controlled amount of a drug or sometimes of another fluid (such as insulin or opioid analgesic drugs). The fluid is delivered through a needle that is inserted into a vein or under the skin.
pump, insulin
A type of infusion pump (see pump, infusion) used to administer a continuous dose of insulin to some patients with diabetes mellitus. The rate of flow is adjusted so that the level of blood glucose (sugar) is constant.

punch-drunk
A condition that is characterized by slurred speech, impaired concentration, and slowed thought processes. It is caused by brain damage from several episodes of brief loss of consciousness due to head injury.

PUO
See pyrexia of unknown origin.

pupil
The circular opening in the centre of the iris. In bright conditions, the pupil constricts; in dim light, it dilates.

LOCATION OF THE PUPIL
The pupil is the circular opening in the centre of the iris. It can be widened or narrowed by muscles in the iris to adjust the amount of light entering the eye.

purpura
Any of a group of disorders that are characterized by purple to red-brown areas (or spots) on the skin, caused by bleeding within the skin or mucous membranes. The term purpura also refers to the discoloured areas themselves, which do not blanch (go pale) when pressure is applied to the skin (see glass test).

purpura can be associated with purpura can be associated with purpura can be associated with purpuric drugs. Recurrent purpura can lead to kidney failure. (See also vesicoureteric reflux.)

purpura
Any of a group of disorders that are characterized by purple to red-brown areas (or spots) on the skin, caused by bleeding within the skin or mucous membranes. The term purpura also refers to the discoloured areas themselves, which do not blanch (go pale) when pressure is applied to the skin (see glass test).

purulent
A term that means containing, producing, or consisting of pus.

pus
A pale yellow or green, creamy fluid that is found at the site of a bacterial infection. The creamy fluid is composed of many millions of dead white blood cells, as well as partly digested tissue, dead and living bacteria, and some other substances. When a collection of pus occurs within a solid area of tissue, this is called an abscess.

pustule
A small skin blister that contains pus.

PUVA
A type of phototherapy that is used to treat a variety of skin conditions, in particular psoriasis. PUVA is a combination of a psoralen drug and a controlled dose of long-wavelength ultraviolet light.

pyelitis
See pyelonephritis.

pyelography
Another term for urography (see intravenous urography).

pyelolithotomy
An operation that is performed in order to remove a kidney stone (see calculus, urinary tract). Pyelolithotomy has been largely replaced by other procedures that are less invasive. One example is lithotripsy, which uses ultrasonic waves to break up the stones.

pyelonephritis
Inflammation of the kidney, which is usually the result of a bacterial infection. Pyelonephritis is more common in women and is most likely to occur during pregnancy. Symptoms include a high fever, chills, and back pain. Septicaemia (blood poisoning) may be a complication. Treatment is with antibacterial drugs. Recurrent pyelonephritis can lead to kidney failure. (See also vesicoureteric reflux.)

pyeloplasty
A surgical procedure that is used to relieve hydronephrosis (a buildup of fluid in the kidney) that results from structural defects in the renal pelvis (the part of the kidney involved in collecting urine) or in the ureter (the tube carrying urine from the kidney to the bladder). The operation involves reshaping the affected areas.

pyloric sphincter
The valve situated at the base of the stomach; its function is to control movement of food into the duodenum.

pyloric stenosis
A condition that is characterized by narrowing of the pylorus (the lower outlet from the stomach). Pyloric stenosis causes an obstruction to the passage of food into the duodenum (the first part of the small intestine).
CAUSES
Pyloic stenosis occurs in babies as a result of thickening of the pyloric muscle. When it occurs in adults, however, the condition is due to scarring from a peptic ulcer or stomach cancer.

SYMPTOMS
Babies start projectile vomiting (profuse vomiting in which the stomach contents may be ejected several feet) two to five weeks after birth. Adults with the disorder vomit undigested food several hours after a meal.

DIAGNOSIS
In infants, ultrasound scanning is the procedure used for confirmation of the diagnosis. In adults, however, diagnosis is likely to be made by means of a barium X-ray examination and a gastroscopy (examination of the stomach using a viewing instrument).

TREATMENT
In infants, surgical treatment involves making an incision along the thickened muscle. In adults, surgery is carried out to correct the underlying cause.

PYLORIC STENOSIS IN INFANTS
In infantile pyloric stenosis, the muscle surrounding the outlet from the stomach is abnormally thickened, as shown in the enlarged drawing (below). The condition occurs more often in male than female babies and tends to run in families – infants of a woman who was affected with pyloric stenosis as a baby may develop it.

pyloroplasty
An operation in which the pylorus (the outlet leading from the stomach) is widened in order to allow free passage of food into the intestine. Pyloroplasty may be performed as part of the surgery for a peptic ulcer, or may be performed in order to prevent tightening of the pyloric muscles after vagotomy (cutting of the vagus nerve to reduce stomach acid production).

pyo-
A prefix that is used to denote a relationship to pus. The prefix py- is also used in the same way.

pyoderma gangrenosum
A rare condition that is characterized by ulcers, usually on the legs, that turn into hard, painful areas surrounded by discoloured skin. Pyoderma gangrenosum occurs as a rare complication in ulcerative colitis.

pyogenic granuloma
A common, noncancerous skin tumour that develops on exposed areas after minor injury. The tumour can be removed surgically, by electrocautery, or by cryosurgery.

pyrazinamide
A drug sometimes used to treat tuberculosis. Possible adverse effects are nausea, joint pains, gout, and liver damage.

pyrexia
A medical term for fever.

pyrexia of unknown origin
Persistent fever, lasting ten days or more, with no apparent cause. It is usually due to an illness that is difficult to diagnose or a common disease that appears in an unusual way. Such illnesses include viral infections; tuberculosis; cancer, particularly lymphoma; and collagen diseases, such as systemic lupus erythematosus and temporal arteritis. Another possible cause of pyrexia of unknown origin is a reaction to a drug.

pyridoxine
Vitamin B_6_ (see vitamin B complex). Dietary deficiency of this vitamin is very rare but can be induced by some drugs. Supplements of pyridoxine (50 to 100 mg per day) are sometimes used to treat premenstrual syndrome. There is a possible risk of toxicity if high doses of the supplement are taken long term.

pyrimethamine
A drug that is used in combination with other drugs to treat resistant malaria.

pyrogen
A substance that produces fever. The term is usually applied to proteins released by white blood cells in response to infections. The word is also sometimes used to refer to chemicals released by microorganisms.

pyromania
A persistent impulse to start fires. It is more often seen in males, and may be associated with a low IQ, alcohol abuse, and a psychosexual disorder.

pyruvate kinase deficiency
A disorder in which there are abnormally low levels of an enzyme called pyruvate kinase, which is carried in red blood cells. Normally, pyruvate kinase aids the breakdown of glucose to create energy in anaerobic (low-oxygen) conditions. If there is a deficiency of the enzyme, the red cells cannot generate enough energy for themselves; they also develop chemical imbalances that cause them to be destroyed prematurely by the spleen, thereby causing anaemia (see anaemia, haemolytic) and enlargement of the spleen. The disorder is usually the result of an autosomal recessive gene defect (see genetic disorders).

The severity of the disease varies. Most people require no treatment. Blood transfusions may be needed in some cases, particularly when the person is under physiological stress (such as acute illness or pregnancy), at which times the disease tends to be worse. Splenectomy (removal of the spleen) may be recommended in severe cases.

pyuria
The presence of white blood cells in the urine, which is often an indication of an infection of a kidney or urinary tract infection and inflammation.
QALY
A quality-adjusted life year. QALY is used by health economists to compare the relative costs and outcomes of treatment for various diseases. Each year of life saved or prolonged is adjusted by a factor, Q, which takes account of how close to normal the individual’s lifestyle is before and after treatment.

Q fever
An uncommon illness causing symptoms that are similar to those of influenza. Q fever occurs throughout the world.

CAUSES
Q fever is caused by the rickettsia (a type of small bacterium) Coxiella burnetti and may be contracted by inhaling dust contaminated with faeces, urine, or birth products from infected farm animals. Rarely, it is spread by tick bites.

SYMPTOMS
Symptoms develop suddenly about 20 days after infection. They include high fever (lasting up to two weeks), severe headache, muscle and chest pains, and a cough. A form of pneumonia subsequently occurs. Most people recover, but the disease is sometimes prolonged: occasionally, hepatitis (liver inflammation) or endocarditis (inflammation of the inner lining of the heart) may develop.

DIAGNOSIS AND TREATMENT
After diagnosis is confirmed by a blood test, treatment is with antibiotic drugs. A vaccine is available for people at risk.

quackery
A false claim by someone to have the ability to diagnose and treat disease.

quadrantectomy
A surgical procedure that involves the removal of tissue in one quadrant of a breast in order to treat breast cancer. (See also lumpectomy, mastectomy.)

quadriceps muscle
A large muscle with four distinct parts, located at the front of the thigh. The quadriceps muscle straightens the knee.

DISORDERS
The most common quadriceps disorder is a haematoma (collection of blood), due to a direct blow. Bruising may follow after a few days. Rarely, bone forms in the haematoma, restricting movement.

Sudden stretching of the leg may tear the muscle, especially in middle-aged or elderly people. Rupture of the quadriceps tendon can be caused by a direct blow to the leg or stumbling. Knee disorders that cause pain or swelling, limiting full extension of the leg, cause the muscle to begin to waste away within 48 hours, making the knee feel as if it is giving way when weight is placed on the affected leg. Exercises to strengthen the quadriceps are used to treat certain knee disorders.

quadripareisis
Muscle weakness in all four limbs and the trunk. (See also quadriplegia.)

quadriplegia
Paralysis of all four limbs and the trunk, also known as tetraplegia. Quadriplegia may be caused by damage to the spinal cord in the neck region. The condition results in loss of feeling and power in the affected parts. (See also paraplegia.)

quarantine
The isolation of a person or animal recently exposed to a serious infectious disease in order to prevent the spread of the disease by symptomless individuals.

Quarantine procedures are now rarely used due to the reduced incidence of serious infectious diseases and the availability of vaccinations for many of them. The principal remaining quarantine regulations apply to animals imported into countries that are free from rabies.

quickening
The first fetal movements felt by a pregnant woman, which usually occur after about 18 weeks’ gestation.

quinapril
An ACE-inhibitor drug used in the treatment of hypertension and heart failure.

quinine
The oldest drug treatment for malaria. Quinine is mainly used in large doses to treat strains that are resistant to other antimalarials. There is a high risk of side effects such as headache, nausea, ringing in the ears, hearing loss, and visual disturbance. It is also prescribed in low doses to help prevent leg cramps at night; side effects in this case are rare.

quinolone drugs
COMMON DRUGS
- Ciprofloxacin
- Levofloxacin
- Nalidixic acid
- Norfloxacin
- Ofloxacin

A group of antibiotic drugs used to treat bacterial infections. Quinolones are derived from chemicals, rather than from living organisms. They are used to treat a range of conditions, including prostatitis (inflammation of the prostate), urinary tract infections, acute diarrhoeal diseases (such as those caused by salmonella infections), and enteric fever. Ciprofloxacin may also be used as an initial treatment for anthrax. The absorption of quinolones is reduced by antacid drugs.

POSSIBLE ADVERSE EFFECTS
Side effects include nausea, diarrhoea, headache, sleep disorders, rash, and blood disorders. Rarely, there is tendon damage (especially in the elderly and those taking corticosteroid drugs).

WARNING
Quinolones should be used with caution by people with epilepsy, during pregnancy and breast-feeding, and by children and adolescents. Swelling and pain in the tendons should be reported.

quinsy
Another name for a peritonsillar abscess (an abscess in the soft tissue around the tonsils), a complication of tonsillitis.
Rabies
An acute viral infection of the nervous system, once known as hydrophobia, that affects mammals, including bats. The virus travels along nerve pathways to the brain; once symptoms develop, rabies is usually fatal.

Causes and Incidence
Rabies can be transmitted from a rabid animal to a human by a bite or a lick over broken skin; most human cases result from being bitten by a rabid dog. Rabies is an extremely rare disease in the UK.

Symptoms
The average incubation period (the time between exposure to the infection and the appearance of symptoms) is one to two months, depending on the site of the bite. The first symptoms of rabies are slight fever and headache. These are followed by restlessness, hyperactivity, and, in some cases, strange behaviour, hallucinations, and paralysis. The victim develops seizures, arrhythmias (see arrhythmia, cardiac), and paralysis of the respiratory muscles. There is often intense thirst but drinking induces painful spasms of the throat. Death usually occurs ten to 14 days after the onset of symptoms.

Treatment and Prevention
Following an animal bite, immunization with human rabies immunoglobulin and a course of rabies vaccine is necessary; this may prevent the onset of rabies. If symptoms appear, they are treated with sedative drugs and analgesics (painkillers).

Emphasis is placed on preventing the disease through quarantine regulations and human and animal immunization. Prophylactic immunization is recommended for certain people, for example wild animal handlers and travellers to countries where rabies is endemic. (See also bites, animal.)

Rachitic
A term that is used to describe abnormalities associated with rickets (a bone disease caused by a deficiency of vitamin D) or to refer to people or populations particularly afflicted by rickets.

Rad
A unit of absorbed dose of ionizing radiation (see radiation unit), which has been superseded by the gray (Gy). “Rad” stands for radiation absorbed dose.

Radial Keratotomy
See keratotomy, radial.

Radial Nerve
A branch of the brachial plexus. The radial nerve, one of the main nerves of the arm, runs from the shoulder to the hand. The radial nerve controls the muscles that straighten the wrist. It conveys sensation from the back of the forearm; the thumb, second, and third fingers; and the base of the thumb.

The radial nerve may be damaged by a fracture of the humerus (upper-arm bone) or by persistent pressure on the arm pit, such as from the use of a crutch. Such damage may result in wrist drop (an inability to straighten the wrist) and numbness in the areas of skin supplied by the radial nerve.

Radiation
The emission of energy (as electromagnetic waves) or matter (as particles) from unstable atoms, which turns them into a more stable form. Some types of radiation are harmful to life; other types are essential, such as light and heat energy radiated from the sun. Even harmful radiation may be used for beneficial purposes. In treatment by radiotherapy, for example, the biologically damaging effects of radiation are used to destroy cancerous cells.

Ionizing Radiation
Four significant types of harmful radiation are gamma radiation, X-rays, alpha particles, and beta particles. Gamma radiation and X-rays are types of electromagnetic waves and are similar to more energetic forms of light. The principal difference between the two is that gamma rays are produced by the spontaneous decay of radioactive materials whereas X-rays are produced by a machine. Particle radiation may be produced either during the decay of radioactive atoms or by machine.

All four types of harmful radiation cause damage by ionization: the waves or particles knock out electrons from atoms in the matter that they pass through, turning them into highly reactive ions. In the case of living tissue, the ions formed can cause biological damage. Radioactive substances that emit any of these types of radiation constitute a health hazard. However, alpha particles cannot penetrate the skin, and therefore sources of alpha radiation are only dangerous if they are ingested or inhaled. Gamma radiation can travel large distances through many substances; even distant gamma sources can pose a risk to humans.

Most sources of radiation are natural. Natural sources of ionizing radiation include cosmic rays from space and radioactive minerals. In some areas, the gas radon, which is found in soil, rocks, or building materials, is a major source of ionizing radiation. Sources of ionizing radiation that are artificial include X-ray machines, radioactive isotopes used in diagnosis and treatment (see radionuclide scanning), and nuclear reactors.

Nonionizing Radiation
Less energetic types of radiation, such as ultraviolet light, may cause biological damage by mechanisms other than ionization. Ultraviolet radiation from the sun does not penetrate the body deeply, but can damage genetic material in cells and may lead to skin cancer.

Other types of nonionizing radiation to which people are subjected are ultrasound, used in medicine for diagnosis and treatment, and radio waves that are generated during MRI (magnetic resonance imaging). These techniques are not thought to have any adverse side effects. (See also radiation hazards; radiation sickness; radiation unit.)

Radiation Dermatitis
A type of dermatitis (inflammation of the skin) that may be caused by single exposure to a high dose of radiation.

Radiation Enteritis
A potentially long-standing form of enteritis (inflammation of the small intestine) that is caused by exposure of the intestine to radiation, including the use of radiotherapy. The symptoms of radiation enteritis include nausea, vomiting, and diarrhoea.

Radiation Fibrosis
Scarring and thickening of the tissues around an area of the body that has been treated with radiotherapy.

Radiation Hazards
Hazardous brought about by radiation (the emission of energy in the form of waves or particles) that may arise either from external sources of radiation, such...
as X-rays or gamma rays, or from radioactive materials taken into the body. The effects of radiation depend on the dose, the duration of exposure, and the organs exposed.

With some forms of radiation, damage occurs only when the radiation dose exceeds a certain limit – this is usually 1 sievert (Sv) (see radiation unit). Examples of such damage are radiation dermatitis, cataract, organ failure (which may occur many years later), or radiation sickness (an early reaction to massive irradiation).

For other types of radiation damage, the risk that damage will occur increases with repeated doses of radiation. Cancer that is caused by radiation-induced mutation (a change in the genetic material of living cells) is a major example of this type of damage. Radioactive leaks from nuclear reactors can cause a rise in mutation rates, which may lead to an increase in the incidence of cancers, such as leukaemias; birth defects in succeeding generations; and hereditary diseases. Cancer usually develops years after exposure.

Damage can be controlled by limiting exposure to radiation. People exposed to radiation at work should have their exposure closely monitored to ensure that it does not exceed safe limits. People of reproductive age or younger should have their reproductive organs shielded when having X-rays or undergoing radiotherapy.

There is no evidence of radiation hazards arising from visual display units (VDUs) or the irradiation of food.

radiation sickness

The term applied to the acute effects of ionizing radiation on the whole, or a major part, of the body when the dose exceeds 1 gray (Gy) of X-rays or gamma rays or 1 sievert (Sv) of other types of radiation (see radiation unit).

The effects of radiation depend on the dose and the duration of exposure. Total-body doses of less than 2 Gy are unlikely to be fatal to a healthy adult. At doses of 1 to 10 Gy, transient nausea and occasional vomiting may occur, but these usually disappear rapidly and are often followed by a two- to three-week period of relative wellbeing. By the end of this period, the effects of radiation damage to the bone marrow and immune system begin to appear, with repeated infections (which may be fatal unless treated with antibiotic drugs) and petechiae (pinpoint spots of bleeding under the skin). Some people are successfully treated with a bone marrow transplant or by isolation in a sterile environment until the bone marrow recovers.

With a dose of 10 to 30 Gy there is also an early onset of nausea and vomiting, but these symptoms tend to disappear a few hours later. However, damage to the gastrointestinal tract, which causes severe and frequently bloody diarrhoea (known as the gastrointestinal syndrome), and overwhelming infection due to damage to the immune system are likely to result in death between four and 14 days after exposure.

Acute exposures of 30 to 100 Gy cause the rapid onset of nausea, vomiting, anxiety, and disorientation. Within hours, the victim usually loses consciousness and dies due to damage to the nervous system and oedema (accumulation of fluid) of the brain; these combined effects are known as the central nervous system syndrome.

radiation unit

Several different internationally agreed units (called SI units) are used to measure ionizing radiation. For example, the becquerel (symbol Bq) is the SI unit of spontaneous activity of a radioactive source such as uranium. In medicine, the most commonly used units are the gray (symbol Gy) and sievert (symbol Sv).

The gray is the SI unit of radiation that is actually absorbed by any tissue or substance as a result of exposure to radiation. One Gy is the absorption of one joule of energy (from gamma radiation or X-rays) per kilogram of irradiated matter. The gray supersedes an older unit called the rad (1 Gy = 100 rads).

Because some types of radiation affect biological organisms more than others, the sievert is used as a measure of the impact of an absorbed dose. It uses additional factors, such as the kind of radiation and its energy, to quantify the effects on the body of equivalent amounts of different types of absorbed energy. (See also Radiation units box, overleaf.)

radical surgery

Extensive surgery that is aimed at eliminating a major disease, usually cancer, by removing all the affected tissue and any surrounding tissue that might also be diseased.

Some examples of radical surgery are radical mastectomy performed to treat breast cancer, which involves removing the entire affected breast along with chest muscles, underarm lymph nodes, and other tissue; radical neck dissection (see neck dissection, radical), in which the lymph nodes in the neck are removed; and amputation, which is usually performed to prevent the spread of gangrene (tissue death).

radiculopathy

Damage to the nerve roots that enter or leave the spinal cord. Radiculopathy may be caused by disc prolapse, spinal arthritis, diabetes mellitus, or ingestion of heavy metals, such as lead. Symptoms of radiculopathy are severe pain and, occasionally, loss of feeling in the area supplied by the affected nerves. There may also be weakness, paralysis, and wasting of the muscles that are supplied by the nerves.

Where possible, the underlying cause is treated; otherwise, symptoms may be relieved by analgesic drugs (painkillers), physiotherapy, or, in some cases, surgery.

radioactivity

The emission of alpha particles, beta particles, and/or gamma radiation that occurs during the spontaneous disintegration of the nuclei (see nucleus) of unstable atoms.

Many radioactive substances, such as uranium ores, are naturally occurring. However, the majority of elements can be made radioactive by bombarding them with high-energy particles, such as neutrons.

radioallergosorbsent test

See RAST.

radiography

The use of radiation to obtain images of parts of the body. Radiographers prepare patients for X-ray examinations, take and develop X-ray pictures, and assist with other imaging techniques, such as radionuclide scanning, ultrasound scanning, and MRI (magnetic resonance imaging). (See also radiology.)

radioimmunoassay

A sensitive laboratory technique that uses radioactive isotopes to measure the concentration of specific proteins, such as hormones or antibodies, in a person’s blood. (See also immunoassay.)

radioisotope scanning

See radionuclide scanning.
**Radiology**

The medical specialty that uses X-rays, ultrasounds, MRI (magnetic resonance imaging), and radionuclide scanning to investigate, diagnose, and treat disease.

Radiological methods provide images of the body in a noninvasive way so that exploratory surgery is not required. The techniques also enable instruments (such as needles and catheters) to be accurately guided into different parts of the body both for diagnosis and for treatment, a subspeciality known as intervention radiology.

**Radionuclide scanning**

A diagnostic technique that is based on the detection of radiation emitted by radioactive substances introduced into the body. Different substances are taken up in different concentrations by different tissues, allowing specific organs to be studied. For example, iodine is taken up mainly by the thyroid gland, so by “tagging” a sample of iodine with a radioactive marker (radionuclide), the thyroid gland’s uptake of iodine can be monitored to investigate the functioning of the gland.

**How it works**

Radionuclide scanning is the swallowing or alternatively injected into the bloodstream and then accumulates in the target organ. The organ emits radiation in the form of gamma radiation, which is detected by a gamma camera and then an image is produced. Cross-sectional images (“slices”) can be obtained by using a computer-controlled gamma camera that rotates around the patient. This specialized form of radionuclide scanning is known as SPECT (single photon emission computed tomography). Moving images can also be taken with the use of a computer; a series of images is recorded immediately following the administration of the radionuclide.

**Why it is done**

Radionuclide scanning is capable of detecting some disorders at an earlier stage than other types of imaging techniques because changes in the functioning of an organ often occur before the structure of the organ is affected. The technique is also used to detect disorders that affect only the function of an organ. Moving images can provide information about blood flow, the movement of the heart walls, the flow of urine through the kidneys, and bile flow through the liver.

**Risks**

Radionuclide scanning is a safe procedure, requiring only minute doses of radiation that are excreted within hours. The radionuclides carry virtually no risk of toxicity or hypersensitivity.

**Radiopaque**

A term describing anything that is able to block radiation, especially X-rays and gamma rays. As many body tissues are radiolucent (almost transparent to X-rays), some X-ray imaging procedures require the introduction of radiopaque substances into the body in order to make the organs stand out clearly. (See also radiotransparent.)

**Radiolucent**

A term referring to anything that is almost transparent to radiation, especially X-rays and gamma rays. Some X-ray imaging procedures require the introduction of radiopaque substances into the body to make radiolucent organs and/or body tissues stand out more clearly.

---

### Radiation Units

In the SI system (the internationally agreed system of units), three main units are used to measure radiation levels — the becquerel, the gray, and the sievert. These three units are defined below, along with two other radiation units (the rad and rem) that have now been largely superseded but are still occasionally used for some purposes.

**Becquerel**

The SI unit of radioactivity. One becquerel (symbol Bq) is defined as one disintegration (or other nuclear transformation) per second. Although the number of becquerels is a measure of how strongly radioactive a particular source is, it takes no account of the different effects of different types of radiation on tissue; for medical purposes, the sievert is generally more useful.

**Gray**

The SI unit of absorbed dose of ionizing radiation, the gray (symbol Gy) has superseded the rad. One gray is defined as an energy absorption of 1 joule per kilogram of irradiated material. One gray is equivalent to 100 rads.

**Rad**

An acronym for radiation absorbed dose, the rad is a unit of absorbed dose of ionizing radiation. One rad is equal to an energy absorption of 100 ergs (an erg is a unit of work or energy) per gram of irradiated material. The rad has been superseded by the gray (the corresponding SI unit); 1 rad is equivalent to 0.01 grays.

**Rem**

An acronym for roentgen equivalent man, the rem is the absorbed dose of ionizing radiation that produces the same biological effect as 1 rad of X-rays or gamma rays. The rem was introduced as a result of the observation that some types of ionizing radiation, such as neutrons, produce a greater biological effect for an equivalent amount of absorbed energy than X-rays or gamma rays. In short, the rem is a measure of the biological effectiveness of irradiation. For X-rays and gamma rays, the rem is equal to the rad. For other types of radiation, the number of rems equals the number of rads multiplied by a special factor (called the quality factor or relative biological effectiveness) that depends on the type of radiation involved. The rem has been superseded by the sievert in the SI system of units; 1 rem is equivalent to 0.01 sieverts.

**Sievert**

The SI unit of equivalent absorbed dose of ionizing radiation, the sievert (symbol Sv) has superseded the rem. One sievert is the absorbed dose of radiation that produces the same biological effect as 1 gray of X-rays or gamma rays. One sievert is equivalent to 100 rems.
active sources produce ionizing radiation, which destroys or slows down the development of abnormal cells. Normal cells should suffer little or no damage in the long term, but short-term damage is a side effect of radiotherapy.

WHY IS IT DONE
Radiotherapy may be used on its own in an attempt to destroy all the abnormal cells in various types of cancer, such as squamous cell carcinoma (a type of skin cancer) and Hodgkin’s disease (a cancer of lymphoid tissue). It may also be used in conjunction with other cancer treatments. For example, surgical excision of a cancerous tumour is often followed by radiotherapy to destroy any remaining tumour cells, such as in the treatment of breast cancer.

Radiotherapy may also be used to relieve the symptoms of a cancer that is too advanced to be cured. An example of such palliative treatment is radiotherapy to reduce the size of a brain tumour in order to relieve headaches and paralysis.

If the benefits of destroying diseased tissue outweigh the risks of damage to healthy tissue, radiotherapy may be used to treat noncancerous diseases; for example, part of an overactive thyroid gland (see thyrotoxicosis) may be destroyed using radioactive iodine.

HOW IT IS DONE
Radiotherapy is usually performed on an outpatient basis. X-rays (or sometimes electrons), which are produced by a machine called a linear accelerator, are aimed at the tumour from many directions. Alternatively, a source of radiation, in the form of tiny pellets, is inserted into the tumour through a hollow needle (see interstitial radiotherapy) or into a body cavity (see intracavitary therapy). These techniques

USE OF RADIOThERAPY

Radiotherapy destroys cancer cells using radiation. A linear accelerator is used for external radiation (right). The position and dose of radiation are carefully calculated to minimize exposure of normal cells to the radiation, allowing them to recover with little or no long-term damage.

Internal radiation (below) involves placing radioactive materials in the body, directly into or around a cancer.

External radiation
The patient lies still on a table under the machine. A radiographer operates the machine, which sends X-rays, in the predetermined directions and amounts, through the diseased areas of the patient’s body. The machine can be tilted to irradiate the cancer from different angles (see below, centre). The procedure causes no discomfort, and usually lasts a few minutes, but setting up the equipment may take 30 minutes.

INTERNAL RADIATION

Rays from different directions
By aiming relatively low-energy rays coming from many directions at a tumour, a large enough dose of radiation is achieved in the locality of the tumour to destroy it completely (see above).

Before treatment
There is a proliferation of lymphoid tissue in this lung X-ray of a patient with Hodgkin’s disease.

After treatment
The invading lymphoid tissue has diminished following radiotherapy.

Use of radioactive pellets
Tiny radioactive pellets are inserted, via a hollow needle, directly into the organ or tissue to be treated (here, the prostate gland).
are both types of brachytherapy. Radioactive iodine used to treat thyrotoxicosis is given by mouth.

**Complications and Results**
There may be some unpleasant side effects of radiotherapy, such as fatigue, nausea and vomiting (for which *anti-emetic drugs* may be prescribed), and loss of hair from irradiated areas. Rarely, there may be reddening and blistering of the skin, which can be alleviated by *corticosteroid drugs*.

Radiotherapy can be used successfully to treat most types of cancer; the chances of success increase the earlier the treatment is started.

**Radiotransparent**

A term referring to anything that is entirely transparent to *radiation*, especially to *X-rays* and gamma rays. Some X-ray imaging procedures require the introduction of *radiopaque* substances into the body to make radiotransparent and *radiolucent* organs and/or body tissues stand out more clearly.

**Radium**

A rare, radioactive, metallic element that occurs naturally only as compounds in *uranium* ores. Radium has four naturally occurring isotopes (varieties of the element that are chemically identical but differ in some physical properties): *radium 226*, *radium 228*, *radium 224*, and *radium 223*. Radium 226 was used to treat tumours but it has been superseded by other radioisotopes, such as cobalt 60.

**Radius**

The shorter of the two long bones of the forearm; the other is the *ulna*. The radius is the bone on the thumb side of the arm, which articulates with the humerus (the upper arm bone) at the elbow and the carpal bones (upper wrist bones) at the wrist.

The radius takes most of the strain when weight is placed on the wrist, and it is a common site of fractures (see *Colles’ fracture; radius, fracture of*). A fall or a blow may sometimes cause dislocation of the radius from the elbow joint, along with fracture of the ulna, a condition that is known as Monteggia’s fracture.

**Radius, fracture of**

A common type of fracture that may affect the lower end, upper end, or shaft of the *radius* (the shorter of the two long bones in the forearm).

Fracture of the radius just above the wrist (see *Colles’ fracture*) is the most common of all fractures in people over 40. It is usually caused by falling on the palm of a hand, resulting in backward displacement of the wrist and hand.

Fracture of the disc-shaped head of the radius, just below the elbow, is one of the most common fractures in young adults. Treatment depends on the type and severity of the fracture. A minor fracture may heal if placed in a soft, supportive bandage; others may require surgical correction. If the head of the bone is crushed or splintered, it may need to be removed.

Fracture of the shaft of the radius may result in displacement of the broken ends of the bone. An operation may be required in order to reposition the bone ends and fix them together before the limb is immobilized.

Fractures of the radius usually take approximately six weeks to heal.

**Radon**

A colourless, odourless, tasteless, radioactive gaseous element produced by the radioactive decay of *radium*.

**Raloxifene**

A drug that is prescribed to prevent and treat postmenopausal *osteoporosis*. Raloxifene has no beneficial effect on other menopausal problems, such as hot flushes. The drug may carry an increased risk of developing a deep vein thrombosis (see *thrombosis, deep vein*).

**Ramipril**

An *ACE inhibitor drug* used in the treatment of hypertension (high blood pressure) and *heart failure* (reduced pumping efficiency). Ramipril is also used to prevent or delay kidney damage in patients with *diabetes mellitus*. Side effects may include a persistent dry cough, a disturbance in taste, hypotension (low blood pressure), and other effects common to all ACE inhibitors.

**Ramsay–Hunt syndrome**

A type of *herpes zoster* (shingles) that affects the facial nerve. Symptoms of Ramsay–Hunt syndrome include facial paralysis, intense ear pain, hearing loss, loss of taste, a painful rash on the affected part of the face, and pain in other parts of the body supplied by the facial nerve. Treatment of the condition is with *antiviral drugs* and, sometimes, *anti-inflammatory drugs*.

**Randomized controlled trial**

A type of *controlled trial* used to evaluate the effectiveness of a drug or treatment in which subjects are randomly allocated to one of the study groups. This random allocation means an individual is equally likely to be selected to receive the treatment being investigated as to be part of the control group of the trial, which may be given a placebo (a chemically inert substance). A comparison is made between various results of the two groups to assess the benefit of the treatment in question.

**ranitidine**

An ulcer-healing drug belonging to the *H₂-receptor antagonist* group. Ranitidine is used to prevent and treat *peptic ulcers* and to treat *oesophagitis* (inflammation of the oesophagus). Side effects may include headache, skin rash, nausea, constipation, and lethargy.

**ranula**

A cyst in the floor of the mouth, which produces a translucent bluish swelling. Ranulas probably arise from damage to a *salivary gland*. Treatment of the ranula is by surgical removal.

**Rape**

Sexual intercourse with an unwilling partner, achieved by the use or the threat of force or violence. Rape is rarely sexually motivated; it is a crime of dominance, anger, and hostility, not a crime of passion. Rape is a criminal offence.
rash
A group of spots or an area of red, inflamed skin. A rash is usually temporary and is only rarely a sign of a serious underlying problem. A rash may be accompanied by itching or fever.

TYPES
Rashes are classified according to whether they are localized (affecting a small area of skin) or generalized (covering the entire body) and also by the type of spots present.

A macular rash consists of spots that are level with the surrounding skin and discernible from it only by a difference in colour or texture. Nodular and papular rashes are composed of small, raised bumps, which may or may not be the same colour as the surrounding skin. A bullous rash has large blisters, a vesicular rash has small blisters, and a pustular rash has blisters filled with pus. A butterfly rash is a skin eruption across the cheeks with a narrow connecting band across the nose; it is characteristic of systemic lupus erythematosus.

CAUSES
Rashes are the main sign of many infectious diseases, such as chickenpox, and are a feature of many skin disorders, such as eczema and psoriasis. A rash may also indicate an underlying medical problem, such as the rashes of scurvy or pellagra, which are caused by vitamin deficiency. The rashes that are characteristic of articularia (nettle rash) or contact dermatitis may be caused by an allergic reaction (see allergy). Drug reactions, particularly those to antibiotic drugs, are another common cause.

DIAGNOSIS AND TREATMENT
Diagnosis is based on the appearance and distribution of the rash, the presence of any accompanying symptoms, and the possibility of allergy (for example, to drugs).

Any underlying cause of the rash is treated where possible. An itching rash may be relieved by a soothing lotion, such as calamine, or an antihistamine drug. (See also meningococcal rash.)

RAST
An abbreviation for radioallergosorbent test. RAST is a type of radioimmunoassay used to detect antibodies (proteins manufactured by the immune system) to specific antigens (substances that can trigger an immune response).

Rats, diseases from
Rats are rodents that live close to human habitation. They damage and contaminate crops and food stores and can spread disease.

The organisms responsible for plague and one type of typhus are transmitted to humans by the bites of rat fleas. Leptospirosis (Weil's disease) is caused by contact with anything contaminated with rat's urine.

Rat-bite fever is a rare infection transmitted directly by a rat bite. There are two types of rat-bite fever, each caused by different bacteria. Symptoms include inflammation at the site of the bite and in nearby lymph nodes and vessels; bouts of fever; a rash; and, in one type, painful joint inflammation. Treatment for both types is with antibiotic drugs.

The rabies virus can be transmitted by the bites of infected rats. Lassa fever, another viral disease, may be contracted from the urine of infected rats in West Africa. Rats also carry the viral infection lymphocytic chorio-meningitis, as well as the bacterial infection tularemia.

Raynaud's disease
A disorder of the blood vessels in which exposure to cold causes the small arteries supplying the fingers and toes to contract suddenly. This action cuts off blood flow to the digits, which become pale. The fingers are more frequently affected than the toes. The cause of Raynaud's disease is unknown, but young women are most commonly affected.

Symptoms develop with no known cause. On exposure to cold, the digits turn white due to lack of blood. As sluggish blood flow returns, the digits become blue; when they are warmed and normal blood flow returns, they turn red. During an attack, there is often tingling, numbness, or a burning feeling in the affected fingers or toes. In rare cases, the artery walls gradually thicken, permanently reducing blood flow, leading to painful ulceration or even gangrene (tissue death) at the tips of the affected digits.

Diagnosis is made from the patient's history. Treatment involves keeping the hands and feet as warm as possible. Vasodilator drugs or calcium channel blockers may be prescribed in severe cases. (See also Raynaud's phenomenon.)

Raynaud's phenomenon
A circulatory disorder affecting the fingers and toes that shares the mechanism, symptoms, and signs of Raynaud's disease but which results from a known underlying disorder.

Possible causes of Raynaud's phenomenon include arterial diseases, such as atherosclerosis (fat deposits on the artery walls); connective tissue diseases, such as rheumatoid arthritis; and various drugs, such as beta-blocker drugs. The disorder is a recognized occupational disorder of people who use pneumatic drills, chain saws, or other vibrating machinery, and other people whose fingers suffer repeated trauma.

Treatment is the same as for Raynaud's disease, along with treatment of the underlying disorder.

Reactive arthritis
Inflammation of the joints due to an abnormal immune response (the body's defensive response to foreign substances) that occurs after an infection of
the genital tract, such as *chlamydial infection*, or of the intestinal tract, such as *gastroenteritis*. If there is additional inflammation elsewhere in the body, such as in the eyes, the condition is known as *Reiter’s syndrome*.

**reactive depression**
A term that was formerly used to describe a type of depression (feelings of sadness, hopelessness, and a lack of interest in life) resulting from a stressful or emotional event or period of life. In contrast, another type of depression known as “endogenous depression” was seen to originate from biological factors within an individual. In the majority of cases, however, depression is a combination of these two types.

**reactive hypoglycaemia**
A form of hypoglycaemia (low blood glucose levels) that occurs within a few hours of eating foods that are rich in glucose. In reactive hypoglycaemia, the body overreacts to the sudden rise in blood sugar by releasing large amounts of *insulin*. This results in a rapid and excessive drop in the blood sugar level causing hypoglycaemic symptoms.

**reagent**
A term that is used for any chemical substance that takes part in a chemical reaction. The term usually refers to a chemical or a mixture of chemicals that are used in chemical analysis (see *analysis, chemical*) or used to detect a biological substance.

**rebound**
A term that describes a return of symptoms after the effects of a medication or treatment have worn off.

**rebound hypoglycaemia**
A form of hypoglycaemia that occurs when the body releases large amounts of *insulin* in response to a sudden drop in blood sugar levels. This can cause symptoms such as weakness, dizziness, and sweating.

**recessive chin**
Underdevelopment of the lower jaw. The condition can be corrected by the use of orthodontic appliances if used in the growth spurt at adolescence or by cosmetic surgery.

**recessing gums**
Withdrawal of the gums from around the teeth, resulting in the exposure of part of the roots. The teeth may become sensitive to hot and cold substances and...
the attachment of the tooth in the socket may weaken, causing the tooth to become loose. Severe cases of receding gums are usually a sign of gum disease (see gingivitis; periodontitis).

**receding hairline**
A feature that is characteristic of male-pattern baldness (see alopecia).

**receptor**
A general term for any sensory nerve cell (one that converts stimuli into nerve impulses). The term receptor is also used to refer to specific structures that occur on the surface of a cell (see Types of receptor box, left) that allow chemicals to bind with the cell in order to exert their effects.

**recessive**
A term used in genetics to describe one of the ways by which a gene is passed from parent to offspring. Many characteristics are determined by a single pair of genes, one of each pair being inherited from each parent. A recessive gene is overridden by an equivalent dominant gene. For example, the gene for blue eye colour is recessive; therefore, if a child inherits the gene for brown eyes from one parent and the gene for blue eyes from the other, the “blue eye” gene is overridden by the “brown eye” gene, and the child ends up with brown eyes. The child must inherit the recessive blue eye gene from both parents in order to develop blue eyes.

Many genetic disorders are determined by a recessive gene. Examples include cystic fibrosis and sickle cell anaemia. The child will only have the disease if he or she inherits the gene from both parents.

**recombinant DNA**
A section of DNA (genetic material) from one organism that has been artificially spliced into the DNA of another organism, often that of a viral or bacterial cell. This procedure may be carried out in order to make the recipient cell produce a substance that it would not normally be able to produce. An example of this technique is the addition of a DNA section containing the genetic code for the hormone insulin into a recipient cell. If this cell can be encouraged to replicate, it is possible for large amounts of the hormone to be obtained. (See also genetic engineering.)

**rectal bleeding**
The passage of blood from the rectum or anus. The blood may range in colour from bright red to dark brown or black. It may be mixed with, or on the surface of, faeces or passed separately. Rectal bleeding may or may not be accompanied by pain.

Haemorrhoids (swollen veins in the lining of the anus) are the most common cause of rectal bleeding. Small amounts of bright red blood appear on the surface of faeces or on toilet paper. Anal fissure (an ulcer or tear at the margin of the anus), anal fistula (an abnormal anal channel), proctitis (inflammation of the rectum), or rectal prolapse (protrusion of the rectal lining) may also cause rectal bleeding.

Cancer of the colon (see colon, cancer of) or the rectum (see rectum, cancer of) or polyps (grape-like growths) can also cause bleeding. Disorders of the colon, such as diverticular disease, may cause dark red faeces. Black faeces (see melena) may be due to bleeding from high in the digestive tract. Bloody diarrhoea may be caused by ulcerative colitis, amoebiasis, or shigellosis.

Diagnosis may be made from a rectal examination, proctoscopy, sigmoidoscopy, or colonoscopy (internal examination using a}

---

**RECOMBINANT DNA AND GENETICALLY ENGINEERED INSULIN**

Genetic engineering can force bacteria to produce human insulin. The insulin gene is obtained (by removing it from human DNA, then purifying it) and spliced into the DNA of a bacterium, causing it to produce human insulin. The bacterium is then cultured for large-scale insulin extraction.
rigid or flexible viewing instrument), or a double-contrast barium X-ray examination. Rectal bleeding in anyone over the age of 40 should be carefully investigated to rule out the possibility of colorectal cancer.

**rectal examination**
Examination of the **anus** and **rectum**, which may be performed as part of a general **physical examination**. A rectal examination is usually used to assess symptoms of pain, changes in bowel habits, the size of the prostate gland, or to check for the presence of **tumours** of the rectum or **prostate gland**.

**rectal prolapse**
Protrusion outside the **anus** of the lining of the **rectum**, usually brought on by straining to defaecate. The condition commonly causes discomfort, a mucus discharge, and **rectal bleeding**.

Rectal prolapse is usually temporary in young children, but it is often permanent in elderly people due to a weakening of the tissues that support the perineum (the area between the anus and the external genitals). In cases in which the prolapse is large, leakage of **faeces** may occur.

Treatment is with a fibre-rich diet. Surgery may also be performed, especially on older people.

**rectocele**
A bulging inwards and downwards of the back wall of the **vagina**, which occurs as a result of the **rectum** pushing against weakened tissues in the vaginal wall. A rectocele is usually associated with a **cystocele** (protrusion of the bladder into the front wall of the vagina) or a prolapsed uterus (see **uterus**, **prolapse of**).

There may be no symptoms or the rectocele may cause **constipation**. Pelvic floor exercises may help to relieve symptoms. If they do not, an operation to tighten the tissues at the back of the vagina may be recommended.

**rectum**
A short, muscular tube that forms the lowest part of the large intestine and connects it to the **anus**.

**STRUCTURE**
The first part of the rectum consists of four layers: an outermost serous layer; a muscular layer; a submucous layer; and an innermost mucous layer that lubricates the rectum. There is no serous layer in the last third of the rectum.

**FUNCTION**
The rectum collects **faeces** that have formed in the alimentary tract (the tube-like structure that extends from the mouth to the anus). Pressure on the rectal wall causes nerve impulses to pass to the brain; the urge to defaecate occurs when the collected faeces distend (stretch) the rectum.

**DISORDERS**
Rarely, a baby is born with no rectum or anus (see **anus**, **imperforate**).

There are a number of diseases and disorders that affect the rectum; these include **proctitis** (inflammation), **polyps** (grapelike growths), and cancer (see **rectum**, **cancer of**).

The rectum can become obstructed as a result of narrowing, which may be caused by **radiotherapy**, **granuloma inguinale** (a sexually transmitted infection), or a pelvic infection. In rare cases, an **ulcer** develops in the rectum, causing bleeding and a discharge.

**Rectal prolapse** occurs when the lining of the rectum protrudes outside the anus. In a **rectocele**, the rectum and rear wall of the vagina bulge downwards into the vagina.

Rectal disorders are usually diagnosed by means of **rectal examination** and **proctoscopy or sigmoidoscopy** (internal examination using a rigid or flexible viewing instrument).

**rectum, cancer of**
A malignant **tumour** in the **rectum** (the muscular tube that forms the last part of the large intestine). There may be a genetic basis for some types of rectal cancer. In particular, an inherited disorder called familial adenomatous **polyposis** (in which large numbers of polyps develop in the large intestine) increases the risk. In most cases, however, the precise cause is unknown. Dietary factors, such as eating a lot of meat and fatty foods and not enough fibre, may also increase the risk. Cancer of the rectum is most common between the ages of 50 and 70.

**SYMPTOMS**
Early symptoms of cancer of the rectum are **rectal bleeding** during defaecation and diarrhoea or constipation. Later, pain may occur. Left untreated, the cancer may eventually cause severe bleeding and pain and block the intestine, preventing the passage of faeces. The cancer may also spread to other organs.

**DIAGNOSIS AND TREATMENT**
Rectal cancer may be suspected from a positive result in a **faecal occult blood test**, which is used to check for hidden blood in the faeces. It may also be detected during a **rectal examination** and confirmed using **proctoscopy or sigmoidoscopy** (internal examination using a rigid or flexible viewing instrument) and a **biopsy** (removal of a small sample of tissue for microscopic analysis).

Treatment is usually with surgery. For a tumour in the upper rectum, the affected area and the last part of the colon are removed and the two free ends of the intestine are sewn together. To promote healing, a temporary **colostomy** (which diverts faeces through a surgical opening in the abdomen) may be made. For a growth in the lower rectum, the entire rectum and anus are removed. Because there is no outlet for faeces, a permanent colostomy is created.

**Radiotherapy** and **anticancer drugs** may be used in addition to, or instead of, surgery. The outlook depends on how widespread the cancer is at the time treatment is commenced.

**recurrent pregnancy loss**
Another term for **habitual abortion**.

**red blood cell**
Also known as an erythrocyte, a **blood cell** containing the red, oxygen-carrying pigment **haemoglobin**. The main function of a red blood cell is that of transporting
oxygen around the body. A mature red blood cell is a biconcave disc shape and does not possess a nucleus. (See also white blood cell.)

red-eye
Another name for conjunctivitis.

reduction
The process of manipulating a displaced part of the body back into its original position. Reduction may be carried out to realign fractured bone ends (see fracture), to replace a dislocated joint in its socket (see dislocation, joint), or to treat an abdominal hernia by pushing the protruding intestine back through the abdominal wall.

Reference Nutrient Intake (RNI)
Figures, based on the needs of a healthy individual, that establish the minimum daily requirements of vitamins and minerals. Requirements of certain vitamins and minerals may differ according to factors such as age, gender, and stage of life.

referred pain
Pain felt in a part of the body at some distance from its cause. Referred pain occurs because some remote parts of the body are served by the same nerve or group of nerves. Occasionally, nerve impulses that reach the brain from one of these areas may be misinterpreted as coming from another.

Common examples of referred pain are sciatica and the pain down the inside of the left arm caused by angina pectoris (chest pain due to impaired blood supply to the heart muscle) or a myocardial infarction (heart attack).

reflex
An action that occurs automatically and predictably in response to a particular stimulus; a reflex is independent of the will of the individual.

In the simplest reflex, a sensory nerve cell reacts to a stimulus, such as heat or pressure, and sends a signal along its nerve fibre to the central nervous system (the brain and spinal cord). There, another nerve cell becomes stimulated and causes a muscle to contract or a gland to increase its secretory activity. The passage of the nerve signal from original sensation to final action is known as a reflex arc.

Reflexes may be inborn or conditioned. Some inborn reflexes occur only in babies (see reflex, primitive), such as the grasp reflex that occurs when an adult’s finger is placed in the baby’s palm. Inborn reflexes include those that control basic body functions, such as contraction of the bladder after it has filled beyond a certain point. Such inborn reflexes are managed by the autonomic nervous system.

Conditioned reflexes are acquired through experience in a process called conditioning. For example, a person may follow a familiar route home from work without making a conscious effort. Several simple reflexes, such as the knee-jerk reflex and constriction of the pupil in response to light, are tested in a physical examination. Changes in reflexes may indicate damage to the nervous system. The examination of vital reflexes provides the mechanism by which images are focused on the retina in the eye, thereby permitting vision.

Refsum’s disease
A rare genetic disorder that affects lipid metabolism (the processing of fats by the body). Refsum’s disease causes excessively high levels of phytanic acid, a fatty acid, in the body.

One major symptom is polyneuritis (inflammation of nerves around the body). This may result in weakness and numbness, often affecting the limbs. Other common features of the condition are a visual defect called retinitis pigmentosa and ataxia, an unsteady gait caused by damage to the brain’s cerebellum. Symptoms usually appear before the age of 20. The disease is progressive, although there are periods of remission.

Phytanic acid may be obtained from the diet. Therefore, people with Refsum’s disease are advised to avoid all...
foods containing this substance. The main sources of phytanic acid are meat from animals that feed on grass (cows, sheep, and goats) and dairy products.

Regaine
A brand name for minoxidil. Regaine is used as a topical (applied to the skin) lotion in the treatment of male-pattern baldness (see alopecia).

regression
A term that is used in psychoanalytic theory to describe the process of returning to a childhood level of behaviour, such as thumb-sucking. (See also fixation.)

regurgitation
A backflow of fluid. In medicine, the term is commonly used to describe the return of swallowed food or drink from the stomach into the oesophagus and mouth. The term is also used to describe the backflow of blood through a heart valve that does not close fully because of a disorder such as mitral incompetence. (See also reflux.)

recovery therapy
The treatment of dehydration by administering fluids, salts, and sugars usually by mouth (oral rehydration) or by intravenous infusion. The amount of fluid needed depends on the patient’s age and weight and the degree of dehydration.

Mild dehydration, which occurs in many young children with diarrhoea, can usually be treated with oral solutions, which are available as an effervescent tablet or powder to be made up at home. In severe dehydration, or if the patient cannot take fluids by mouth because of nausea or vomiting, an intravenous infusion of saline and/or glucose solution may be given in hospital.

reimplantation, dental
The replacement of a tooth in its socket after an accident so that it can become reattached to supporting tissues. The front teeth are those that are most commonly reimplemented.

The tooth needs to be reimplanted soon after the accident; it is then maintained with the help of a splint (see splinting, dental) while healing takes place. Keeping the tooth sterile and moist (with saliva or milk, for example) increases the chances of success. Healing may take several weeks.

Reiter’s syndrome
A condition in which there is a combination of urethritis, reactive arthritis, and conjunctivitis. There may also be uveitis. Reiter’s syndrome is more common in men than in women.

Reiter’s syndrome is caused by an immune response and usually develops only in people with a genetic predisposition. Most patients have the HLA-B27
tissue type (see histocompatibility antigens). The syndrome’s development is induced by infection: usually by non gonococcal urethritis, but sometimes by bacillary dysentery.

Reiter’s syndrome usually starts with a urethral discharge, followed by conjunctivitis, and then arthritis. The arthritis usually affects one or two joints (generally the knee and/or ankle) and is often associated with fever and with malaise. Attacks can last for several months. Tendons, ligaments, and tissue in the soles of the feet may also become inflamed. Skin rashes are common.

Diagnosis is from the symptoms. Analgesic drugs (painkillers) and nonsteroidal anti-inflammatory drugs (NSAIDs) relieve pain and inflammation but may have to be taken long term. Relapses occur in about one third of cases.

rejection
An immune response that is aimed at destroying organisms or substances recognized as foreign by the body’s immune system. Rejection also refers to nonacceptance of tissue grafts (see grafting) or organ transplants (see transplant surgery). To avoid rejection, donor tissues are closely matched to recipient ones (see tissue-typing). Immunosuppressant drugs, such as corticosteroids and ciclosporin, are given to organ transplant recipients to suppress rejection by damping down the activity of the immune system.

relapse
The recurrence of a disease after an apparent recovery, or the return of symptoms after a period of remission.

relapsing fever
An illness that is caused by infection with spirochaetes (spiral-shaped bacteria). Relapsing fever is transmitted to humans by ticks or lice and is characterized by high fever. The condition does not occur in the UK.

A high fever of up to 40°C suddenly develops, with shivering, headache, muscle pains, nausea, and vomiting. The symptoms persist for three to six days, culminating in a crisis with a risk of collapse and death. The affected person then seems to recover but suffers another attack seven to ten days later. If the fever is tick-borne, there may be several such relapses, each progressively milder.

The spirochaetes can be seen in a blood film and they can be eliminated with antibiotic drugs.

relationship counselling
Formerly known as marriage guidance, relationship counselling is a type of professional therapy for established partners aimed at resolving the problems within their relationship. The couple attends regular sessions together in which the counsellor promotes communication and attempts to help resolve differences. Relationship counselling is largely based on the ideas and methods of behaviour therapy. If some of the couple’s problems are sexual, the counsellor may also refer them for sex therapy.

relaxation techniques
Methods of consciously relaxing muscular tension to achieve a state of mental calm. Relaxation techniques can assist people with symptoms of anxiety, help to reduce hypertension (high blood pressure), and relieve stress. They may also be used to help pregnant women to cope with labour pains (see childbirth, natural). Active relaxation consists of tensing and relaxing each of the body’s muscles in turn. Passive relaxation involves clearing the mind and concentrating on a single phrase or sound. Breathing exercises help to prevent hyperventilation (rapid, shallow breathing), which often brings on or worsens anxiety. Traditional concentration methods, such as yoga and meditation, employ similar techniques.

releasing factors
A group of hormones produced by the hypothalamus in the brain that stimulate the release of other hormones. Luteinizing hormone-releasing hormone is one such releasing factor.

Relenza
The brand name for zanamivir, an antiviral drug used to treat at-risk people who develop influenza.

rem
An outdated unit of absorbed radiation dose, now superseded by the sievert. (See also radiation unit.)

remission
Temporary disappearance or reduction in severity of the symptoms of a disease, or the period during which this occurs.

REM sleep
The abbreviation for rapid eye movement sleep, the period of sleep during which the brain is more active and dreaming takes place. REM sleep alternates with non-REM (NREM) sleep during the course of the night.

renal
Related to the kidney.

renal biopsy
See kidney biopsy.

renal calculus
A kidney stone (see calculus, urinary tract).

renal cell carcinoma
The most common type of kidney cancer.

renal colic
Spasms of severe pain on one side of the back, extending down to the groin, that are usually caused by a kidney stone (see calculus, urinary tract) passing down the ureter (a tube that carries urine from the kidney to the bladder). There may also be nausea, vomiting, sweating, and blood in the urine.

The treatment of renal colic usually consists of bed rest and plenty of fluids. Injections of a strong analgesic drug (painkiller), such as diclofenac or pethidine, help to ease the pain.

renal failure
See kidney failure.

renal transplant
See kidney transplant.

renal tubular acidosis
A condition in which the kidneys are unable to excrete normal amounts of acid made by the body. In renal tubular acidosis, the blood is more acidic than normal, and the urine less acidic.

Possible causes of renal tubular acidosis include kidney damage that may be due to disease, drugs, or a genetic disorder. However, in many cases the cause of the condition is unknown.

The acidosis may result in osteomalacia (softening of the bones), kidney stones (see calculus, urinary tract), nephrocalcinosis (calcification of the kidney), and hypokalaemia (an abnormally low level of potassium in the blood).

renin
An enzyme that is involved in the regulation of blood pressure. When the blood pressure falls, the kidneys release renin, which changes a substance called angiotensinogen into angiotensin I. This is rapidly converted into angiotensin II,
which acts to increase blood pressure by constricting (narrowing) blood vessels and stimulating the release of aldosterone, a hormone that causes the kidneys to retain sodium in the body.

Blood pressure can be lowered by drugs that affect the renin–angiotensin system, such as beta-blocker drugs, which inhibit the production of renin, and ACE inhibitor drugs, which interfere with the conversion of angiotensin I to angiotensin II.

renography
A technique, also known as renal scintigraphy, that uses a radioactive substance to measure kidney function. Renography is quick and painless and is used, for example, when obstruction of the passage of urine is suspected.

The radioactive substance is injected into the bloodstream and passes via the kidneys into the urine. Radiation counts are taken continually throughout the procedure and both kidneys are examined simultaneously to compare their function. Normally, the radiation count rises and then falls as the substance passes into the bladder. If an obstruction is present, the substance accumulates in the kidneys and the count continues to rise. (See also kidney imaging.)

repaglinide
An oral hypoglycaemic drug (see hypoglycaemics, oral) that is used either alone or in combination with metformin in the treatment of type 2 diabetes mellitus.

Repaglinide stimulates the release of insulin (a hormone that regulates the level of glucose in the blood). Side effects of repaglinide may include abdominal pain, diarrhea or constipation, nausea, and vomiting.

repetitive strain injury (RSI)
An overuse injury that affects people who do repetitive movements for long periods, such as keyboard workers and musicians, causing pain and weakness in the wrists, fingers, or arms. RSI can become chronic, with continuous pain that does not cease when the causative activity is stopped.

repression
A term used in psychoanalysis to refer to the burial of an unacceptable idea or memory deep from an individual’s consciousness. The data that has been repressed is generally out of the reach of voluntary recall. One of the aims of psychoanalysis is to return repressed material to conscious awareness in order that it can be accepted and therefore dealt with in a rational manner.

reproduction, sexual
The process of producing offspring by the fusion of two cells from different individuals; this is achieved in humans by the fusion of one sperm and one ovum. This fusion (which is known as fertilization) may be achieved by sexual intercourse or artificial insemination.

FEMALE REPRODUCTIVE SYSTEM
Each month an ovum from one ovary is carried along the fallopian tube. If fertilized, it begins to divide and implants into the endometrium (lining of the uterus) to develop into an embryo. If the ovum is not fertilized, the endometrium is shed in the form of menstrual bleeding.

RENOGRAPHY
The female organs involved in ovulation, sexual intercourse, nourishing a fertilized ovum (egg) until it has developed into a full-grown fetus, and childbirth. With the exception of the vulva (the external genitalia that protects the opening of the vagina), these organs lie within the pelvic cavity.

An ovum is released each month from one of the two ovaries, which also secrete oestrogen hormones and progesterone hormones — hormones that are involved in the control of the reproductive cycle, together with follicle-stimulating hormone and luteinizing hormone. The ovum travels through the fallopian tubes to the uterus (womb). Fertilization takes place if a sperm that has been released into the vagina during sexual intercourse or artificial insemination travels through the cervix and uterus to penetrate the ovum while it is in the fallopian tube.

The normal functioning of the female reproductive system begins at puberty with the onset of menstruation; the potential for reproduction ends at the time of menopause.

reproductive system, male
The male organs involved in the production of sperm and in sexual intercourse. Sperm and male sex hormones (see androgen hormones) are produced in the testes (see testis), which are suspended in the scrotum. From each testis, sperm pass into an epididymis (a long coiled tube behind the testis), where they mature and are stored. Shortly before ejaculation, sperm are propelled into a duct called the vas deferens, which carries them to the seminal vesicles behind the bladder. These two sacs produce seminal fluid, which is added to the sperm to produce semen.

Semen travels along two ducts to the urethra (a tube that acts as a passage for urine and semen). The two ducts pass through the prostate gland, which produces secretions that are added to the semen. At orgasm, semen is ejaculated from the urethra through the erect penis, which is placed in the woman’s vagina during sexual intercourse. (See also fertilization.)

rescue breathing
The forced introduction of air into the lungs of someone who has stopped breathing (see respiratory arrest) or who has inadequate breathing. Rescue breathing was known as artificial respiration.
As an emergency first-aid measure, rescue breathing can be given mouth-to-mouth or mouth-to-nose in order to prevent brain damage due to oxygen deprivation; a delay in breathing for more than three minutes can cause death. Cardiac compressions may also be necessary if the heartbeat stops (see cardiopulmonary resuscitation).

Mouth-to-mouth resuscitation involves opening the victim's airway, pinching the nose shut, and forcefully exhaling air into his or her mouth until help arrives or the victim begins breathing unaided. Mouth-to-nose resuscitation is an alternative if the victim has a facial injury. If there are no signs of circulation after rescue breathing has been given, cardiopulmonary resuscitation may also be required.

An alternative to rescue breathing that is commonly used by healthcare professionals is the "bag and mask" system. A mask is placed over the patient's face and the attached bag (which may be linked to a supply of oxygen) is squeezed hard to inflate the lungs. Ventilation can also be carried out in hospital by use of a mechanical ventilator.

**respiration**
A term for the processes by which oxygen reaches body cells and is utilized by them (see metabolism) and by which carbon dioxide is eliminated.

Air, containing oxygen, is breathed into the lungs and enters the alveoli (tiny, balloonlike sacs; see alveolus, pulmonary). Oxygen diffuses into the blood, which then carries it to cells in the body, where it is used to metabolize glucose to provide energy. Carbon dioxide is produced as a waste product and passes into the blood from the body cells. It is transported via the blood to the lungs to be breathed out.

Respiration is controlled automatically by the respiratory centre in the brainstem (see Respiration box, overleaf). (See also respiratory system.)

**respirator**
See ventilator.

**respiratory arrest**
Sudden cessation of breathing that may be due to problems affecting the respiratory apparatus, such as severe asthma, sudden exacerbation of chronic obstructive pulmonary disease (see pulmonary disease, chronic obstructive), or obstruction of the airways; to any process that depresses the function of the respiratory centre in the brainstem, including prolonged seizures, an overdose of opioid analgesic drugs, electrical injury, serious head injury, or stroke; or to cardiac arrest.

Respiratory arrest leads rapidly to anoxia (lack of oxygen to tissues) and, if the condition is left untreated, it will progress to cardiac arrest (due to a reduced oxygen supply to the coronary
The function of respiration is to provide the energy needed by body cells. Cells obtain this energy mainly by metabolizing glucose with oxygen, and so they require a constant supply of oxygen. In addition, the waste products of the metabolic process (mainly carbon dioxide) must be carried away from the cells.

Respiration includes the breathing of air into the lungs, the transfer of oxygen from the air to the blood, the transport of oxygen in the blood to the body cells, the metabolism of glucose with oxygen in the cells, and the transport of carbon dioxide to the lungs to be breathed out.

During exercise, respiration increases to compensate for higher energy demands by muscle cells.

**Cellular Respiration**

- Glucose ($C_6H_{12}O_6$) + Oxygen ($O_2$) → Carbon dioxide ($CO_2$) + Water ($H_2O$) + Energy

**Breathing Volumes**

One way the body copes with varied demands for oxygen is through changes in breathing volume. The tidal volume – the amount breathed into and out of the lungs at each breath – may vary from 0.5 litre at rest, up to 4.5 litres (near the maximum or vital capacity) during heavy exercise.
arteries), brain damage, coma, and death. The patient should be given rescue breathing and, if necessary, placed on a ventilator without delay. The cause of the respiratory arrest will be treated.

### respiratory distress syndrome

An acute lung disorder that makes breathing difficult and leads to respiratory failure, resulting in life-threatening hypoxia (an inadequate supply of oxygen to the tissues). The condition may also cause failure of other systems; for example, heart failure or kidney failure.

There are two types of respiratory distress syndrome. The first is seen in premature babies (see prematurity): the lungs are stiff and do not inflate easily due to a lack of surfactant, a group of chemicals that keep the alveoli (tiny air sacs in the lungs; see alveolus, pulmonary) open. In adults, the condition is known as acute respiratory distress syndrome (ARDS) and may develop as a result of a severe injury or overwhelming infection (particularly septicemia).

Breathing becomes laboured and more rapid as the condition develops. Affected babies make grunting noises and the chest wall is drawn in when they breathe. If the condition worsens, progressive deoxygenation of the blood makes the sufferer turn blue (see cyanosis). Without any treatment, death may eventually occur.

Treatment is for the underlying cause, as well as with artificial ventilation and oxygen; inhaled surfactant is given to babies thought to be at risk of respiratory distress syndrome. In cases in which premature delivery is seen to be inevitable, the mother is given corticosteroid injections in order to promote the production of fetal lung surfactant.

### respiratory failure

A condition in which there is a fall in the blood oxygen level (see hypoxia) caused by the inadequate exchange of gases in the lungs. Respiratory failure may have a number of causes: lung disorders, such as severe asthma or pneumonia; depression of the respiratory centre in the brainstem due, for example, to an overdose of opioid analgesic drugs, a stroke, or a head injury; damage to the chest wall, such as flail chest; and nerve and muscle diseases that affect breathing, including poliomyelitis.

The symptoms of respiratory failure include breathlessness, cyanosis (bluish coloration of the skin), confusion, and agitation. Treatment is for the underlying cause, and oxygen and/or assisted ventilation may also be given if required. In some cases, a respiratory stimulant drug may be prescribed.

### respiratory function tests

See pulmonary function tests.

### respiratory syncytial virus (RSV)

A paramyxovirus that is responsible for some nose and throat infections. The RSV is one of the principal causes of bronchiolitis (inflammation of the bronchioles in the lungs) and pneumonia (inflammation of the lungs) in babies and young children.

### respiratory system

The organs responsible for carrying oxygen from the air to the blood and expelling carbon dioxide.

The upper part of the respiratory system consists of two nasal passages, the pharynx (throat), the larynx (voice-box), and the trachea (windpipe). The lower part of the respiratory system consists of two lungs, which are enclosed in a double membrane called the pleura, and the lower airways (the bronchi and smaller bronchioles). These structures are encased in, and protected by, the bony ribcage. The airways terminate in millions of balloonike sacs known as alveoli (see alveolus, pulmonary), where gas exchange with the tiny surrounding blood vessels takes place. These small blood vessels feed into larger pulmonary vessels for transport to and from the heart (see Respiration box, left).

Air is inhaled and exhaled (see breathing) by the action of the dome-shaped diaphragm and the abdominal and chest muscles, including the intercostal muscles located between the ribs. Respiration is controlled by the respiratory centre in the brainstem.

### DISORDERS

Some disorders of the respiratory system can affect the air passages, causing obstruction of the air flow into or out of the lungs; other disorders can affect the lung tissues, resulting in a poor exchange of oxygen and carbon dioxide. The functioning of the respiratory system may also be impaired by certain disorders (such as poliomyelitis) that have an adverse effect on the chest muscles and diaphragm, thereby impeding the inflation of the lungs. (See also respiratory tract infection.)

### respiratory tract infection

Infection of the breathing passages, which extend from the nose to the alveoli (the tiny, balloonlike sacs in the lungs; see alveolus, pulmonary). This type of infection is divided into upper and lower respiratory tract infections.

Upper respiratory tract infections affect the nose, the pharynx (throat), the sinuses, and the larynx (voice-box). Examples are the common cold, (see cold, common) and inflammatory conditions such as pharyngitis, tonsillitis, sinusitis, laryngitis, and croup.

Lower respiratory tract infections, which involve inflammation of the trachea (windpipe), bronchi, and lungs, include acute bronchitis, acute bronchiolitis, and pneumonia.

### restless legs

A syndrome characterized by unpleasant tickling, burning, prickling, or aching sensations in the leg muscles.

Symptoms of restless legs tend to come on at night in bed and can interrupt sleep; they may also be triggered by prolonged sitting. The condition tends to run in families and is most common in middle-aged women, people with rheumatoid arthritis, smokers, and pregnant women.

The cause of restless legs is unknown and there is no single cure; some patients benefit from cooling the legs; others from warming them. Relief may be obtained through movement, such as walking.
as walking. Treatment with levodopa, benzodiazepine drugs (such as clonazepam), or certain anticonvulsant drugs (such as carbamazepine) may help to improve the condition.

**restoration, dental**

The reconstruction of part of a damaged tooth. Restoration also refers to the material or substitute part used to rebuild the tooth.

Small repairs are usually made by filling the tooth (see filling, dental). For more extensive repairs, an inlay (see inlay, dental) or a crown (see crown, dental) may be fitted. Chipped front teeth may be repaired by bonding (see bonding, dental), in which the surface of the tooth is etched with an acidic solution and plastic or porcelain material is attached to the roughened surface.

**restricted growth**

See short stature.

**resuscitation**

See cardiopulmonary resuscitation; rescue breathing.

**retardation**

The slowing up of a process. The term mental retardation was once commonly used to refer to impaired intellectual development (see learning difficulties).

**retching**

Repeated unsuccessful, usually involuntary, attempts to vomit (see vomiting).

**reticular formation**

A network of nerve cells that are scattered throughout the brainstem (the stalk of nerve tissue that links the brain to the spinal cord).

**reticulocyte**

The medical term for a newly formed red blood cell. Reticulocytes are made in the bone marrow from stem cells. They remain in the bone marrow for between one and two days and then pass into the bloodstream, where they eventually mature into red blood cells.

**reticulosarcoma**

See lymphoma, non-Hodgkin’s.

**retina**

The light-sensitive membrane that lines the back inner surface of the eye, and on which images are cast by the cornea (the transparent dome that forms the front of the eyeball) and the lens (the part of the eye responsible for focusing). The retina contains specialized nerve cells (rods and cones) that convert light energy into nerve impulses. The impulses travel from the rods and cones through other cells in the retina and along the optic nerve to the brain.

The rods are extremely sensitive and respond to very dim light; the cones are responsible for colour vision, producing impulses that vary in strength depending on the colour of the light striking them. Near the centre of the retina is the fovea, the area of the eye that is responsible for detailed vision because it contains the highest concentration of light-sensitive cells. (See also Disorders of the retina box, opposite.)

**retinal artery occlusion**

Blockage of an artery supplying blood to the retina (the light-sensitive inner layer at the back of the eye), most commonly due to thrombosis (abnormal blood clot formation) or embolism (in which a blood clot or fatty deposit is carried in the bloodstream to lodge in another area). Retinal artery occlusion may affect either the main retinal artery or one of its branches.

The disorder can result in sudden blindness or loss of part of the visual field, which is painless and can be permanent. The extent of visual loss depends on the artery affected and how quickly the condition can be treated. (See also retinal vein occlusion.)

**LOCATION OF THE RETINA**

The retina is like the light-sensitive film in a camera. It forms a concave membrane over the back inner surface of the eye.

**retinal detachment**

Separation of the retina (the light-sensitive inner layer at the back of the eye) from the outer layers at the back of the eye. Retinal detachment may follow an eye injury but usually occurs spontaneously. It is usually preceded by a retinal tear (a split in the retina), and is more common in highly myopic (shortsighted) people and in people who have had cataract surgery.

**SYMPTOMS**

Retinal detachment is painless. The first indication may be the appearance of bright flashes of light caused by stimulation of the light-sensitive cells as the tear occurs. This may be accompanied by floaters (fragments perceived to be floating in the field of vision) that result from the release of blood or pigment into the vitreous humour (the gel-like substance that fills the rear compartment of the eye). Alternatively, the appearance of a black “drape” that gradually obscures vision may be the first sign of retinal detachment.

**TREATMENT**

Urgent treatment is required to prevent detachment of the macula (the site of central vision) and usually involves surgical repair of the underlying tear. A soft silicone rubber sponge may be sewn onto the outside of the sclera (the outer layer of the eye) overlying the detachment. The sponge indents the sclera and results in the absorption of the fluid under the retina, causing the retina to settle back into place. The retina is then fixed in place by cryopexy (the application of extreme cold), by diathermy (the application of heat), which causes an inflammatory adhesiveness of the underlying tissues, or by laser treatment. If the macula has not been detached, the results can be excellent.

**retinal haemorrhage**

Bleeding into the retina (the light-sensitive inner layer at the back of the eye) from one or more blood vessels, due to diabetes mellitus, hypertension (high blood pressure), or retinal vein occlusion (blockage of a vein that drains blood from the retina).

When the macula (the site of central vision) is involved, vision is severely impaired. Peripheral haemorrhages may be detected only when the eye is examined using an ophthalmoscope.

**retinal tear**

The development of a split in the retina (the light-sensitive inner layer situated at the back of the eye), usually caused
**DISORDERS OF THE RETINA**

Despite its small size, the retina is subject to a wide variety of disorders, many of which seriously affect vision and, in some cases, result in blindness.

**Congenital and genetic disorders**

Colour blindness (see colour vision deficiency), an abnormality of retinal cones (colour receptors in the retina), usually has a genetic basis. Hereditary degenerative disorders of the macula may appear at any age, leading to serious impairment of central vision. Other degenerative disorders of the retina with a genetic basis include Tay-Sachs disease and retinitis pigmentosa.

Retrorenal fibroplasia may result from exposure of a premature baby to excessive oxygen concentration (needed to treat lung immaturity), which causes abnormalities in the retinal vessels.

**Infection**

Toxoplasmosis is an infection of the retina that is acquired before birth and recurs later in life, causing progressive damage to the retina.

**Toxocara canis** is a parasitic worm whose larvae may lodge in the retina and cause severe retinal destruction, producing a white mass resembling a tumour (see toxocariasis). Onchocerciasis, an infestation by a tropical worm, may cause severe retinal damage.

Bacterial and fungal infections elsewhere in the body can be carried in the blood to the retina. People whose immune systems are impaired are more susceptible to infections that can involve the retina.

**Tumours**

Retinoblastoma is a cancerous tumour that usually appears in the first three years of life. There may be visual loss in the affected eye and a visible whiteness in the pupil; squint often develops. The tendency to this cancer can be inherited.

Secondary cancerous tumours, spreading to the eye from primary tumours elsewhere in the body, can also occur. Malignant melanoma (see melanoma, malignant) can arise from the choroid (the layer beneath the retina). A variety of noncancerous tumours may also occur in the retina.

**Injury**

The retina may be torn or detached due to severe penetrating or blunt (non-penetrating) injury (see retinal detachment; retinal tear). Permanent damage may be caused by a retinal burn, which is sometimes caused by looking directly at an eclipse of the sun.

**Metabolic disorders**

Diabetes mellitus may cause retinopathy, with fluid leakage and haemorrhage into the retina (see retinal haemorrhage) and with the growth of new, fragile blood vessels on the retinal surface, which bleed readily. Vitreous haemorrhage (bleeding into the vitreous humour, the gel-like substance that fills the rear compartment of the eye) may occur from blood vessels, and fibrous tissue can grow forwards on to the vitreous humour in cases of “proliferative” retinopathy. This is a major cause of permanent loss of vision.

**Impaired blood supply**

Retinal vein occlusion (or retinal artery occlusion), a common cause of blindness, results from blockage of the central vein (or artery) of the retina. Hypertensive retinopathy is damage to the retina caused by high blood pressure, which leads to narrowing and atherosclerosis (fat deposits on the artery walls) of the retinal arteries, both of which may lead to retinal damage.

**Poisons**

A combination of heavy tobacco-smoking, heavy alcohol intake, and poor nutrition may lead to visual loss. Vitamin deficiency in combination with lead poisoning may cause visual loss. Methanol causes widespread and permanent destruction of certain retinal tissues, leading to blindness.

**Drugs**

Many drugs can damage the retina. Examples are chloroquine, used in large doses over a long period for the treatment of conditions such as rheumatoid arthritis.

**Other disorders**

Age-related macular degeneration, causing progressive loss of vision, is a common condition in older people. Detachment of the retina often occurs in the absence of any injury, and it may be more common in individuals who suffer from severe myopia (shortsightedness).

---

**INVESTIGATION**

Retinal disorders are investigated by checking the visual acuity and the visual fields (see vision tests; retinoscopy). After dilating the pupils with drops, the retinas are inspected by means of a direct or indirect ophthalmoscope (an instrument used to examine the eye). Fluorescein can be injected into an arm, where it is carried by the blood to outline the retinal vessels and to detect leaks. Electrophysiological tests can also be carried out to study certain ocular diseases. Ultrasound scanning can be used to study tumours in or under the retina.

---

by degeneration. A retinal tear is more likely to occur in people who have severe myopia (shortsightedness) but the condition may also be caused by a severe eye injury. Retinal detachment usually follows a retinal tear.

If a retinal tear is diagnosed at a stage before detachment has occurred, the hole may be sealed by means of laser treatment or cryopexy (the application of extreme cold).

**retinal vein occlusion**

Blockage of a vein carrying blood from the retina (the light-sensitive inner layer at the back of the eye). It usually results from thrombosis (abnormal blood clot formation) in the affected vein and is more common in people who have glaucoma (a condition in which the pressure of fluid in the eye is abnormally high). Retinal vein occlusion may affect either the main retinal vein or one of its branches.

**retinal vein occlusion**

Retinal vein occlusion may cause visual disturbances, glaucoma, and can result in blindness, depending on the vein affected and how quickly the condition can be treated. (See also retinal artery occlusion.)

**retinitis**

Inflammation affecting the retina (the light-sensitive inner layer at the back of the eye). (See also retinopathy.)
retinitis pigmentosa
An inherited condition in which there is degeneration of the rods and cones of the retina (the light-sensitive inner layer at the back of the eye) in both eyes.

The first symptoms of retinitis pigmentosa usually appear during or after adolescence and include night blindness (the inability to see well in dim light). Tests show a ring-shaped area of blindness which, over some years, extends to destroy an increasing area of the visual field, although central vision is often retained for many years.

Ophthalmoscopy (a noninvasive examination of the retina) reveals several masses of black pigment corresponding to the areas of visual loss. Affected individuals and their parents should seek genetic counselling.

retinoblastoma
A cancer of the retina (the light-sensitive inner layer at the back of the eye) that affects infants. The first indications of this disorder may be a squint, caused by blindness in the affected eye, or a visible whitening in the pupil. Without early treatment, retinoblastoma can spread to the orbit (eye socket) and along the optic nerve to the brain.

Retinoblastoma has a genetic basis. People with this cancer lack part of one of the chromosomes in pair number 13. Newborn infants from affected families are given regular eye examinations; prospective parents in affected families should seek genetic counselling.

Treatment is by surgically removing the affected eye or by radiotherapy. If both eyes are involved, the one worst affected may be removed and the other given radiotherapy.

retinoids
A group of drugs derived from vitamin A, of which tretinoin is an example.

retinol
The principal form of vitamin A found in the body.

retinopathy
Disease affecting the retina (the light-sensitive inner layer at the back of the eye), which is usually caused by diabetes mellitus or persistent hypertension (high blood pressure).

In diabetic retinopathy, the capillaries (tiny blood vessels) within the retina are affected by aneurysms (balloonlike swellings). They also leak fluid and haemorrhage (bleed) into the retina. Abnormal capillaries then grow on the retinal surface and, as these are fragile, vitreous haemorrhage (bleeding into the vitreous humour, the gel-like substance that fills the rear compartment of the eye) may occur. Fibrous tissue may also grow into the vitreous humour. Laser treatment can often halt the progress of the condition.

In hypertensive retinopathy, the retinal arteries become narrowed. Areas of retina may be destroyed and bleeding and white deposits may occur in the retina. (See also retrolental fibroplasia.)

retnoscope
A type of vision test in which a beam of light is shone from an instrument called a retinoscope into each eye in turn. The effect of different lenses on the beam of light determines whether glasses are needed to correct refractive errors such as hypermetropia (longsightedness), myopia (shortsightedness), or astigmatism. Retinoscopy is particularly useful for assessing the sight of babies and young children.

retractile testis
See tests, retractile.

retractor
A surgical instrument used to hold an incision open or to hold back surrounding tissue so that the surgeon has free access to the area being operated on.

retnobulbar neuritis
A form of optic neuritis in which the optic nerve becomes inflamed behind the eyeball.

retrage
Moving backwards or in the opposite direction to normal. In retrograde ejaculation, for example, semen is forced into the bladder rather than out through the tip of the penis (see ejaculation, disorders of).

retnoblenatal fibroplasia
A condition, also called retinopathy of prematurity, that mainly affects the eyes of premature infants. The usual cause of retrolental fibroplasia is high concentrations of oxygen being given to premature infants as part of the treatment for respiratory distress syndrome (an acute lung disorder that makes breathing difficult). Excess oxygen causes the tissues at the margin of the retina (the light-sensitive inner layer at the back of the eye) to shut down their blood vessels. When oxygen concentrations return to normal, the affected tissues may send strands of new blood vessels and fibrous scar tissue into the vitreous humour (the gel-like substance that fills the rear compartment of the eye), which may interfere with vision and cause retinal detachment.

Retrolental fibroplasia may be successfully treated by laser treatment.

retroperitoneal fibrosis
Inflammation and scarring of tissues at the back of the abdominal cavity. Retroperitoneal fibrosis often blocks the ureters, preventing urine flow from the kidneys to the bladder. In severe cases, this results in kidney failure.

Retroperitoneal fibrosis usually occurs in middle-aged men and is of unknown cause; it may be an autoimmune disorder. However, the condition may be associated with long-term treatment with the drug methysergide (used to treat migraine). Treatment may involve corticosteroid drugs, insertion of a stent (a rigid tube) to relieve obstruction of the ureters, and surgery.

retrosternal pain
Pain in the central region of the chest, behind the sternum (breastbone). Causes include irritation of the oesophagus, angina pectoris (chest pain due to impaired blood supply to the heart muscle), or myocardial infarction (heart attack). (See also chest pain.)

retrovirus
A type of virus whose genetic material is RNA, rather than DNA, and that uses an enzyme called reverse transcriptase to produce DNA from the RNA template. The DNA can then be incorporated into its host cells. One notable example of a retrovirus is HIV (human immunodeficiency virus).

Rett’s syndrome
A brain disorder, thought to be a genetic disorder, that affects only girls. Symptoms usually first appear when the child is between 12 and 18 months old. Acquired skills, such as walking and communication skills, disappear and the girl becomes progressively handicapped, sometimes with signs of autism. Repetitive writhing movements of the hands and limbs and inappropriate outbursts of crying or laughter are characteristics of the condition.
There is no cure for Rett’s syndrome and sufferers need constant care and attention. Parents of an affected child should receive genetic counselling if they are thinking of having another child.

**reverse transcriptase inhibitors**

A class of drugs used in the treatment of certain infectious diseases, including HIV infection and hepatitis B infection. The drugs affect the ability of the virus to reproduce by blocking reverse transcriptase, a key enzyme. Examples of reverse transcriptase inhibitors are lamivudine, zidovudine (AZT), efavirenz, and stavudine.

**reversible monoamine oxidase inhibitors (RIMAs)**

A reversible type of monoamine oxidase inhibitor (MAOI), which is a type of antidepressant drug. Reversible monoamine oxidase inhibitors are reported to have fewer adverse interactions with other drugs and with foods such as cheese and red wine than other MAOIs. Moclobemide is currently the only RIMA available.

**Reye’s syndrome**

A rare disorder in which brain and liver damage follow a viral infection. People over the age of 16 are rarely affected. The cause is unknown, but taking aspirin seems to be a predisposing factor to developing the condition; the drug is, therefore, not recommended for use by children under 16.

**SYMPTOMS AND SIGNS**

The disorder starts as the child recovers from the infection. Symptoms include uncontrollable vomiting, lethargy, memory loss, and disorientation. Swelling of the brain may cause seizures, disturbances in heart rhythm, coma, and cessation of breathing.

**TREATMENT AND OUTLOOK**

Brain swelling may be controlled by corticosteroid drugs and by intravenous infusion of mannitol. Dialysis or blood transfusions may be needed to correct changes in blood chemistry caused by damage to the liver. If breathing stops, the patient is placed on a ventilator.

The death rate in Reye’s syndrome is at least ten per cent, and higher for those who have seizures, lapse into deep coma, and stop breathing. Patients who survive a serious attack may suffer permanent brain damage.

**rhabdomyolysis**

 Destruction of muscle tissue accompanied by the release of myoglobin (the oxygen-carrying muscle pigment) into the blood. The most common cause of rhabdomyolysis is a severe, crushing muscle injury (see crush syndrome). Other causes of the condition include polymyositis (a viral infection of muscle) and, rarely, excessive exercise.

There is usually temporary paralysis or weakness of the affected muscle. Except in cases of severe injury, the condition usually clears up without any form of treatment.

**rhabdomyosarcoma**

A very rare cancerous muscle tumour. Rhabdomyosarcoma may develop during infancy, usually affecting the throat, bladder, prostate gland, or vagina; it may also occur in old age when it may affect a large muscle in the arm or leg. The tumour grows rapidly and quickly spreads to other tissues. Treatment involves surgical removal, radiotherapy, and anticancer drugs.

**rhesus immunoglobulin**

See anti-D(Rh<sub>+</sub>) immunoglobulin.

**rhesus incompatibility**

A mismatch between the blood group of a Rhesus (Rh)-negative pregnant woman and that of her baby. In certain circumstances, this mismatch may lead to haemolytic disease of the newborn.

**CAUSES**

The Rh system is based on the presence or absence in the blood of several factors, the most important of which is a substance called D antigen (a substance that can trigger an immune response). Rh-positive blood contains D antigen, whereas Rh-negative blood does not. Blood type is determined by genes (units of the material of heredity).

A common way in which rhesus incompatibility results is if a Rh-negative woman is exposed to the blood of her Rh-positive baby while it is being born. There are usually no problems during the first pregnancy with a Rh-positive baby. However, the woman may produce antibodies (proteins manufactured by the immune system) against the D antigen; in a subsequent pregnancy with a Rh-positive baby, these antibodies may cross the placenta and attack the red blood cells of the fetus.

A Rh-negative woman can also be sensitized to Rh-positive blood if she has had a miscarriage, abortion, or amniocentesis in which the fetus’s Rh-positive blood enters her circulation. A placental abruption (separation of part or all of the placenta from the wall of the uterus) may also cause a transfer of blood between the mother and the fetus.

**TREATMENT**

Rhesus incompatibility is now uncommon because injections of anti-D(Rh<sub>+</sub>) immunoglobulin are given routinely to Rh-negative women during pregnancy and at delivery. This substance destroys any of the baby’s blood cells that have entered the mother’s system before she is able to become sensitized to them.

Anti-D(Rh<sub>+</sub>) immunoglobulin is also given to Rh-negative women after miscarriage, abortion, amniocentesis, or following any other procedure that might result in exposure of the mother to fetal blood cells.

**HOW RHESUS (Rh) INCOMPATIBILITY OCCURS**

Without preventive treatment, an Rh-negative woman who is exposed to Rh-positive blood during pregnancy may develop antibodies that will attack the red blood cells of any future Rh-positive babies.
rhesus isoimmunization

The development of antibodies (proteins that are manufactured by the immune system) against Rhesus (Rh)-positive blood in a person who has blood that is Rh-negative (see haemolytic disease of the newborn; Rhesus incompatibility).

rheumatic fever

A disease that causes inflammation throughout the body, especially in the joints. Now rare in developed countries, it is an important cause of heart disease in developing countries and is most common in children aged five to 15 years.

CAUSE

Rheumatic fever is believed to be an autoimmune disorder (in which the body’s immune system attacks its own tissues) induced by certain strains of streptococcal bacteria. Rheumatic fever always follows a throat infection. The development of rheumatic fever can usually be prevented by treatment with antibiotic drugs.

SYMPTOMS AND SIGNS

Rheumatic fever causes fever with pain, inflammation, and swelling of one or more of the larger joints. The heart valves may be scarred, leading to mitral stenosis (narrowing of the mitral valve) or mitral incompetence (leaking of the mitral valve). If the nervous system is involved, Sydenham’s chorea may be caused, in which there are irregular, uncontrolable, jerky movements and usually some emotional upset.

DIAGNOSIS AND TREATMENT

Rheumatic fever may be suspected whenever arthritis (joint inflammation) moves from joint to joint, but may be discovered only after development of heart failure or a heart murmur.

Treatment is with penicillin drugs to eradicate streptococci; with aspirin or other salicylate drugs to control joint pain and inflammation and to minimize heart damage; and, in some cases, with corticosteroid drugs. If damage to the heart valves occurs, heart valve surgery may be required.

rheumatism

A popular term for any disorder that causes pain and stiffness in muscles and joints. The term is used to refer both to minor aches and twinges as well as to disorders such as rheumatoid arthritis, osteoarthritis, and polymyalgia rheumatica.

rheumatoid arthritis

A type of arthritis (joint inflammation) in which the joints in the limbs, and sometimes in other parts of the body, become painful, swollen, stiff, and, in severe cases, deformed. Tissues that are outside the joints, for example the heart, can also be affected.

CAUSES AND INCIDENCE

Rheumatoid arthritis is an autoimmune disorder (in which the body’s immune system attacks its own tissues) that usually starts in early adulthood or middle age but can also develop in children (see juvenile chronic arthritis) or elderly people. Women are affected more commonly than men. There are usually recurrent attacks.

SYMPTOMS AND SIGNS

Early symptoms of rheumatoid arthritis include mild fever and aches followed by swelling, redness, pain, and stiffness in the joints, particularly in the morning. Ligaments, tendons, and muscles around the affected joint may also be involved. Raynaud’s phenomenon (a condition in which the fingers turn white on exposure to cold) may occur and there may also be rheumatoid nodules (small lumps under the skin) over pressure points, such as the elbows or finger joints. Swelling of the wrist may cause carpal tunnel syndrome (tingling and pain in the fingers due to pressure on the median nerve) and also tenosynovitis (inflamed, painful tendon sheaths).

Complications of severe rheumatoid arthritis may include anaemia (a reduced level of the oxygen-carrying pigment haemoglobin in the blood), pericarditis (inflammation of the membranous heart covering), ulcers on the hands and feet, pleural effusion (accumulation of fluid around the lungs), pulmonary fibrosis (scarring and thickening of lung tissue), and Sjögren’s syndrome (in which the eyes and mouth become excessively dry).

DIAGNOSIS AND TREATMENT

A diagnosis can be confirmed through X-rays of the affected joints and blood tests (including a check for specific antibodies known as rheumatoid factor). Initially, rheumatoid arthritis may be treated with nonsteroidal anti-inflammatory drugs (NSAIDs) to relieve joint pain and stiffness; corticosteroid drugs may be RHEUMATOID ARTHRITIS

One of the most serious forms of joint disease, rheumatoid arthritis may occur as a single episode or a succession of progressively severe attacks. It results from a disturbance in the body’s immune system, causing the body to attack its own tissues. The joints are usually the worst affected, but other tissues such as the heart and lungs may also be involved.

RHEUMATOID ARTHRITIS

One of the most serious forms of joint disease, rheumatoid arthritis may occur as a single episode or a succession of progressively severe attacks. It results from a disturbance in the body’s immune system, causing the body to attack its own tissues. The joints are usually the worst affected, but other tissues such as the heart and lungs may also be involved.

The hands in rheumatoid arthritis

This condition commonly affects the fingers. In this photograph, there is pronounced swelling around the knuckles, particularly of the right hand.

Disease progression

The synovium (membrane lining the capsule of an affected joint) becomes inflamed and thickened (right). Later, inflammation may spread to the cartilage and bone.
given in the short term if NSAIDs are not effective. Disease-modifying antirheumatic drugs are then prescribed to slow or arrest the progress of the disease; these include antirheumatic drugs (such as sulfasalazine, gold, and penicillamine) and immunosuppressant drugs (such as methotrexate), which suppress the body’s immune system if the anti-rheumatics have not proved effective.

**Physiotherapy** is needed to prevent or limit deformity and to help relieve symptoms and maintain mobility. People who are disabled by arthritis can be helped to cope with everyday tasks through **occupational therapy**.

In severe cases, surgery may be performed to replace damaged joints with artificial ones (see **arthroplasty**). Hip and knee replacements are the most common operations of this type.

Most sufferers must continue drug treatment for life, but many can achieve a near-normal level of activity with effective control of their symptoms.

**rheumatoid factor**

A specific autoantibody (a protein manufactured by the immune system that acts against the body’s own cells) that attaches itself to naturally occurring immunoglobulin G (another type of antibody that, in this case, has actually triggered the immune response). This combination of immunoglobulin and autoantibody is a type of immune complex; it can settle in joints, causing **rheumatoid arthritis**. Most people with rheumatoid arthritis have rheumatoid factor in their blood. (See also **autoimmune disorders; hypersensitivity**.)

**rheumatoid nodules**

Small lumps that may develop under the skin in people suffering from **rheumatoid arthritis**. They may also develop in the lungs and can be identified on a chest X-ray. Rheumatoid nodules are granulomas (clumps of a type of cell associated with chronic inflammation); they are found particularly in areas of the body that are often under pressure, such as the elbows.

**rheumatoid spondylitis**

See **ankylosing spondylitis**.

**rheumatology**

The branch of medicine concerned with the causes, development, diagnosis, and treatment of diseases that affect the joints, muscles, and connective tissue.

**rhinitis**

Inflammation affecting the mucous membrane that lines the nose, which may lead to a feeling of stuffiness, with nasal discharge and sneezing.

**TYPES**

1. **Viral rhinitis** is a feature of the common cold (see cold, common), and may sometimes lead to **sinusitis**.

2. **Rhinitis due to allergy** (see rhinitis, allergic) may be seasonal (usually caused by pollens) or occur throughout the year (due to house dust, moulds, or pets). Allergic rhinitis commonly occurs with vasomotor rhinitis.

3. **Vasomotor rhinitis** may be intermittent or continual. The nose becomes over-responsive to stimuli such as pollutants, changes or extremes in temperature or humidity, certain foods or medicines, or certain emotions. Vasomotor rhinitis is common in pregnancy and in those taking combined **oral contraceptives** or other **oestrogen drugs**.

        **Hypertrophic rhinitis**, which is characterized by thickening of the mucous membrane in the nose and chronic congestion of the nasal veins, can result from repeated nasal infections. The condition results in constant stuffiness and sometimes impairment of the sense of smell. In severe cases, treatment may involve surgical removal or shrinkage of part of the swollen tissue.

        **Atrophic rhinitis** is characterized by wasting of the mucous membrane in the nose and can result from aging, chronic bacterial infections, or extensive nasal surgery. Features include persistent nasal infection, a nasal discharge, loss of smell, and an unpleasant odour. Treatment may include **antibiotic drugs** and nose drops.

**rhinitis, allergic**

A common condition that is characterized by inflammation of the mucous membrane lining the nose due to **allergy** to pollen, dust, or other airborne substances. Allergic rhinitis causes sneezing, a runny nose, nasal congestion, and, in most cases, waterering eyes. The eyes, soft palate, and ears may also itch. The eyes may also be affected by **conjunctivitis**, making them red and sore.

**CAUSES**

In some people, the inhalation of particles of certain harmless substances, known as allergens, provokes an exaggerated response by the immune system, which forms antibodies against them. These allergens also trigger the release of histamine and other chemicals that cause inflammation and fluid production in the linings of the nose and nasal **sinuses** (air cavities around the nose). Allergens that cause allergic rhinitis include tree, grass, and weed pollens; moulds; animal skin scales, hair, or feathers; house dust; and **house dust mites**.

Seasonal allergic rhinitis is pollen-induced and is commonly known as hay fever. Tree pollens are most prevalent in spring, grass pollens in summer, and weed pollens in summer and autumn. Sufferers are worst affected during hot and windy weather, especially in heavily vegetated, low-lying areas. People affected by household allergens, such as dust, tend to have less severe symptoms but are affected throughout the year, a condition that is known as perennial rhinitis.

**PREVENTION AND TREATMENT**

**Antihistamine drugs** and topical **corticosteroid drugs** are used to treat mild attacks of allergic rhinitis. The drug **sodium cromoglicate**, if inhaled regularly throughout the pollen season, may help to prevent attacks by blocking the allergic response. Long-term relief of symptoms can sometimes follow desensitization to an allergen by a course of injections (see **hyposensitization**).

**rhinophyma**

A bulbous deformity and redness of the nose that occurs almost exclusively in elderly men. Rhinophyma is a complication of severe **rosacea** (a skin disorder of the nose and cheeks). The tissue of the nose thickens, small blood vessels enlarge, and the **sebaceous glands** become overactive, which results in making the nose excessively oily.

An operation to cut away the swollen tissue, performed under general anaesthetic (see **anaesthesia, general**), can restore the nose to a satisfactory shape.

**rhinoplasty**

An operation that is carried out to alter the structure of the nose in order to improve its appearance or to correct a deformity caused by injury or disease.

Under either a local or general anaesthetic (see **anaesthesia**), incisions are made within the nose to avoid visible scars. The **septum** (the vertical wall of cartilage and bone that divides the nose) may be altered if breathing passages are blocked; the cartilage and bone are then reshaped. The nose is finally splinted in position for about ten days.
Rhinoplasty usually causes considerable bruising and swelling and the results may not be clearly visible for a number of weeks or months.

**Rhinorrhea**

The discharge of watery mucus from the nose, usually due to *rhinitis*. Rarely, the discharge consists of cerebrospinal fluid and is the result of a head injury. (See also *nasal discharge.*)

**Rhinovirus**

Any one of a group of RNA-containing viruses that cause infections of the upper respiratory tract, typically the common cold (see *cold, common*).

**Rhythm method**

See *contraception, natural methods of.*

**Rib**

Any of the flat, curved bones that form a framework for the chest and a protective cage around the heart, lungs, and other underlying organs.

There are 12 pairs of ribs, each joined at the back of the ribcage to a vertebra in the spine (see *Anatomy of the ribs*, right). The upper seven pairs, known as "true ribs", link directly to the sternum (breastbone) at the front of the body by flexible costal cartilage (connective tissue formed of collagen). The next two or three pairs of "false ribs" connect indirectly to the sternum by way of cartilage attached to the cartilage of the ribs above. The lowest two pairs of ribs are not attached to the sternum at the front and, therefore, they are known as "floating ribs". Between and attached to the ribs are thin sheets of muscle (called intercostal muscles) that expand and relax the chest during *breathing*. The spaces between the ribs also contain nerves and blood vessels.

**Disorders**

The ribs can easily be fractured by a fall or blow (see *rib, fracture of*). A rib is also a common site for a noncancerous bone tumour or for a metastasis (a secondary cancerous tumour that has spread from elsewhere in the body). *Tietze’s syndrome* is a condition in which chest pain is caused by inflammation of one or more areas of rib cartilage.

In rare cases a person is born with one or more extra ribs, known as cervical ribs, above the uppermost normal rib. Cervical ribs may cause a variety of problems, such as putting pressure on nerves supplying the arm.

**Ribavirin**

An antiviral drug, also called tribavirin, used to treat children with severe *bronchiolitis* caused by respiratory syncytial virus. Ribavirin is administered by aerosol inhalation or by a nebulizer. Adverse effects are rare.

**Rib, fracture of**

A crack or break in one or more of the rib bones. Such a fracture may be caused by a fall or blow or by stress on the ribcage, such as that produced by prolonged coughing.

The fracture of a rib causes severe pain, which worsens during periods of deep breathing, as well as tenderness and swelling of the overlying tissue. Pain may be relieved by analgesic drugs (painkillers) or by an injection of a local anaesthetic (see *anaesthesia, local*). X-rays may be used to confirm a diagnosis.

Most rib fractures are undisplaced (the bone ends remain in alignment) and usually heal without specific treatment. Strapping is rarely used because it hinders chest expansion and thereby increases the risk of pneumonia. Instead, the patient is encouraged to take deep breaths while holding the injured side.

A fracture that is displaced or splintered may pierce a lung, thereby causing lung collapse (see *pneumothorax*). Multiple rib fractures can result in *flail chest* (a chest injury in which part of the chest wall moves in the direction opposite to normal during breathing).

**Riboflavin**

The chemical name of vitamin B₂ (see *vitamin B complex*).

**Ribonucleic acid**

See RNA.

**Rickets**

A disease caused by nutritional deficiency that results in bone deformities in childhood. Bones become deformed because inadequate amounts of calcium and phosphate are incorporated into them as they grow. A similar deficiency of calcium and phosphate in adults results in *osteomalacia*.

**Causes**

The most common cause of rickets is deficiency of vitamin D, which is vital for the absorption of calcium from the intestines into the blood and for its incorporation into bone. Vitamin D is

**Anatomy of the ribs**

There are seven true ribs attached to the sternum; three false ribs, each attached to a rib above; and two floating ribs, attached only to the spine, on each side. Every rib is attached to the spine at the back. The intercostal muscles (between the ribs) pull the ribs up, expanding the chest and drawing air into the lungs. The front ends of the true ribs are linked to the sternum by cartilages.
found in fat-containing animal substances, such as oily fish, butter, egg yolk, and liver. There are also small amounts in human and animal milk. Vitamin D is also made in the body through the action of sunlight on the skin.

Rickets occasionally develops as a complication of a digestive disorder that causes malabsorption (failure to absorb nutrients from the intestine). It may also occur in certain rare forms of kidney and liver disease.

**SYMPTOMS AND SIGNS**
The principal feature of advanced rickets is deformity of the bones, especially of the legs and spine. Typically, there is bowing of the legs and, in infants, flattening of the head as a result of softness of the skull. Infants with rickets often sleep poorly and show delay in crawling and walking. Other features that occur in rickets include kyphoscoliosis (spinal curvature), a tendency to fractures, and enlargement of the wrists, ankles, and ends of the ribs. There may also be pelvic pain and muscle weakness.

**DIAGNOSIS AND TREATMENT**
The doctor makes a diagnosis based on the child's physical appearance and the results of X-rays and blood tests.

Rickets due to dietary deficiency is treated with vitamin D supplements, which can restore normal bone growth. Deformities usually disappear as the child grows. The type of rickets that occurs as a complication of another disorder is treated according to the cause.

**rickettsia**
A type of parasitic microorganism. Rickettsiae resemble small bacteria but, much like viruses, they can multiply only by invading other living cells. Rickettsiae are primarily parasites of arthropods, such as ticks, lice, fleas, and mites, but they can be transmitted to the blood of larger animals via insect bites. Human diseases caused by rickettsiae include Q fever, Rocky Mountain spotted fever, and typhus.

**rifabutin**
A drug used in the treatment of tuberculosis and in the prevention of other mycobacterial infections.

**rifampicin**
An antibacterial drug used principally in the treatment of tuberculosis, but also that of leprosy and legionnaires’ disease. Rifampicin may also be used to prevent meningococcal meningitis in people who are in very close contact with the disease. The drug is usually prescribed in combination with other antibacterials because some strains of bacteria develop resistance to it if it is used alone.

Side effects of rifampicin include harmless, orange-red discoloration of the urine, saliva, and other body secretions; muscle pain; nausea and vomiting; diarrhoea; jaundice (yellowing of the skin and the whites of the eyes); flu-like symptoms; rash; and itching. Rifampicin also interferes with the action of oral contraceptives.

**Rift Valley fever**
A viral disease found in East Africa and South Africa that is transmitted from animals to humans by mosquitoes. The symptoms of Rift Valley fever resemble those of dengue or influenza, although in some cases the condition may be symptomless. In extremely severe and rare cases, Rift Valley fever may lead to retinitis (inflammation of the retina), encephalitis (inflammation of the brain), haemorrhage (bleeding), and even death.

### rigidity
Increased tone in one or more muscles, causing them to feel tight; the affected part of the body becomes stiff and inflexible.

Causes of rigidity include muscle injury, arthritis in a nearby joint, a neurological disorder (such as Parkinson’s disease), stroke (damage to part of the brain caused by an interruption to its blood supply), or cerebral palsy (a movement disorder caused by damage to the brain). Rigidity of the abdominal muscles is a sign of peritonitis (inflammation of the membranous lining of the abdominal cavity). (See also spasticity.)

**Rinne’s test**
A type of hearing test that is used to determine whether deafness is conductive (due to the faulty conduction of sound from the outer ear to the inner ear) or sensorineural (due to problems of the inner ear, the nerves, or the auditory area of the brain).
A vibrating tuning fork is placed against the mastoid process (the bone behind the ear) and then held close to the ear. A positive result, when the sound conducted by the air is heard more clearly than that conducted by the bone, indicates sensorineural deafness. A negative result, when the sound conducted by bone is heard more loudly, indicates conductive deafness. Rinne’s test is used in conjunction with other hearing tests.

**risk factor**

Any feature or attribute that predisposes a person to increased risk of developing an illness. Tobacco smoking, working with asbestos (see asbestos-related diseases), or having a family history of a condition are all considered to be risk factors.

**risperidone**

An antipsychotic drug used in the treatment of acute psychiatric disorders and long-term psychotic illness such as schizophrenia. Possible side effects include insomnia, anxiety, headache, difficulty in concentrating, and weight gain. Risperidone has less sedative effect and is less likely to cause movement disorders than some other antipsychotics, however.

**ritodrine**

A drug used to prevent or delay premature labour (see prematurity) by relaxing the muscles of the uterus (womb). Possible side effects of ritodrine include tremor, chest pain, palpitations, nausea, vomiting, and hot flushes.

**rivalry, sibling**

See sibling rivalry.

**river blindness**

See onchocerciasis.

**RNA**

The abbreviation for ribonucleic acid. RNA and DNA (deoxyribonucleic acid) carry the inherited, coded genetic instructions in cells. In all animal and plant cells, DNA carries the instructions and RNA helps to decode them, but, in some viruses, the instructions are held by RNA. (See also nucleic acids; protein synthesis).

**RNI**

See reference nutrient intake.

**Rocky Mountain spotted fever**

A rare, infectious disease causing fever and a rash with spots that spread over the body, darken, enlarge, and bleed. Rocky Mountain spotted fever occurs in North and South America and is caused by a microorganism called a *rickettsia* that is transmitted from small mammals to humans by tick bites (see ticks and disease). Treatment is with chloramphenicol or tetracycline.

**rod**

One of the two specialized types of nerve cell within the retina (the light-sensitive inner layer at the back of the eye) that convert light energy into nerve impulses. The rods are very sensitive and can respond to very dim light. (See also cone.)

**rodent ulcer**

A common name for basal cell carcinoma.

**rofecoxib**

A type of COX-2 inhibitor drug used to relieve the pain and inflammation of osteoarthritis and rheumatoid arthritis. Side effects may include mouth ulcers, sleep disturbance, and muscle cramps. Rofecoxib has, however, been found to increase the risks of myocardial infarction and stroke, and has now been withdrawn.

**Rohypnol**

The brand name for flunitrazepam, a benzodiazepine drug that was formerly used as a sleeping drug to treat insomnia but has now been withdrawn.

**role-playing**

The acting of a role (a pattern of behaviour expected in a given situation). The phrase “sick role” describes the type of passive behaviour expected and allowed of a patient; people with social or emotional problems may unconsciously adopt this role to gain sympathy.

**root-canal treatment**

A dental procedure that is performed in order to save a tooth in which the pulp (the living tissue within the tooth) has died or become untreatedly diseased, usually as the result of extensive dental caries (see caries, dental). Root-canal treatment may be performed under a local anaesthetic (see anaesthesia, local). X-rays are first taken in order to establish the length of the root canal. The main stages of treatment are shown in the illustrations (right).

A hole is drilled into the crown to remove all material from the pulp chamber. The root canals are then slightly enlarged and shaped with fine-tipped instruments, and their length is measured. The procedure is often monitored by X-rays. The cavity is washed out, and antibiotic paste and a temporary filling are packed into it. Some days later, the filling is removed and the canals are checked for sterility. If no infection is detected, the cavity is filled with a sealing paste and/or tapering solid “points” made of gutta-percha resin mixed with zinc and bismuth oxides. The roots are then sealed with cement. If the cavity is not filled completely, bacteria may enter, leading to periodontitis (inflammation of the tissues surrounding the teeth).

Treated teeth may turn grey but their appearance can be restored by the use of bonding techniques (see...
rounding reflex
An automatic reflex action seen in newborn infants (see reflex, primitive). The rounding reflex, which can be evoked by touching the baby’s cheek with the fingertip, enables the baby to find the mother’s nipple to suckle.

root pain
Pain resulting from damage to, pressure on, or disease of the roots of a sensory nerve. Root pain is felt in areas of skin supplied by the affected nerve roots.

Rorschach test
A psychological test based on a person’s responses to a set of ink-blot pictures. The test was intended to reveal an individual’s attitudes, conflicts, and emotions, but is now rarely used. (See also personality tests.)

rosacea
A chronic skin disorder in which the nose and cheeks are abnormally red. The cause is usually unknown. Rosacea is aggravated by the use of corticosteroid creams. The disorder is most common among middle-aged women.

Rosacea usually begins with temporary flushes, but may develop into permanent redness of the skin, sometimes accompanied by acne-like pustules. In elderly men, it may lead to rhinophyma (bulbous swelling of the nose).

Treatment includes oral tetracycline or topical (applied to the skin) metronida-zole. Rosacea tends to recur for five to ten years before disappearing.

roseola infantum
A common infectious disease, caused by a type of herpes virus, that mainly affects children between the ages of six months and two years. Roseola infantum is characterized by an abrupt onset of irritability and fever. The child’s temperature drops to normal after four or five days and, at about the same time, a rash appears on the trunk, often spreading to the neck, face, and limbs. The rash usually clears up within two days.

Other symptoms may include a sore throat and enlargement of lymph nodes in the neck. Convulsions (see convulsion, febrile) may occur during the fever, but there are no serious effects.

The only treatment for roseola infantum is to keep the child cool and give paracetamol to reduce the fever.

rosiglitazone
An oral hypoglycaemic drug (see hypoglycaemics, oral) that is used in combination with other oral hypoglycaemics (either metformin or a sulphonylurea) in the treatment of type 2 diabetes mellitus. Rosiglitazone acts by reducing peripheral insulin resistance. Side effects of rosiglitazone may include gastrointestinal disturbances, weight gain, and anaemia (a reduced level of the oxygen-carrying pigment haemoglobin in the blood).

rotator cuff
A reinforcing structure around the shoulder joint, composed of four muscle tendons that merge with the fibrous capsule enclosing the joint.

The rotator cuff may be torn as the result of a fall. A partial tear may cause painful arc syndrome (pain when the arm is lifted away from the body in a particular arc). A complete tear seriously limits the person’s ability to raise the arm and, in cases of severe disability, may require surgical repair.

rotavirus
A type of virus that is a common cause of gastroenteritis; rotavirus particularly affects young children.

rougahage
See fibre, dietary.

roundworms
A class of elongated, cylindrical worms, also known as nematodes. Some types of roundworm are human parasites (the table below summarizes the main ones). The adult worms usually inhabit the human intestines, often without causing symptoms. Sometimes worm larvae pass through other parts of the body, which may cause symptoms.

The only common roundworm disease in the UK is threadworm infestation, which mainly affects children; occasionally, ascariasis, whipworm infestation, and toxocariasis occur. Some people return from abroad with hookworm infestation.

In tropical countries, roundworm diseases are much more common; they include those mentioned above as well as strongyloidiasis, guinea worm disease, and various types of filariasis.

For the majority of roundworm in-fes-

tations, treatment is with the use of anthelmintic drugs.

**Roussy–Levy disease**

A rare genetic disorder affecting nerves and muscles; symptoms usually begin in early childhood. Roussy–Levy disease resembles *peroneal muscular atrophy* and results from degeneration of the nerves supplying the lower legs and forearms.

Features include weakness, muscle wasting, and poor coordination of the legs; *claw-foot*; and tremors of the hands. There may also be abnormal curvature of the spine (see *kyphoscoliosis*). Roussy–Levy disease displays an autosomal dominant pattern of inheritance.

**RSI**

The abbreviation used for repetitive strain injury, a type of overuse injury.

**rubber dam**

A rubber sheet used to isolate one or more teeth during certain dental procedures. The dam acts as a barrier against saliva and prevents the inhalation of debris. To fit a dam, the dentist punches small holes in a rubber sheet, through which the teeth protrude. The sheet is then secured in place with clamps and a frame.

**rubefacient**

A substance that causes redness of the skin by increasing blood flow to it. Rubefacients are sometimes included in ointments used to relieve muscular aches and pains and they work by producing counter-irritation: they stimulate nerve endings to create a superficial feeling of heat or cold and distract the brain from the deeper muscular pain. Examples of rubefacients include methyl salicylate and menthol.

**rubella**

A viral infection, also known as German measles. Rubella is serious only if it affects a nonimmune woman in the early months of pregnancy, when there is a risk that the *virus* will cause severe *birth defects* (known as congenital rubella syndrome) in the fetus.

**TRANSMISSION AND SYMPTOMS**

The rubella virus is spread through mother-to-baby transmission and from person to person in airborne droplets; it has an *incubation period* of two to three weeks. Infection usually occurs in children between the ages of six and 12 and is almost invariably mild. The first symptoms may be a slight fever, malaise, and enlarged *lymph nodes* at the back of the neck. A rash then appears on the face, spreads to the trunk and limbs, and results within about three days. In adolescents and adults the symptoms may be more marked, such as a headache before the rash appears and a more pronounced fever.

The virus may be transmitted from about a week before the rash appears until a few days after its onset. An unborn baby is at risk if the mother is infected during the first four months of pregnancy. The earlier the infection occurs, the more likely the infant is to be affected and the more serious the resulting abnormalities tend to be. The most common abnormalities are *deafness*, congenital *heart disease*, *learning difficulties*, *cataract*, *purpura*, *cerebral palsy*, and bone abnormalities. About one in five affected babies dies in early infancy.

**DIAGNOSIS AND TREATMENT**

Rubella is easily confused with other viral infections, *scarlet fever*, and drug reactions, which may produce similar symptoms. Rubella can be positively diagnosed only by laboratory isolation of the virus, for example from a throat *swab* or by tests to look for *antibodies* (proteins manufactured by the immune system) to the virus in the blood.

There is no specific treatment. *Paracetamol* can be given to reduce fever. Treatment of congenital rubella syndrome depends on the defects present.

**PREVENTION**

Rubella vaccine provides long-lasting immunity to the disease; it is now given in the MMR vaccine (see *MMR vaccination*) to babies aged 12 to 15 months, with a booster at school entry. Rubella infection also confers immunity.

Any woman who is planning a pregnancy should have her rubella status checked. If she is not immune, she should be vaccinated immediately. If a nonimmune pregnant woman comes into contact with a person who has rubella, passive immunization by *immunoglobulin injection* may help to prevent infection of the fetus.

**Rubeola**

Another name for *measles*.

**running injuries**

Disorders resulting from the effects of jogging or running. Running injuries are common but most can be avoided by taking some simple precautions, such as wearing the correct footwear.

**TYPES**

Common types of running injury include *tendinitis* (inflammation of a tendon, particularly the *Achilles tendon*); *stress fractures* of bones in the leg and foot; *plantar fasciitis* (inflammation of tissue in the sole of the foot); torn *hamstring muscles* at the back of the thigh; back pain due to jarring of the spine; *tibial compartment syndrome* (painful cramp in the lower leg due to muscle compression); knee pain; ligament injuries in the ankle; and *shin splints* (pain along the tibia or shin).

**PREVENTION**

Shoes should fit snugly to provide stability but they should not cramp the foot; insoles help to cushion the jarring force on the legs and spine. Shoes that have become worn down should not be used because this can cause abnormal positioning of the foot during running, leading to foot strain.

Before running, warming-up exercises should be performed to reduce the risk of injury. Beginners should run only short distances at first and experienced runners should keep within sensible bounds. Runners should maintain an upright posture, with trunk, neck, and arms relaxed. Long periods of running uphill, downhill, or along the side of a slope should be avoided as they increase stress on the ankles and knees.

After a running injury has been diagnosed, assessment by a sports physiotherapist may be required in order to help prevent a recurrence of the injury.

**rupture**

A common term for a *hernia*. The term also refers to a complete break in a structure, as in rupture of a tendon.

**Rynacrom**

A brand name for *sodium cromoglicate*, an antiallergy drug. Rynacrom is used specifically in the prevention of allergic rhinitis (see *rhinitis, allergic*).
S

sac
A baglike organ or body structure.

saccharin
An artificial sweetener.

sacralgia
Pain in the sacrum (the triangular spinal bone below the lumbar vertebrae) that is caused by pressure on a spinal nerve. Sacralgia is usually the result of a disc prolapse. Rarely, it may be due to bone cancer. (See also back pain.)

sacralization
Fusion of the fifth (lowest) lumbar vertebra with the upper sacrum (the triangular spinal bone that is positioned below the lumbar vertebrae). Sacralization may be present at birth, in which case there are usually no symptoms. Sacralization may also be produced deliberately by a surgical procedure for the treatment of a disc prolapse or spondylolisthesis. (See also spinal fusion.)

sacroiliac joint
One of a pair of rigid joints on each side of the body that form an interface between the sacrum (the triangular spinal bone below the lumbar vertebrae) and the ilium (hip bone). The bony surfaces within the joint are lined with cartilage and have a small amount of synovial fluid between them. Strong ligaments positioned between the sacrum and ilium allow only minimal movement at the joint.

The sacroiliac joint can be strained, usually by childbirth or overstriding when running. Such an injury causes pain in the lower back and buttocks. The sacroiliac joint can also become inflamed (see sacroiliitis).

sacroiliitis
Inflammation of a sacroiliac joint, one of a pair of joints situated between each side of the sacrum (the triangular spinal bone below the lumbar vertebrae) and each ilium (hip bone).

Sacroiliitis can be due to various disorders, such as ankylosing spondylitis, Reiter’s syndrome, rheumatoid arthritis, or arthritis associated with psoriasis. The main symptom is pain in the lower back, buttocks, groin, and back of the thigh. Treatment is with nonsteroidal anti-inflammatory drugs.

sacrum
The large triangular bone in the lower spine. The sacrum lies in the centre back of the pelvis. Its broad upper part articulates with the fifth (lowest) lumbar vertebra, and its narrow lower part with the coccyx. The sides are connected by the sacroiliac joints to each ilium (hip bone). Disorders affecting the sacrum include sacralgia, spondylolisthesis, and sacralization. (See also spine, disorders of.)

SAD
The abbreviation for seasonal affective disorder.

sadism
The tendency or practice of deriving pleasure, particularly sexual pleasure, from inflicting pain or suffering on others. (See also sadomasochism.)

sadomasochism
The tendency or practice of deriving sexual pleasure by inflicting pain (see sadism) and receiving abuse (see masochism); one trait usually predominates. It also describes a sexual relationship in which one partner is very dominant and one is submissive.

safe period
See contraception, natural methods of.

safer sex
Preventive measures that are undertaken to reduce the risk of sexually transmitted infections. These include taking simple precautions such as maintaining a monogamous sexual relationship with someone who is free of infection; avoiding casual sex or sex with multiple partners; avoiding activities that can damage the skin or mucous membranes, or that involve contact with body fluids; and using a condom.

salbutamol
A bronchodilator drug that is used in the treatment of asthma, chronic bronchitis, and emphysema. It is also occasionally used to help prevent premature labour (see prematurity).

salicylate drugs
A group of drugs, including aspirin and benorilate, that have anti-inflammatory, fever-reducing, and mild analgesic action. An overdose of salicylate drugs causes hyperventilation, tinnitus, sweating, abnormal bleeding, biochemical disturbances, and, in severe cases, leads to convulsions and coma.
SAFETY SEX: HOW TO USE A CONDOM

Using a condom is not a guarantee against transmission of HIV (the AIDS virus) or other sexually transmitted infections, but it does reduce the risks substantially. Condoms that are prelubricated with a spermicide offer extra protection against pregnancy. Hypoallergenic condoms are available for people who are sensitive to rubber. In addition, condoms are available that are made from a thicker type of rubber and these should be used during anal intercourse.

1. The penis should be fully erect before the condom is put on. The condom should be in place before any vaginal or anal penetration by the penis and before oral sex.

2. Use a brand of condom that conforms to British Standards. Do not use one that has no teat, is beyond its “use by” date or appears to be defective. Open the condom carefully to avoid tearing it.

3. The teat-end should be squeezed so it is free of air and the condom unrolled fully over the penis. Do not stretch the condom tightly because a tight condom is more likely to burst.

4. The penis should be withdrawn soon after ejaculation. During withdrawal, the base of the condom should be held in order to prevent the semen from spilling out of the condom.

salicylic acid

A keratolytic drug that is used to treat skin disorders such as dermatitis, eczema, psoriasis, dandruff, ichthyosis, acne, warts, (including verrucas) and callouses (see callos, skin). Salicylic acid is also sometimes used to treat fungal infections. Side effects are few; and they may include irritation and dryness of the skin.

saline

A solution of salt (sodium chloride). Solutions with the same concentration of salt as body fluids are known as normal, or physiological, saline. Saline is used in contact lens solutions and may be given by intravenous infusion to replace fluids lost in severe dehydration.

saliva

The slightly alkaline fluid secreted into the mouth by the salivary glands and the mucous membranes lining the mouth. Saliva contains the digestive enzyme amylase, which helps to break down carbohydrates in food. In addition, saliva keeps the mouth moist, lubricates food to aid swallowing, and helps the tongue and mouth to register taste.

salivary glands

Three pairs of glands that secrete saliva, via ducts, into the mouth.

The sublingual glands lie on the floor of the front of the mouth, where they form a low ridge on each side of the frenulum (the band of tissue that attaches the underside of the tongue to the floor of the mouth). This ridge has a row of small openings through which saliva is excreted.

The submandibular glands lie towards the back of the mouth, close to the sides of the jaw. Their ducts run forwards and open under the tongue at two small swellings, one on each side of the frenulum.

DISORDERS

The parotid glands can be infected with the mumps virus, and stones (calculi) can form in a salivary gland or duct. A stone in a duct causes a swelling that enlarges during eating because saliva flow is blocked; it may also cause pain. Surgical removal of a stone from a duct is usually straightforward, but if the stone is within the gland, the entire gland may have to be removed.

Poor oral hygiene may allow bacterial infection in a gland, sometimes leading to an abscess. Tumours may develop; however, they are rare, except for a type of parotid tumour that is slow-growing, noncancerous, and painless.

Insufficient salivation causes a dry mouth (see mouth, dry). This problem may be due to dehydration or Sjögren’s syndrome, or it may occur as a side effect of certain drugs.

salivation, excessive

The production of too much saliva. Excess salivation sometimes occurs during pregnancy and prior to vomiting. Other causes include mouth problems such as irritation of the mouth lining, gingivitis (gum inflammation), or mouth ulcers; digestive tract disorders such as peptic ulcers and oesophagitis; and nervous system disorders such as Parkinson’s disease. In some cases, it may be reduced by anticholinergic drugs.
salmeterol
A bronchodilator drug used in the treatment of asthma. The drug is usually inhaled twice a day to prevent asthma attacks. Side effects may include slight tremor, agitation, insomnia, and, rarely, a rapid heartbeat.

salmonella infections
Infections caused by any of the salmonella group of bacteria. One type of salmonella causes typhoid fever; another causes paratyphoid fever, others commonly result in bacterial food poisoning. Infants, elderly people, and those who are debilitated are most susceptible.

In many cases, the source of salmonella poisoning has been traced to poultry products, and particularly to hens’ eggs and chicken meat. The infection of eggs can originate in the hen’s ovaries or may occur as a result of faecal contamination via the egg shell.

SYMPTOMS
Symptoms of salmonella food poisoning usually appear suddenly 12–24 hours after infection and include headache, nausea, abdominal pain, diarrhoea, and sometimes fever. They usually last for only two or three days, but in severe cases dehydration or septicaemia (blood poisoning) may develop, especially in the very young and old.

TREATMENT
Treatment is by rehydration therapy to replace lost fluids. In severe cases, fluid may need to be replaced by means of intravenous infusion.

PREVENTION
In general, it is advisable to avoid foods that contain raw egg (such as homemade mayonnaise, mousse, and ice cream). The risk of infection is reduced in very fresh eggs. Salmonella organisms are not killed by light cooking, and eggs given to children or the frail or elderly should be well cooked.

salmon patch
See stork mark.

salpingectomy
Surgical removal of one or both fallopian tubes. Salpingectomy may be performed if the tube is infected (see salpingitis) or to treat ectopic pregnancy. (See also salpingo-oophorectomy.)

salpingitis
Inflammation of a fallopian tube. Salpingitis is commonly caused by infection (this is usually a sexually transmitted type, such as gonorrhoea or chlamydial infection) spreading up from the vagina, cervix, or uterus. Salpingitis is also a feature of pelvic inflammatory disease.

Symptoms, include abdominal pain and fever, which may be severe. Pus may collect in the fallopian tube, and a pelvic abscess may develop.

Diagnosis is by examination of vaginal and cervical discharge, to identify the infectious organism, or laparoscopy to view the abdominal cavity. Blood tests may be carried out if septicaemia is suspected and the woman is very unwell. Treatment of the condition is with antibiotics. Surgery may be needed if an abscess has formed.

If the infection has damaged the inside of the fallopian tubes, infertility or an increased risk of an ectopic pregnancy may result. In some cases, damage to a tube can be corrected surgically.

salpingo-oophorectomy
Removal of one or both fallopian tubes and ovaries. This operation may be performed to treat some types of ovarian cyst. It may also be performed together with a hysterectomy to treat cancer of the ovary (see ovary, cancer of) or the uterus (see uterus, cancer of).

salt
A substance formed when an acid and a base react. The word is commonly used to refer to sodium chloride (table salt).

salve
A healing, soothing ointment.

sandfly bites
Bites from sandflies, which are found in many warm climates and can pass disease to humans. In tropical and subtropical areas they transmit leishmaniasis. In parts of Asia and the Mediterranean, they transmit sandfly fever, an illness like influenza. In the western Andes, they transmit bartonellosis, different forms of which cause either joint pain and fever or a rash. The risk of bites can be minimized by wearing clothing with long arms and legs that fits closely at the wrists and ankles, and using insect repellent, especially after dusk (when the flies are most active).

sanitary protection
A variety of articles, including pads and tampons, that are used to absorb blood and protect the clothing during menstruation. Most are disposable.

saphenous vein
A major vein that runs the length of the leg just under the skin (see circulatory system). The saphenous vein is sometimes removed and used to bypass blockages in blood vessels supplying the heart (see coronary artery bypass).

sarcoïdosis
A rare disease of unknown cause in which there is inflammation of tissues throughout the body, especially the lymph nodes, lungs, skin, eyes, and liver. It occurs mainly in young adults.

Symptoms do not always occur. When they do, they include fever, generalized aches, painful joints, and eye problems such as conjunctivitis and uveitis (painful, bloodshot eyes). Sarcoïdosis may also cause enlargement of the lymph nodes, breathlessness, erythema nodosum (purplish swellings on the legs), a purplish facial rash, and areas of numbness. Possible complications of sarcoïdosis include hypercalcaemia (excess calcium in the blood), which may damage the kidneys, and pulmonary fibrosis (scarring of lung tissue).

Treatment is not always needed. Most people recover fully within two years, with or without treatment, but some develop a persistent, chronic form of the disease. Corticosteroids are given to treat persistent fever or erythema nodosum, to prevent blindness in an affected eye, and to reduce the risk of permanent lung damage.

sarcoma
A cancer of connective tissue (which holds body structures together). Types include osteosarcoma, Kaposi’s sarcoma, chondrosarcoma, and fibrosarcoma.

SARS
The abbreviation for severe acute respiratory syndrome, a potentially serious viral infection that may cause pneumonia.

SARS is believed to be due to a new strain of coronavirus and, in most cases, is spread by close personal contact.

Symptoms appear after two to seven days and include acute fever (sometimes with chills), aching muscles, and headache. After a further three to seven days, a dry (non-productive) cough (accompanied by shortness of breath that may become severe) may develop, which may indicate pneumonia.

A number of investigations, including chest X-ray, sputum microscopy, and blood tests may be performed to exclude
other causes of pneumonia. Reliable tests to detect the presence of the virus are being developed.

Treatment includes oxygen therapy, (with artificial ventilation if necessary) and, sometimes, antibiotic and/or antiviral drugs, although there is no specific drug therapy that is effective. There is no vaccine or curative treatment available at present, and therefore control of the disease depends on physical measures, which include the use of face masks, hand washing, and isolation of infected individuals.

Not all people with SARS will develop pneumonia: most recover with no specific treatment. However, the condition may be fatal in 1 in 7 people who develop pneumonia.

**saturated fats**

See fats and oils; nutrition.

**scab**

A crust that forms on the skin or on a mucous membrane at the site of a healing wound or infected area. (See also blood clotting.)

**scabies**

A skin infestation caused by the mite Sarcoptes scabiei, which burrows into the skin to lay eggs. Scabies is highly contagious by close physical contact. It is most common in infants, children, and young adults.

The mite’s burrows may appear on the skin as grey, scaly swellings, usually between the fingers, on the wrists and genitals, and in the armpits. Later, small papules may appear on the limbs and trunk. The infestation causes intense itching, particularly at night, and scabs may form on the papules.

Treatment is with an insecticide lotion that is usually applied to all of the skin including the head. All occupants of the person’s household, and any sexual partners, should be treated at the same time.

**scald**

A burn due to hot liquid or steam.

**scalded skin syndrome**

A rare skin disease that causes redness followed by peeling of large areas of skin. It is caused by certain toxins from the bacterium Staphylococcus aureus. Children are particularly susceptible. Treatment is with intravenous injection or infusion of antibiotics.

**scaling, dental**

Removal of hard deposits from the teeth (see calculus, dental) to prevent or treat periodontal disease in the tissues supporting the teeth.

**scapula**

The skin of the head and its underlying tissue layers. The scalp is normally covered with hair. The skin is tougher than other skin and overlies a sheet of muscle that extends from the eyebrows, over the top of the head, to the nape of the neck.

The scalp may suffer injuries such as cuts and tears; it is richly supplied with blood vessels, so such wounds bleed profusely. Disorders affecting the scalp include dandruff, alopecia (hair loss); sebaceous cysts; psoriasis; fungal infections such as tinea (ringworm); and parasitic infestations such as lice. Cradle cap is common in infants.

**scalpel**

A surgical knife for cutting tissue.

**scan**

An image produced by one of several scanning techniques.

**scanning techniques**

Methods of producing images of organ structures (or sometimes function) using sound waves, radio waves, X-rays, or other forms of radiation directed through body tissues.

Ultrasound scanning is a widely used technique in which inaudible, ultra-high-frequency sound waves are passed into the body. These sound waves are reflected by various body structures in a pattern that is detected by one or more transducers and displayed on a screen.

CT scanning uses X-rays to measure variations in the density of an organ. The method compiles an image or picture by computer analysis.

Radionuclide scanning, which is also known as scintigraphy, involves the injection into the body of radioactive substances, which are taken up in different amounts by different organs. Radioactive iodine, for example, becomes concentrated in the thyroid gland. A detector is positioned in close proximity to the organ being examined and the pattern of radiation being emitted is recorded and displayed on a screen.

PET scanning (positron emission tomography) is based on the detection of positively charged particles that are emitted by radioactively marked substances introduced into the body. A computer is used to build up an image that reflects the chemical activity of the tissue that is being studied.

**scapoid**

One of the eight wrist bones. It is the outermost bone on the thumb side of the hand, in the row of wrist bones nearest the elbow.

A fracture of the scapoid is a common wrist injury usually caused by a fall on an outstretched hand. A characteristic symptom is tenderness in the anatomical snuffbox (the space between the tendons at the base of the thumb on the back of the hand). Treatment is by immobilizing the wrist in a cast.

**scapula**

The anatomical term for the shoulder-blade. The two scapulae are flat, triangular bones situated in the upper back. On the rear surface of each one is a prominent spine (which can be felt under the skin) that runs diagonally upwards and outwards to a bony prominence (the acromion) at the shoulder tip. The acromion articulates with the

**LOCATION OF THE SCAPULAE**

The two scapulae are the prominent wing-shaped bones in the upper back. They form a major part of the shoulder joint.
end of the clavicle (collarbone) to form the acromioclavicular joint. Just below the acromion is a socket (the glenoid cavity) into which the head of the humerus (upper arm bone) fits to form the shoulder joint.

The scapula serves as an attachment for some of the muscles and tendons of the arm, neck, chest, and back and aids movements of the arm and shoulder.

**scar**
A mark left where damaged tissue has healed. Scar tissue forms not only on the skin but on all internal wounds, such as at the site of a muscle tear or where surgery has been performed.

The body repairs a wound or other lesion by increasing production of the tough, fibrous protein collagen at the site of the damage. This helps to form new connective tissue around the lesion. If the edges of a lesion are brought together during healing, a narrow, pale scar forms; if they are left apart, more extensive scarring occurs.

**ABNORMAL SCARS**
A hypertrophic scar is a large, unsightly scar that may develop at the site of an infected wound. Some people have a family tendency to develop such scars.

A keloid is a large, irregularly shaped scar that continues to grow in size as the body continues to produce extra collagen after a wound has healed. This type of scar is more common in black people than in white.

Adhesions are areas of scar tissue that form between unconnected parts of internal organs. They are a potential complication of intestinal surgery.

**scarlatina**
Another name for scarlet fever.

**scarlet fever**
An uncommon infectious disease, more often seen in childhood, that is caused by a strain of streptococcal bacteria and spread by exhaled breath or coughing. Symptoms appear four to seven days after infection; they include a severe sore throat, high fever, vomiting, and a rapidly spreading rash of tiny red spots on the neck and upper trunk. The face is flushed, except around the mouth. A white coating with red spots may develop on the tongue (“strawberry tongue”), which then comes off after a few days to reveal a bright red colour. After this event, the fever soon subsides, the rash fades, and the skin may peel.

As with other streptococcal infections, glomerulonephritis (inflammation within the kidney) or rheumatic fever may, rarely, develop some weeks later. Antibiotics prevent this and promote a rapid recovery.

**Scheie syndrome**
A mucopolysaccharidosis (an inherited metabolic disorder) causing clouding of the cornea (surface of the eye), deformed hands, and aortic disease, but normal motor development.

**Scheuermann’s disease**
A form of osteochondritis juvenilis, a bone disorder affecting children and adolescents. It causes degeneration of the thoracic vertebrae (the spinal bones that support the rib cage), leading to kyphosis (a forward bend in the spine).

**Schilling test**
A test used to measure intestinal absorption of vitamin B₁₂, in order to detect disorders such as pernicious anaemia (failure to absorb vitamin B₁₂). A person is given a radioactive dose of the vitamin by mouth, then the urine is tested over 24 hours to see how much of the radioactive substance is excreted.

**schistosome**
A fluke (parasitic flatworm) that causes the tropical disease schistosomiasis.

**schistosomiasis**
A parasitic tropical disease, also called bilharzia, that is caused by flukes (parasitic flatworms) called schistosomes, and acquired from infested lakes, rivers, or other waters. The larvae penetrate the skin and develop in the body into adult flukes, which settle in the veins of the bladder and intestines. Their eggs cause inflammatory reactions; there may be bleeding and ulceration in the bladder and intestinal walls, and the liver may be affected.

The first symptom is usually tingling and an itchy rash where the flukes have entered the skin. An influenza-like
illness may develop many weeks later, when the adults produce eggs. Subsequent symptoms include blood in the urine or faeces, abdominal or lower back pain, and enlargement of the liver or spleen. Complications of long-term infestation include liver cirrhosis, bladder tumours, and kidney failure.

Treatment is with the drug praziquantel. No vaccine is available, so people visiting infested areas should avoid bathing or wading in fresh water.

**schizoid personality disorder**
An inability to relate socially to other people. Individuals who have this trait, which is apparent from childhood, are often described as “loners” and make few, if any, friends. They are eccentric, seem to lack concern for others, and are apparently detached from normal day-to-day activities.

**schizophrenia**
A general term for a group of psychotic illnesses (disorders in which a person loses contact with reality) that are characterized by disturbances in thinking, emotional reaction, and behaviour. Schizophrenia is a disabling illness with a prolonged course that almost always results in chronic ill health and some degree of personality change.

Onset can be at any age but is most common in late adolescence and the early 20s. No causes have been identified, but many have been implicated. It is likely that inheritance plays a role. Disruption of the activity of some neurotransmitters (chemicals that transmit signals between nerve cells) in the brain is a possible mechanism. Brain imaging has revealed abnormalities of structure and function in affected people.

**SYMPTOMS AND SIGNS**
Schizophrenia may begin insidiously, with the person becoming slowly more withdrawn and losing motivation. In other cases, it comes on suddenly, often in response to external stress. The main signs are delusions (fixed, irrational ideas) such as those of persecution (which are typical of paranoid schizophrenia); hallucinations (perceptions that occur without any external stimulus), and thought disorder. Hallucinations are usually auditory (in which the person hears voices talking about him or her), but may also be visual or tactile. Thought disorder leads to impaired concentration and thought processes; it is often reflected in muddled and disjointed speech and bizarre responses to questions. The person may believe that his or her thoughts are being controlled by outside forces or broadcast to others.

As the illness progresses, the person’s emotions become blunted; he or she also becomes detached from others and loses interest in usual occupations. Behaviour is eccentric, and self-neglect common. In a rare form of schizophrenia, catatonia may occur. In this condition, rigid postures are adopted for prolonged periods, or there are outbursts of repeated movement.

**DIAGNOSIS AND TREATMENT**
Diagnosis may take some time, and in some cases, it may be difficult to make a diagnosis at all. Treatment is mainly with antipsychotic drugs, such as phenothiazine drugs, and the new atypical antipsychotic drugs such as risperdone. In some cases, the drugs are usually given as monthly depot injections. Once the symptoms are controlled, community care, vocational opportunities, and family counselling can help to prevent a relapse.

Some people may make a complete recovery; however, most sufferers have relapses punctuated with partial or full recovery. A small proportion have a severe life-long disability.

**sciatica**
Pain that radiates along the sciatic nerve. The pain usually affects the buttock and thigh, sometimes extending down the leg to the foot. In severe cases, the pain may be accompanied by numbness and/or weakness in the affected area.

The most common cause is a ruptured intervertebral disc pressing on the nerve root (see disc prolapse). Other causes include a muscle spasm, sitting awkwardly for long periods, or, less commonly, pressure on the nerve from a tumour. Sometimes the cause is unknown.

Treatment is with analgesic drugs (painkillers). If the pain is severe, a short period of bed rest may be helpful, although prolonged rest may cause the sciatica to worsen. Physiotherapy, osteopathy, or chiropractic may help in some cases, but neurosurgery may be needed for the relief of the nerve compression. It is important to try and maintain a healthy posture and weight.

**sciatic nerve**
The main nerve in each leg and the largest nerve in the body. It is formed from roots in the spinal cord. The sciatic nerve supplies the hip joint, some of the thigh muscles, and the back of the thigh. Lower down it branches to form the nerves supplying the lower leg and the foot.

**SCID**
The abbreviation for severe combined immune deficiency.

**scintigraphy**
A less common alternative name for radionuclide scanning. Renal scintigraphy is also known as renography.

**scirrhus**
A term meaning “hard and fibrous”. It is usually applied to cancerous tumours containing dense, fibrous tissue.

**sclera**
The white, fibrous, tough coating that protects the eye. The sclera may be injured by sharp objects. Disorders of the sclera include scleritis (inflammation) and osteogenesis imperfecta (in which the sclera is abnormally thin and may appear blue).
such as --, a swollen SCROTUM and a cold compress may be or hydrocele ophthalmicus and (the white outer varicocele may be needed. SCLERA of the lymph nodes in the in which the, and and parts of the sclera to become thin and perforated. It is usually persistent but often responds to corticosteroid eye-drops.

scleritis
Inflammation of the sclera. It usually accompanies a collagen disease such as rheumatoid arthritis, but also occurs in herpes zoster ophthalmicus and Wegener's granulomatosis. Scleritis may cause some parts of the sclera to become thin and perforated. It is usually persistent but often responds to corticosteroid eye-drops.

scleroderma
A slowly progressive condition that is characterized by hardening and thickening of the skin. With progression of the condition, the internal organs are affected (see systemic sclerosis).

scleromalacia
Softening of the sclera (the white outer coat of the eye). It is a common complication of scleritis, especially when associated with rheumatoid arthritis.

sclerosing cholangitis
A rare condition in which many of the bile ducts are narrowed, causing progressive liver damage for which the only treatment may be a liver transplant. In many cases, it is related to inflammatory bowel disease. (See also cholangitis.)

sclerosis
Hardening of a body tissue. The term is usually used to refer to hardening of blood vessels (as in arteriosclerosis) or of nerve tissue (as occurs in the later stages of multiple sclerosis).

tsclerotherapy
A method of treating varicose veins, especially those that occur in the legs; haemorrhoids; and oesophageal varices. The affected vein is injected with an irritant solution, which causes inflammation in the lining; this reaction leads to scar tissue formation and the obliteration of the vein.

scoliosis
A deformity in which the spine is curved to one side. The thoracic (chest) or lumbar (lower back) regions are most commonly affected. Scoliosis usually starts in childhood or adolescence and becomes progressively more marked until growth stops. In many cases, another part of the spine curves to compensate, resulting in an S-shaped spine. Scoliosis may also be associated with kyphoscoliosis. The condition may be very mild and cause no symptoms, or it may be noticed by a doctor during investigation of back pain.

If an underlying cause is found, it will be treated. In some cases, physiotherapy may be sufficient to control scoliosis of unknown cause. Progressive or severe scoliosis may require immobilization of the spine in a brace, followed by a surgical procedure (see spinal fusion) to straighten it.

scorpion stings
Injections of venom from the sting in scorpions’ tails. Many species of scorpions are not dangerous, but some in North Africa, the southern US, South America, the Caribbean, and India are highly venomous. Some stings may cause only mild pain and tingling; but in more venomous species severe pain, restlessness, sweating, diarrhoea, and vomiting can occur. They are rarely fatal in adults, but pose a greater risk to children and elderly people.

Scorpion stings require prompt attention. If pain is the only symptom, analgesics and a cold compress may be enough. In severe cases, treatment with antivenom may be needed.

scotoma
An area of abnormal vision occurring within the visual field.

testing for juvenile scoliosis is not known. Rarely, the condition is due to a congenital abnormality of the vertebrae (bones forming the spine). Sometimes it may occur temporarily as a result of a spinal injury.

If an underlying cause is found, it will be treated. In some cases, physiotherapy may be sufficient to control scoliosis of unknown cause. Progressive or severe scoliosis may require immobilization of the spine in a brace, followed by a surgical procedure (see spinal fusion) to straighten it.

scrofululoderma
A type of tuberculosis in which the infection spreads from inside the body, most commonly from the lymph nodes in the neck (see scrofula), to the skin. It causes painless swellings under the skin that develop into abscesses or ulcers.

scrotum
The pouch that hangs behind the penis and contains the testes. It consists of an outer layer of thin, wrinkled skin over a layer of muscular tissue. Swelling of the scrotum may have a number of causes including inguinal hernia, a swollen testis, hydrocele, varicocele, or fluid accumulation due to heart failure or injury.

scuba-diving medicine
A medical speciality concerned with the physiological hazards of diving with self-contained underwater breathing apparatus (SCUBA). Most hazards stem from the increase in atmospheric pressure
that occurs with depth. At a depth of 10 m, the total pressure is twice the surface pressure. At 30 m, it is four times the surface pressure.

**MECHANICAL EFFECTS OF PRESSURE**

During descent, divers must introduce gas into their middle-ear cavities and facial sinuses to prevent damage as the pressure mounts. This mounting pressure is what airline passengers experience during descent and repressurization (see barotrauma).

Whatever depth they attain, divers must be supplied with breathing mixtures at a pressure equal to the external water pressure. During ascent, gas in the lungs expands and can rupture lung tissues if the diver panics and inadvertently holds his or her breath. This is a serious condition, which is known as pulmonary barotrauma (burst lung). Symptoms may include coughing up of blood, inability to pass urine, breathing difficulties, and unconsciousness.

**TOXIC EFFECTS OF GASES**

Amateur divers breathe compressed air, which consists mainly of nitrogen and oxygen. These gases are harmless at surface pressures but become toxic at high pressure. Nitrogen impairs the nervous system when air is breathed at depth, causing slowed mental functioning and other symptoms that mimic alcohol intoxication (a condition known as nitrogen narcosis). Oxygen becomes toxic when air is breathed at increased pressure, and in such situations it can cause convulsions or lung damage.

To attain greater depths without risking nitrogen and oxygen poisoning, professional divers use gas mixtures other than air. A typical mixture consists of helium, with the addition of only small amounts of oxygen and nitrogen; the helium is relatively nontoxic.

**THE BENDS**

At depth, divers accumulate in their tissues excess quantities of any inert gas they are breathing (nitrogen, if air is being breathed). If pressure is released too quickly (that is, if the diver’s ascent occurs too quickly) and if a large amount of gas has accumulated because the diver remained at depth for too long, this gas can no longer be held in solution in the body and may form bubbles in tissues and blood, causing decompression sickness.

**OTHER HAZARDS**

Additional hazards include hypothermia (dangerous chilling) due to immersion in cold water, and bites or stings from marine animals (see bites, animal; venomous bites and stings). In addition, there is a risk of drowning.

**ACCIDENT PREVENTION AND TREATMENT**

Anyone who is thinking of taking up scuba diving should first have a medical checkup and undergo training at a recognized diving school.

Pressure-related accidents, such as burst lung and decompression sickness, are treated by recompression of the diver in a special pressure chamber. This allows any bubbles or pockets of gas that are in the blood or tissues to be reabsorbed. The following stage is slow release of the pressure.

**SCURVY**

A disease, now rare in developed countries, caused by inadequate vitamin C intake. Scurvy disturbs the production of collagen, a protein in connective tissue (which supports body structures). The collagen is unstable, causing weakness of small blood vessels and poor wound healing. Haemorrhages (bleeding) may occur anywhere in the body, including the brain. If it occurs in the skin, the bleeding appears as bruising. Bleeding into the gums and loosening of teeth are common. Bleeding into the muscles and joints causes pain.

Scurvy is treated with large doses of vitamin C. Bleeding stops in 24 hours, healing resumes, and muscle and bone pain quickly disappear.

**SEAFOOD POISONING**

Bacterial or viral infections caused by eating shellfish that has been badly stored or cooked, or has been in water contaminated by human faeces. Symptoms include vomiting, diarrhoea, and abdominal pain. They may be relieved with plenty of fluids and salts (see rehydration therapy), but severe cases may need hospital treatment.

**SEALANTS, DENTAL**

Plastic coatings that are applied to the chewing surfaces of the back teeth to help prevent decay.

**SEASICKNESS**

A type of motion sickness.

**SEASONAL AFFECTIVE DISORDER**

A form of depression in which mood changes occur with the seasons. People with seasonal affective disorder, or SAD, tend to become depressed in winter, when natural light decreases, and feel better in spring. In some people, exposure to bright light for two to four hours each morning seems to prevent it.

**SEBACEOUS CYST**

A harmless, smooth nodule under the skin, most commonly on the scalp, face, ear, or genitals. The cyst contains a yellow, cheesy material and may become very large and infected by bacteria, making it painful. Large or infected cysts may be surgically removed.

**SEBACEOUS GLANDS**

Glands in the skin that secrete a lubricating substance called sebum. Sebaceous glands either open into hair follicles or discharge directly on to the surface of the skin. These glands are most numerous on the scalp, face, and anus, but do not exist on the palms or the soles of the feet. Disorders of the glands may lead to seborrhoea or acne vulgaris.
seborrhoea
Excessive secretion of sebum, causing oiliness of the face and a greasy scalp. The cause is unclear, but androgen hormones play a part. Seborrhoea is most common in adolescent boys; those affected are more likely to develop seborrhoeic dermatitis and acne vulgaris. The condition usually improves in adulthood without any treatment.

seborrhoeic dermatitis
See dermatitis.

seborrhoeic wart
Also called a seborrhoeic keratosis, a small, harmless, brown or black skin growth with a rough, greasy surface.

sebum
The oily secretion that is produced by the sebaceous glands. Sebum has several functions: it lubricates the skin, keeps it supple, and protects it from becoming waterlogged or dried out and cracked. It also protects against bacteria and fungi. Sebum production is partly controlled by androgen hormones. Over-secretion (see seborrhoea) of sebum causes greasy skin and may lead to seborrhoeic dermatitis or acne.

secondary
A term applied to a disease or disorder that results from or follows another disease (the primary disease). It also refers to a malignant tumour that has spread from a primary cancer elsewhere in the body (see metastasis).

secondary haemorrhage
Bleeding that results from an injury or surgical procedure but that occurs at a later time, rather than immediately. Secondary haemorrhage may be the result of infection.

secondary infection
An infection that results from or follows a pre-existing infection. One example is a bacterial respiratory infection that follows a viral infection. (See also superinfection).

secretin
A hormone produced by the duodenum (the first part of the small intestine) when acidic food enters it from the stomach. Secretin stimulates the release of pancreatic juice, which contains sodium bicarbonate to neutralize the acid, and bile from the liver.

secretion
The manufacture and release by a cell, gland, or organ of substances (such as enzymes) needed for metabolic processes elsewhere in the body.

secretory otitis media
An alternative name for glue ear.

sectioning
A commonly used term for the implementation of a section of the Mental Health Act to detain a mentally ill person against his or her will.

security object
A significant item, such as a favourite blanket, garment, or soft toy, that provides comfort and reassurance to a young child. These items are sometimes referred to as transitional objects. The child may become deeply attached to the object and show great distress if it is lost or if any attempt is made to take it away from him or her.

Security objects are often important during the toddler stage and may be used for several years. However, most children grow out of the need for such an item by the time they are about seven or eight years old.

sedation
The use of a drug to calm a person. Sedation is used to reduce excessive anxiety and control dangerously aggressive behaviour. It may also be used as part of premedication (drugs given to prepare a person for surgery). Sleeping drugs are used for night sedation.

sedative drugs
A group of drugs that are used to produce sedation. Sedatives include sleeping drugs, anxiolytic drugs, antipsychotic drugs, and some antidepressant drugs.

sedimentation rate
See ESR.

seizure
A sudden episode of abnormal electrical activity in the brain. Recurrent seizures occur in epilepsy.

Seizures may be partial or generalized. In a partial seizure, the abnormal activity is confined to one area of the brain. Symptoms include tingling or twitching of a small area of the body, hallucinations, fear, or déjà vu. In a generalized seizure, the abnormal activity spreads through the brain, causing loss of consciousness.

Causes of seizures include head injury, stroke, brain tumour, infection, metabolic disturbances, withdrawal in alcohol dependence, or hereditary alcohol intolerance. In children, high fever may cause seizures (see convulsion, febrile). Anticonvulsant drugs can control seizures or reduce their frequency.

selective serotonin reuptake inhibitors (SSRIs)
A type of antidepressant drug used to treat depression, panic disorder, bulimia, premenstrual syndrome, and obsessive-compulsive disorder. SSRIs block the re-absorption of serotonin following its release in the brain; the increased serotonin levels that result are associated with improved mood. Common SSRIs include fluoxetine, paroxetine, and sertraline. The drugs are usually taken orally once a day; beneficial effects may not be felt for up to three weeks. SSRIs usually produce fewer side effects than other types of antidepressant but may cause diarrhoea, nausea, restlessness, and anxiety. Stopping SSRIs suddenly can cause withdrawal symptoms.

selegiline
A drug that is used in the treatment of Parkinson’s disease, either alone (in the disease’s early stage) or in combination with levodopa. Selegiline is also used to treat the symptoms of parkinsonism due, for example, to repeated head injury; it is not used if the symptoms are drug-induced. Side effects may include nausea, vomiting, diarrhoea or constipation, dry mouth, and sore throat.
selenium
A trace element that may help to preserve the elasticity of body tissues. The richest dietary sources are meat, fish, whole grains, and dairy products.

self-help organizations
Charity or voluntary organizations, usually set up by patients or their relatives, that provide people affected by particular conditions with information, support, and, sometimes, financial aid.

self-image
A person’s view of his or her own personality and abilities. Some neurotic disorders stem from an incongruity between self-image and how others see one. Psychotherapy aims to treat neurosis by changing a person’s self-image.

self-injury
The act of deliberately injuring oneself. It most often occurs in young adults, many of whom are drug or alcohol abusers, and is three times more common in women. It may take the form of cutting the wrists or burning the forearms with cigarettes. In some, it is a way of dealing with stress, such as that caused by child abuse. It may also occur as a feature of autism.

There are more unusual forms of self-harm, for example mutilation of the genitals, and these are usually due to psychosis. Self-destructive biting features in Lesch–Nyhan syndrome, which is a rare metabolic disorder.

semen
Fluid discharged from the penis on ejaculation. Semen comprises fluid from the seminal vesicles, fluid from the prostate and Cowper’s glands, and sperm. (See also reproductive system, male.)

semen analysis
Analysis of sperm concentration, shape, and motility (ability to move) to investigate male infertility. It is also performed about 12 weeks after vasectomy to ensure that semen no longer contains sperm.

semen, blood in the
A usually harmless condition in which a small amount of blood appears in the semen. Occasionally, there is an underlying cause (for example, infection or, very rarely, cancer of the testis) that requires treatment. Blood in the semen may also occur after a prostate biopsy.

semicircular canal
A structure in the inner ear that plays a role in balance. There are three semicircular canals in each ear, at right angles to each other, and connected via a chamber called the vestibule. The fluid-filled canals contain small hairs that detect movement and acceleration and transmit information to the brain via the vestibular nerve.

semenal vesicle
One of a pair of sacs behind the bladder in the male that produce seminal fluid, which is mixed with sperm to make semen (see reproductive system, male).

seminoma
See testis, cancer of.

senile dementia
See dementia.

senile purpura
A skin condition in which some areas become purple or red-brown in appearance. Senile purpura occurs in middle to old age and is more common in women. It is caused by bleeding from small blood vessels beneath the skin due to thinning of supporting tissues.

senility
Old age or, more commonly, the decline in mental ability that may occur with age.

senna
A laxative drug from leaves and pods of the Arabian shrubs Cassia acutifolia and Cassia angustifolia. It stimulates bowel contractions and may darken the urine.
sensate-focus technique
A method taught to couples who are experiencing sexual difficulties caused by psychological rather than physiological factors. The technique’s aim is to make people more aware of their own and their partner’s pleasurable bodily sensations, and to reduce anxiety about performance. It is particularly effective in treating loss of sexual desire (see sexual desire, inhibited), or inability to achieve orgasm (see orgasm, lack of), and in helping men to overcome impotence or premature ejaculation (see ejaculation, disorders of).

sensation
A feeling or impression (such as a sound, smell, touch, or hunger) that has entered consciousness. The senses convey information about the external environment and the body’s internal state to the central nervous system (the brain and spinal cord).

SENSORY RECEPTORS
Information is collected by millions of receptors (specialized nerve structures) found throughout the body in the skin, muscles, and joints, in the internal organs, in the walls of blood vessels, and in special sense organs such as the eye and inner ear.

Receptors are attuned to a particular stimulus, such as light of a certain wavelength, chemical molecules of a particular shape, vibration, or temperature. Each receptor “fires” (sends an electrical signal) when stimulated.

Some receptors are the terminals (free nerve endings) of long nerve cell fibres, others are specialized cells that connect to such fibres. When a receptor fires, a signal passes along the appropriate nerve fibre to the spinal cord and/or brain. A proportion of this information reaches the sensory cortex of the brain and is consciously perceived.

SPECIAL SENSES
The special senses include vision, hearing, taste, and smell. The receptor cells for these senses are collected into special organs: the retina in the eye, the auditory apparatus in the ear, the taste buds in the tongue, and the organ for smell in the nose. Information from these organs passes directly to the brain via the cranial nerves. Much of the collected information passes to the cerebral cortex, although some goes to other areas of the brain (for example, from the eyes to the cerebellum, where it is used to help maintain balance).

INTERNAL AND TOUCH SENSES
These senses include pain, temperature, pressure, and proprioception (position), sensations. Proprioception relies on receptors in the muscles and joints to provide information on the position in space of parts of the body. Pain is one of the most primitive senses; its role is to warn of harmful stimuli through receptors that occur both at the surface of the skin and internally.

Many types of receptors are found in the skin. Some are sensitive to pressure, others to the movement of hairs or to temperature changes. Skin receptors are made up of the terminals of nerve fibres, which are wrapped around the roots of hairs, formed into discs, or surrounded by a series of membranes to form onionlike structures called pacinian corpuscles. Different patterns of stimulation of these receptors produce such sensations as pain, tickling, firm or light pressure, heat or cold. Certain skin areas (lips, palms of the hands, and genitals) have a particularly high concentration of receptors.

Most of the signals from these receptors pass through the cranial or spinal nerves and tracts in the brain or spinal cord, to the thalamus and then to two regions of the sensory cortex called the somatosensory cortices. Sensations that are perceived at certain points within these regions correspond to the parts of the body from which the signals originated. Much larger areas of cortex are devoted to sensations originating from the highly receptive hands and lips than from less sensitive parts.

sensation, abnormal
Dull, unpleasant, or otherwise altered sensations in the absence of an obvious stimulus. Abnormal sensation is also known as paraesthesia,

TYPES
Numbness and pins-and-needles are common abnormal sensations, which are sometimes combined with pain or feelings of coldness or burning. Neuralgia is characterized by pain with a brief stabbing, repetitive quality.

More examples of unusual abnormal sensations include a feeling that fluid is trickling down the skin, tight constriction in part of the body, and the feeling that insects are crawling over the skin (known as formication).

The special senses can also be impaired or altered as a result of damage to the relevant sensory mechanism or nerve tracts (see deafness; smell; tinnitus; vision, disorders of).

CAUSES
Neuropathy (peripheral nerve damage) from thiamine (vitamin B₁₂) deficiency in alcoholics, diabetes mellitus, or certain types of poisons (such as lead) is a common cause of abnormal sensation. The sufferer may complain of tingling or a feeling of walking on cotton wool. The peripheral nerves may also be damaged or irritated by infections such as

SENSATION, ABNORMAL
herpes zoster (shingles) or by a tumour pressing on a nerve, which often causes severe pain. Spinal injury, head injury, stroke, and multiple sclerosis are other causes of disruption to nerve pathways in the brain or spinal cord.

Damage to the thalamus (a relay station for sensory pathways in the brain) can produce particularly unpleasant results, such as a spreading sensation like an electric shock that occurs after a simple pinprick. Damage that affects the parietal lobe in the brain can lead to loss of the ability to locate or recognize objects by touch.

DIAGNOSIS AND TREATMENT
Various tests may be needed to find the cause of abnormal sensation. These include simple neurological sensory testing; testing of reflexes; tests on blood and urine; and CT scanning and MRI.

Pressure on or damage to nerves can sometimes be relieved by surgery or other treatments for the cause. In other cases, distressing abnormal sensation can be relieved by drugs or by cutting the relevant nerve fibres or giving injections to block the transmission of signals.

senses
See sensation. (See also hearing; taste; touch; smell; vision.)

sensitization
The initial exposure of a person to an allergen or other substance recognized as foreign by the immune system, which leads to an immune response. On subsequent exposures to the same substance, there is a much stronger and faster immune reaction. This response forms the basis of allergy and other types of hypersensitivity reaction.

sensorineural deafness
A type of deafness that occurs as a result of problems either relating to the inner ear itself, or to the nerves connecting the inner ear to the brain, or to the auditory area of the brain.

sensory cortex
A region of the outer cerebrum of the brain in which sensory information comes to consciousness.

Pressure, pain, and temperature sensations are perceived in the parietal lobes of the cerebrum, as is taste. Visual sensations are perceived in the occipital lobes, at the back of the cerebrum; sound is perceived in the temporal lobes, at the sides.

sensory deprivation
The removal of normal external stimuli, such as sight and sound, from a person’s environment. Prolonged sensory deprivation can produce feelings of unreality, difficulty in thinking, and hallucinations (perceptions occurring without any external stimulus).

sensory nerve
A type of nerve fibre that carries information from a receptor or sense organ towards the brain.

separation anxiety
The feelings of distress experienced by a young child parted from his or her parents or home. Signs include crying and clinging to a parent. This is a normal aspect of infant behaviour and usually diminishes by the age of three or four.

In separation anxiety disorder, the reaction to separation is greater than that expected for the child’s age and maturity. The anxiety may manifest as physical symptoms such as headaches, nausea, and difficulty in sleeping. Separation anxiety disorder may sometimes be a feature of depression.

sepsis
Bacterial infection of a wound or body tissue that leads to the formation of pus or to the multiplication of the bacteria in the blood. (See also bacteraemia; septicaemia; septic shock.)

septal defect
A congenital heart abnormality in which there is a hole in the septum (partition) between the left and right sides of the heart. The hole can be either the atrial (upper) or the ventricular (lower) chambers. Commonly known as a hole in the heart, septal defect varies in its effects according to its type and size. Usually, the cause is unknown.

TYPES
When the hole is in the septum separating the two ventricles, the abnormality is known as a ventricular septal defect; when it is in the septum between the two atria, it is called an atrial septal defect. In both types, the hole allows some of the freshly oxygenated blood in the left half of the heart (which supplies tissues throughout the body) to flow into the right half, mix with deoxygenated blood and recirculate through the lungs.

Some children are born with both types of defect. Either type may be accompanied by one or more additional heart abnormalities and/or some other congenital defects.

SYMPTOMS AND SIGNS
A small defect has little or no effect. A large ventricular hole may cause heart failure six to eight weeks after birth, causing breathlessness, feeding difficulties, pallor, and sweating. A large atrial defect may cause heart failure to develop around the age of 30 or there may be no heart failure at all, but fatigue may occur on exertion. Pulmonary hypertension (high blood pressure in the arteries supplying the lungs) may develop in both types of defect but is especially likely if there is a large ventricular defect.

With a ventricular defect there is also a slight risk of endocarditis (inflammation of the lining of the heart); in atrial septal defect, atrial fibrillation (rapid, irregular beating of the atria) may occur after the age of 30.

DIAGNOSIS AND TREATMENT
Diagnosis may be aided by a chest X-ray, ECG, or echocardiography. Atrial holes are repaired surgically if they cause symptoms or if complications develop. Small ventricular holes often become smaller, or even close, on their own as the child grows. A ventricular defect that is
causing heart failure is treated with drugs such as diuretics. If the hole does not close spontaneously, it may be repaired by open heart surgery, usually before the child reaches school age. The operation has a very high success rate and most children go on to lead normal lives.

**septate uterus**
A defect in which the interior of the uterus (womb) is divided by a septum (wall of tissue). A septate uterus may result in miscarriages; however, it can be corrected surgically, and most women have successful pregnancies after treatment.

**septic abortion**
A complication of miscarriage or abortion (see abortion, induced) in which the uterus, and any tissue retained from the fetus and the placenta, become infected. Symptoms include fever, abdominal pain, and a vaginal discharge that may contain blood. Hospital treatment is needed to prevent septic shock. (See also septicemia.)

**septicemia**
A serious or even life-threatening condition, also called blood poisoning, in which bacteria multiply rapidly in the bloodstream and bacterial toxins are present in the blood.

Septicaemia is usually due to bacteria that have escaped from a site of infection, such as an abscess. The condition is more likely to occur in people whose resistance to infection is lowered by an immunodeficiency disorder or immunosuppressant drugs. Those with cancer or diabetes mellitus, and drug addicts who inject, are also at higher risk.

Signs include a high fever, chills, rapid breathing, headache, and clouding of consciousness. The sufferer may go into life-threatening septic shock.

Glucose and/or saline are administered by intravenous infusion, and antibiotics given by injection or infusion. Tests are performed to identify the bacteria and, if necessary, the site of infection. Surgery may be needed to remove tissue at the site. If treatment is given before septic shock develops, the outlook is good.

**septic arthritis**
A type of arthritis caused by a bacterial infection entering a joint via an open wound or from the bloodstream. Symptoms of septic arthritis appear suddenly and may include swelling, tenderness, and fever. If pus builds up, the joint may be permanently damaged.

Fluid is taken from the joint and is analysed to determine the presence of infection (see aspiration), and pus may be drained to help relieve pain. Initially, treatment is with intravenous antibiotic drugs, followed by oral antibiotics for several weeks or months after that.

**septic shock**
A life-threatening condition in which there is tissue damage (especially affecting the kidneys, heart, and lungs) and a dramatic drop in blood pressure as a result of septicemia (multiplication of bacteria and the presence of bacterial toxins in the blood).

In many cases, the main danger comes from the toxins because they can damage cells and tissues, promote blood clotting in the smallest blood vessels, and seriously interfere with the normal circulation of the blood. Toxins may also cause fluid leakage from blood vessels and reduced ability of the vessels to constrict. This leads to a drop in blood pressure and may also lead to a further problem, disseminated intravascular coagulation (a clotting disorder).

**CAUSES**
Septic shock is most common in people who have debilitating disorders, such as diabetes mellitus, cancer, or liver cirrhosis, who also have an infection (often in the intestines and urinary tract) that has led to septicemia. Septic shock is particularly likely to occur in people with an immunodeficiency disorder, and in individuals taking immunosuppressant drugs. Newborn babies are also particularly susceptible.

**SYMPTOMS AND SIGNS**
The symptoms vary with the extent and site of major tissue damage but they are broadly the same as those that occur in septicemia. Additionally, however, there may be cold hands and feet, often with cyanosis (blue coloration) due to slowed blood flow, a weak, rapid pulse, and much reduced blood pressure. There may be vomiting and diarrhoea. Heart failure, abnormal bleeding, and damage to the kidneys, leading to kidney failure, may also develop.

**TREATMENT**
Septic shock requires immediate treatment with antibiotic drugs, and sometimes surgery to remove the focus of infection. Rapid fluid replacement to prevent kidney failure occurring is an essential aspect of treatment. Measures are also taken to raise blood pressure and promote better blood supply to the tissues.

**Septin**
A brand name for the antibacterial drug co-trimoxazole.

**septum**
A thin dividing wall that occurs within or between parts of the body; an example is the nasal septum, the partition between the nostrils.

**sequela**
A condition that results from or follows a disease, disorder, or injury. The term is usually used in the plural (sequelae) to refer to complications of a disease.

**sequestration**
Separation of a sequestrum (a piece of dead bone) from healthy living bone. Sequestration also refers to loss of blood or other fluid into body spaces, removing it from the circulation and causing hypotension. Sequestration crises, in which blood pools in the spleen and liver, occur in sickle cell anaemia.

**seroconversion**
The development, in the blood serum, of antibodies (proteins made to combat a specific infection) that can be detected by testing (see serology).

**serology**
A branch of laboratory medicine concerned with analysis of blood serum. Applications of serological techniques include the diagnosis of infectious diseases by the identification of antibodies, the development of antiserum preparations for passive immunization, and the determination of blood groups in paternity testing and forensic investigations.

**seronegative**
A term that is used to describe blood serum that has undergone testing for an infection (see serology) and is found to have no antibodies to the infectious organism under investigation. The term also refers to the absence of an autoantibody (one that reacts against the body’s own cells) in a specific condition. An example of this usage is the lack of rheumatoid factor that occurs in seronegative rheumatoid arthritis.

**seropositive**
A term that is used to describe blood serum that has undergone testing for a certain infection (see serology) and is found to contain antibodies to the infectious organism.
serotonin
Also known as 5-hydroxytryptamine (5HT), a substance found in many tissues, particularly in blood platelets, digestive tract lining, and brain. Serotonin is released from platelets at sites of bleeding, where its function is to constrict small blood vessels, thereby reducing blood loss. In the digestive tract, serotonin inhibits gastric secretion and stimulates smooth muscle in the intestine wall. In the brain, it acts as a neurotransmitter (a chemical that passes signals between nerve cells). Serotonin levels in the brain are reduced in people who are depressed, but certain anti-depressant drugs raise the level. Serotonin antagonists are used in the treatment of acute migraine attacks.

serotonin agonists
A group of drugs, also known as 5HT1 agonists, used to treat acute attacks of migraine, in which the headache is caused by dilation of blood vessels in the brain. Serotonin agonists act on the same receptors in the brain as serotonin (a chemical messenger), returning the dilated vessels to their normal size and thereby relieving the symptoms of the migraine attack.

Common serotonin agonists include naratriptan and sumatriptan. These drugs can cause chest pain, particularly in people with heart disease. They should be used with caution in those at increased risk of coronary artery disease. Other side effects include flushing, tingling, and nausea.

serotonin antagonists
A group of drugs, also known as 5HT1 antagonists, used to treat nausea and vomiting that is caused by radiotherapy and anticancer drugs or following general anaesthesia given for surgery. In these cases, the symptoms occur when serotonin stimulates the vomiting centre in the brain; the drugs prevent them by inhibiting the action of serotonin. Common serotonin antagonists include granisetron and ondansetron.

serous
A word that refers to blood serum or clear, watery body fluid. It is also used of body structures containing or producing these substances.

Seroxat
The brand name for paroxetine, an SSRI antidepressant drug.

Sertoli cell tumour
A tumour arising from the Sertoli cells (which support and nourish the developing sperm) within the testis. Some Sertoli cell tumours are malignant (see testis, cancer of).

sertraline
A selective serotonin reuptake inhibitor drug used in the treatment of depression and obsessive–compulsive disorder.

serum
The clear fluid that separates from blood when it clots. It contains salts, glucose, and proteins, including antibodies. Serum from the blood of a person who has had an infection usually contains antibodies to the infectious organism; if injected into other people, it can protect them from that disease. The serum preparation is called an antiserum; its use forms the basis of passive immunization. (see also plasma).

serum sickness
A type of hypersensitivity reaction that may develop about 10 days after injection with an antiserum of animal origin or after taking certain drugs, such as penicillins. Symptoms may include an itchy rash, joint pain, fever, and enlarged lymph nodes. In severe cases, a state that is similar to shock develops. Symptoms of serum sickness usually clear up in a few days; antihistamine drugs may hasten recovery. In severe cases, a corticosteroid drug may be prescribed.

severe acute respiratory syndrome (SARS)
See SARS.

severe combined immunodeficiency (SCID)
A rare congenital (present from birth) disorder in which the immune system functions inefficiently, or not at all. Babies born with severe combined immunodeficiency (SCID) are highly susceptible to infections. They may fail to thrive and have many severe infections (such as those of the respiratory and gastrointestinal tracts), skin rashes, recurrent oral thrush (see candidiasis), and pneumonia.

Early diagnosis of SCID is vital; the disorder is confirmed by blood tests to check levels of lymphocytes (a type of white blood cell). A bone marrow transplant offers the best chance of a cure, provided it is performed in the first few months of life. Many children with SCID are treated successfully and are able to lead normal lives thereafter.

sex
Another term for gender; also a commonly used term for sexual intercourse.

sex change
Radical surgical procedures, usually combined with hormone therapy, that alter a person’s anatomical gender. Sex-change operations are performed on transsexuals (see transsexualism) and on infants whose external sex organs are neither completely male nor completely female (see genitalia, ambiguous). The procedures are carried out in order to give a person the physical appearance that coincides with his or her psychological gender identity, or to provide a more defined sexual identity.

PROCEDURES
For transsexuals, sex-change procedures involve a series of major operations on the genito-urinary tract, which are carried out after courses of hormone therapy and extensive counselling. The male-to-female sex change operation is the one more commonly performed and the results are more satisfactory than the female-to-male procedure.

Babies with ambiguous genitalia are assigned a gender as soon as possible after birth, and given appropriate surgical and hormonal treatment.

OUTLOOK
Hormone therapy may need to be continued for life to maintain secondary sexual characteristics, such as body shape and hair distribution. Female transsexuals can have intercourse but cannot conceive; males cannot ejaculate, and achieve an erection only with mechanical aids.

sex chromosomes
The pair of chromosomes that determines a person’s sex. All the cells in the human body (except for egg or sperm cells) contain a pair of sex chromosomes together with 22 other pairs of chromosomes known as autosomes. In women, the sex chromosomes are of similar appearance and are called X chromosomes. In men, one sex chromosome is an X and the other, smaller, one is a Y. The normal sex chromosome complement for women is XX, and for men, XY.

FUNCTION
Like all chromosomes, the X and Y chromosomes exert their effects in the
body through the activities of their constituent genes. These genes contain the coded instructions for chemical processes within cells and for aspects of growth and development within the whole body.

The X and Y chromosomes differ in one way: genes on the Y chromosome are concerned solely with sex determination. Their presence ensures a male: their absence a female. The X chromosome, occurring in both sexes, contains many genes vital to general development and functioning. Absence of the X chromosome is incompatible with life.

The presence of a single X chromosome and 22 pairs of autosomes in the nuclei of ordinary body cells appears to provide the blueprint for general body functioning and development, which seems to have an underlying female pattern. This can be seen in people with Turner’s syndrome, who have only one sex chromosome, an X. Although full female sexual characteristics never develop, these people are unmistakably female in appearance and identity. The full complement of female sexual characteristics will develop only in the presence of a second X chromosome. It is the addition of a Y chromosome that is responsible for converting the female to the male pattern.

**sex determination**

The factors that determine biological sex. The underlying determinants are the sex chromosomes in a person’s cells: two X chromosomes in females and one X and one Y chromosome in males. Early in embryonic development, these chromosomes cause the development of different gonads (the testes in males and the ovaries in females). In males, the testes then produce hormones that cause the development of a male reproductive tract, including a penis. In females, absence of these male hormones leads to a different pattern of development, with the formation of fallopian tubes, uterus, and vagina. At puberty, another surge of hormones from the gonads leads to the appearance of secondary sexual characteristics, such as facial hair in males, breasts in females, and pubic hair in both sexes.

Defects sometimes occur in the process of sex determination, and may result in ambiguous sex (see genitalia, ambiguous). Some people acquire an abnormal complement of sex chromosomes (see chromosomal abnormalities) and all the characteristics of one sex do not develop. True hermaphroditism (the presence of both ovaries and testes in the body) is a very rare occurrence.

**sex hormones**

Hormones that control the development of primary and secondary sexual characteristics and that regulate sex-related functions, such as the menstrual cycle. There are three main types: androgen hormones, oestrogen hormones, and progesterone hormone.

**sex-linked inheritance**

The passing on to the next generation of a trait or disorder that is determined by the sex chromosomes, or by the genes that are carried on them.

Disorders due to an abnormal number of sex chromosomes include Turner’s syndrome and Klinefelter’s syndrome. Most other sex-linked traits or disorders are caused by recessive genes on the X chromosome (see X-linked disorders).

**sex therapy**

Counselling for and treatment of sexual difficulties not due to a physical cause. Sex therapy (also called psychosexual therapy) may involve changing the partners’ attitudes towards sex, increasing their understanding of sexual needs, and teaching techniques, such as the sensate-focus technique or pelvic floor exercises, for specific problems. Sex therapy is particularly successful in treating certain disorders including vaginismus, premature ejaculation (see ejaculation, disorders of), lack of orgasm (see orgasm, lack of), and impotence.

**sexual abuse**

Subjection of a person to sexual activity that has caused, or is likely to cause, physical or psychological harm. (See also child abuse; incest; rape.)

**sexual characteristics, primary**

Physical features, which are present from birth, that show a person’s sex, such as a penis and testes in a male or a vagina and vulva in a female.

**sexual characteristics, secondary**

Physical features appearing at puberty that indicate the onset of adult reproductive life. In girls, breast enlargement is the first sign. Shortly afterwards, pubic and underarm hair appears, and body fat increases around the hips, stomach, and thighs to produce the female body shape. In boys, the first sign is enlargement of the testes, followed by thinning of the scrotal skin and enlargement of the penis. Pubic, facial, underarm, and other body hair appears, the voice deepens, and muscle bulk and bone size increase.

**sexual desire, inhibited**

Lack of sexual desire (libido) or of the ability to become physically aroused during sexual activity. Either condition may be physical or psychological.

**LACK OF DESIRE**

A high proportion of women and some men experience loss of sexual desire at some time in the their lives. Common physical causes include fatigue, ill health, and discomfort after childbirth. Certain drugs, including sleeping pills, antidepressants, antihypertensives, oral contraceptives, and alcohol, can also reduce sexual desire. Psychological factors include depression, anxiety, stress, unsatisfactory relationships, fear of pregnancy, or a traumatic sexual experience.

**LACK OF PHYSICAL AROUSAL**

It is rare for anyone of either sex to be incapable of some degree of physical sexual arousal. A common reason for failure is the partner’s poor or insensitive sexual technique, although guilt about the sex act or anxiety about sexual inadequacy may contribute to the problem.

**TREATMENT**

Sex therapy or relationship counselling may be helpful in resolving problems with a psychological basis. Sexual problems with a physical or chemical cause often improve once the underlying condition is resolved.

**sexual deviation**

See deviation, sexual.

**sexual dysfunction**

See psychosexual dysfunction.

**sexual intercourse**

A term sometimes used to describe a variety of sexual activities, but which specifically refers to the insertion of a man’s penis into a woman’s vagina. Sexual intercourse is the usual means of achieving fertilization. It is also a means of achieving orgasm for one or both partners.

**sexuality**

A term describing the capacity for sexual feelings and behaviour, or a person’s sexual orientation or preference. Heterosexuality is sexuality directed towards
SEXUAL INTERCOURSE

The term sexual intercourse usually refers to the act during which the male’s penis is inserted into the female’s vagina. However, some people use the term more broadly to refer to a much wider range of sexual activity. Physiologically, intercourse falls into four main stages – arousal (which generally includes a period of foreplay), a plateau (during which penetration usually occurs), orgasm, and resolution. The duration of each stage of intercourse varies.

Arousal in men
Sexual thoughts, the sight and feel of his partner’s body, and foreplay may sexually arouse a man. Blood enters the penis so that it becomes firm and erect.

Plateau phase in men
Vaginal penetration usually takes place during this phase and thrusting movements begin. The penis reaches maximum size and the testes elevate.

Orgasm in men
Muscular contractions in the ducts connecting the testes, prostate, and penis, force semen out of the penis, accompanied by intensely pleasurable sensations.

Resolution in men
The penis returns to half its fully erect size and the testes descend.

Arousal in women
Similar factors lead to arousal in women as in men, though foreplay may be more important. The clitoris lengthens, the vagina enlarges, and its walls secrete a lubricating fluid.

Plateau phase in women
Muscular contractions in the walls of the vagina help grip the penis. The uterus rises, and the clitoris may pull back beneath its hood of skin.

Orgasm in women
The walls of the outer part of the vagina contract rhythmically and strongly several times and an intense sensual feeling spreads from the clitoris and throughout the body.

Resolution in women
The clitoris subsides and, more gradually, the vagina relaxes and the uterus falls.

SEXUALLY TRANSMITTED INFECTION

An infection transmitted primarily (but not exclusively) by sexual intercourse. Common sexually transmitted infections (STIs) include genital herpes, chlamydial infections, pubic lice, genital warts, trichomoniasis, gonorrhoea, and HIV infection.

Certain sexual activities carry a high risk of infection with STIs. They include casual sex or having multiple partners (particularly if partners are not known to be free of disease); activities that involve contact with sperm or other bodily fluids; and activities that may damage the skin or mucous membranes. Practising safer sex can minimize these risks and help prevent STIs.

Antibiotics can be used to treat most bacterial STIs. Confidential tracing and treatment of an affected person’s partners is essential in the management of STIs (see contact tracing).

sexual problems
Any difficulty associated with sexual performance or behaviour. Sexual problems are often psychological in origin; sex therapy may help such problems. They may also be due to physical disease, such as a disorder affecting blood flow; a hormonal dysfunction; or a disorder of the genitals. Such problems are addressed by treating the cause, where possible. See also ejaculation, disorders of; impotence; orgasm, lack of; sexual desire, inhibited; vaginismus.

Sézary syndrome
A rare condition in which there is an abnormal overgrowth of lymphocytes (white blood cells active in the immune system) in the skin, liver, spleen, and lymph nodes. It mainly affects middle-aged and elderly people. The first symptom is the appearance of red, scaly patches on the skin that spread to form an itchy, flaking rash. There may also be an accumulation of fluid under the skin; baldness; and distorted nail growth.

Sézary syndrome is sometimes associated with leukaemia. Treatment includes anticancer drugs and radiotherapy.

shared care
Management of a pregnant woman’s care by her general practitioner and the community midwives (see primary care), in combination with a hospital antenatal team. The term shared care also refers increasingly to the management of certain chronic conditions, for example asthma and diabetes.

Sheehan’s syndrome
A form of hypopituitarism (under-activity of the pituitary gland) in women who have just given birth. The disorder occurs when cells in the pituitary die as a result of heavy bleeding or shock during the delivery. The treatment for Sheehan’s syndrome involves replacement of the deficient hormones.

shellfish poisoning
See seafood poisoning.
shell shock
See post-traumatic stress disorder.

shigellosis
An acute infection of the intestine by Shigella bacteria; also called bacillary dysentery. The bacteria exist in faeces and are spread by poor hygiene. Endemic in some countries, shigellosis occurs in isolated outbreaks in the UK.

The disease usually starts suddenly, with bloody diarrhoea, abdominal pain, nausea, vomiting, generalized aches, and fever. Persistent diarrhoea may cause dehydration, especially in certain groups such as babies and elderly people. Occasionally, toxæmia (the presence of bacterial toxins in the blood) develops.

Shigellosis usually subsides after a week or so, but hospital treatment may be needed for severe cases. Dehydration is treated by rehydration therapy. Antibiotics may be given.

shingles
See herpes zoster.

shin splints
Pain in the front and sides of the lower leg that develops or worsens during exercise. There may also be tenderness and swelling in the area. Shin splints is a common problem in runners. Possible causes include inflammation of a tendon or muscle or periostitis (inflammation of the outer layer of a bone). (See also compartment syndrome.)

In most cases, the pain in the shins disappears after one or two weeks of rest; however, in cases where it is severe or recurrent, a course of nonsteroidal anti-inflammatory drugs or corticosteroids may be needed. In rare cases, surgery is performed in order to alleviate excessive pressure in a muscle. Some people benefit from physiotherapy.

shivering
Involuntary trembling of the entire body caused by rapid contraction and relaxation of muscles. Shivering is the body’s normal automatic response to cold; it also occurs in fever.

When the body becomes cold, temperature-sensitive nerve cells in the hypothalamus (part of the brain) act as a thermostat, initiating the shivering reflex. This causes muscles to contract, generating heat. Shivering caused by cold usually disappears as soon as the body is warmed and starts to approach a near normal temperature. Shivering during fever is caused by the release of certain substances by the white blood cells. The trigger for this release is usually an infection. These substances effectively “reset” the thermostat at a higher point, causing the body to shiver when it needs to lose, rather than retain, heat.

A dangerous reduction of blood flow throughout the body tissues, which may occur with severe injury or illness. Shock in this sense is a physiological reaction, as distinct from the mental distress that may follow a traumatic experience.

In most cases, reduced blood pressure is a major factor in causing shock and it is also one of its main features. Shock may develop in any situation in which blood volume is reduced, blood vessels are abnormally widened, the heart’s action is weak, blood flow is obstructed, or there is a combination of a few of these factors. Causes of shock include severe bleeding or burns, persistent vomiting or diarrhoea, myocardial infarction (heart attack), pulmonary embolism (a blood clot in the lung), peritonitis (inflammation of the abdominal lining) and some types of poisoning.

Signs include rapid, shallow breathing; cold, clammy skin; a rapid, weak pulse; dizziness; weakness; and fainting. If left untreated, shock can impair the oxygen supply to vital organs, such as the brain, which will eventually lead to collapse, coma, and death.

Emergency treatment is needed. This involves an intravenous infusion of fluid, a blood transfusion, oxygen therapy, and, if pain relief is necessary, morphine or similar powerful analgesic drugs (painkillers). Any further treatment that is given depends on the underlying cause. (See also anaphylactic shock; hypovolaemia; septic shock; toxic shock syndrome.)

The sensation that is caused by an electric current passing through the body, and its effects. A current of sufficient size and duration can cause loss of consciousness, cardiac arrest, respiratory arrest, burns, and tissue damage. (See also electrical injury.)

shock therapy
See ECT.

shock wave lithotripsy
See lithotripsy.
**SHOULDER**

**shoulder**
The area of the body where the arm attaches to the trunk. The rounded bony surface at the front of the shoulder is the upper part of the humerus (upper-arm bone); the bony surfaces that form the top and back of the shoulder are parts of the scapula (shoulderblade). The clavicle (collarbone) articulates with the acromion (the bony prominence at the outer top part of the scapula) at the acromioclavicular joint and extends across the top of the chest to the sternum (breastbone), to which it is attached at the sternoclavicular joint.

Just below the acromion, on the outer wall of the scapula, is a socket (called the glenoid cavity) into which the head of the humerus fits to form the shoulder joint. A bursa (fluid-filled sac) under the acromion reduces friction at the joint. The shoulder joint is a ball-and-socket joint with the widest range of movement of all joints; movement is produced by part of the biceps muscle, several small muscles that make up the rotator cuff, various muscles in the chest wall, and the deltoid muscle at the top of the upper arm and shoulder.

**DISORDERS**
Shoulder injuries are relatively common, including dislocation of the shoulder joint (see shoulder, dislocation of) or of the acromioclavicular joint, and fractures of the clavicle or of the upper part of the humerus. Fractures of the scapula are less common.

**shoulder–hand syndrome**
Pain and stiffness of one shoulder and the hand on that side; the hand may also become hot, sweaty, and swollen. Arm muscles may waste through lack of use.

The cause of shoulder–hand syndrome is not known, but the condition may sometimes occur as a complication of myocardial infarction (heart attack), stroke, herpes zoster (shingles), or shoulder injury. Recovery usually occurs in about two years. However, this recovery period may be shortened by physiotherapy and corticosteroid drugs. In rare cases, a cervical sympathectomy is performed.

**shunt**
An abnormal passage between two normally unconnected body parts (as in a septal defect of the heart). The term also refers to a passage created surgically between unconnected areas for purposes such as draining excess fluid.

**Shy–Drager syndrome**
A rare degenerative disorder of unknown cause that progressively damages the autonomic nervous system. It begins gradually between the ages of 60 and 70 and is more common in men. Symptoms include dizziness and fainting due to postural hypotension; urinary incontinence; impotence; reduced ability to sweat; and Parkinsonism. The condition eventually leads to disability and sometimes premature death. There is no cure or means of slowing degeneration, but many symptoms are relieved by drugs.

**SIADH**
The abbreviation for “syndrome of inappropriate antidiuretic hormone (secretion)”, in which excessive secretion of antidiuretic hormone (ADH) results in water retention and a low sodium level in the body. SIADH is associated with certain lung disorders such as COPD (see pulmonary disease, chronic obstructive) or pneumonia. Other conditions, for example brain disorders such as encephalitis or brain haemorrhage, and some cancers including small cell carcinoma (see lung cancer) and cancer of the pancreas (see pancreas, cancer of), may also be associated with SIADH.

**Siamese twins**
See twins, conjoined.

**sibling rivalry**
A term that describes the intense competition that sometimes occurs between siblings.

**sibutramine**
A centrally acting appetite suppressant drug that is used to treat obesity in people who have not responded to other methods of weight loss, such as dieting and exercise. Common side effects include constipation, dry mouth, and hypertension. People taking this drug should have regular follow-ups with their blood pressure and pulse monitored.

**sicca syndrome**
Occurring in Sjögren’s syndrome, dryness of the eyes, mouth, and other mucous membranes (such as the lining of the vagina) due to destruction of exocrine (such as tear, salivary, or sweat) glands.

**sick building syndrome**
A collection of symptoms reported by some workers in office buildings. Symptoms include loss of energy,
fatigue, poor concentration, headaches, and dry, itchy eyes, nose, and throat. Although the exact cause is unknown, various factors may be involved, including air conditioning, passive smoking, lack of natural light and ventilation, and psychological stress.

**sickle cell anaemia**

An inherited genetic disorder in which the red blood cells contain an abnormal type of haemoglobin (oxygen-carrying pigment) called haemoglobin S. When red cells enter capillaries (tiny blood vessels) under conditions of low oxygen (due to the atmosphere or infection or dehydration, for example), haemoglobin S crystallizes. The cells become sickle-shaped and fragile, leading to haemolytic anaemia. Also, because the abnormal cells are unable to pass easily through capillaries, they intermittently block the blood supply to organs. The result is a sickle cell crisis, which may also occur for no apparent reason.

**CAUSE**

Sickle cell anaemia occurs mainly in black African people, and the defective gene is inherited from both parents. (If the gene is passed on from only one parent, the result is sickle cell trait, in which “carriers” are at risk of passing the gene to their children.)

**SYMPTOMS AND SIGNS**

Symptoms usually appear after six months of age and often begin with painful swelling of the hands and feet. Chronic haemolytic anaemia causes fatigue, headaches, shortness of breath on exertion, pallor, and jaundice. Sickle cell crises start suddenly; there may be pains (especially in the bones), blood in the urine (from kidney damage) or damage to the lungs or intestines. If the brain becomes enlarged and traps red cells at the brain's surface, the spleen usually stops functioning, thereby increasing the risk of infection in those affected.

In some affected children, the spleen becomes enlarged and traps red cells at a very high rate, which causes a life-threatening form of anaemia. After adolescence, the spleen usually stops functioning, thereby increasing the risk of infection in those affected.

People who have sickle cell trait generally have no disability, and may be protected from falciparum malaria, but they may experience similar blood-vessel blocking events if oxygen levels are low.

**DIAGNOSIS AND TREATMENT**

Diagnosis is made from examination of a blood smear and electrophoresis to detect haemoglobin S. Supportive treatment may include supplements of folic acid, and penicillin and immunization to protect against infection. The treatment of life-threatening crises involves the use of intravenous infusions of fluids, oxygen therapy, antibiotics, and analgesic drugs (painkillers). If the crisis still does not respond, an exchange blood transfusion may be performed. This may be done regularly for people who suffer from frequent severe crises.

**sick sinus syndrome**

Abnormal function of the heart’s sinoatrial node (its natural “pacemaker”) that leads to episodes of bradycardia (slow heart rate), alternating bradycardia and tachycardia (fast heart rate), or very short episodes of cardiac arrest.

The cause of sick sinus syndrome is usually coronary artery disease; alternatively, it may be a cardiomyopathy (a condition that leads to weakened heart muscle contractions). Symptoms may include lightheadedness, fainting, and palpitations. The diagnosis is confirmed by a 24-hour ECG recording. The condition is usually treated with anti-arrhythmic drugs and the fitting of an artificial pacemaker.

**side effect**

A reaction or consequence of medication or therapy that occurs in addition to the desired effect. The term is usually used with reference to an unwanted or adverse effect usually following a normal dose, rather than the toxic effects resulting from a drug overdose.

**siderosis**

Any condition in which there is too much iron in the body, including pneumoconiosis, when it is caused by inhalation of iron particles. (See also haemdsiderosis.)

**SIDS**

An abbreviation for sudden infant death syndrome.

**siewert**

A unit for measuring doses of ionizing radiation. (See radiation units.)

**sight**

See vision.

**sight, partial**

Loss of vision short of total blindness. Partial sight may involve loss of visual acuity and/or visual field.

**sigmoid colon**

The S-shaped part of the colon in the lower abdomen, extending from the brim of the pelvis, usually down to the third segment of the sacrum. It is connected to the descending colon above and the rectum below.

**sigmoidoscopy**

Endoscopy (examination with a viewing instrument) of the rectum and sigmoid colon (parts of the large intestine).

Sigmoidoscopy is used to investigate symptoms relating to the lower gastrointestinal tract, such as bleeding from the rectum or lower colon, and to look for evidence of disorders, such as polyps (small noncancerous growths), ulcerative colitis, or cancer (see colon, cancer of). Attachments on the end of the sigmoidoscope allow a biopsy (removal of a tissue sample for analysis) to be performed if necessary.

**sign**

An objective indication of a disease or disorder (for example, jaundice) that is observed or detected by a doctor, as opposed to a symptom (for example, pain), which is noticed by the patient.

**sign, vital**

See vital sign.

**sildenafil**

A drug used in the treatment of impotence. Commonly known by its brand name Viagra, sildenafil is available only on prescription due to the potential risk of serious side effects in certain people. Sildenafil should be avoided in people who have had a recent heart attack or those being treated with nitrate drugs.

**silent myocardial infarct**

A heart attack (see myocardial infarction) that occurs without the usual signs and symptoms (such as sudden chest pain).

**silicone**

A long-chain, carbon-containing compound of silicon and oxygen. Synthetic silicone implants are sometimes used in cosmetic surgery. Leakage can occur and may cause autoimmune disorders (in which the immune system attacks the body’s own tissues).

**silicosis**

A lung disease caused by the inhalation of dust containing silica from rock or sand. (See also pneumoconiosis.)
silver sulfadiazine
An antibacterial drug applied as a cream to prevent infection after skin grafts or in burns, leg ulcers, and pressure sores. Side effects may include permanent grey skin discoloration, rashes, or itching.

simian crease
A single deep, horizontal crease on the palm of the hand. This feature is associated with chromosomal disorders such as Down's syndrome.

simple linctus
See linctus.

simvastatin
A lipid-lowering drug that acts on the liver enzymes that produce cholesterol. Simvastatin may cause bowel upsets, headaches, and muscle pains. It may also raise liver enzyme levels, which must be monitored.

Sinemet
The brand name for co-careldopa, a preparation of levodopa and carbidopa, drugs for Parkinson’s disease.

sinew
A nonmedical term for a tendon.

singer’s nodes
Small, greyish-white nodules that develop on the vocal cords. Singer’s nodes are the result of constant voice strain, causing hoarseness or loss of voice.

A biopsy (removal of a sample of tissue for microscopic examination) may be carried out to exclude the possibility of a malignant tumour (see larynx, cancer of) being present. Treatment of acute cases of singer’s nodes consists of resting the voice. In chronic cases, surgical removal of the nodes may be necessary.

sinoatrial node
The natural pacemaker of the heart. The sinoatrial node consists of a cluster of specialized muscle cells in the right atrial wall. These cells emit rapid electrical impulses that initiate the heart’s contractions (beats). Various hormones and nervous system activities may alter the rate at which the node emits impulses. (See also heart rate.)

sinus
A cavity in a bone; in particular, one of the air-filled spaces in the bones surrounding the nose (see sinus, facial).

The term “sinus” also refers to any wide channel that contains blood, or to an abnormal, often infected, tract.

sinus arrhythmia
A normal variation in the heart rate that occurs with breathing and is particularly found in children and young adults. During inspiration (breathing in), the heart rate is increased; during expiration (breathing out) it decreases.

sinus bradycardia
A slow, but regular, heart rate (fewer than 60 beats per minute) that is the result of reduced electrical activity in the sinoatrial node. The symptom of sinus bradycardia is normal in athletes and people who are fit, but in others it may be caused by hypothyroidism, a myocardial infarction, or drugs such as beta-blockers or digoxin.
**sinus, facial**
Also referred to as a paranasal sinus, any of the air-filled cavities in the bones surrounding the nose. Facial sinuses include two frontal sinuses that are situated in the lower forehead; two ethmoidal sinuses between the eyes; two maxillary sinuses in the cheekbones; and the sphenoidal sinuses in the skull behind the nose. The sinuses decrease the weight of the skull and alter voice resonance. Each sinus is lined with mucous membrane; and mucus drains along a channel that opens into the nose.

**sinusitis**
Inflammation of the membrane that lines the facial sinuses (see sinus, facial). Sinusitis is most often due to infection, usually spread from the nose. The maxillary and ethmoidal sinuses are most commonly affected.

Sinusitis may cause pressure, headache, facial pain, and a feeling of fullness in the affected area; there may also be fever, a stuffy nose, and loss of the sense of smell. A common complication is the formation of pus, causing pain and nasal discharge.

Treatment of sinusitis is usually by steam inhalations and a decongestant, but in some cases antibiotics may be necessary. If sinusitis persists despite treatment, surgical drainage of the affected sinuses may be performed.

**sinus tachycardia**
A fast but regular heart rate (more than 100 beats per minute) due to increased electrical activity in the sinoatrial node. Such a heartbeat is normal in sudden stressful moments or during exercise. Persistent sinus tachycardia at rest may be caused by fever or hyperthyroidism.

**situs inversus**
An unusual condition in which the internal organs are situated in a mirror image of their normal positions. No treatment is needed provided that all the organs are functioning normally.

**Sjögren’s syndrome**
A condition, mostly affecting middle-aged women, in which the eyes and mouth are excessively dry. Other areas including the nasal cavity, throat, and vagina may also be affected. Sjögren’s syndrome tends to occur with certain autoimmune disorders (in which the immune system attacks the body’s own tissues), such as rheumatoid arthritis and
systemic lupus erythematosus. The dryness is due to destruction by the immune system of the lubricant-producing exocrine glands.

**skeletal muscle**
See: muscle.

**skeleton**
The framework of bones that gives the body its shape and provides attachment points for the muscles and underlying soft tissues. The average human adult skeleton has 213 bones (counting each of the nine fused vertebrae of the sacrum and coccyx as individual bones), joined to muscles by tendons, and joined with ligaments at sites called joints.

**STRUCTURE**
The skeleton consists of two main parts: the axial and appendicular skeletons.
- The axial skeleton comprises the skull, spine, ribs, and sternum (breastbone). Together, these total 87 bones: 29 in the skull (including the hyoid bone and three pairs of auditory ossicles); 33 in the spine (seven cervical, 12 thoracic, and five lumbar vertebrae, the five fused vertebrae of the sacrum, and the four fused vertebrae of the coccyx); and 25 in the chest (12 pairs of ribs and the sternum).
- The appendicular skeleton consists of the limb girdles (the shoulder and the pelvis) and their attached limb bones. Altogether there are 126 bones: 64 in the shoulders and upper limbs and 62

### DISORDERS AFFECTING THE SKIN

**Injury**
The skin is vulnerable to many minor injuries, including cuts and bites (see bites, animal; insect bites) as well as more serious wounds. Burns can be among the most serious of all skin injuries and may cause extensive scarring or death.

**Hormonal disorders**
Acne is partly related to the action of androgens (male sex hormones) on the sebaceous glands; it is particularly common among adolescents.

**Nutritional disorders**
Deficiency of vitamins A, B, and C can cause rashes and other problems.

**Impaired blood supply**
Leg ulcers, which are particularly common in the elderly, may be caused by poor blood flow to the skin as a result of atherosclerosis, by poor drainage of blood through varicose veins, or by the leg swelling associated with heart failure.

**Drugs**
Many drugs, including antibiotics, barbiturates, and sulphonamides, may cause a rash. Some cause urticaria (hives), others cause eczema or a measles-like rash, and some cause photosensitivity.

**Radiation**
All forms of radiation are potentially damaging to the skin. Overexposure to sunlight (ultraviolet radiation) causes premature aging of the skin and increases the risk of skin cancer (see sunlight, adverse effects of). High doses of other forms of radiation, such as X-rays, may cause severe injury to the skin and may lead to cancer.

### Autoimmune disorders
Many autoimmune disorders are systemic but have manifestations in the skin. They include lupus erythematosus, which may affect the skin alone or the skin and other organs; vitiligo, which is characterized by unpigmented patches and caused by destruction of the skin’s pigment cells; dermatomyositis, which is characterized by a specific skin rash and muscle weakness; morphea and systemic sclerosis, in which there is progressive hardening of the skin and other tissues; and pemphigoid and pemphigus, in which large blisters develop on the skin.

### Other disorders
A keloid is an abnormally large and protruding scar caused by the continuing production of scar tissue long after healing would usually be complete. Striae (stretch-marks) often develop during pregnancy and may also develop as a side effect of corticosteroid drugs.

Erythema simply means redness and has many possible causes. Purpura is a condition in which blood leaks into tissues, giving rise to petechiae (tiny pinpointsof blood) or larger bruises. Xanthelasma are fatty yellowish patches that tend to occur on the eyelids; they are associated with raised levels of cholesterol in the blood.

### INVESTIGATION
Most skin disorders can be diagnosed from their physical characteristics. A skin biopsy (removal of a tissue sample for microscopic analysis) may also be performed, usually to confirm the diagnosis of a skin problem or to exclude skin cancer.
in the pelvis and lower limbs. There are two bones in each shoulder: the clavicle (collarbone) and scapula (shoulderblade); three in each arm: the humerus (upper-arm bone) and radius and ulna (forearm bones); eight carpals in each wrist; five metacarpals in each palm; and 14 phalanges in the digits of each hand (two in each thumb and three in each finger).

The pelvic girdle is made up of two hip bones. There are 30 bones in each of the lower limbs: a femur (thighbone), patella (kneecap), and tibia and fibula (lower-leg bones) in each leg; seven tarsals in the ankle, heel (see calcaneus), and the back part of the foot; five metatarsals in the middle section of each foot; and 14 phalanges in the toes (two of which are in each big toe and three in each of the other toes).

There are minor differences between the skeletons of men and women. In general, men’s bones tend to be larger and heavier, but the female pelvic cavity is wider to facilitate childbirth.

FUNCTION
The skeleton plays an indispensable role in movement by providing a strong, stable, but mobile framework on which muscles can act to move the body. It also supports and protects internal body organs, notably the brain and spinal cord, which are encased in the skull and spine, and the heart and lungs, which are protected by the ribs.

However, the skeleton is not an inert frame. It is an active organ that produces blood cells (formed in bone marrow) and acts as a reservoir for minerals such as calcium, which can be drawn on, if required, by other parts of the body.

skin
The outermost covering of body tissue, which also forms the largest organ in the body. Skin has two layers: the epidermis (outer layer) and the dermis (inner layer), beneath which is the fatty subcutaneous tissue.

EPIDERMIS
The epidermis comprises sheets of flat cells, which resemble paving stones when viewed under the microscope. It varies in thickness, being thickest on the soles and palms and thinnest on the eyelids.

The outermost part of the epidermis is composed of dead cells, which form a tough, horny, protective coating. As these dead cells are worn away, they are replaced by new ones that are produced by the rapidly dividing living cells in the innermost part of the epidermis.

Between the outer and inner parts is a transitional region that consists of both living and dead cells.

Most of the cells produce the protein keratin, a tough substance that is the main constituent of the outermost part. Some of the cells make the pigment melanin, which protects the body from ultraviolet light in sunlight and determines skin colour.

DERMIS
The dermis is composed of connective tissue that is interspersed with hair follicles, sweat glands, sebaceous glands, blood and lymph vessels, and sensory receptors (specialized nerve structures) that are capable of detecting pressure, temperature, and pain.

FUNCTION
The skin’s most important function is a protective one. It acts as the main barrier between the environment and the internal organs of the body, shielding them from injury, the harmful rays of sunlight, and infection with microorganisms such as bacteria.

The skin is a sensory organ containing many cells that are sensitive to touch, temperature, pain, pressure, and itching. The skin also plays a role in keeping body temperature constant. When the body is hot, the sweat glands cool it by producing perspiration and the blood vessels in the dermis dilate (widen) to dissipate heat; if the body gets cold, blood vessels in the skin constrict (narrow), to conserve the body’s heat.

The epidermis contains a fatty substance that waterproofs the skin and stops it soaking up moisture like a sponge. The outer epidermis also has an effective water-holding capacity, which contributes to its elasticity and helps maintain the body’s balance of fluid and electrolytes. If the water content drops below a certain level, the skin becomes cracked and its barrier effect less efficient.

SKIN ALLERGY
Irritation of the skin following contact with an allergen (a substance that provokes an inappropriate reaction from the immune system).

There are two main types of allergic skin reaction. In contact allergic dermatitis, red, itchy patches develop a few hours to two days after skin contact. Trigger substances include adhesives in plasters, nickel in jewellery, and cosmetics. In contact urticaria, red, raised areas appear a few minutes after skin contact. Possible causes include certain chemicals, plants, and insect bites.

If possible, contact with the trigger substance should be kept to a minimum. In many cases the trigger is
obvious, but sometimes skin tests are needed to identify the allergen. (See also atopic eczema.)

**skin biopsy**
Removal of a portion of skin for laboratory analysis to diagnose a skin disorder.

**skin cancer**
A malignant skin tumour. Basal cell carcinoma, squamous cell carcinoma, and malignant melanoma (see melanoma, malignant) are forms associated with exposure to sun. Bowen’s disease, a rare disorder that can become cancerous, may also be related to sun exposure. Less common types include Paget’s disease of the nipple and mycosis fungoides. Kaposi’s sarcoma is a type usually found in AIDS patients. Most skin cancers are curable if treated early.

**skin flap**
A surgical technique in which a section of skin and underlying tissue, sometimes including muscle, is moved to cover an area from which skin and tissue have been lost or damaged by injury, disease, or surgery. Unlike a skin graft, a skin flap retains its blood supply. Therefore, skin flaps can be either attached (in which they remain attached to their donor site) or free (in which they are reattached to blood vessels at the recipient site by microsurgery). Skin flaps adhere well, even where there is extensive loss of deep tissue. For this reason, they may be used to cover areas that have lost their blood supply.

**skin graft**
A technique that is carried out in order to repair areas of lost or damaged skin that are too large to heal naturally, that are slow to heal, or that would otherwise leave tightening or unsightly scars. A skin graft is often used in the treatment of burns or sometimes for ulcers that are not healing.

A piece of healthy skin is detached from one part of the body and transferred to the affected area. New skin cells grow from the graft and cover the damaged area. In a meshed graft, donor skin is removed and made into a mesh by cutting. The mesh is stretched to fit the recipient site; new skin cells grow to fill the spaces in the mesh. In a pinch graft, multiple small areas of skin are pinched up and removed from the donor site. Placed on the recipient site, the new skin cells gradually expand to form a new sheet of healthy skin. (See also skin flap.)

**skin patch**
See transdermal patch.

**skin peeling, chemical**
A cosmetic procedure to remove acne scars, freckles, delicate wrinkles, or other skin blemishes. The procedure involves application of a caustic paste to peel away the outer layers of skin.

**skin tag**
A harmless, small, brown or flesh-coloured flap of skin that is often found on the neck, under the breasts, or in skin folds. A skin tag may appear spontaneously, or it may result from poor healing of a wound.

**skin tests**
Procedures to determine how the body reacts to various substances by applying them to the skin (usually on patches) or by injecting a small quantity of a substance under the skin. Patch tests are used in the diagnosis of contact allergic dermatitis; allergens will cause patches of reddened or blistered skin. Injections are used to help identify substances causing allergic illnesses such as asthma. They may also be used to test immunity to certain infectious diseases (as in the tuberculin test for tuberculosis).
skin tumour
A growth developing on or in the skin that may be cancerous (see skin cancer) or noncancerous. Keratoses and squamous papillomas are common types of noncancerous tumour; other types include sebaceous cysts, cutaneous horns, keratoacanthomas, and haemangiomas.

skull
The bony skeleton of the head, which protects the brain; houses the special sense organs (eyes, ears, tongue, and nose); provides points of attachment for facial, scalp, and neck muscles; and forms part of the respiratory and digestive tracts.

STRUCTURE
All the skull bones, except the mandible (lower jaw) are fixed to one another by immovable sutures; the skull bones do not fuse until about 18 months of age (see fontanelle). The cranial cavity houses the brain; other skull structures include the nasal cavity and eye orbits.

Several of the skull bones, especially those around the nasal area, contain sinuses (air spaces). In the cranium, there are many holes for the passage of nerves and blood vessels. The largest of the holes, called the foramen magnum, is situated in the occipital bone (which forms part of the base and back of the cranium); this hole allows the brainstem to enter the spinal canal, where it continues as the spinal cord.

The skull rests on the atlas (the first cervical vertebra), which is a ring-shaped bone that articulates with the occipital bone and permits nodding movement of the head. Turning the head is a function of the joint between the atlas and the second cervical vertebrae, which is called the axis. The occipital bone, atlas, and axis are connected together by numerous small muscles.

DISORDERS
The skull may be affected by any disorder that involves the skeleton, such as Paget’s disease, but the most common disorder is injury. A blow to the head may cause a fracture (see skull, fracture of), possibly leading to brain damage. (See also head injury.)

skull, fracture of
A break occurring in one or more of the skull bones as a result of a head injury. In most skull fractures, there are no complications. In a severe injury, however, the broken bones may be displaced. If this happens, bone fragments may rupture blood vessels in the meninges (the membranes covering the brain) or, rarely, tear the meninges, resulting in bleeding and, in some cases, brain damage.

An uncomplicated fracture of the skull usually heals by itself. However, if there is any damage to brain structures neurosurgery is often required. (See also depressed skull fracture; extradural haemorrhage; subarachnoid haemorrhage; subdural haemorrhage).
**skull X-ray**
A technique for providing images of the skull. The X-rays are taken after some cases of head injury to look for a fracture or foreign body, or to evaluate disorders affecting the skull bones.

**slapped cheek syndrome**
Another name for *fifth disease*. Slapped cheek syndrome is an infection caused by erythrovirus, in which the predominant feature is reddening of the cheeks.

**SLE**
The abbreviation for the disorder systemic lupus erythematosus.

---

**FUNCTIONS OF SLEEP**
Sleep is a fundamental human need, as is shown by the detrimental effects of sleep deprivation. The way in which sleep is beneficial is not understood, however.

**SLEEP REQUIREMENTS**
The need for sleep decreases with age. A one-year-old infant needs about 14 hours of sleep a night, a five-year-old child about 12 hours, and adults seven or eight hours on average. (Some adults, however, need more than 10 hours’ sleep, while others can manage on five hours or less.) Elderly people tend to sleep less than young adults at night, but doze during the day.

**SLEEP DISORDERS**
Sleep disorders are divided into four main categories: difficulty in falling or remaining asleep (see *insomnia*); difficulty in staying awake (see *narcolepsy*); disruption of the sleeping/waking cycle, for example, by working shifts or traveling across time zones (see *jet-lag*); and other miscellaneous problems such as bedwetting, night terrors, or sleepwalking. (See also *sleep apnoea*.)

**sleep apnoea**
A disorder in which breathing briefly stops several times (for periods of 10 seconds or longer) during sleep. Affected people may not be aware of any problem during the night, but may be sleepy during the day, with poor memory and concentration. Severe sleep apnoea is potentially serious; it may lead to hypertension, heart failure, myocardial infarction (heart attack), or stroke.

Obstructive sleep apnoea is the most common form. It may affect anyone, but more often occurs in middle-aged men, especially those who are overweight. The most common cause is over-relaxation of the muscles of the soft palate; another possible cause is enlarged tonsils or adenoids. These problems cause obstruction of the airway,
and result in snoring. If complete blockage occurs, breathing stops. This triggers the brain to restart breathing; the person may gasp and wake briefly.

In central sleep apnoea, breathing stops because the chest muscles and diaphragm muscle temporarily cease to work, probably due to a disturbance in the brain’s control of breathing. Causes include paralysis of the diaphragm and disorders of the brainstem (the part of the brain that controls breathing). Snoring is not a main feature.

Overweight people may find that losing weight helps. (In contrast, alcohol and sleeping drugs aggravate sleep apnoea.) In one treatment, air from a compressor is forced into the airway via a mask worn over the nose. Night-time artificial ventilation may be needed. Tonsillectomy, adenoidectomy, or surgery on the soft palate may be performed.

**sleep deprivation**

Insufficient sleep. Irritability and a shortened attention span may occur after a short night’s sleep. Longer sleepless periods leave a person less able to concentrate or perform normal tasks. Three or more sleepless nights may lead to hallucinations and, sometimes, to paranoia.

**sleeping drugs**

**COMMON DRUGS**

BENZODIAZEPINE DRUGS  • Flurazepam  • Loprazolam  • Lormetazepam  • Nitrazepam  • Temazepam

OTHERS  • Clomethiazole  • Diphenhydramine  • Promethazine  • Zolpidem  • Zopiclone

A group of drugs that are used for the treatment of insomnia. Sleeping drugs include benzodiazepine drugs; antihistamine drugs, which are often available over-the-counter; antidepressant drugs; and chloral hydrate. These drugs promote sleep by reducing the activity of nerve cells in the brain.

Sleeping drugs should always be taken in the smallest effective dose for the shortest period of time. In general, they should be used for no more than three weeks, and preferably not every night. Sleeping drugs do not treat the underlying cause of insomnia, which needs to be investigated.

**ADVERSE EFFECTS**

Sleeping drugs may cause drowsiness, unsteadiness, and impaired concentration on waking. They can be especially hazardous to anyone driving or operating machinery. Long-term use may induce tolerance (needing a higher dose to achieve the same effect) and dependence (withdrawal symptoms when the person stops taking the drug).

**sleeping sickness**

A serious infectious disease of tropical Africa caused by the protozoan parasite Trypanosoma brucei, which is transmitted to humans by the bite of a tsetse fly.

One form of the disease, which occurs in West and Central Africa, takes a slow course, with bouts of fever and lymph-node enlargement. After months or years, the disease spreads to the brain, causing headaches, confusion, and, eventually, severe lassitude. Without treatment, coma and death follow. The other, East African, form runs a faster course. Fever develops after a few weeks of infection, and the heart may suffer fatal effects before the disease has reached the brain.

Drugs may effect a cure, but there may be residual brain damage if the infection has already spread to the brain. People in infested areas should wear long clothing fastened at the wrists and ankles to help prevent tsetse fly bites.

**sleep paralysis**

The sensation of being unable to move at the moment of going to sleep or waking up. It usually lasts only a few seconds, and may be accompanied by hallucinations. Sleep paralysis most often occurs in people with narcolepsy.

**sleep terror**

See night terror.
**LIFE-CYCLE OF TRYPANOSOMES IN SLEEPING SICKNESS**

The life-cycle of the trypanosomes that cause sleeping sickness is shown. They multiply in a person’s blood and lymph vessels and may spread to the brain or heart with serious effects.

**sleepwalking**
Walking while asleep, also known as somnambulism. It occurs during NREM (nonrapid eye movement) sleep, or during arousal from this type of sleep, and does not represent the acting out of dreams. Some people regularly sleepwalk. Usually a sleepwalker gets calmly out of bed, wanders around aimlessly for a few minutes, and then goes back to bed. Sometimes, however, sleepwalking occurs with night terror, in which case the person may show distress or cry out. Waking a sleepwalker can be difficult and is not necessary; he or she should simply be steered gently back to bed.

In children, sleepwalking is not normally a cause for concern and tends to disappear with age. In adults, it may be related to anxiety or the use of sleeping drugs, especially in the elderly.

**slimming**
See: weight reduction.

**sling**
A triangular bandage used to immobilize, support, or elevate an injured arm. The arm may be supported horizontally or held elevated, depending on the injury.

**slipped disc**
See: disc prolapse.

**slipped femoral epiphysis**
See: femoral epiphysis, slipped.

**slit-lamp**
An illuminated type of microscope that is used to examine the internal structures of the front part of the eye. A slit-lamp may also be used to view the retina at the back of the eye. (See also eye, examination of.)

**slough**
Dead tissue that has been shed from its original site; for example, dead cells from the skin’s surface. Sloughing is also part of the healing process.

**Slow-Fe Folic**
A brand name for a vitamin and mineral supplement containing folic acid and iron.

**Slow-K**
A brand name for a mineral supplement containing potassium.

**slow virus diseases**
A group of diseases of the central nervous system that occur many months or even years after infection with a virus. They cause gradual widespread destruction of nerve tissue, with progressive loss of brain function and a fatal outcome. Examples include Creutzfeldt–Jakob disease and kuru.

**small cell carcinoma**
The most rapidly spreading and dangerous form of lung cancer.

**small intestine**
The section of the digestive tract (see digestive system) that lies between the stomach and large intestine. The small intestine, which consists of the duodenum, jejunum, and ileum, is the area in which nutrients are extracted from food and absorbed into the body.

**smallpox**
A highly infectious disease, caused by the variola virus, that was declared to be eradicated in 1980 following a global vaccination campaign.

Smallpox was transmitted from person to person. It caused an illness resembling influenza and was characterized by a rash that spread over the body and eventually developed into pustulated blisters. The blisters became crusted and would sometimes leave deeply pitted scars. Complications included blindness, pneumonia, and kidney damage. There was no effective treatment for the disease, which killed up to 40 per cent of its victims.

Eradication of smallpox was achieved through cooperative international use of a highly effective vaccine. Routine vaccination has now been discontinued throughout the world. Recently, however, vaccination is being considered in certain circumstances (see bioterrorism).

**smear**
A specimen for microscopic examination prepared by spreading a thin film of cells (such as blood cells) on to a glass slide. Common types of smear include cells collected from the inside of the cheek (known as a buccal smear), the neck of the uterus (see cervical smear test).

**smegma**
An accumulation of sebaceous gland secretions under the foreskin in an uncircumcised male, usually due to poor hygiene. Fungal or bacterial infection of smegma may cause balanitis (inflammation of the foreskin and the head of the penis).

**smell**
One of the five senses. In the nose, hair-like projections from smell receptor cells lie in the mucous membrane. When the receptors are stimulated by certain molecules, they transmit impulses along the olfactory nerves to the smell centres in the limbic system and the temporal and frontal lobes of the brain, where smell is perceived.
Loss of sense of smell may result from inflammation of the nasal membrane, as in a common cold; cigarette smoking; hypertrophic rhinitis, in which a thickened nasal membrane obscures olfactory nerve endings; atrophic rhinitis, in which the nerves waste away; head injury that tears the nerves; or a tumour of the meninges (membranes covering the brain) or nasopharynx (upper part of the throat).

The perception of illusory, unpleasant odours may be a feature of depression, schizophrenia, some forms of epilepsy, or alcohol withdrawal.

smelling salts
A preparation of ammonia that was once used to revive a person who felt faint.

Smith’s fracture
A break that occurs in the lower part of the radius (one of the two bones of the forearm) in which the fragment underneath the fracture is displaced forwards. The wrist joint is deformed, but in contrast to a Colles’ fracture (a type of wrist fracture), the hand and wrist are moved forward of their normal position. This type of fracture usually results from a fall on to the back of the hand, which caused bending of the wrist joint forwards so that it breaks.

smoking
Inhalation of tobacco smoke from cigarettes, cigars, or pipes. More than 100,000 deaths per year in the UK are attributed to smoking. It causes serious diseases such as lung cancer, bronchitis, emphysema, coronary artery disease, and peripheral vascular disease, and also increases the risk of mouth cancer, lip cancer, and throat cancer (see pharynx, cancer of).
SMOOTH MUSCLE

EFFECTS OF SMOKING

About 20 per cent of all deaths in the UK are attributed to smoking. The main harmful effects of smoking are respiratory diseases (lung cancer and COPD) and cardiovascular diseases (coronary artery disease and peripheral vascular disease). Smoking also causes a range of other cancers, including cancer of the bladder, cervix, tongue, larynx, and stomach. Smoking kills around half of all smokers.

Smoking is extremely harmful during pregnancy. Babies of women who smoke are smaller and are less likely to survive than those whose mothers are nonsmokers. Children with parents who smoke are more likely to suffer from asthma or other respiratory diseases.

There is also evidence that passive smokers are at increased risk of tobacco-related disorders. Also, passive smokers suffer immediate discomfort when breathing in smoke as demonstrated by coughing, wheezing, and sore eyes.

Tobacco is known to contain many toxic chemicals. Addiction to tobacco is caused by nicotine. Nicotine acts as a tranquilizer but also stimulates the release of adrenaline into the bloodstream, which can raise blood pressure. Tar in tobacco produces chronic irritation of the respiratory system and is thought to be a major cause of lung cancer. Carbon monoxide passes from the lungs into the bloodstream, where it easily combines with haemoglobin in red blood cells, interfering with oxygenation of tissues. In the long term, persistently high levels of carbon monoxide in the blood cause hardening of the arteries, which greatly increases the risk of coronary thrombosis.

smooth muscle
A type of muscle.

snails and disease
Snails act as host to a variety of flukes, such as liver flukes, that infest humans.

snail track ulcer
A shallow, greyish mouth ulcer. Snail track ulcers are a characteristic symptom that occur during the secondary stage of syphilis.

snake bites
Every year, hundreds of thousands of people all over the world are bitten by snakes, but the chance of death or serious injury following a bite is relatively small. Most bites are by nonvenomous species of snake; furthermore, medical treatment of poisonous bites is usually effective, provided the victim can be taken to hospital quickly. Even the most powerful snake venom takes hours or days to kill a human being.

VENOMOUS SPECIES
Venomous snakes are found mainly in the tropics; the only poisonous species native to the UK is the adder, a member of the Viperidae (viper family). Round the world, this group of snakes includes lance-headed vipers, water moccasins (cottonmouths), and American rattle-snakes. The saw-scaled or carpet viper, which is native to parts of Africa, the Middle East, and the Indian subcontinent, probably kills more people than any other species of snake.

Another group of venomous snakes, Elapidae, includes cobras, coral snakes, kraits, and mambas. Venomous bites are caused by other snakes including Atractaspididae (burrowing asps), Hydrophididae (sea snakes), and a relatively small number of the Colubridae family.

EFFECTS OF A BITE
The effects of a venomous bite depend on the species and size of the snake, the amount of venom injected, and the age and health of the victim.

A bite from a viper such as a rattle-snake is characterized by two distinct puncture wounds. Typically, there is an immediate burning pain and swelling at the site, followed by dizziness and nausea. The blood pressure drops and heart rate increases. A pins-and-needles sensation, thirst, and headache are other common symptoms. The venom may prevent the blood from clotting, causing bleeding from the wound and bruising under the skin. There may also be internal bleeding from the urinary tract, mouth, rectum, or vagina.

Elapidae also make puncture wounds but may chew the skin. Their venom primarily affects the nervous system. Serious symptoms develop from 10 minutes to eight hours after the bite and may include drooping eyelids, slurred
speech, and double vision. The victim becomes drowsy or delirious and may have convulsions. If treatment is not given, respiratory paralysis will eventually lead to death.

**TREATMENT**
Snakebite victims need medical help as quickly as possible. *Antibiotic drugs* and *tetanus* antitoxin injections are given for all bites, venomous or not, to prevent infection and tetanus. For a venomous bite, an injection of *antivenom* (a serum that contains antibodies against the poison) is given. Most victims recover completely with prompt treatment.

**sneezing**
An involuntary expulsion of air through the nose and mouth as a result of irritation of the upper respiratory tract. Sneezing may result from the common *cold*, allergic *rhinitis*, the presence of mucus, or inhaling an irritant substance.

**Snellen chart**
A method of measuring *visual acuity* used during *vision tests*. The Snellen chart has several rows of letters, of standard sizes, with each row smaller than the one above. The patient is positioned 6 m from the chart, then each eye in turn is covered and the patient is asked to read down the chart as far as possible with the open eye.

**snoring**
Noisy breathing through the open mouth produced by vibrations of the soft palate during sleep. Snoring is often caused by a condition that hinders breathing through the nose, such as a *cold*, allergic *rhinitis*, or enlarged *adenoids*. It is also a feature of *sleep apnoea*. Snoring is more common in people sleeping on their backs. If the underlying cause can be treated, it may stop.

**snow-blindness**
A common name for actinic *keratopathy*.

**snuff**
A preparation of powdered *tobacco* (often with other substances) for inhalation. Snuff is addictive because it contains *nicotine*; it also irritates the nasal lining and increases the risk of cancer of the nose and throat.

**snuffles**
A general term that is used to describe nasal obstruction, especially that occurring in infants suffering from an upper *respiratory tract infection*.

**soap**
A substance made from fat (often vegetable oil or purified animal fat) and alkali that is used to cleanse the body.

**social and communication disorders**
A collective term for disorders such as *Asperger’s syndrome* and *autism*, which are marked by difficulties in social interaction with obsessive behaviour. Problems begin in childhood and tend to persist throughout life.

**social skills training**
A type of behaviour modification in which individuals are encouraged to improve their ability to communicate. It is an important part of *rehabilitation* for people with *learning difficulties* or those with chronic psychological disorders, such as *schizophrenia*. *Role-playing* is a commonly used technique in which various social situations are simulated in order to improve the individual’s confidence and performance.

**sociopathy**
An outdated term for *antisocial personality disorder*.

**sodium**
A *mineral* that helps to regulate the body’s water balance and maintain normal heart rhythm. Sodium is also involved in the conduction of nerve impulses and contraction of muscles. The level of sodium in the blood is controlled by the kidneys, which eliminate any excess in the urine. Almost all foods contain sodium naturally or as an ingredient added during processing or cooking; the main forms are sodium chloride (salt) and sodium bicarbonate. Consequently, deficiency is rare and usually results from excessive loss of sodium through persistent diarrhoea or vomiting, or profuse sweating. Signs include weakness, dizziness, and muscle cramps. In severe cases, there may be a drop in blood pressure, leading to confusion, fainting, and palpitations.

Treatment is with supplements, which, in hot climates, may help to prevent *heat disorders* by compensating for sodium lost through heavy sweating. Excessive intake of sodium is thought to be a contributory factor in *hypertension* (high blood pressure). Another adverse effect is fluid retention, which may cause dizziness and swelling of the legs in severe cases.

**sodium aurothiomalate**
An injected preparation of *gold*.

**sodium bicarbonate**
An alkali used to neutralize acid in *cystitis* and severe *acidosis* (blood acidity) in kidney failure. It is also an ingredient in over-the-counter *antacid drugs* for *indigestion, heartburn*, and *peptic ulcer*. Sodium bicarbonate often causes symptoms such as belching and abdominal discomfort. Long-term use can cause swollen ankles, muscle cramps, tiredness, and nausea.

**sodium citrate**
A drug used to relieve discomfort in urinary infections such as *cystitis*, by making the urine less acidic.

**sodium cromoglicate**
An injected preparation of *gold*. A drug given by inhaler to control mild *asthma* in children and allergic or exercise-induced asthma in adults. The drug is also used as a nasal spray to treat allergic *rhinitis*, in eye-drops for allergic *conjunctivitis*, and orally for *food allergy*. Side effects include coughing and throat irritation on inhalation of powder.

**sodium picosulfate**
A stimulant *laxative* drug used to treat *constipation* and to empty the bowel prior to procedures such as *X-ray, endoscopy*, and intestinal surgery. Side effects may include abdominal cramps and diarrhoea. The drug should be avoided in cases of intestinal obstruction.

**sodium valproate**
An *anticonvulsant drug* used to treat *epilepsy*. Side effects may include drowsiness, abdominal discomfort, temporary hair loss, weight gain, and rash. Long-term treatment may, rarely, cause liver damage.

**Sofradex**
A brand name for the corticosteroid drug *dexamethasone* used as drops or ointment to treat inflammatory conditions of the ears and eyes.

**soft-tissue injury**
Damage, such as a *sprain* or *tendinitis*, to the tissues (such as *ligaments, tendons*, or *muscles*) that surround bones and joints. (See also *sports injuries*.)

**soiling**
Inappropriate passage of *faeces* that, in children, occurs after the age at which bowel control is achieved (usually
at about two or two and a half years). It can also occur in elderly people and those with physical or mental disability.

Causes include slowness in developing bowel control, longstanding constipation (in which faecal liquid leaks around hard faeces blocking the large intestine), poor toilet-training, and emotional stress (caused, for example, by starting school). Soiling due to constipation is usually resolved with treatment. If no physical cause can be found, a course of psychotherapy may help.

Encopresis is a type of soiling in which children deliberately pass faeces in inappropriate places, such as behind furniture. Such children have no specific physical problem, but often refuse to use a potty or toilet. Encopresis usually improves with time and is rare after the age of 10.

**solar keratosis**

A crumbly yellow-white crust occurring on the skin in older people as a result of repeated overexposure to sunlight. The skin growth is also known as an actinic keratosis.

**solar lentigo**

Also known as a liver spot, a flat, brown frecklelike patch that appears on exposed skin. Solar lentigos occur in older white people. (See also lentigo.)

**solar plexus**

The largest network of autonomic nerves in the body, located behind the stomach between the adrenal glands. The solar plexus incorporates branches of the vagus nerve and the splanchnic (visceral) nerves, and sends branches into the stomach, intestines, and other abdominal organs.

**Solvadeine**

A brand-name analgesic drug (pain-killer) containing paracetamol, caffeine, and codeine.

**solvent abuse**

The practice of inhaling the intoxicating fumes given off by certain volatile liquids. Glue-sniffing is the most common form. The usual method of inhalation is from a plastic bag containing the solvent, but sometimes aerosols are sprayed into the nose or mouth. Solvent abuse is usually a group activity, especially among boys.

Inhalation of solvent fumes produces a feeling of intoxication similar to that produced by alcohol. Solvent abuse can cause headache, vomiting, confusion, and coma. Death may occur due to a variety of reasons including a direct toxic effect on the heart, a fall, choking on vomit, or asphyxiation by a clinging plastic bag. The effects of repeated solvent abuse include erosion of the lining of the nose and throat, and damage to the kidneys, liver, and nervous system.

The signs of solvent abuse include intoxicated behaviour, a flushed face, ulcers around the mouth, a smell of solvent, and personality changes, such as moodiness and nervousness. Acute symptoms such as vomiting or coma require urgent medical attention. In the longer term, counselling may be helpful in discouraging the behaviour.

**somatostatin analogues**

Synthetic versions of somatostatin, a hormone that acts on the pituitary gland controlling the release of growth hormone. The drugs are used to treat acromegaly and symptoms associated with some other hormone-secreting tumours (particularly in carcinoid syndrome). Octreotide is a common somatostatin analogue.

**somatotype**

A person’s physical build.

**somatropin**

A synthetic growth hormone given to children to treat short stature as a result of growth-hormone deficiency.

**somnambulism**

See sleepwalking.

**sorbitol**

A carbohydrate that is used as a substitute for cane sugar in foods manufactured for diabetics. Sorbitol is also used in disorders of carbohydrate metabolism and in drip feeding. (See also artificial sweeteners.)

**sore**

A term that is used to describe any disrupted area of the skin or mucous membranes. The word is also used as a description of an unpleasant feeling of pain or tenderness.

**sore throat**

A rough or raw feeling in the back of the throat that causes discomfort, especially when swallowing.

Sore throat is a common symptom, usually caused by pharyngitis and occasionally by tonsillitis. It is often the first symptom of the common cold, influenza, laryngitis, infectious mononucleosis, and many childhood viral illnesses, such as chickenpox, measles, and mumps.

A sore throat may be relieved by gargling with salt water. Sore throats that are due to bacterial infection are usually treated with antibiotic drugs. (See also strep throat.)

**space medicine**

A medical speciality that is concerned with the physiological effects of space flight. Examples are the effects of acceleration or motion sickness that are caused by weightlessness.

**spacer device**

A plastic device that is used to aid the delivery of drugs from metered-dose inhalers as part of the treatment of asthma and other lung conditions. The mouthpiece of the inhaler is slotted in to one end of the spacer and the user’s mouth is positioned tightly over the other end. During administration of a dose, the inhaler is compressed so that the drug enters the air in the spacer, then the user breathes in and out slow-
ly, drawing the drug particles into the lungs. A valve prevents the gas from escaping out of the spacer except during the time it is being inhaled through the mouthpiece. Spacers are particularly helpful for people who have difficulty coordinating their breathing with activating an inhaler.

**Spasm**

An involuntary contraction of a muscle. Spasms are not necessarily painful. Examples of spasm include cramps (often affecting the calf muscles), hiccups (in which the diaphragm goes into spasm) and tics (which frequently affect the facial muscles).

Less commonly, a spasm may be caused by an abnormality in the central nervous system (brain and spinal cord) or a symptom of a muscle disorder. Spasms caused by disease of the nervous system include myoclonus and chorea. Other disorders that are characterized by spasm include trigeminal neuralgia (affecting the muscles of the face and head), tetany (spasm caused by a drop in blood calcium level), and tetanus (a serious bacterial infection). Bronchospasms is a contraction of muscles in the small airways of the lungs that occurs in asthma. In vasospasm (which is one of the symptoms of Raymond’s disease) there is a tightening of the muscles in the walls of blood vessels.

**Spasms, clonic**

A type of spasm in which the affected muscle undergoes rapid contractions and relaxations. (See also clonus.)

**Spasms, facial**

See tic.

**Spasms, infantile**

A severe condition that affects infants and is associated with deterioration of brain function. The spasms involve forward flexion of the head, neck, and trunk and extension or flexion of the arms and legs.

**Spasms, tonic**

A prolonged, involuntary muscular contraction. (See also tetany; tetanus; tonic–clonic seizure.)

**Spastic diplegia**

Also called spastic paraplegia, a condition in which the lower body muscles are paralysed and abnormally rigid.

**Spasticity**

Increased rigidity in a group of muscles, causing stiffness and restricted movement. It occurs in Parkinson’s disease, multiple sclerosis, cerebral palsy, and tetanus.

**Spastic paralysis**

Inability to move a part of the body, accompanied by rigidity of the muscles. Causes of spastic paralysis include stroke, cerebral palsy, and multiple sclerosis. (See also paralysis.)

**Specific gravity**

The ratio of the density of a substance to that of water. The specific gravity of urine, for example, indicates whether the urine has a large amount of material dissolved in it (near 1.030) or whether it is almost water (near 1.010).

**Specific learning disability**

Difficulty in one or more areas of learning in a child of average or above-average intelligence. Specific learning disabilities include dyslexia, in which the child cannot recognize letters, and dyscalculia, in which the child has a problem with mathematics.

**Specimen**

A sample of tissue, fluids, waste products, or an infective organism taken from the body for analysis, identification, and/or diagnosis. The specimen may be prepared in a particular way for examination under a microscope.

**SPECT**

The abbreviation for single photon emission computed tomography, a type of radionuclide scanning.

**Spectacles**

See glasses.

**Speculum**

A device for holding open an orifice (body opening) to enable a doctor to perform an examination. For example, a speculum is used to perform a cervical smear or gynaecological swab.

**Speech**

A system of sounds by which humans communicate. Speech involves the muscles that are used in breathing and the larynx (voicebox), tongue, palate, lips, jaw, and face.

**Speech production**

The production of speech sounds originates in two regions of the cerebral cortex, on each side of the brain, that are linked to the centre for language expression (Broca’s area) in the dominant
hemisphere of the brain. The areas send signals down nerve pathways to muscles controlling the larynx, tongue, and other parts involved in speech; the cerebellum, at the back of the brain, plays a part in coordinating movements of these parts. Air from the lungs is vibrated through the vocal cords in the larynx. The vibration produces a noise that is amplified in the cavities of the throat, nose, and sinuses. The vibrated air is shaped by movements of the tongue, mouth, and lips in order to produce speech sounds.

Children learn speech by listening to and imitating the speech of others. Normal speech development occurs in several stages (see Speech development in childhood table, previous page). It depends on maturation of the child’s nervous system and muscles, normal hearing, and the child’s interaction with other people and the environment.

speech disorders
Defects or disturbances in speech that lead to inability to communicate effectively. Some of these disorders are more accurately described as disturbances of language rather than speech, as they are caused by impaired ability to understand or to form words in the language centres of the brain, rather than any fault of the apparatus of speech production. Most people who have speech disorders can be helped with the use of speech therapy.

DISORDERS OF LANGUAGE
Damage to the language centres of the brain (usually due to a stroke, head injury, or brain tumour) leads to dysphasia (difficulty with, or disorder of, language skills). Both children and adults can be affected. The ability to speak and write and/or to comprehend written or spoken words is impaired to a varying degree, depending on the site and extent of the damage.

Delayed development of language in a child is characterized by slowness to understand speech and/or slow growth in vocabulary and sentence structure. Delayed development has many causes, including hearing loss (see deafness), lack of stimulation, or emotional disturbance (see developmental delay).

DISORDERS OF ARTICULATION
Articulation is the ability to make speech sounds. A defect of articulation is sometimes referred to as dysarthria. Damage to nerves passing from the brain to muscles in the larynx (voicebox), mouth, or lips can make speech slurred, indistinct, slow, or nasal. The causes of the damage are similar to those that cause aphasia or dysphasia (including stroke, head injury, multiple sclerosis, or Parkinson’s disease), although they affect different regions of the brain. A structural abnormality of the mouth, such as a cleft lip and palate, can also be a cause of poor articulation.

DISORDERS OF VOLUME PRODUCTION
Disorders of voice production include hoarseness, inappropriate pitch or loudness, and abnormal nasal resonance. In many cases, the cause is a disorder affecting closure of the vocal cords (see larynx, disorders of). A voice that is too high or too low or too soft or loud may be caused by a hormonal or psychiatric disturbance or by hearing loss.

Abnormal nasal resonance is caused by too much air (hypernasality) or too little air (hyponasality) flowing through the nose during speech. Hypernasality may result from damage to the nerves supplying the palate (roof of the mouth) or from cleft palate, and causes deterioration in the intelligibility of speech. Hyponasality is caused by blockage of the nasal airways which may be a result of congestion or excess mucus.

DISORDERS OF FLUENCY
Disorders of fluency include stuttering, which is marked by hesitant speech and sound repetition. The underlying cause of such problems is not understood.

speech therapy
A form of treatment for people who suffer from a speech disorder. A speech therapist tests speech and hearing and devises exercises to improve the deficient aspect of speech.

sperm
The male sex cell, also called a spermatozoon (or spermatozoa in the plural), which is responsible for fertilization of the female cell (ovum). Each sperm is about 0.05 mm long and consists of a head, which contains genetic material, and a tail, which propels the sperm through the woman’s reproductive tract after ejaculation. The top of the sperm’s head contains enzymes that enable it to penetrate the ovum’s outer covering.

Sperm production starts at puberty. The sperm are formed in the seminiferous tubules of the testes and mature in the epididymis, just behind each testis. This process depends on testosterone and gonadotrophin hormones secreted by the pituitary gland. Oligospermia (low sperm count) or azoospermia (absence of sperm) can be causes of infertility. (See also reproductive system, male; semen analysis.)

spermatocoele
A harmless cyst of the epididymis (the tube that conveys sperm from the testis) containing fluid and sperm. A very large or uncomfortable spermatocoele is usually removed surgically.

spermatocoza
See sperm.

spermicides
Contraceptive preparations in the form of creams, gels, foams, and pessaries that kill sperm. They are usually recommended for use with a barrier device such as a condom or diaphragm.

SPF
The abbreviation for sun protection factor.

sphenoid bone
A bone at the base of the cranium (the part of the skull holding the brain). It contains the sphenoidal sinuses (see.
sphincter, hereditary
An inherited disorder in which there are a large number of unusually small, round red blood cells (spherocytes) in the circulation. These abnormal cells are fragile and easily broken up when blood passes through the spleen. At times, the rate of red blood cell destruction (haemolysis) exceeds the rate at which new cells can be made in the bone marrow, leading to anaemia.

SYMPTOMS
The characteristic symptoms of anaemia, such as tiredness, shortness of breath, and pallor, may develop. Other symptoms include jaundice (yellowing of the skin and whites of the eyes) and enlargement of the spleen. Occasionally, crises occur (usually triggered by infection) in which all of the symptoms worsen. Gallstones are a frequent complication of hereditary spherocytosis.

DIAGNOSIS AND TREATMENT
The diagnosis of spherocytosis is made by blood tests. Splenectomy (removal of the spleen) usually leads to permanent improvement.

sphincter
A ring of muscle around a natural body opening or passage that regulates inflow or outflow, such as the anal sphincter.

sphincter, artificial
A surgically created valve or other device used to treat or prevent urinary or faecal incontinence.

sphincterotomy
A surgical procedure that involves cutting a sphincter muscle that closes a body opening or constricts the opening between body passages.

sphymgmanometer
An instrument for measuring blood pressure. A cuff attached to the device is wrapped around a person’s arm and inflated until it compresses the main artery in the arm; it is then deflated while the user listens to the blood flow with a stethoscope. Depending on the device used, the blood pressure measurement may be read off a graduated, mercury-filled glass column, a graduated dial, or a digital display.

spider bites
Almost all spiders produce venom, which they use to kill their prey. Only a few species, such as the black widow in North America, are harmful to humans, however. Antivenoms are available as an antidote for many of the potentially fatal spider bites.

spider naevus
A red, raised pinhead-sized dot, from which a number of small blood vessels radiate. A spider naevus is formed by a dilated minor artery and its connecting capillaries. Small numbers of spider naevi are common in children and pregnant women, but larger numbers may indicate liver disease.

spina bifida
A congenital defect in which one or more of the vertebrae fails to develop completely in a fetus. As a result, when the baby is born a portion of the spinal cord is left exposed. Spina bifida is a type of neural tube defect.

spinal anaesthesia
Injection of an anaesthetic into the cerebrospinal fluid in the spinal canal to block pain sensations before they reach the central nervous system. Spinal anaesthesia is used mainly during surgical procedures on the lower abdomen and legs and in obstetrics. (See also epidural anaesthesia.)

spinal canal decompression
see decompression, spinal canal.

spinal cord
A cylinder of nerve tissue, about 45 cm long and about the width of a finger, that runs from the brain down the central canal in the spine to the first lumbar vertebra. Below that point, the lowest nerve roots continue within the canal as the cauda equina. The spinal cord is a major component of the central nervous system.
**STRUCTURE**

At the core of the spinal cord is grey matter, which contains the cell bodies of nerve cells, along with supporting cells. Some of the nerve cells are motor neurons from which long projecting fibres (called axons) pass out of the spinal cord in bundles with the spinal nerves, branching to supply a fairly distinct segment of trunk. Those emerging from the top and bottom of the spine join to form networks, called plexuses, from which branches arise to supply the arms and legs.

Spinal nerve roots. These combine to form the spinal nerves, which link the cord to all areas of the trunk and limbs. The cord is bathed in cerebrospinal fluid and surrounded by three protective membranes known as the meninges.

**FUNCTION**

The nerve tracts in the white matter act mainly as highways for sensory information passing up to the brain or motor signals passing down; however, the cord processes some sensory information, and provides motor responses, without any involvement of the brain. Many reflex actions are controlled in this way.

**DISORDERS**

The spinal cord may be injured by trauma to the spine (see spinal injury). Severing of nerve tracts interrupts communication between the brain and the parts of the body served from the section of the cord below the injury. This can lead to various types of paralysis and/or loss of sensation, which are usually permanent because nerve cells and fibres within the cord are not able to regenerate. However, the reflexes that are controlled by the spinal cord are usually maintained. Pressure on the cord, which may be caused by a blood clot or a tumour, for example, can also
The spine is made up of a column of 33 roughly cylindrical bones called vertebrae. Running through the centre of this bony structure is the spinal cord.

**Infections**

Infections of the spinal cord are rare but can cause serious damage. One such infection is *poliomyelitis*. In *multiple sclerosis*, a degenerative disease, there is patchy loss of the insulating sheaths around nerve fibres.

**Spinal Fusion**

Major surgery in which two or more adjacent vertebrae are joined together. It is performed if there is abnormal movement between adjacent vertebrae that causes severe back pain or risks damaging the spinal cord.

**Spinal Injury**

Damage to the spine and sometimes to the spinal cord. Spinal injury is most often the result of falling from a height or of a road traffic accident.

Many disorders of the spine, despite their different causes, result in just one symptom: back pain.

**Congenital disorders**

Some children are born with a gap in the vertebrae because part of one or more vertebrae has failed to develop completely. This leaves part of the spinal cord exposed. The condition, known as *spina bifida*, may cause paralysis of the lower limbs and incontinence.

**Infection**

Osteomyelitis (infection of bone and bone marrow) may in rare cases affect a vertebra, destroying both bone and disc. The most common cause of osteomyelitis is the spread of an infection, such as *tuberculosis*, from elsewhere in the body.

**Inflammation**

In *ankylosing spondylitis*, and in some cases of *rheumatoid arthritis*, the joints in the spine become inflamed and eventually fuse, causing permanent stiffness. *Osteochondritis juvenilis* (inflammation of the growing area of bone in children and adolescents) can affect the vertebrae, when the disease may cause deformity of the spine.

**Injuries**

Lifting heavy objects, twisting suddenly, or adopting bad posture can cause any of the following spinal injuries: sprained ligament, torn muscle, *spinal stenosis* (dislocated vertebrae), dislocated facet joint, or *disc prolapse* (rupture of the tough outer layer of the disc).

A direct blow, a fall from a height, or sudden twisting can result in fracture of one or more vertebrae.

**Tumours**

Tumours of the bones of the spine are usually malignant; in most cases, they have spread from cancer elsewhere in the body (see *bone cancer*).

**Degeneration**

*Osteoarthritis* (degeneration of joint cartilage due to wear and tear) affects the spine joints of virtually everyone over 60, particularly people who do heavy manual work or those whose spines have already been affected by disease or injury.

*Osteoporosis* (thinning and softening of bone), which is most common in postmenopausal women, can weaken the vertebrae. Vertebrae may fracture and collapse, under the weight of the trunk.

**Other disorders**

In some people, the spine is abnormally curved. Excessive curvature may be inwards in the lower back (see *lordosis*), outwards in the upper back (see *kyphosis*), or to one side (see *scoliosis*). Causes include infection, osteoporosis, and congenital and muscle disorders.

Spinal disorders are investigated by *X-rays*, *CT scanning*, and *MRI*. Other bone imaging techniques, such as *radionuclide scanning*, may also be performed.

**Spinal Nerves**

A set of 31 pairs of nerves that connect to the spinal cord. The nerves emerge in two rows from either side of the spinal cord and leave the spine through gaps between adjacent vertebrae. They then branch out to supply all parts of the trunk, arms, and legs with sensory and motor nerve fibres.
Disc prolapse may lead to pressure on a spinal nerve, which causes pain. Nerve injury may result in loss of sensation or movement in the specific area that is supplied by the nerve.

spinal tap
See lumbar puncture.

spine
The column of bones and cartilage that extends from the base of the skull to the pelvis, enclosing the spinal cord and supporting the trunk and head.

STRUCTURE AND FUNCTION
The spine is made up of 33 roughly cylindrical bones called vertebrae. Each pair of adjacent vertebrae is connected by a facet joint, which helps both to stabilize the spine and allow movement in it. Between the vertebrae lie pads of tough fibrous cartilage with a jellylike core, called intervertebral discs (see disc, intervertebral). These pads act as shock-absorbers during such movements as running and jumping.

In a normal spine, the topmost section, consisting of seven vertebrae and known as the cervical spine, curves forward; the thoracic spine, made up of the 12 vertebrae at the rear of the chest, curves backwards; the lumbar (lower back) section curves forwards, particularly in women; and the pelvic section curves backwards.

The spine encloses the spinal cord, a column of nerve tracts running from the brain. Spinal nerves branch off from the spinal cord, at the nerve roots, to form the peripheral nerves (see peripheral nervous system), the roots of which pass between the vertebrae to supply every part of the body.

The vertebrae are bound together by two long, thick ligaments running the length of the spine and by smaller ligaments between the individual bones. Attached to the spine are several groups of muscles, which control its movement and help to support it. See Structure of the spine box and Disorders of the spine box, previous page.

spiral fracture
A type of fracture in which the bone is broken by severe twisting.

spirochaete
Any of a group of spiral-shaped bacteria that cause various infections, including syphilis, leptospirosis, relapsing fever, and Lyme disease.

SPIRAL FRACURE

A spirometer is used to measure the volume of air (in litres) that you can inhale and exhale over a period of time. The results of spirometry show whether or not the airways are narrowed as a result of lung disorders such as asthma. The procedure can also be used to monitor the effectiveness of certain treatments for lung disorders, such as bronchodilator drugs, which widen the airways.

spirometry
A pulmonary function test used to diagnose or assess a lung disorder or to monitor treatment. It records the rate at which a person exhales air from the lungs and the total volume exhaled.

Spirometry may be used to assess conditions in which the airways are narrowed, such as asthma, or those in which lung expansion is restricted, such as interstitial pulmonary fibrosis.

spironolactone
A potassium-sparing diuretic drug used to treat heart failure and ascites (fluid buildup in the peritoneal cavity of the abdomen). Spironolactone may cause side effects including gastrointestinal upset, lethargy, rash, impotence, and irregular menstruation. High doses may cause gynaecomastia (abnormal breast enlargement) in men.

spleen
A fist-sized, dark red spongy organ in the upper left of the abdomen behind the lower ribs. The spleen removes worn-out and defective red blood cells from the circulation and helps to fight infection by producing some of the antibodies (proteins) and lymphocytes and phagocytes (types of white blood cell) that destroy invading microorganisms.

The spleen enlarges in many diseases, including infections such as malaria and infectious mononucleosis; blood disorders such as leukaemia, thalassaemia, and sickle cell anaemia; and tumours such as lymphomas. Enlargement may be accompanied by hypersplenism (overactivity of the spleen). The organ may be ruptured by a severe blow to the abdomen; this may cause potentially fatal haemorrhage, needing an emergency splenectomy (removal of the spleen).

splenectomy
Surgical removal of the spleen. Splenectomy is performed after the spleen has been seriously injured, or to treat hypersplenism or certain forms of anaemia. The absence of the spleen does not normally cause any problems because its function is largely taken over by other parts of the lymphatic system and the liver. People who have had a splenectomy are more susceptible to certain infections
and are given pneumococcal, meningococcal, Hib, and influenza vaccines and long-term antibiotics.

**splint**

A device used to immobilize a part of the body. Splints are usually made of firm or rigid material and sometimes they are padded. An uninjured part of a person’s own body may also be used as a “splint”.

**splinter haemorrhage**

Bleeding under the fingernails, visible as tiny, splinter-like marks. Although splinter haemorrhage is usually due to trauma, it can also be a sign of infective endocarditis.

**splinting**

The application of a splint, most often used to immobilize a fractured or otherwise injured limb or digit.

**splinting, dental**

The mechanical joining of several teeth to hold them in place while an injury heals or while periodontal disease is treated.

**split personality**

A common term for multiple personality. It is also used, incorrectly, to describe schizophrenia.

**spondylitis**

Inflammation of the joints between the vertebrae in the spine. Spondylitis is usually caused by osteoarthritis, rheumatoid arthritis, or ankylosing spondylitis.

**spondylolysis**

The slipping of a vertebra over the one below it. In most cases, the fifth (lowest) lumbar vertebra slips; in other cases, it is the fourth lumbar vertebra or a cervical (neck) vertebra. The displaced bone may press on nearby spinal nerves.

Lumbar spondylolisthesis may be due to bone weakness caused by spondyloysis or spondylolysis and osteoarthrosis, and may result in back pain and sciatica. Cervical spondylolisthesis may be due to neck injury, spinal abnormality, or rheumatoid arthritis; it leads to neck pain and stiffness and, in severe cases, pain, numbness, and weakness in the hands or arms.

Treatment may include traction, immobilizing the area in a plaster corset or with an orthopaedic collar, and physiotherapy. If there is nerve damage or severe back pain, spinal fusion may be needed to fuse the affected vertebrae.

**spondyloysis**

A disorder of the spine in which the arch of the fifth (or, rarely, the fourth) lumbar vertebra consists of soft fibrous tissue instead of normal bone. As a result, the arch is weak and prone to damage under stress, which may produce spondylolisthesis. Otherwise, the condition is usually symptomless.

**spongiform encephalopathy**

A brain disorder in which the brain tissue shrinks and spaces develop in it, which produces severe signs such as paralysis and dementia. (See also Creutzfeldt–Jakob disease; encephalopathy; kuru; slow virus diseases.)

**spontaneous abortion**

See miscarriage.

**spontaneous remission**

A situation in which the signs and symptoms of a disease lessen or disappear temporarily (see remission) for no known reason.

**sporotrichosis**

A chronic infection caused by the fungus *Sporothrix schenckii*, which grows on plants. The infection is most often contracted through a skin wound; gardeners are particularly vulnerable. An ulcer develops at the site of the wound; nodules then form in lymph channels around the site. Potassium iodide solution taken orally usually clears up the infection. Rarely, in people with reduced immunity, sporotrichosis spreads to other parts of the body and requires treatment with amphotericin, an antifungal drug.

**sports, drugs and**

The use of drugs to improve athletic performance has been universally condemned by authorities because it both endangers the health of users and gives them an unfair advantage. Random tests on urine and other body fluids to detect abuse are performed in most sports, especially during competitions.

**PROHIBITED DRUGS**

Various classes of drugs are prohibited in international sports and their use may lead to an athlete being banned from competitions. The main types include the following:

**Stimulants**

Drugs included in this group prevent fatigue and increase confidence. However, they also impair judgement and may cause excessive aggression. Stimulants such as amphetamines carry the risk of causing cardiac arrhythmias (irregularities of heartbeat); prolonged use may cause heart failure (reducing pumping efficiency) and increase the risk of a brain haemorrhage.

Caffeine in coffee, tea, and some soft drinks, and also as tablets, is a popular stimulant. Most sports authorities prohibit its use only in high doses.

**Hormones**

Types of hormone drugs that may be abused include anabolic steroids (see steroids, anabolic) to speed muscle recovery after exercise, and to increase muscle strength; erythropoietin to boost the blood’s haemoglobin content, which may increase stamina; and growth hormone to stimulate muscle growth.

Risks of abusing anabolic steroids include liver damage and liver tumours. In men, these drugs can cause infertility and impotence: in women, virilization. If taken in childhood, anabolic steroids can cause short stature by affecting the growing areas of bones.

The main side effect of erythropoietin, a hormone also produced by the kidneys, is raised blood pressure. Growth hormone may cause excessive bone growth (see acromegaly) and diabetes mellitus.

**Other drugs**

Analogic drugs may be used to mask the pain of an injury and are prohibited if they contain opioids. Beta-blockers are taken to reduce tremor in sports that require a steady hand. Diuretics may be used for quick weight loss and to dilute urine, making prohibited substances more difficult to detect. Many authorities now prohibit these drugs unless there is proof of a medical condition requiring their use.

**sports injuries**

Any injury that arises during participation in sports. Typical sports injuries include fractures, head injury (including concussion), muscle strain or compartment...

syndrome, tendinitis or tendon rupture, ligament sprain, and joint dislocation or subluxation. Some ‘sports’ injuries, such as tennis elbow, are in fact a type of overuse injury. (See also running injuries.)

sports medicine
A medical speciality concerned with the assessment and improvement of fitness and the treatment and prevention of injuries and disorders related to sports.

spot
A general term for a small lump, mark, or inflamed area on the skin.

spotting
See breakthrough bleeding.

sprain
Tearing or stretching, due to a sudden pull, of the ligaments that hold the bone ends together in a joint. The ankle is the most commonly sprained joint. A sprain causes painful swelling, and the joint cannot be moved without increasing the pain. There may also be spasm of surrounding muscles.

Treatment consists of applying an ice-pack, wrapping the joint in a bandage, resting it in a raised position, and taking analgesic drugs. In severe cases, surgical repair may be necessary.

sprue
An intestinal disorder that prevents the small intestine absorbing sufficient nutrients from food. There are two forms: tropical sprue (see sprue, tropical), and coeliac disease, which is more common and is caused by sensitivity to gluten.

sprue, tropical
A disease of the small intestine that interferes with the absorption of nutrients from food. Occurring mainly in India, the Far East, and the Caribbean, sprue may be due to an intestinal infection. Symptoms include loss of appetite and weight, an inflamed mouth, and fatty diarrhoea. Sprue leads to malnutrition and megaloblastic anaemia.

Diagnosis is confirmed by jejunal biopsy (taking a tissue sample from the small intestine). The condition responds well to antibiotic drug treatment and vitamin and mineral supplements.

sputum
Also called phlegm, mucous fluid that is produced by cells lining the airways in the lungs. Sputum production may be increased by respiratory tract infection, an allergic reaction, or inhalation of irritants.

squamous cell carcinoma
Also known as SCC, a cancer that arises in epithelial cells, which line most hollow structures within the body and cover the body’s surface. SCC can occur in many body organs, including the mouth (see mouth cancer) and lungs (see lung cancer). SCC of the skin is one of the most common types of skin cancer and is linked to long-term exposure to sunlight; it is most common in fair-skinned people over 60.

SCC of the skin starts as a small, painless lump or patch, usually on the lip, ear, or back of the hand. It enlarges fairly rapidly, often resembling a wart or ulcer. It can also arise from a preexisting solar keratosis (a patch of rough or thickened skin). Left untreated, the cancer may spread to other parts of the body and prove fatal.

Diagnosis is based on a skin biopsy. The tumour is removed surgically or destroyed by radiotherapy. (See also basal cell carcinoma; melanoma, malignant.)

In adults, squint may be a symptom of stroke, diabetes mellitus, multiple sclerosis, hyperthyroidism, or a tumour. A squint in adults causes double vision.

Treatment in children up to six to seven years may include covering the normal eye with a patch, which forces the child to use the weak eye. Deviation of the squinting eye may be controlled by glasses and/or surgery. The sudden onset of a squint in adults may have a serious underlying cause and must be investigated promptly.

SSRIs
See selective serotonin reuptake inhibitors.

stable
A term used in medicine to describe a patient’s condition that is neither deteriorating nor improving; a personality that is not susceptible to mental illness; or a chemical substance that is resistant to changes in its composition or physical state, or is not radioactive.

stage
A term that is used in medicine to describe a phase in the course of a disease; it is used particularly to describe the progression of cancer. Staging is a method of assessing cancer according to the size of the main tumour, the degree to which it has invaded surrounding tissues, and the extent to which it has spread to other parts of the body. Treatment and outlook of diseases depend on the stage, hence the importance of staging investigations.

staghorn calculus
A large kidney stone, with several branches, that forms in the renal pelvis (the central area of the kidney, where urine collects before leaving the organ). (See calculus, urinary tract.)
staining
The process of dyeing specimens of cells, tissues, or microorganisms to make them clearly visible or easily identifiable under a microscope.

stammering
See stuttering.

Stanford–Binet test
A type of intelligence test.

stanozolol
A type of anabolic steroid drug (see steroids, anabolic).

stapedectomy
An operation on the ear to replace the stapes (the innermost of the three sound-conducting bones in the middle ear) with a device that takes over the bone’s function. It is used to treat deafness due to otosclerosis.

stapes
The innermost of the three tiny, sound-conducting bones in the middle ear. The stapes is the smallest bone in the body. Its head articulates with the incus and its base fits into the oval window in the wall of the inner ear.

In otosclerosis, the stapes becomes fixed and cannot transmit sound to the inner ear. The resultant hearing loss can be treated by stapedectomy.

staphylococcal infections
Infections caused by bacteria of the genus Staphylococcus. Different species of staphylococci are responsible for a range of disorders, including skin infections such as pustules, abscesses, and boils, and a rash in newborn babies (see necrosis, toxic epidermal; pneumonia; toxic shock syndrome in menstruating women; urinary tract infection; and food poisoning. If the bacteria enter the circulation, they may cause septicaemia or septic shock, infectious arthritis, osteomyelitis, or bacterial endocarditis.

Staphylococcus aureus
A species of Staphylococcus bacterium that produces toxins, causing a range of staphylococcal infections.

stapling
A surgical procedure to treat severe obesity, in which the stomach is partitioned using surgical staples, to leave only a small volume for digestion and food storage. Staples are also used for suturing.

starch
See carbohydrates.

startle reflex
A reflex action seen in newborn babies that is similar to the Moro reflex.

starvation
A condition that results from lack of food over a long period and results in weight loss, changes in metabolism (the body’s chemical processes) and extreme hunger. (See also anorexia nervosa; fasting; nutritional disorders.)

stasis
Slowing down or cessation of flow.

stasis ulcer
An open sore that develops on the lower leg (see leg ulcer) as a result of poor blood flow in that area.

statins
A type of lipid-lowering drug used to treat high blood levels of cholesterol, or to lower blood lipid (fat) levels in people with coronary artery disease.

statistics, medical
The collection and analysis of numerical data that relates to medicine. Information on the incidence and prevalence of various conditions is an important aspect of medical statistics.

statistics, vital
Assessment of the health of a country’s population, which relies on the collection of data on birth and death rates and on causes of death.

status asthmaticus
A severe and prolonged asthma attack. This condition is potentially life-threatening and needs urgent treatment.

status epilepticus
Prolonged or repeated epileptic seizures in which there is no recovery of consciousness between the attacks. Status epilepticus is a medical emergency, which may be fatal if it is not treated promptly. It is more likely to occur in people with epilepsy if anticonvulsant drugs are taken erratically or are withdrawn suddenly. (See also epilepsy.)

STDs
The abbreviation for sexually transmitted diseases; another name for sexually transmitted infections.

steal syndrome, subclavian
See subclavian steal syndrome.

steam inhalation
A method of relieving some of the symptoms of colds, sinusitis, and laryngitis by breathing in vapour from a bowl of hot water. The moisture loosens secretions in the nose and throat, making them easier to clear.

steatorrhoea
The presence of excessive fat in the faeces. Steatorrhoea causes bulky, loose, pale-coloured, greasy, and offensive-smelling faeces that float in the toilet. Steatorrhoea may occur in pancreatitis and coeliac disease (which interfere with the breakdown of fat from food) and after the removal of substantial segments of small intestine. It is also a side effect of some lipid-lowering drugs.

Stein–Leventhal syndrome
See ovary, polycystic.

stem cell
A basic cell in the body from which more specialized cells are formed. Stem cells in the bone marrow produce blood cells. The cells are also found in blood and in a baby’s umbilical cord.

Stem cells can be transplanted as an alternative to bone marrow transplantation. This procedure is used mainly for people being treated for leukaemia and other cancers but may, in the future, be used for noncancerous disorders. Cells may be taken from a donor sibling, a matched but unrelated donor, or from stored umbilical blood. Patients can also act as their own donors: they may have their stem cells harvested and stored, to be reinjected later after treatment has damaged the bone marrow.

stenosis
Narrowing of a duct, canal, passage, or tubular organ.

stenosis, pyloric
See pyloric stenosis.

stent
A rigid metal or plastic tube that is surgically inserted to open up, or keep open, a body canal that has become narrowed or closed due to disease. Stents are used to open narrowed coronary arteries or to relieve a blockage caused by a tumour (in the bile duct, for a tumour of the pancreas, for example).
sterculia
A bulk-forming laxative that is used to treat constipation. Sterculia is especially useful when stools are small and hard. However, it should only be used if fibre intake cannot be increased. During the use of sterculia, adequate fluid intake must be maintained to avoid intestinal obstruction. Side effects may include flatulence, bloating, and gastrointestinal obstruction or impaction.

stereotaxic surgery
Brain operations that are carried out by the insertion of delicate instruments through a surgically created hole in the skull and guiding them, with the aid of CT scanning, to a specific area. Stereotaxic procedures can be used to treat pituitary tumours; for a brain biopsy; or to destroy small areas of the brain as treatment for some disabling neurological disorders.

sterile abscess
An abscess in which the contents are not pyogenic (pus-forming) and they do not grow bacteria when cultured (see culture).

sterility
The state either of being germ-free or of permanent infertility.

sterilization
Complete destruction or removal of living microorganisms, which is usually carried out to prevent the spread of infection. The term also refers to a procedure that renders a person infertile. (See also sterilization, female; vasectomy.)

sterilization, female
A usually permanent method of contraception in which the fallopian tubes are sealed in order to prevent sperm from reaching the ova. Female sterilization is usually performed by laparoscopy, a procedure that involves two small incisions in the abdomen. Sometimes it is performed by minilaparotomy, in which a single incision is made in the pubic area. The fallopian tubes are sealed using clips or by cutting and tying. The operations have a low failure rate. Although sterilization is usually permanent, fertility can sometimes be restored using microsurgery.

sterilization, male
See vasectomy.

sterilizer
A piece of apparatus that is used to make medical equipment sterile. (See also autoclave.)

sternum
The long, narrow, flat plate of bone at the front of the chest. The sternum consists of the manubrium (uppermost part); the body (long middle part); and the xiphoid process, or xiphisternum (a small, leaf-shaped projection). The top of the sternum articulates with the inner ends of the clavicles (collarbones).
The ribs are attached to the sides by cartilage. Between the manubrium and the body is a synphysis that joins the two parts firmly but allows the sternum to move slightly during breathing.

Great force is required to fracture the sternum, the main danger of which is the possibility of the broken bone being driven inwards, damaging the heart, which lies behind the sternum.

steroid
A term used to describe either a naturally occurring hormone or a steroid drug. Steroid hormones include the sex hormones and hormones produced by the adrenal glands (see corticosteroid hormones). Steroid drugs include corticosteroid drugs and andabolic steroids (see steroids, anabolic).

steroids, anabolic
COMMON DRUG
• Nandrolone

Drugs that have an anabolic (protein-building) effect similar to testosterone. Anabolic steroids build tissue, promote muscle recovery after an injury, and strengthen bones. They are used medically to treat some types of anaemia. The drugs may, however, be abused by athletes (see sports, drugs in).

Possible adverse effects of anabolic steroids include acne, oedema, liver damage, infertility, impotence in men, and virilization in women.

stethoscope
An instrument used for listening to sounds within the body, particularly those made by the heart or lungs (see auscultation). A stethoscope has ear pieces; a diaphragm, which picks up high-pitched sounds; and a bell-shaped piece, which picks up low sounds.

STETHOSCOPE

Stevens–Johnson syndrome
A rare, life-threatening type of erythema multiforme that is characterized by severe blistering and sometimes bleeding in the mucous membranes of the eyes, mouth, nose, and genitals.

sticky eye
A sign of the eye condition conjunctivitis in which the eyelids become stuck together with discharge.

stiff neck
A common symptom, which is usually due to muscle spasm at the side or back of the neck. In most cases, it occurs suddenly and for no apparent reason. It may result from a neck injury, such as a ligament sprain, disc prolapse, or whiplash injury. A rare cause of stiff neck is meningitis.

Mild stiffness may be relieved by massage, warming, and use of a liniment. Severe or persistent stiffness requires medical attention. (See also torticollis.)

stiffness
A term for difficulty in moving a joint or stretching a muscle. Morning joint stiffness is characteristic of conditions such as rheumatoid arthritis. In degenerative conditions, such as osteoarthritis, pain and stiffness may be worse at the end of the day. Cramp and spasticity (muscle rigidity) may cause stiffness.

stilbestrol
See diethylstilbestrol.

stillbirth
Delivery of a dead fetus after the 24th week of pregnancy.

CAUSES
The cause of stillbirth is often unknown. Some stillbirth babies have severe malformations, such as anencephaly, spina bifida, or hydrocephalus. Other possible causes include a maternal disorder that damages the placenta (the organ supplying nutrients to the baby), such as antepartum haemorrhage or hypertension; diabetes; kidney disease; or severe Rhesus incompatibility (in which antibodies from the mother attack the baby’s red blood cells).

Infectious diseases such as rubella, chickenpox, influenza, toxoplasmosis, cytomegalovirus, and herpes simplex) may harm the fetus if contracted during pregnancy, increasing the risk of stillbirth.

PSYCHOLOGICAL EFFECTS
After a stillbirth, the parents usually experience a sense of loss as intense as if any other loved one had died. Often, they experience feelings of depression, guilt, anger, and inadequacy. Emotional support from friends, relatives, and self-help groups is useful; some people are helped by professional counselling.

Still’s disease
See juvenile chronic arthritis.

stimulant drugs
COMMON DRUGS
• Caffeine
• Dexamphetamine
• Methylphenidate

RESPIRATORY STIMULANTS
• Doxapram

Drugs that increase brain activity by initiating the release of noradrenaline (norepinephrine). There are two types of stimulant drug: central nervous system stimulants (such as amphetamines), which are used in the treatment of narcolepsy and ADHD; and respiratory stimulants (see analeptic drugs), which encourage breathing.

stimulus
Anything that causes a direct response in the entire body or any individual part of the body.

stings
Sharp structures, on plants or animals, that discharge venom or irritants. Stinging animals include scorpions, some insects, jellyfish, and some fish (see venomous bites and stings). Stinging plants may cause an allergic skin reaction. (See also poisonous plants.)

STIs
See sexually transmitted infections.

stitch
A temporary, sudden, sharp pain in the abdomen or side that occurs during severe or unaccustomed exercise. A stitch is also the common name for a suture (see suturing) to close a wound.

St John’s wort
A herbal remedy that is derived from the plant Hypericum perforatum. Tablets, capsules, or infusions taken orally are effective in treating mild depression. St John’s wort is also used in creams for burns, wounds, and joint problems. It interacts with a wide variety of other medications, however, so St John’s wort preparations should not be used unless a doctor or pharmacist has been consulted beforehand.
**stockinette**
A soft, elasticated fabric used for items such as bandages.

**Stokes–Adams attacks**
Recurrent episodes of temporary loss of consciousness due to insufficient blood flow from the heart to the brain. Stokes–Adams attacks are caused by an irregular heartbeat (see arrhythmia, cardiac), which prevents the heart from pumping properly, or by complete heart block, which causes the heart to stop briefly. Most affected people are fitted with a pacemaker to prevent attacks.

**stoma**
A term with the literal meaning mouth or orifice. A common use of the term is to describe the stoma that can be created surgically in the abdominal wall (see colostomy; ileostomy) to allow the intestine to empty into a bag or pouch on the surface of the skin.

**stomach**
A hollow, baglike organ of the digestive system located in the left side of the abdomen under the diaphragm. At its upper end, the stomach is connected to the oesophagus (gullet), and at the lower end it joins the duodenum (the first part of the small intestine).

**STRUCTURE**
The stomach is flexible and in the average adult can expand to hold around 1.5 litres of food. Its wall consists of layers of longitudinal and circular muscle, lined by special glandular cells that secrete gastric juice, and supplied by blood vessels and nerves. A strong muscle at the lower end of the stomach forms a ring called the pyloric sphincter that can close the outlet leading to the duodenum.

**DISORDERS OF THE STOMACH**
Disorders of the stomach have a variety of causes. Because the stomach is a reservoir, disorders of the emptying of stomach contents occur. Other problems relate to the stomach’s role in the preparation of ingested food for digestion.

**Infection**
The large amount of hydrochloric acid secreted by the stomach protects it from some infections by destroying many of the bacteria, viruses, and fungi that are taken in with food and drink. When the protective power is insufficient, a variety of gastrointestinal infections may occur.

**Tumours**
Stomach cancer is one of the commonest forms of cancer. Early symptoms are often mistaken for indigestion, and diagnosis is often delayed until it is too late for a cure. Any change in the customary functioning of the digestive system is important, especially after the age of 50. A persistent feeling of fullness, or pain before or after meals, should never be ignored. Unexplained loss of appetite or frequent nausea should always be reported to a doctor. A tumour in the upper part of the stomach, near the opening of the oesophagus, can cause obstruction and difficulty in swallowing. Sometimes a stomach tumour remains “silent” and the first signs are due to the appearance of secondary growths elsewhere in the body. Benign (noncancerous) polyps can also develop in the stomach.

**Ulceration**
The acid and other digestive juices secreted by the stomach sometimes attack the stomach lining. The healthy stomach is prevented from digesting itself mainly by the protective layer of mucus secreted by the lining and by the speed with which damaged surface cells are replaced by the deeper layers. Many influences can upset this delicate balance. One of the most important is excessive acid secretion. The resulting peptic ulcers are probably the most common serious stomach disorder. Peptic ulcers are most often caused by Helicobacter pylori infection, but are sometimes caused by stress, severe injury such as major burns, or after surgery and serious infections; often they occur for no apparent reason. The stomach lining can be damaged by large amounts of aspirin or alcohol, sometimes causing gastritis (inflammation of the stomach lining). This may eventually lead to ulceration.

**Autoimmune disorders**
Pernicious anaemia (see anaemia, pernicious) is caused by the failure of the stomach lining to produce intrinsic factor, a substance that facilitates the absorption of vitamin B12 (necessary for red blood cell formation). Failure to produce intrinsic factor occurs if there is atrophy of the stomach lining, which also causes failure of acid production. Tests that determine a person’s ability to absorb vitamin B12 are important in the investigation of this condition. Pernicious anaemia is usually due to an autoimmune disorder.

**Other disorders**
Enlargement of the stomach may be caused when scarring from a chronic peptic ulcer occurs at the stomach outlet. It may also be a complication of pyloric stenosis, a rare but serious condition in which there is narrowing of the stomach outlet. Rarely, the stomach may become twisted and obstructed, a condition called volvulus.

**INVESTIGATION**
Stomach disorders are investigated primarily by barium X-ray examinations and/or gastroscopy. Occasionally, a biopsy (removal of a tissue sample for microscopic analysis) is performed.
FUNCTION
The main function of the stomach is to contribute to the breakdown of food that is started in the mouth and completed in the small intestine. However, it also acts as a storage organ; if storage were not possible, food would have to be eaten about every 20 minutes.

The sight and smell of food, and its arrival in the stomach, stimulate the stomach lining to secrete gastric juice. This fluid contains pepsin, an enzyme that breaks down protein; hydrochloric acid, which kills bacteria and creates the optimum pH for pepsin activity; and intrinsic factor, which is essential for absorption of vitamin B12 in the small intestine. The lining also secretes mucus to stop the stomach from digesting itself.

The layers of muscle in the stomach wall produce rhythmic contractions about every 20 seconds that churn the food and gastric juice. This process converts semi-solid food into a creamy fluid (chyme). At regular intervals, the stomach muscles contract, as the pyloric sphincter relaxes, propelling partially digested food into the duodenum.

stomachache
Discomfort in the upper abdomen. (See also indigestion.)

stomach cancer
A malignant tumour that arises from the lining of the stomach. The exact cause is unknown, but Helicobacter pylori infection is linked to increased risk. Other likely factors include smoking and drinking alcohol. Diet may also play a part, particularly eating large amounts of salted or pickled foods. Pernicious anaemia, partial gastrectomy, and belonging to blood group A also seem to increase the risk. Stomach cancer rarely affects people under 40 and is more common in men, especially Japanese men. Symptoms may start with loss of appetite and weight loss; they may also be indistinguishable from those of peptic ulcer and may include burning abdominal pain, nausea, and vomiting.

Diagnosis is usually made by gastroscopy and biopsy, or by barium X-ray examination. Partial gastrectomy may be performed if the tumour is detected early; otherwise, the only effective treatment is gastrectomy (removal of the stomach). In advanced cases, in which the tumour has spread, radiotherapy and anticancer drugs may prolong life.

stomach imaging
See barium X-ray examinations.

stomach pump
See lavage, gastric.

stomach ulcer
Also called a gastric ulcer, a type of peptic ulcer.

stomatitis
Any type of inflammation or ulceration of the mouth.

stones
Small, hard collections of solid material within the body. (See also calculus, urinary tract; gallstones.)

stool
Another word for faeces; in particular, a quantity of faeces passed in one bowel movement.

stork mark
A harmless small, flat, pinkish-red, skin blemish found in many newborn babies, usually around the eyes or at the nape of the neck. Stork marks, a type of haemangioma, may be only temporary.

strabismus
A medical term for a squint.

straight leg raising
A neurological test carried out during investigation of lower-back or leg pain. With the patient lying down, the leg is fully extended and slowly raised by the examiner, who aims to reach a 90º angle from the horizontal. The patient’s reactions will be noted at each degree of elevation. The limit of the test is reached, and the angle noted, when pain is felt or the pelvis moves.

strain
Tearing or stretching of muscle fibres as a result of suddenly pulling them too far. There is bleeding into the damaged area of muscle, causing pain, swelling, muscle spasm, and bruising.

Treatment may include resting the affected part (in a raised position if possible) and applying an ice-pack to reduce pain and swelling; taking analgesic drugs; and physiotherapy. (See also sprain.)

strangulation
Constriction (usually by twisting or compression) of a tube or passage in the body, blocking blood flow and interfering with the function of the affected organ. Strangulation may occur with a hernia, for example.

Strangulation of the neck is a life-threatening accidental or deliberate injury involving compression of the jugular veins, preventing blood from flowing out of the brain, and compression of the windpipe, which restricts breathing. The victim loses consciousness; brain damage and death caused by lack of oxygen follow.

strangury
A painful and frequent urge to empty the bladder, although only a few drops of urine can be passed. Causes include inflammation (see cystitis; prostatitis), bladder stones (see calculus, urinary tract), and bladder cancer (see bladder tumours).

strapping
The application of adhesive tape to part of the body to exert pressure and thus reduce pain and swelling, or to support a weakened area.

strawberry naevus
A bright red, raised spot appearing in early infancy. Strawberry naevi are a type of haemangioma. Treatment is not usually needed unless they occur near the eye, where they might interfere with visual development.

strawberry tongue
A white coating with red spots that develops on the tongue in a person with scarlet fever.

strep throat
A streptococcal infection of the throat that is most common in children. The bacteria are spread in droplets coughed or breathed into the air.

In some people, the bacteria cause no symptoms. In others, sore throat, fever, and enlarged lymph nodes in the neck occur. In some cases, the bacterial toxins produce a rash (see scarlet fever).

Treatment is usually with a penicillin drug. Untreated, strep throat may lead to glomerulonephritis (inflammation in the kidneys) or rheumatic fever.

streptococcal infections
Infections caused by bacteria of the Streptococcus genus. Streptococci are spherical bacteria that grow in lines, like beads on a string. They are among the most common disease-causing bacteria in humans.
Certain types of streptococci are present harmlessly in the mouth and throat of most people. If the bacteria enter the bloodstream (which may happen after dental treatment), they are usually destroyed. However, in some people with heart-valve defects, bacteria can settle in the heart to cause bacterial endocarditis. Another type of streptococcus is normally present harmlessly in the intestines but can spread to cause a urinary tract infection.

Haemolytic streptococci can cause tonsillitis, strep throat, scarlet fever, otitis media (middle-ear infection), pneumonia, erysipelas, and wound infections.

**Streptococcus pneumoniae**
Also called *Pneumococcus*, a type of *Streptococcus* bacterium that can cause pneumonia and other serious disorders such as meningitis and septicaemia.

**streptokinase**
A *thrombolytic drug* that is used to dissolve blood clots following a myocardial infarction (heart attack) or pulmonary embolism (a clot which blocks a blood vessel in a lung). Streptokinase is given under strict supervision due to the side effect of excessive bleeding; other adverse effects include nausea, rash, and cardiac arrhythmias.

**streptomycin**
An *antibiotic drug* that is used to treat certain uncommon infections, including tuberculosis, tularemia, plague, and brucellosis. It may damage nerves in the inner ear, disturbing balance and causing dizziness, tinnitus (noises in the ears), or deafness. Other side effects include facial nummness, tingling in the hands, and headache.

**stress**
Any disturbance of a person’s mental and physical wellbeing. Stress may be felt in response to a range of physical and emotional stimuli. In stressful situations, the body responds by increasing production of the hormones adrenaline (epinephrine) and hydrocortisone, which produce changes in heart rate, blood pressure, and metabolism to improve performance. Above a certain level, however, they impair a person’s ability to cope. Continued exposure to stress often leads to mental and physical symptoms such as anxiety and depression, indigestion, palpitations, and muscular aches and pains. Post-traumatic stress disorder is a severe response to a specific stressful event. (See also relaxation techniques; stress ulcer.)

**stress fracture**
A fracture that results from repetitive jarring of a bone. Common sites include the metatarsal bones in the foot (see march fracture), the tibia and fibula (lower leg bones), the neck of the femur (thigh bone), and the lumbar spine (lower back). The main symptoms are pain and tenderness at the fracture site. Diagnosis is by bone imaging. Treatment consists of resting the affected area for four to six weeks, depending on the site; the fracture may be immobilized in a cast.

**stress ulcer**
An acute (of sudden onset) peptic ulcer that develops after shock, a severe burn or injury, or during major illness. Stress ulcers are usually multiple and most commonly occur in the stomach. The exact cause is unknown. Severely ill hospital patients are often given drugs to prevent stress ulcers from developing.

**stretcher**
A horizontal frame used to carry seriously ill or injured people. The stretcher keeps the person’s body flat and still, minimizing the risk of further injury or disturbance to the body.

**stretch-mark**
See stria.

**strata**
Also called a stretch-mark, a line on the skin caused by thinning and loss of elasticity in the dermis. Striae appear as red, raised lines, before turning purple; they eventually fade to form shiny, silvery streaks.

Striae often develop, during the adolescent growth spurt, on the shoulders in boys and on the hips and thighs in athletic girls. They are a common feature of pregnancy, occurring on the breasts, thighs, and lower abdomen. Purple striae are a characteristic feature of Cushing’s syndrome.

The marks are thought to be caused by an excess of corticosteroid hormones, which decreases the level of collagen (fibrous tissue) in the skin. There is no means of prevention, but in some cases laser treatment may be used.

**Striae**
Commonly known as stretch-marks, striae often develop on the abdomen, thighs, and breasts of pregnant women. The striae shown here result from obesity associated with Cushing’s syndrome.
narrowing
Narrowing of a passage in the body. Stricture may be due to inflammation, development of scar tissue, or a growth such as a tumour. In some cases, it may be congenital (present at birth).

stridor
An abnormal sound, on breathing, that is due to narrowing or obstruction of the larynx or trachea. Stridor is most common in young children and usually occurs in croup. Other causes include epiglottitis, an inhaled foreign body, hypocalcaemia, and some larynx disorders.

stroke
Damage to part of the brain due to interruption to its blood supply. The most common cause is blockage of a cerebral artery by a blood clot, which may have formed in the artery (see thrombosis) or may have been carried in the circulation from another part of the body (see embolism). Stroke may also result from localized haemorrhage due to a ruptured blood vessel (including an aneurysm or bleeding disorder) in or near the brain.

The incidence of stroke rises with age and is higher in men. Certain factors increase the risk; the most important are hypertension and atherosclerosis, which damage artery walls. Smoking increases the risk of stroke by increasing the risk of all these disorders; and the risk of atherosclerosis is increased with diabetes. Atrial fibrillation (irregular, very rapid heartbeats), a damaged heart valve, or a recent myocardial infarction (heart attack) can cause clots in the heart that may migrate to the brain.

SYMPTOMS AND SIGNS
Symptoms usually develop abruptly and depend on the site, cause, and extent of the brain damage. The movement, function, or sensation controlled by the damaged area of the brain is impaired (see Types and causes of stroke box, opposite). The possible complications of a major stroke include pneumonia and blood clots in the legs (see thrombosis, deep vein), which could lead to pulmonary embolism. Roughly one third of major strokes are fatal, a third result in some disability, and the final one third have no lasting ill effects (see transient ischaemic attack).

DIAGNOSIS AND TREATMENT
A range of techniques may be used to investigate the cause and extent of brain damage. These include ECG, CT scanning, chest X-rays, blood tests (which may include clotting tests), angiography, MRI, and carotid doppler scanning (to assess narrowing of the carotid artery).

In some cases of stroke, urgent treatment may improve the chances of recovery. If a scan shows that the stroke is due to thrombosis, thrombolytic drugs may be given to dissolve the clot. Anti-coagulants may be given if there is an obvious source of an embolism, such as atrial fibrillation. Antiplatelet agents such as aspirin may be used in order to help prevent further clotting.

Attention to hydration and pressure areas, and good nursing care, are important influences on outcome. Physiotherapy may restore lost movement or sensation; speech therapy may help language disturbances.

stroma
The tissue that forms an organ’s framework, as distinct from functional tissue (the parenchyma) and the fibrous outer layer that holds the organ together.

strongyloidiasis
An infestation of the intestines by the parasitic worm Strongyloides stercoralis. Strongyloidiasis is a widespread disease in the tropics. It is contracted in affected areas by walking barefoot on soil that is contaminated with faeces. Larvae penetrate the soles and migrate via the lungs and throat to the small intestine, where they develop into adults and produce larvae. Most of the larvae are passed out in the faeces, but some enter the skin around the anus to begin a new cycle. An individual may be infested for more than 40 years. The larvae cause itching and red weals where they enter the skin. In the lungs they may cause asthma or pneumonia. Heavy intestinal infestation may cause symptoms such as swelling of the abdomen and diarrhoea. Occasionally, an infected person with reduced immunity dies of complications, such as septicaemia or meningitis.

Treatment with an anthelmintic drug, usually thiabendazole, kills the worms.

strontium
A metallic element occurring in various compounds in certain minerals, seawater, and marine plants. A radioactive variety, strontium 90, is produced during nuclear reactions and may be present in nuclear fallout. Strontium 90 accumulates in bone, where the radiation it emits may cause leukaemia and/or bone tumours. Other forms of radioactive strontium have been used in the diagnosis and treatment of certain types of bone tumour.

Strümpell–Marie disease
Another name for ankylosing spondylitis.

strychnine poisoning
Strychnine is a poisonous chemical found in the seeds of Strychnos species (a group of tropical trees and shrubs). Its main use is in some rodent poisons; most cases of strychnine poisoning occur in children who accidentally ingest such poisons.

The symptoms, which begin soon after ingestion of the poison, include restlessness, stiffness of the face and neck, increased sensitivity of hearing, taste, and smell, and photophobia, followed by alternating episodes of seizures and floppiness. Death may occur from respiratory arrest.

The victim is given intravenous injections of a tranquilizer or barbiturate, with a muscle-relaxant drug if needed, to help prevent seizures. Breathing may be maintained by a ventilator. With prompt treatment, recovery usually occurs in about 24 hours.

stuffy nose
See nasal congestion.

stump
The end portion of a limb that remains after amputation.

stupor
A state of almost complete unconsciousness from which a person can be aroused only briefly and by vigorous external stimulation. (See also coma.)

STURGE–WEBER SYNDROME
A rare, congenital condition, affecting the skin and the brain, in which there is abnormal distribution of blood vessels. Typically, a large, purple birthmark (port wine stain) extends over one side of the face, including the eye. Malformation of cerebral blood vessels may cause weakness on one side of the body, progressive learning difficulties, and epilepsy. Glaucoma may develop in the affected eye, leading to loss of vision.

Seizures can usually be controlled with anticonvulsant drugs. However, in severe cases of this syndrome, brain surgery may be necessary.
Stroke may be caused by any of three mechanisms (below): cerebral thrombosis, cerebral embolism, or haemorrhage. Thrombosis and embolism both lead to cessation of the blood supply to part of the brain and thus to infarction (tissue death). Rupture of a blood vessel in or near the brain may cause an intracerebral haemorrhage or a subarachnoid haemorrhage. Any part of the brain may be affected by a stroke; accordingly the symptoms vary considerably.

**CEREBRAL THROMBOSIS**

- **Thrombosis**
  - Blockage by a thrombus (clot) that has built up on the wall of a brain artery accounts for 40 to 50 per cent of strokes.

**CEREBRAL EMBOLISM**

- **Emboli**
  - Blockage by an embolus (usually a clot) swept into an artery in the brain accounts for 30 to 35 per cent of strokes.

**HAEMORRHAGE**

- **Bleeding**
  - Rupture of a blood vessel and bleeding within or over the surface of the brain accounts for 20 to 25 per cent of strokes.

**Cerebral haemorrhage**

This CT (computed tomography) scan shows a subdural haematoma. The left side of the brain (right on image) is filled with blood, which has clotted to form a solid mass.

**Key**

- Cerebral infarction
- Intracerebral haemorrhage
- Subarachnoid haemorrhage

**Incidence with age**

Strokes are rare under age 45. Incidence of cerebral infarction increases with age, but incidence of intracerebral haemorrhage and subarachnoid haemorrhage falls after age 75.

**SYMPTOMS**

The symptoms of a stroke usually develop abruptly over minutes or hours, but occasionally over several days. Depending on the size, site, cause, and extent of damage, any or all of the symptoms shown on the right may be present, in any degree of severity. A serious stroke may lead to rapid loss of consciousness, coma, and death. Up to 30 per cent of people are dependent on others after stroke, but some strokes cause barely noticeable symptoms.

**Hemiplegia**

Weakness, paralysis, or loss of sensation on one side of the body are the more common effects of a serious stroke.

**RISK FACTORS**

- Age
- High blood pressure
- Atherosclerosis (narrowing of arteries by fatty deposits)
- Heart disease
- Diabetes mellitus
- Smoking
- Polycythaemia
- Hyperlipidaemia
- Obesity
often helps.

Subacute bacterial endocarditis
See endocarditis.

Subacute combined degeneration of the spinal cord
Progressive damage to columns of nerves running through the spinal cord due to vitamin B₁₂ deficiency. Subacute combined degeneration of the spinal cord may occur as a complication of pernicious anaemia. Symptoms may include tingling and numbness of the limbs. Weakness and dementia (deterioration in brain function) may eventually develop. If left untreated, the disease may be fatal after around five years. Treatment is with vitamin B₁₂ injections.

Subacromial bursitis
Inflammation of the fluid-filled sac that cushions the acromion, part of the scapula (shoulderblade). The common source of the bleeding is a burst berry aneurysm (a swollen, weakened area of artery wall).

An attack may cause loss of consciousness, sometimes preceded by a sudden, violent headache at the back of the head. If the person remains conscious, photosophobia (abnormal sensitivity to light), drowsiness, nausea, vomiting and a stiff neck may develop. Both conscious and unconscious patients can recover, but it is common to have further attacks, which are often fatal.

Diagnosis of a subarachnoid haemorrhage is by CT scanning and angiography. Treatment includes life-support procedures and control of blood pressure to prevent recurrence. Burst or leaking aneurysms are usually treated by surgery. Ninety per cent of those people who survive for a month survive for at least a year; some of these have a complete recovery, and some may have a residual disability such as paralysis.

Stuttering
A speech disorder in which there is repeated hesitation and delay in uttering words, unusual prolongation of sounds, and repetition of word elements. Stuttering usually starts before the age of eight and may continue into adult life. It is more common in males, twins, and left-handed people, and may occur with tics or tremors. The severity may be related to social circumstances. The exact cause is unknown, although it tends to run in families. Speech therapy often helps.

Subconjunctival haemorrhage
Bleeding under the conjunctiva (the clear membrane covering the white of the eye), due to rupture of tiny, fragile

Subacute Sturge–Weber syndrome
Sturge–Weber syndrome is evident in this MRI of the brain. The black areas are the fluid-filled ventricles, and the white section (bottom left of the image) is part of the brain that has calcified.

Subclinical
A term for a disorder that produces no symptoms or signs, being either mild or in the early stages of development.

Subconjunctival haemorrhage
The bleeding causes a bright red area to appear in the white of the eye. A subconjunctival haemorrhage may look alarming but is usually harmless.

Stye
Also called a hordeolum, a small, pus-filled abscess at the base of an eyelash that is caused by bacterial infection.

Sydenham’s chorea
See St Vitus’ dance.

**St Vitus’ dance**
see Sydenham’s chorea.

**Stye**
Also called a hordeolum, a small, pus-filled abscess at the base of an eyelash that is caused by bacterial infection.

Stye on eyelid
Caused by infection at the base of an eyelash, a stye most often forms near the inner corner of the eye. This stye has formed in the centre, resulting in swelling and inflammation of the upper eyelid.

Sturge–Weber syndrome
Sturge–Weber syndrome is evident in this MRI of the brain. The black areas are the fluid-filled ventricles, and the white section (bottom left of the image) is part of the brain that has calcified.
blood vessels. A subconjunctival haemorrhage is usually harmless and disappears in a few days without any treatment.

**subconscious**
A term that is used to describe various mental events (such as thoughts) of which one is temporarily unaware but that can be recalled under the right circumstances.

**subcutaneous**
A term meaning “beneath the skin”.

**subdural haemorrhage**
Bleeding into the space between the outer and middle meninges (the membranes surrounding the brain), usually following head injury. The trapped blood forms a large clot within the skull that presses on brain tissue.

Signs and symptoms tend to fluctuate and may include headache, confusion, drowsiness, and one-sided weakness or paralysis. Bleeding occurs slowly; the interval between the injury and start of symptoms varies from days to months.

Diagnosis is by CT scanning or MRI to locate the clot. In many cases, surgery is needed. This involves drilling burr holes in the skull (see craniotomy) to drain the blood and repair damaged blood vessels. If treatment is carried out at an early enough stage, the person usually makes a full recovery. A small subdural haemorrhage that produces few symptoms may not require treatment. The affected person is usually monitored with regular scans, and the clot may clear up on its own. (See also extradural haemorrhage.)

**sublimation**
In psychoanalytic theory, the unconscious process by which primitive, unacceptable impulses are redirected into socially acceptable forms of behaviour.

**sublingual**
A term meaning “under the tongue”.

Drugs taken sublingually, either as tablets or spray, are rapidly absorbed through the lining of the mouth into the bloodstream. For example, nitrate drugs are given sublingually to provide rapid relief of an angina attack.

**subluxated tooth**
A tooth displaced in its socket following an accident. The upper front teeth are the most vulnerable. A subluxated tooth can usually be manipulated back into position before being immobilized (see splinting, dental). If the blood vessels of the tooth are torn in the accident, root canal treatment is required.

**subluxation**
Incomplete dislocation of a joint, in which the bone surfaces are displaced but remain in partial contact.

**suction**
The removal of unwanted fluid or semi-fluid material from the body with a syringe and a hollow needle or an intestinal tube and a mechanical pump.

**suction lipectomy**
See body contour surgery.

**Sudafed**
The brand name for the decongestant drug pseudoephedrine.

**sudden death**
See death, sudden.

**sudden infant death syndrome (SIDS)**
Also known as cot death, the sudden, unexpected death of an infant that cannot be explained.

Possible risk factors include: laying the baby face-down to sleep; overheating; parental smoking after the birth; prematurity and low birth weight; and poor socioeconomic background.

Preventive measures include: ensuring that the baby sleeps on its back at the foot of the cot; regulating the baby’s temperature (using one light layer of clothing and blankets more than an adult would need); and stopping smoking.

**Sudeck’s atrophy**
Swelling and loss of use of a hand or foot after a fracture or other injury. Treatment includes elevation of the affected hand or foot, gentle exercise, and heat treatment. Full recovery is usual within about four months.

**suffocation**
A condition in which there is a lack of oxygen due to obstruction to the passage of air into the lungs. (See also asphyxia; choking; strangulation.)

**sugar**
See carbohydrates.
sugar-free medicines

Drugs in liquid form that do not contain any sugar. These products have been developed in an attempt to reduce the exposure of children’s teeth to excessive amounts of sugar.

suicide

The act of intentionally killing oneself. Suicide results from a person’s reaction to a problem that he or she perceives as overwhelming, such as social isolation, death of a loved one, serious physical illness, or financial problems. Suicide is often the result of a psychiatric illness, such as severe depression or schizophrenia.

Suicide is most common among elderly people. More men than women commit suicide, although women attempt the act more often but are unsuccessful (see suicide, attempted). The most common method of suicide is poisoning, usually by drug overdose.

suicide, attempted

A deliberate act of self-harm that is or is believed to be life-threatening but proves to be nonfatal.

Attempted suicide occurs more commonly in women and is most common in the 15–30 age group. The rate is highest in people who have personality disorders and in those who live in deprived urban areas or have alcohol or drug problems. Trigger factors for attempted suicide include the death of a loved one, breakdown of a relationship, financial worries, or severe loss of any kind that results in depression. The most common method is drug overdose.

Urgent treatment is needed for drug poisoning. Longer-term therapy aims to provide support and treat depression.

sulphasalazine

A disease-modifying antirheumatic drug that is also used to relieve intestinal inflammation in Crohn’s disease and ulcerative colitis. Important side effects include aplastic anaemia (see anaemia, aplastic) and reduction in white blood cells and platelets (see thrombocytopenia); regular blood counts are usually carried out. Sulfasalazine may also cause other adverse effects including nausea, headache, fever, and appetite loss.

sulfinpyrazone

A drug that is used to reduce the frequency of attacks of gout. The side effects of sulfinpyrazone include nausea and abdominal pain.

sulindac

A nonsteroidal anti-inflammatory drug (NSAID) that is used to relieve joint pain and stiffness in arthritis and acute gout. Side effects of sulindac are the same as for other NSAIDs and include indigestion and sometimes bleeding or ulcers in the stomach.

sunburn

Inflammation of the skin caused by overexposure to the sun. The ultraviolet light in sunlight may destroy cells in the outer layer of the skin and damage tiny blood vessels beneath. Severe sunburn in childhood increases the risk of skin cancer in later life.

Fair-skinned people are most susceptible. The affected skin becomes red and tender and may blister. The dead skin cells are later shed by peeling.

Calamine lotion soothes burnt skin. Analgesic drugs can relieve discomfort. Avoiding exposure to the midday sun, wearing protective clothing, and applying a high protection factor sunscreen help to prevent sunburn.

sunlight, adverse effects of

Problems resulting from overexposure to the sun and in particular from the effects of the ultraviolet light in sunlight. Fair-skinned people are most susceptible. Short-term overexposure causes sunburn and, in intense heat, can lead to heat exhaustion or heatstroke. Repeated overexposure over a long period can cause premature aging of the skin and solar keratoses, and increases the risk of skin cancer. Protecting the skin with sunscreens helps to prevent sun damage.

Other adverse effects of sunlight include photosensitivity (an abnormal sensitivity to sunlight), resulting in a rash. Exposure to sunlight can also affect the eyes, causing irritation of the conjunctiva, actinic keratopathy, or pterygium. Good quality sunglasses help to prevent eye problems.

sun protection factor (SPF)

A measure of the amount of UVB radiation that a sunscreen absorbs and thus the degree of protection that it provides against sunburn. It is given as a number (SPF number); the higher the SPF number, the greater the protection. The number refers to how many times longer an individual can stay out in the sun without burning.

sunscreens

Also called sunblocks, preparations that help to protect the skin from the harmful effects of sunlight. To remain effective, however, sunscreens must be reapplied on a regular basis.

WARNING

Some suntanning preparations do not contain a sunscreen and therefore provide no protection against sunburn.
sunstroke
A common form of heatstroke.

suntan
Darkening of the skin after exposure to sunlight. Specialized cells in the epidermis (the outer skin layer) respond to ultraviolet light by producing the protective pigment melanin. Even if a suntan develops, however, the skin may suffer damage from overexposure to the sun. (See also sunburn; sunlight, adverse effects of.)

superego
The part of the personality, as described in psychoanalytic theory, that is thought to be responsible for maintaining a person’s standards of behaviour. Popularly termed the “conscience”, the superego arises as a result of a child incorporating the moral views of those in authority (usually parents).

superficial
Situated near the surface.

superinfection
A second infection that occurs during the course of an existing infection. The term usually refers to an infection by a microorganism that is resistant to drugs being used against the original infection. One example is candidiasis (thrush) caused by treatment with antibiotic drugs. The antibiotic destroys the body’s normal flora (microorganisms that are present in the body but do not produce any ill effects), which usually keep the candida yeast under control, preventing it from proliferating.

superiority complex
An individual’s exaggerated and unrealistic belief that he or she is better than other people. In modern psychoanalytic theory, a superiority complex is considered to be a compensation for unconscious feelings of inadequacy or low self-esteem.

superior vena cava obstruction
A condition in which blood flow through the superior vena cava (the major vein that returns blood to the heart from the upper body) is restricted, often by pressure in the chest. The restriction is most commonly the result of a tumour, particularly lung cancer or lymphoma. Pressure may build up in the blood vessels behind the obstruction, causing swelling of the face, neck, and arm.

supernumerary
A term meaning “more than the normal number”. Supernumerary teeth can also occur; they are usually extracted.

supernumerary nipple
One or more nipples in excess of the usual number.

supernumerary (extra) nipple
Additional nipples can develop along a line that extends from the armpit to the groin; the extra nipples are not usually associated with underlying glandular tissue.

supination
The act that involves turning the body to a supine position (lying on the back with the face upwards) or of turning the hand to a position in which the palm faces forwards. The opposite position to supination is pronation.

suppository
A solid medical preparation, of cone or bullet shape, designed to be placed in the rectum to dissolve. Suppositories are used to treat rectal disorders such as haemorrhoids or proctitis, or to soften faeces and stimulate defaecation. They may also be used to administer drugs into the general circulation via blood vessels in the rectum, if vomiting is likely to prevent absorption after oral administration or if the drug would cause irritation of the stomach.

suppressor T-cell
A type of white blood cell, also known as a suppressor T-lymphocyte (see lymphocyte) that is involved in the immune system. These cells act to prevent the immune response.

suppuration
The formation or discharge of pus.

suprarenal glands
Another name for the adrenal glands.

suprasellar cyst
See craniopharyngioma.

supraspinatus syndrome
Inflammation of the supraspinatus tendon, which is in the shoulder, causing painful arc syndrome.

supraventricular tachycardia
An abnormally fast but regular heart rate that occurs in episodes that vary in duration from several hours to a number of days. Supraventricular tachycardia occurs when abnormal electrical impulses that arise in the atria (upper chambers) of the heart take control of the heartbeat from the sinoatrial node (the cluster of cells that stimulates heartbeats). Symptoms include palpitations, breathlessness, chest pain, or fainting (see Stokes–Adams syndrome).

Diagnosis is by an ECG. An attack can sometimes be stopped by Valsalva’s manoeuvre or by drinking cold water. Recurrent attacks are treated with anti-arrhythmic drugs. Occasionally, supraventricular tachycardia may require application of an electric shock to the heart (see defibrillation).

surfactant
A substance that reduces surface tension in a liquid. Pulmonary surfactant is secreted by the alveoli in the lungs, preventing them from collapsing during exhalation. Because surfactant is absent in significantly premature babies, breathing difficulties can occur that can lead to respiratory distress syndrome. In such cases, artificial ventilation and an artificial surfactant need to be given.

surfer’s nodules
Multiple bony outgrowths on the foot bones and on the bony prominence just below the knee.

surgeon
A medical practitioner who is qualified to carry out surgery, although this definition does not include dental surgeons, who are not medically qualified.

surgery
Treatment of injury or other disorders by direct physical intervention, often with instruments. The word is also used for aspects of medicine that deal with the study, diagnosis, and management of disorders treated surgically.

surgical emphysema
The presence of gas trapped under the skin tissues following an injury or surgical procedure.
surgical spirit
A liquid preparation, consisting mainly of ethyl alcohol, that has a soothing and hardening effect when applied to the skin. It may be used before injections as an antiseptic.

surrogacy
The agreement by a woman to become pregnant and give birth to a child with the understanding that she will surrender the child after birth to the contractual parents. Pregnancy may be achieved either by artificial insemination or by in vitro fertilization.

susceptibility
Total or partial vulnerability to an infection or disorder.

Sustac
A brand name for glyceryl trinitrate, a drug used to prevent attacks of angina pectoris.

Sustanon
A brand name for the male sex hormone testosterone, given as a treatment to males whose bodies produce too little testosterone.

suture
A type of joint, found only between the bones of the skull, in which the adjacent bones are mobile during birth but then become so closely and firmly joined by a layer of connective tissue that movement between them is impossible.

The term “suture” is also used to refer to a surgical stitch (see suturing).

suturing
The closing of a surgical incision or a wound by sutures (stitches) to promote healing. Suturing may be carried out by means of a single continuous stitch under the skin (subcuticular) or by using individual stitches (interrupted). Some materials used in suturing, such as catgut, eventually dissolve in the body; skin sutures made of other materials are removed about one to two weeks after insertion, depending on the site in the body.

swab
A wad of absorbent material used to apply antiseptics or soak up body fluids during surgery or to obtain a sample of bacteria from an infected patient.

A surgical swab is commonly a folded piece of cotton gauze held in the hand.

METHODS OF SUTURING
Suturing is carried out under either a general or a local anaesthetic. The type of stitch used depends on the nature of the wound or incision (two types are shown below). In all cases the surgeon sews the wound edges together to produce minimal distortion of tissue.

Technique
The surgeon grasps the edge of the wound with forceps held in one hand and inserts the needle through the skin using the other hand. In this illustration, the surgeon is using a needle holder, which gives greater control for very fine stitches. In other cases, the needle may be held in the hand. Suturing sometimes requires assistance.

Suturing

**Standard interrupted sutures**
The needle is passed into one skin edge, through the full depth of the wound, and out of the other skin edge. Each stitch is then knotted at the side.

**Mattress sutures**
For deeper wounds, the needle is passed through the wound twice: first shallowly, close to the skin edges, and then more deeply, farther from the edges.

**OTHER METHODS OF CLOSURE**

Alternatives to suturing include removable staples and clips (staples are also used internally), adhesive tape, and tissue glue.

**Adhesive tape**
When the wound is shallow, tape may be applied directly. For deeper wounds, absorbable stitches are first inserted just beneath the skin.

**Inserting staples**
The wound edges are held up with forceps and staples, which are spaced out at equal intervals, are inserted using an automatic stapling device.
or in a clamp. It is used to apply cleansing and antiseptic solutions to the skin before an incision is made and to soak up blood and other fluids during an operation. The swab often contains material opaque to X-rays to enable it to be detected if it is accidentally left in the body after an operation.

A microbiological swab consists of a twist of cotton wool at the end of a thin stick, supplied in a sterile container. The swab is applied to an infected area of the body to absorb pus or mucus for microscopic examination.

**swallowing**

The process by which food or liquid is sent from the mouth to the stomach via the oesophagus. In the mouth, food is chewed and mixed with saliva to form a soft mass called a bolus; the tongue then pushes the bolus to the back of the mouth and voluntary muscles in the palate push it into the throat.

The rest of the swallowing process occurs by a series of reflexes. Entry of food into the throat causes the epiglottis to tilt down to seal the trachea (windpipe) and the soft palate to move back to close off the nasal cavity. The throat muscles push the food into the oesophagus (gullet). Waves of contractions (peristalsis) along the oesophagus propel the food towards the stomach.

**swallowing difficulty**

Known medically as dysphagia, a common symptom with various possible causes. These include a foreign object in the throat; insufficient production of saliva (see mouth, dry); a disorder of the oesophagus, such as oesophageal stricture; pressure on the oesophagus, for example from a goitre; a nervous system disorder such as myasthenia gravis or stroke; or a psychological problem such as globus hystericus.

Investigations of swallowing difficulty may include barium swallow (see barium X-ray examinations) or oesophagoscopy. Treatment depends on the cause.

**swamp fever**

Another name for leptospirosis, a disorder caused by contact with water contaminated by rats’ urine. The term is also sometimes applied to malaria.

**sweat glands**

Structures deep within the skin that produce sweat (a fluid composed mainly of water with some dissolved substances, including salt).

There are two types of sweat gland: known as eccrine and apocrine glands. Eccrine glands are the most numerous, and they open directly on to the skin’s surface. Apocrine glands open into a hair follicle. Developing at puberty, they occur only in hairy areas, particularly the armpits, pubic region, and around the anus.

The sweat glands are controlled by the autonomic nervous system. They usually release sweat in order to keep the body cool, but they may also do this in response to anxiety or fear. Sweat is odourless until bacteria act on it, producing body odour.

Disorders of the sweat glands include hyperhidrosis (excessive sweating); and hypohidrosis (insufficient sweating); and hidradenitis suppurativa (a disorder of the apocrine glands in which painful resistant papules, nodules, and scars occur in the armpit and groin).

**swimming**

A skin rash that occurs after swimming in fresh water contaminated with a form of fluke that infests snails and wildfowl. The itching is caused by fluke larvae burrowing through the skin. Swimmer’s itch may be a manifestation of *schistosomiasis*.

**sycosis barbae**

Inflammation of the beard area. The disorder is due to infection of the hair follicles, usually with *Staphylococcus aureus* bacteria contracted from razors or towels. Pus-filled blisters appear around the follicles. Treatment is usually with antibiotic drugs.

**Sydenham’s chorea**

Formerly called St Vitus’ Dance, a rare childhood disorder of the central nervous system. The condition, which usually follows rheumatic fever, causes involuntary jerky movements of the head, face, limbs, and fingers; voluntary movements are clumsy, and the limbs become floppy. Sydenham’s chorea usually clears up after two to three months and has no long-term adverse effects.

**Symmetrel**

A brand name for the antiviral drug amantadine.

** sympathectomy**

An operation in which the ganglia (nerve terminals) of certain sympathetic nerves are destroyed to interrupt the nerve pathway.

**WHY IT IS DONE**

The sympathetic nerves form part of the autonomic nervous system and control involuntary (automatic) activities in the body, including widening and narrowing of blood vessels. In peripheral vascular disease (a disorder in which the blood vessels in the legs, and sometimes the arms, become narrowed), stimulation from the sympathetic nerves produces spasms in the blood vessels and worsens the narrowing. Sympathectomy prevents these spasms from occurring and may improve the blood supply flowing to the affected area.
The sympathetic nerves also play an important part in producing the sensation of pain. In some cases of causalgia (persistent severe pain usually caused by nerve injury), only sympathectomy can provide relief.

**sympathetic nervous system**

One of the two divisions of the **autonomic nervous system**, which, along with the parasympathetic nervous system, controls many of the involuntary activities in the body. The sympathetic nervous system increases body activities (it quickens the heartbeat and widens blood vessels in muscles, for example) in preparation for coping with stress (see **fight-or-flight response**).

**sympathomimetic drugs**

Drugs that stimulate the **sympathetic nervous system** by mimicking the effects of natural chemicals that control functions such as heart rate, blood flow, and digestion. Sympathomimetic drugs include **decongestant drugs**, which work by constricting blood vessels in the nasal membranes, and **bronchodilator drugs**, which work by widening the small airways of the lungs.

**symphyseal joint**

A type of joint in which two bones are firmly joined by tough cartilage. Such joints occur in various parts of the body: between the vertebrae; between the pubic bones, at the front of the pelvis; and between the upper and middle parts of the sternum (breastbone).

**symptom**

An indication of a disease or disorder that is noticed by the sufferer him- or herself. By contrast, the indications that a doctor notes are called signs. (See also **withdrawal syndrome**.)

**symptoms, first rank**

Certain features of mental illness, the presence of which indicate a likely diagnosis of **schizophrenia**. They include **auditory hallucinations** (the person hears voices having a conversation or commenting on him or her); thought broadcasting (the belief that one’s thoughts are being broadcast to the outside world); thought insertion (the belief that thoughts are being put into one’s head); thought withdrawal (thoughts are being removed from one’s head); and passivity (thoughts and actions are being controlled from an external source). Such symptoms may be caused by other conditions, such as psychiatric problems related to the toxic effects of certain illegal drugs (see **drug psychosis**), and these other problems must be ruled out before the diagnosis of schizophrenia can be confirmed.

**sympotothermal method**

See **contraception, natural methods of**.

**Synacthen**

A brand name for **tetracosactide**, a drug that is used to assess the function of the adrenal glands.

**synaesthesia**

A condition in which stimulation of one of the senses produces an unusual response in addition to the normal perception that is associated with the particular stimulus; for example, when a sound causes a person to see a colour as well as hear the noise.

**synapse**

A junction between two neurons (nerve cells) across which a signal can pass. At a synapse, the two neurons do not come directly into contact but are separated by a gap called the synaptic cleft. When an electrical signal passing along a neuron reaches a synapse, it causes the release of a chemical called a neurotransmitter. The neurotransmitter crosses the synaptic cleft to the next neuron, where it stimulates an electrical signal in that neuron. Signals can cross a synapse in one direction only.

Most drugs affecting the nervous system work as a result of their effects on synapses. Such drugs may affect the release of neurotransmitters, or they may modify their effects.

**syndactyly**

A congenital defect in which two or more fingers or, more commonly, toes are joined. Syndactyly is often inherited and is more common in males. In mild cases, adjacent digits (fingers or toes) are joined by only a web of skin; in more serious cases, the bones are fused. Surgery to separate the digits may be performed in early childhood.
The term “syndrome X” is also used for a group of factors that are often found in people with ischaemic heart disease, and whose presence is associated with an increased risk. These risk factors include excessive fat around the abdomen (central obesity), hyperlipidaemia (high levels of fats in the blood), hypertension (high blood pressure), and insulin resistance.

**synergistic muscles**
Muscles that work together to produce a particular movement.

**synovectomy**
Surgical removal of the membrane lining a joint capsule to treat recurrent or persistent synovitis, usually in cases of severe rheumatoid arthritis.

**synovitis**
Inflammation of the membrane lining the capsule of a movable joint. The condition may be acute, in which case it is usually caused by an attack of arthritis, injury, or infection; or chronic, due to a disorder such as rheumatoid arthritis. The joint becomes swollen, painful, and often warm and red.

To find the cause of synovitis, joint aspiration (taking a sample of the joint’s lubricating fluid) or biopsy (taking a sample of the membrane) may be needed. Symptoms are relieved by rest, supporting the joint with a splint or cast, analgesics, nonsteroideal anti-inflammatory drugs, and, occasionally, a cortico-steroid injection. Chronic synovitis may be treated by synovectomy.

**synovium**
The membrane lining the capsule around a movable joint. The synovium also forms a sheath for certain tendons of the hands and feet. It secretes synovial fluid, which lubricates the joint or tendon. The synovium can become inflamed; in a joint this problem is known as synovitis, while in a tendon sheath it is known as tenosynovitis.

**syphilis**
An infection caused by Treponema pallidum bacteria. Syphilis is spread by sexual intercourse or other intimate body contact; the organism enters the body through broken skin or mucous membranes, then spreads rapidly via the bloodstream and lymphatic system. Syphilis can also be spread by nonsexual means, such as through broken skin or saliva, but this occurs mainly in the Middle East and Africa. Rarely, it may be transmitted from mother to fetus during pregnancy (congenital syphilis).

**SIGNS AND SYMPTOMS**
In sexual infection, the first sign is a painless ulcer (chancre) that develops on the genitals, anus, rectum, lips, throat, or fingers and heals in four to eight weeks. A rash then develops, which may be transient or recurrent, or may last for months. Other possible signs include lymph-node enlargement, headache, bone pain, loss of appetite, fever, and fatigue. Thickened, grey or pink patches may develop on moist areas of skin and are highly infectious. Meningitis may also develop.

Following this symptomatic phase, the disease becomes latent (hidden) for a few years, or sometimes indefinitely. A few untreated cases proceed, eventually, to a final stage characterized by widespread tissue destruction. Other serious effects include cardiovascular syphilis, which affects the aorta and leads to aneurysm and heart-valve disease; neurosyphilis, with progressive brain damage and paralysis; and tabes dorsalis, a disorder affecting part of the spinal cord.

**LOCATION OF SYNOVUIM**
Every movable joint is enclosed within a fibrous capsule. The inner lining of the capsule is known as the synovium.

**SYNERGISTIC MUSCLES**

Signs of congenital syphilis include a rash, persistent snuffles, bone abnormalities, jaundice, and enlargement of the liver and spleen. Keratitis (inflammation of the cornea), a characteristic flat face, peg-shaped teeth, arthritis, and learning difficulties may appear later in childhood.

**DIAGNOSIS AND TREATMENT**
Diagnosis is by examination of chancre serum or by blood tests. All forms of syphilis are treated with antibacterial drugs. Organ damage already caused by the disease cannot be reversed.

**PREVENTION**
Practising safer sex can help to prevent syphilis infection. People with syphilis are infectious in the early stages but not in the latent and final stages.

**syringe**
A hollow, cylindrical instrument that is commonly used with a needle to inject fluid into, or withdraw fluid from, a body cavity, blood vessel, or tissue.

**syringe driver**
A portable device comprising a syringe of medication attached to a small pump. It is used to provide continuous pain relief in conditions such as cancer. The syringe driver delivers a certain amount of an analgesic (painkiller), over a set period of time, through a needle inserted into the skin.

**syringe, oral**
A form of syringe with no needle, used to give medicines by mouth, especially to young children. A small, accurately measured dose of a drug is drawn up into the syringe, then the tip of the device is placed inside the child’s mouth and the drug is directed against the inside of the cheek.

**syringing of ears**
The flushing of excess earwax or a foreign body from the outer ear canal by introducing water from a syringe into the ear canal.

**syringomyelia**
A rare, progressive condition, of unknown cause, in which a cavity forms in the brainstem (the lowest part of the brain) or in the spinal cord at neck or thoracic level. The cavity gradually expands, filling with cerebrospinal fluid and compressing nearby nerve fibres. Syringomyelia is usually a congenital condition and may be associated with congenital
deformity of the brain. It may also occur after spinal cord injury.

Signs usually appear in early adulthood and include lack of temperature or pain sensation; muscle wasting in the neck, shoulders, arms, and hands; and some loss of the sense of touch. Later, there is difficulty in moving the legs and controlling the bladder and bowel, and the joints may become deformed.

There is no drug treatment. Surgery can relieve pressure in the central cavity to prevent further enlargement, relieve pressure on the distended spinal cord (see decompression, spinal canal), or slow the deterioration.

**EAR SYRINGING**

This procedure should be carried out by a doctor or nurse; amateur attempts can damage the eardrum.

**Syrinx**

An abnormal cavity in the brainstem or spinal cord; a feature of syringomyelia.

**System**

A group of interconnected or interdependent organs with a common function, as in the digestive system.

**Systemic**

A term applied to something that affects the whole body rather than a specific part of it. For example, fever is a systemic symptom, whereas swelling is a localized symptom. The term “systemic” is also applied to the part of the blood circulation that supplies all parts of the body except the lungs.

**Systemic lupus erythematosus**

See lupus erythematosus.

**Systemic sclerosis**

A progressive form of scleroderma, systemic scleroderma is a rare autoimmune disorder (in which the immune system attacks the body’s own tissues). The condition can affect many organs and tissues, particularly the skin, arteries, kidneys, lungs, heart, gastrointestinal tract, and joints. Systemic sclerosis is three times as common in women as in men and is most likely to appear between the ages of 30 and 50.

The disease varies in severity. It often begins with the symptoms of Raynaud’s phenomenon, a disorder in which the fingers and toes become white, numb, and painful when exposed to cold. This is followed some years later by thickening and tightness of the skin of the face, hands, forearms, and feet. In more severe cases, internal organs are affected. Symptoms may include heartburn or difficulty swallowing because of damage to the oesophagus. Pulmonary hypertension (high blood pressure in the arteries supplying the lungs) may develop, sometimes up to 15 years after the onset of the disease.

Systemic sclerosis often progresses rapidly in the first few years and then slows down or even stops. In a minority of people, degeneration is rapid, and leads to death from heart failure, respiratory failure, or kidney failure. There is no cure for systemic sclerosis, but many of the symptoms can be relieved by drug treatment or physiotherapy.

**Systole**

Muscular contraction of a chamber of the heart that alternates with a resting period (diastole). There are two stages of systole, namely atrial and ventricular. With each heartbeat, the atria (upper chambers) contract, squeezing blood into the ventricles (lower chambers). This action is followed by ventricular systole, in which the ventricles squeeze blood into the arteries.

The first of the two heartbeat sounds is associated with systole and represents the closing of the valves between the atria and ventricles; this action prevents blood from flowing back into the atria. The second sound relates to the diastole and signifies the closing of the aortic and pulmonary valves at the exits of the ventricle. (See also pulse; sphygmomanometer.)
tabes dorsalis
A rare complication of untreated syphilis that appears years after infection. The condition affects the spinal cord and causes abnormalities of sensation, sharp pains, incoordination, and incontinence.

tablet
A type of drug preparation in the form of a compressed plug. As well as the drug itself, a tablet contains other ingredients, such as disintegrating agents (to help the tablet dissolve), binding agents, and lubricants, and may have a sugar or membrane coating.

tachycardia
An adult heart rate of over 100 beats per minute. The average heart rate is 68–78 beats per minute. Tachycardia occurs in healthy people during exercise. At rest, tachycardia may be due to fever, anxiety, hyperthyroidism (overactivity of the thyroid gland), coronary artery disease, high caffeine intake, or treatment involving anticholinergic drugs.

There are various types of tachycardia, which originate in different areas of the heart; these include atrial fibrillation, sinus tachycardia, supraventricular tachycardia, and ventricular tachycardia.

The symptoms of tachycardia may include palpitations, breathlessness, and lightheadedness.

tachypnoea
An abnormally fast rate of breathing, which may be caused by exercise, anxiety, or lung or cardiac disorders.

Taenia
A genus of tapeworms (see tapeworm infestation), some species of which can infest humans. These include Taenia solium, which is passed on through contaminated pork, and Taenia saginata, whose larvae develop in beef.

Tagamet
A brand name for cimetidine, an ulcer-healing drug.

T’ai chi
A Chinese exercise system based on a series of over 100 postures between which slow, continuous movements are made. The aim is to exercise the muscles and integrate mind and body.

Takayasu’s syndrome
A disorder, also known as Takayasu’s arteritis, in which the arteries branching from the aorta become inflamed and progressively blocked. The cause is unknown. The condition is rarely diagnosed outside Asian countries such as Japan. Absence of a pulse in the arms or neck is characteristic, and blood pressure is increased. Symptoms such as paralysis of facial muscles and episodes of unconsciousness may occur due to minor strokes.

talipes
A birth defect (commonly called clubfoot) in which the foot is twisted out of shape or position. Most cases are thought to be due to pressure on the baby’s feet from the mother’s uterus in late pregnancy. A genetic factor is also sometimes present. The most common form of talipes is an equinovarus deformity, in which the heel turns inwards and the rest of the foot bends down and inwards. Also, the tibia (shinbone) may be twisted inwards and the lower-leg muscles may be underdeveloped. Both feet may be affected. This defect is twice as common in boys as in girls.

Talipes equinovarus
This birth defect, commonly known as club foot, affects about one baby in 900. Treatment is by gentle manipulation, repeated several times a day.

TREATMENT
Talipes equinovarus is treated by repeated manipulation of the foot and ankle, starting soon after birth. A plaster cast, splint, or strapping may be used to hold the foot in position. If these measures are not successful by the time the baby is three to six months of age, surgery may be performed.

talus
The square-shaped foot bone that forms the ankle joint together with the tibia and fibula bones of the lower leg.

tamoxifen
An anticancer drug used to treat certain forms of breast cancer and some types of infertility. It may cause nausea, vomiting, hot flushes, swollen ankles, and irregular vaginal bleeding. Use of the drug is associated with a slight increased risk of endometrial cancer (see uterus, cancer of) and deep vein thrombosis (see thrombosis, deep vein).

tampon
A plug of absorbent material inserted into a wound or body opening to soak up blood or other secretions. The term commonly refers to a vaginal tampon, used to absorb menstrual blood.

tamponade
Compression of the heart by fluid within the pericardium (the membrane surrounding the heart), which may cause breathlessness and collapse. Causes include pericarditis (inflammation of the pericardium), complications after heart surgery, or a chest injury.

A diagnosis is made by echocardiography. Treatment of tamponade involves removing the fluid.

tamsulosin
An alpha-blocker drug used to treat urinary symptoms due to enlargement of the prostate gland (see prostate, enlarged). Side effects include low blood pressure, drowsiness, dry mouth, and gastrointestinal disturbances.

tan
See suntan.

Tangier disease
A rare autosomal recessive disorder (see genetic disorders) in which cholesterol builds up in various body organs, including the tonsils, liver, and spleen.

tannin
Also known as tannic acid, a chemical that occurs in many plants, particularly tea. It may cause constipation, and large amounts cause liver damage.

tantrum
An outburst of bad behaviour, common in toddlers, usually indicating frustration and anger. During a tantrum, the child
may scream, cry, yell, kick, bang the feet and fists, roll on the floor, go red in the face, spit, and bite. Some toddlers hold their breath, turning blue and, in rare cases, momentarily losing consciousness (see breath-holding attacks).

CAUSES

Tantrums occur at the age when a child starts to gain independence and becomes frustrated by restraints imposed by others, but is not yet able to express feelings verbally. Outbursts are more likely when a child is tired or when normal routine is disrupted, for example, by the birth of another baby. Occasional tantrums are considered normal; frequent outbursts may indicate an underlying behavioural problem or communication difficulty.

TREATMENT

Firm and consistent handling of the child is essential. Tantrums should be ignored as much as possible; a child’s attention can often be diverted to a game or project. Most children grow out of tantrums when they develop the ability to express their feelings.

**tapeworm infestation**

Ribon-shaped worms that infest the intestines of humans and animals. Tapeworms (cestodes) are usually acquired by eating undercooked meat or fish. An adult tapeworm has a flat, segment-ed body and suckers or hooks on its head, by which it attaches itself to the intestinal wall.

**LIFE-CYCLE OF TAPEWORM**

Many tapeworms have life-cycles in which the adult and larval worms infest different hosts. In the cycle on the right, the adult worms infest humans and the larvae infest cattle (called the intermediate hosts). Pigs and fish may also act as intermediate hosts to human tapeworms, and humans may act as intermediate hosts to dog and pig tapeworms.

**TYPES**

Three large species of tapeworms are acquired by eating undercooked, infected beef, pork, and fish. The adults may grow up to 6 to 9 m long. Typically, tapeworms such as this have life-cycles that usually involve another animal host (see illustrated box). Tapeworms occur worldwide but infestations are largely prevented in countries that have adequate measures for inspecting meat and disposing of sewage.

The much smaller dwarf tapeworm, which is only 2.5 cm long, can be acquired through accidental transfer of worm eggs in human faeces to fingers and then to mouth. This worm is most common in the tropics and primarily affects children.

Humans may also act as intermediate hosts to the larvae of a tapeworm for which dogs are the main host.

**SYMPTOMS**

Despite their size, tapeworms from beef, pork, and fish usually only cause mild abdominal discomfort or diarrhoea. However, if eggs of pork worms are ingested, the hatched larvae burrow into tissues to form cysts. This leads to cysticercosis, the symptoms of which are muscle pain and convulsions. Rarely, fish tapeworms cause anaemia. Tapeworm larvae acquired from dogs grow and develop into cysts in the liver and lungs, a condition called hydatid disease.

**DIAGNOSIS AND TREATMENT**

A diagnosis is made from the presence of worm segments or eggs in the faeces. Treatment with anthelmintic drugs is usually effective.

**tar**

A dark, sticky substance distilled from organic materials such as peat, coal, or wood. Coal tar is used as an ingredient in some skin preparations for the treatment of psoriasis and eczema, and in some soaps and shampoos.

Tar residue from burning tobacco in cigarette smoke collects as deposits in smokers’ lungs.

**tardive dyskinesia**

Abnormal, uncontrolled movements, mainly of the face, tongue, mouth, and neck. Tardive dyskinesia may be caused by prolonged use of antipsychotic drugs, and is distinct from the movement disorder parkinsonism.

**tarsal**

A term denoting or relating to any of the seven bones that make up the tarsus.

**tarsalgia**

Pain in the rear part of the foot, usually associated with flat feet.

**tarsal tunnel syndrome**

An uncommon disorder arising from abnormal pressure on the tibial nerve in the foot. Where this nerve curves round the inside of the ankle, it passes through the tarsal tunnel, a space formed between the bones of the ankle joint and bands of supporting fibrous tissue. If this space becomes constricted, the nerve is trapped and compressed.

Tarsal tunnel syndrome sometimes occurs when injury, or stress from overactivity, damages foot structures. It is also more common in people with flat feet. The usual symptoms are pain and a burning or tingling sensation on the sole of the foot.

Rest and anti-inflammatory drugs may be all that is needed. Persistent cases may be treated by physiotherapy, injections of corticosteroid drugs or, possibly, surgery to open up the tarsal tunnel.

**tarsorrhaphy**

Surgery in which the upper and lower eyelids are partially or completely sewn together. Tarsorrhaphy may be used as part of the treatment of corneal ulcer, or to protect the corneas of people who
cannot close their eyes or those with exophthalmos (bulging eyes). The eyelids are later cut apart and allowed to open.

tarsus
The seven bones that make up the back of the foot and the ankle.

tartar
See calculus, dental.

tartrazine
A yellow dye that is commonly used as a food colouring in soft drinks, confectionery, and ready-prepared meals. (See also food additives.)

taste
One of the five senses. Taste can distinguish between sweet, salt, sour, and bitter, but in combination with the sense of smell, many different flavours can be distinguished. A fifth taste, umami, has now been recognized. Tastes are detected by structures called taste buds.

taste bud
One of 10,000 specialized structures located mainly on the tongue, with some at the back of the throat and on the palate. Each bud contains about 50 sensory receptor cells, with tiny taste hairs that respond to food and drink.

**THE SENSE OF TASTE**

Tastes are detected by special structures, which are called taste buds. Every person has some 10,000 taste buds, mainly situated on the tongue, with a few at the back of the throat and on the palate. These taste buds surround pores within papillae (protuberances) on the tongue surface and elsewhere. There are five types of taste buds (sensitive to sweet, salty, sour, bitter, and umami chemicals). All tastes are formed from a mixture of these five elements.

---

**How a substance is tasted**

Chemicals in food or drink dissolve in saliva and enter pores in the papillae on the tongue. Around these pores are groups of taste receptor cells – the taste buds. The chemicals stimulate hairs projecting from the receptor cells, causing signals to be sent from the cells along nerves to taste centres in the brain.

---

**Magnified photograph of tongue surface**

This photograph shows large (fungiform) and small (filiform) papillae. Taste buds are arranged around pores in the surface of the papillae.

---

**TASTE CENTRES**

Taste buds sensitive to sweet, salty, sour, or bitter are grouped in particular areas on the surface of the tongue. The areas sensitive to umami are not yet known.
tattooing
The introduction of permanent colours under the skin surface. Tattooing is used to create a picture on the skin for decorative purposes or may be carried out therapeutically (for example to “draw” on a nipple following breast surgery). Tattooing, even by professionals, is potentially dangerous. Unless strict sterile procedures are followed, the viruses that cause hepatitis and AIDS may be transmitted through the tattooist’s needles.

Tattoo removal is usually difficult and rarely satisfactory. Small tattoos can be cut out; larger ones can sometimes be removed by dermabrasion or laser treatment.

taxanes
A group of anticancer drugs used to treat certain cancers, such as ovarian cancer (see ovary, cancer of) and breast cancer. They work by preventing the growth of cancer cells. Common taxane drugs include paclitaxel and docetaxel.

Tay–Sachs disease
A serious inherited metabolic disorder (see metabolism, inborn errors of) that causes premature death. The cause is deficiency of the enzyme hexosaminidase A, which results in a buildup in the brain of a harmful substance. Symptoms usually appear after the age of six months and include blindness, paralysis, and seizures, leading to death by age three to five years.

Diagnosis is made by analysis of the enzymes of white blood cells. Tay–Sachs disease is now largely prevented by genetic counselling of high-risk groups such as Ashkenazi Jews.

TB
An abbreviation for tuberculosis.

T-cell
A class of lymphocyte.

tear duct
One of the channels, also known as a nasolacrimal duct, through which tears drain into the nose. (See also lacrimal apparatus.)

tear gas
See CS spray.

tears
The watery, salty secretion produced by the lacrimal glands, part of the lacrimal apparatus of the eye. Tears keep the cornea and conjunctiva moist to maintain transparency of the cornea and prevent ulcers; to aid blinking; and to wash away foreign particles. Tear production increases in response to eye irritation and emotion. (See also artificial tears.)

technetium
A radioactive element used in radionuclide scanning.

teeth
Hard, bonelike projections set in the jaws and surrounded by the gums. The teeth are used for mastication (chewing), help to form speech, and give shape to the face. At the centre of each tooth is the pulp, which contains blood vessels and nerves and is surrounded by hard dentine. The crown, the part of the tooth above the gum, is covered by enamel, the hardest substance in the body. The roots of the tooth, which fit into the jawbone, are covered by bonelike cementum. (See Structure and arrangement of teeth box, overleaf.)

Adult humans have 32 permanent teeth, which erupt after the primary teeth are lost, starting from about the age of six. These teeth comprise chisel-shaped, biting incisors; sharp, pointed canines; grinding premolars; and larger grinding molars. (See also anodontia.)

teeth, care of
See oral hygiene.
teething
The period when a baby cuts his or her primary teeth (see eruption of teeth). Usually, the first signs of teething occur at about six months of age.

SYMPTOMS AND SIGNS
While teething, a baby may be irritable, fretful, clingy, may have difficulty sleeping, and may cry more than usual. Extra saliva may be produced, resulting in dribbling, and the baby tends to chew on anything that comes to hand.

Before a tooth emerges, the gum may become red and swollen. When molars erupt, the cheek may feel warm and look red on the affected side.

TREATMENT
Symptoms may be relieved by the use of painkilling gels that are rubbed on the gums, or liquid preparations.

teichopsis
A visual disturbance in which shimmering, jagged patterns of light appear in front of the eyes. Teichopsis is sometimes experienced just before the onset of a migraine attack.

telangiectasia
An increase in the size of small blood vessels beneath the surface of an area of skin, causing redness and a “broken veins” appearance. Telangiectasia is most commonly found on the nose and cheeks. There may be no obvious cause for telangiectasia, or the condition may be caused by many years of excessive alcohol consumption, the skin condition rosacea, overexposure to sunlight, or a disease of connective tissue such as dermatomyositis.

Telangiectasia is not a cause for concern, but if very unsightly the veins can be removed in some cases by electrodesiccation (electrical destruction of the upper layers of the skin) administered by a dermatologist or by laser treatment. (See also spider naevus.)

Cosmetic laser surgery for telangiectasia

A hand-held laser is used to remove the broken veins. Although often referred to as “broken,” the blood vessels are, in fact, simply larger than usual.

telecardiography
The recording of an ECG by transmission of impulses (such as via a telephone line) to a site that is remote from the patient. (See also Holter monitor.)
temazepam
A benzodiazepine drug that is used to treat insomnia. It is also a drug of abuse.

temperature
In the human body, temperature must be maintained at around 37°C for optimum functioning. This varies slightly, not only among individuals but also in the same person, as temperature is affected by such factors as exercise, sleep, eating and drinking, time of day, and, in women, the stage of the menstrual cycle.

TEMPERATURE REGULATION
Body temperature is maintained by the hypothalamus, an area in the brain, which monitors blood temperature and
activates mechanisms automatically to compensate for any changes.

When body temperature falls, the hypothalamus sends nerve impulses to stimulate shivering, which creates heat by muscle activity. Nerve impulses are also sent to constrict blood vessels in the skin, which minimizes heat loss. When the body temperature rises, the hypothalamus stimulates sweating and dilates (widens) blood vessels in the skin to increase heat loss. A large number of factors (such as infections or extremes of heat and cold) may disrupt the body’s heat-regulating system, making temperature too high or too low. (See also fever; heatstroke; hypothermia.)

temperature method
See contraception, natural methods of.

temporal
A medical term meaning of or near the temples or a temple.

temporal arteritis
An uncommon disease of older people in which the walls of the arteries in the scalp over the temples become inflamed. Other arteries in the head and neck may also be affected, as may the aorta (the
SYMPTOMS
Attacks of this form of epilepsy cause dreamlike states, unpleasant hallucinations of smell or taste, the perception of an illusory scene, or déjà vu. There may also be grimacing, rotation of the head and eyes, and sucking and chewing movements. The affected person may have no memory of activities during an attack, which can last for minutes or hours. Sometimes, the seizure develops into a grand mal seizure.

DIAGNOSIS AND TREATMENT
Diagnosis and drug treatment is the same as for other forms of epilepsy.

TEMPOROMANDIBULAR JOINT DYSFUNCTION

Pain and other symptoms affecting the head, jaw, and face that are thought to occur when the temporomandibular joints and the muscles and ligaments attached to them do not work together correctly. CAUSES
A common cause of temporomandibular joint dysfunction is spasm of the chewing muscles, often caused by clenching or grinding the teeth as a result of emotional tension. Malocclusion (an incorrect bite) may be a contributing factor.

LOCATION OF THE TEMPORAL Lobe
The temporal lobe forms much of the lower side of each half of the cerebrum (main mass of the brain).

LOCATION OF THE TEMPORAL ARTERY
In this disorder, the temporal artery and other arteries in the head are inflamed. Early treatment of temporal arteritis is vital, because if the condition is left untreated, there is a risk of sudden blindness.

SYMPTOMS
About half of the cases, the ophthalmic arteries supplying the eyes are affected, which may cause sudden blindness if untreated. Other symptoms and signs include fever and poor appetite. DIAGNOSIS AND TREATMENT
Early reporting of symptoms is essential due to the risk of blindness. The diagnosis of temporal arteritis is made by blood tests, including ESR (erythrocyte sedimentation rate), and in some cases by a biopsy (tissue sample) of the artery.

Treatment with a corticosteroid drug usually has a rapid effect; otherwise, immunosuppressant drugs may be given. Temporal arteritis usually clears up completely within two years.

temporal artery biopsy
A procedure in which a small segment of tissue is taken from the temporal artery (situated at the side of the scalp) and examined under a microscope. Temporal artery biopsies are performed to detect signs of inflammation and thereby to diagnose temporal arteritis.

temporal lobe epilepsy
A form of epilepsy in which abnormal electrical discharges occur in the temporal lobe (most of the lower side of each half of the cerebrum) in the brain.

CAUSES
The usual cause of this type of epilepsy is damage to the temporal lobe, which may be due to a birth injury, head injury, brain tumour, brain abscess, or stroke.

LOCATION OF THE TEMPORAL ARTERY
If the temporal artery is inflamed, it is usually prominent and there is a persistent severe headache and scalp tenderness in the area of the head shown above.

NORMAL ARTERY
In a normal artery, there is a smooth lining, and the blood flow through it is sufficient to meet the needs of the tissues it supplies.

INFILTRATED ARTERY
In arteritis, the walls of the artery become disrupted and thickened, and blood flow through it is therefore markedly reduced.

artery that carries oxygenated blood from the heart) and its main branches. The inflamed vessels become narrowed, reducing blood flow through them.

CAUSES
The cause of temporal arteritis is unknown, but the condition may be associated with polymyalgia rheumatica (pain and stiffness in the muscles of the hips, thighs, shoulders, and neck).

SYMPTOMS
The most common symptom is a severe headache on one or both sides of the head. The temporal artery (located at the side of the head above the earlobe) may be prominent and the scalp tender. In
factor because it places additional stress on the muscles. Temporomandibular joint problems may also be caused by jaw, head, or neck injuries. In rare cases, osteoarthritis may be the cause.

**SYMPTOMS**

Common symptoms include headaches, tenderness of the jaw muscles, and an aching facial pain, especially in or around the ear. There may also be difficulty in opening the mouth, locking of the jaws, clicking noises as the mouth is closed or opened, or pain caused by opening the mouth wide or chewing.

**TREATMENT**

In most cases, treatment involves eliminating muscle spasm and relieving pain with analgesic drugs. In some cases, injections of corticosteroid drugs into the joint may be given. The bite may need to be adjusted by the use of an orthodontic appliance. In severe cases, surgery on one or both temporomandibular joints may be needed.

**tenderness**

Pain or abnormal sensitivity in a part of the body when it is pressed or touched.

**tendinitis**

Inflammation of a tendon, usually due to injury or overuse. Symptoms of tendinitis include restricted movement, pain, and tenderness. Treatment is with non-steroidal anti-inflammatory drugs (NSAIDs), ultrasound treatment, or injection of a corticosteroid drug around the tendon.

**tendolysis**

An operation performed to free a tendon from adhesions (fibrous bands) that limit its movement. The adhesions are usually caused by tenosynovitis (inflammation of the inner lining of a tendon sheath).

**tendon**

A fibrous cord that joins muscle to bone. Tendons are strong and flexible, but inelastic. They are made up principally of bundles of collagen (a white, fibrous protein) and contain some blood vessels. Those in the hands, wrists, and feet are enclosed in synovial sheaths (fibrous capsules) that secrete a lubricating fluid, which allows movement without excessive friction.

**DISORDERS**

Tendinitis, inflammation of a tendon, may follow an injury. Tenosynovitis, inflammation of the inner lining of a tendon sheath, usually affects tendons in the hands and wrists and results from overuse. Inflammation of the outer wall of a tendon sheath, a condition known as tenovaginitis, may restrict movement of the tendon through the sheath.

Injury may cause a tendon rupture. The Achilles tendon in the heel can rupture during vigorous sprinting and jumping. In many cases, however, because tendons are strong, severe stress results in pulling off a piece of bone where the tendon is attached, rather than tearing of the tendon itself.

**tendon release**

See tendolysis.

**tendon repair**

Surgery to join the cut or torn ends of, or to replace, a damaged tendon.

**tendon rupture**

A complete tear in a tendon. A tendon may rupture when the muscle to which it is attached contracts suddenly and powerfully, such as during vigorous exercise. Rupture may also be the result of an injury or joint disorder such as rheumatoid arthritis.

Symptoms include a snapping sensation, impaired movement, pain, and swelling. Diagnosis is usually obvious from the symptoms alone. Surgery to repair the tendon may be needed. In some cases, the tendon may heal if immobilized in a plaster cast.

**tendon transfer**

Surgery to reposition a tendon in order for it to make a muscle perform a different function. The tendon is cut from its original point of attachment and reattached elsewhere, making the muscle lie in a different position. The procedure may be used to treat talipes (club-foot) or permanent muscle injury or paralysis.

**tenecteplase**

A thrombolytic drug used in the treatment of myocardial infarction (heart attack). Tenecteplase is administered by intravenous injection.

**tenesmus**

A feeling of incomplete emptying of the bowel in which an urge to pass faeces accompanies ineffective straining. It may be a symptom of inflammation or of a tumour (see colon, cancer of).

**tennis elbow**

Pain and tenderness on the outside of the elbow and in the back of the forearm. Also called lateral epicondylitis, it is caused by inflammation of the tendon that attaches the muscles that straighten the fingers and wrist to the humerus (upper-arm bone).

The treatment of tennis elbow consists of resting the arm, applying ice packs, and taking analgesic drugs (painkillers) or nonsteroidal anti-inflammatory drugs (NSAIDs). Ultrasound treatment, injection of a corticosteroid drug, or surgery are sometimes needed.

**tenosynovitis**

Inflammation of the lining of the sheath that surrounds a tendon. The usual cause is excessive friction caused by repetitive use.
movements; bacterial infection is a rare cause. The hands and wrists are most often affected in tenosynovitis. Symptoms include pain, tenderness, and swelling over the tendon.

Treatment is with nonsteroidal anti-inflammatory drugs (NSAIDs) or a local injection of a corticosteroid drug. However, if infection is the cause, antibiotics are prescribed. A splint to immobilize the joint, or surgery, may also be needed.

tenovaginitis
Inflammation or thickening of the fibrous wall of the sheath that surrounds a tendon. Tenovaginitis affecting the sheath of one of the tendons that bends a finger results in trigger finger.

TENS
Abbreviation for transcutaneous electrical nerve stimulation, a method of pain relief. Minute electrical impulses, which block pain messages to the brain, are relayed from an impulse generator to electrodes attached to the skin in the area of the pain. TENS can help relieve chronic pain not controlled by analgesic drugs and may be used in childbirth.

tension
A feeling of mental and physical strain associated with anxiety. Muscle tension may cause headaches and stiffness. Persistent tension is related to generalized anxiety disorder. (See also stress.)

tension headache
See headache.

tension pneumothorax
See pneumothorax.

teratogen
A physical, chemical, or biological agent, such as radiation, the drug thalidomide, or the rubella virus, that causes abnormalities in a developing embryo or fetus.

teratoma
A primary tumour, which may be cancerous or noncancerous, consisting of cells totally unlike those normally found in that part of the body. For example, teratomas that develop in the ovary often form cysts that may contain skin, hair, teeth, or bone.

terbinafine
An antifungal drug used to treat fungal nail or skin infections. Side effects are rare with topical use but may include local irritation. Taken as tablets, the drug may cause nausea, abdominal pain, a rash, or, rarely, liver problems.

terbutaline
A bronchodilator drug used to treat asthma and chronic obstructive pulmonary disease, and also to prevent premature labour. Possible adverse effects include nervousness, restlessness, tremor, nausea, and palpitations.

terfenadine
An antihistamine drug used to relieve the symptoms of allergies such as urticaria (nettle rash) and allergic rhinitis (hay fever). The drug is not now commonly prescribed due to the risk of potentially serious arrhythmias (irregular heartbeat) associated with high doses.

terminal care
See dying, care of the.

termination of pregnancy
See abortion, induced.

testicle
See tests.

testicular feminization syndrome
A rare inherited condition in which an individual who is genetically male with internal testes has the external appearance of a female. The syndrome is a form of intersex and is the most common type of male pseudohermaphroditism.

CAUSE
The cause is a defective response of the body tissues to the male sex hormone testosterone. The causative genes are carried on the X chromosome, and so females can be carriers and pass on the genes to their sons.

SYMPTOMS
Those affected seem to be girls throughout childhood. Most develop normal female secondary sexual characteristics at puberty, but menstruation does not occur because there is no uterus and the vagina is short and blind-ending. People with testicular feminization syndrome tend to be tall, and are of normal health.

DIAGNOSIS AND TREATMENT
Testicular feminizing syndrome may be diagnosed before puberty if a girl is found to have an inguinal hernia or a swelling in the labia (skinfolds in front of the vagina) that turns out to be a testis. Otherwise, the diagnosis is usually made during investigations at puberty to find the cause of amenorrhoea (failure to menstruate). This is confirmed by chromosome analysis, which shows the presence of male chromosomes, and blood tests, which show male levels of testosterone. The treatment of testicular feminization syndrome involves surgical removal of the testes, to prevent cancerous change in later life, and therapy with oestrogen drugs. An affected person is not fertile but can live a normal life as a woman.

testicular self-examination
Regular, manual self-examination of the testes in order to detect symptoms that may be an early warning of testicular cancer (see testis, cancer of). The man should gently roll each testis between fingers and thumb to feel for unusual lumps and swellings, or changes in skin texture. Anything that feels different to normal should be reported to a doctor.

testis
One of two male sexual organs, also called testicles, that produce sperm and the hormone testosterone. The testes form within the abdomen early in fetal development. In response to hormones...
produced by both the mother and the fetus, the testes gradually descend. At birth, or within the next few months, they have usually reached the surface of the body and hang suspended in the pouch of skin called the scrotum.

**STRUCTURE**
Within each testis are the seminiferous tubules, delicate coiled tubes that produce sperm. These tubules lead via the vasa efferentia (small ducts) to the epi-
didymis, a structure lying behind the testis in which the newly formed sperm mature. Cells between the semi-
ferous tubules produce testosterone, the male sex hormone, which passes into small blood vessels in the testis and then into the circulation.

Each testis is protected by a tough, fibrous capsule, the tunica albuginea, and is suspended from the body by the spermatic cord. This cord is composed of the vas deferens (the tube that transports sperm from the epididymis to the ure-
thra), and a number of blood vessels and nerves. (See also testis, undescended.)

**testis, cancer of**
A rare, cancerous tumour of the testis. Testicular cancer occurs most common-
ly in young to middle-aged men, and the risk increases in individuals who have a history of undescended testis (see testis, undescended).

**TYPES**
The most common types of testicular cancer are seminomas, which are made up of only one type of cell, and teratomas, which are made up of cells that do not resemble other cells in the testis. Other cancers affecting the testis are extremely rare and develop from testicu-
lar tissue or from lymphatic tissue within the testis (see lymphoma).

**SYMPTOMS**
The cancer usually appears as a firm, pain-
less swelling of one testis. In some cases, there may be pain and inflammation.

**DIAGNOSIS**
Men are recommended to examine their testes regularly to check for unusual changes (see testicular self-examination). If a lump is found, the doctor will perform tests, such as ultrasound scanning, to exclude other causes of testicular swelling (see testis, swollen).

**TREATMENT**
Biopsy, followed by orchidectomy (surgical removal of the testis) is the usual course of action for testicular cancer, and may be combined with chemother-
apy. The tumours usually respond well to treatment. Provided the other testis is healthy, treatment generally does not destroy its fertility.

**testis, swollen**
Swelling of the testis or surrounding tis-
sues in the scrotum. Harmless, painless swellings include epididymal cysts, hydro-
cele, varicocele, and spermatoceles. Can-
er of the testis (see testis, cancer of) is a rare cause of swelling; swelling due to a cancerous tumour is usually painless. Painful swelling may be due to a direct blow, torsion of the testis (see testis, torsion of), orchitis (inflammation of the testis), or epididymo-orchitis (inflammation of the testis and epididymis). Any swelling of the testes should be assessed promptly by a doctor. An ultrasound scan may be done to aid diagnosis.

**testis, torsion of**
Twisting of the spermatic cord that causes severe pain and swelling of the testis. The pain develops rapidly and is sometimes accompanied by abdominal pain and nausea. The testis becomes swollen and very tender, and the skin of the scrotum becomes discoloured. Unless the torsion is treated within a few hours, permanent damage to the testis results. The condition is most common around puberty. It is more likely to occur if the testis is unusually mobile within the scrotum.

**torsion of the testis**
If a testis rotates, veins in the spermatic cord become obstructed, causing severe swelling and pain. The condition is most common around puberty but can occur at any age.
Diagnosis is by physical examination. Surgery is performed to untwist the testis and anchor it in the scrotum with small stitches to prevent recurrence. If the damage is irreversible, orchidectomy (removal of the testis) is performed. In either case, the other testis is anchored to the scrotum to prevent torsion on that side. With prompt treatment, full recovery is complete.

**testis, undescended**

A testis that has failed to descend from the abdomen to the scrotum. The condition usually affects only one testis. An undescended testis often descends within months of birth but rarely descends after this time. The condition is more common in premature baby boys.

An undescended testis does not develop normally, cannot produce normal sperm, and is at increased risk of testicular cancer (see *testis, cancer of*). If both testes are undescended, *infertility* results.

**CAUSES**
The final descent of the testis through the inguinal canal in the groin is controlled by hormones produced by the mother and by the testis itself. If these stimuli do not have an effect, the spermatic cord (which carries the vas deferens and blood vessels to the testis) fails to lengthen sufficiently to allow full descent. Less commonly, a normal testis is prevented from reaching the scrotum because of fibres blocking its route, and remains in the groin.

**DIAGNOSIS AND TREATMENT**
A diagnosis is made during a physical examination after birth or later in infancy. Treatment is by *orchidopexy*, an operation to place the testis in the scrotum, which usually reduces the risk of later infertility or testicular cancer. A poorly developed undescended testis may be removed if the other is normal.

**test meal**
A procedure to measure the output of acid by the stomach. A nasogastric tube is passed into the stomach after an overnight fast, and a sample of gastric fluid is sucked up through the tube. An injection of *histamine* or, more usually, pentagastrin (a synthetic preparation of the hormone gastrin) is given; further samples of stomach fluid are taken at intervals for up to two hours and analysed for hydrochloric acid content.

The test is used for people thought to be suffering from *Zollinger–Ellison syndrome*, and to confirm the absence of stomach acid in people with pernicious anaemia (see *anaemia, pernicious*).

**testosterone**
The main *androgen hormone* (male sex hormone). It stimulates bone and muscle growth and sexual development. It is produced by the testes and, in small amounts, the ovaries. Synthetic or animal testosterone is used to stimulate delayed *puberty* or treat some forms of male *infertility*.

</table>
a disease, or to assess response to treatment. A medical testing programme carried out on people who are apparently in good health to find disease at an early stage is known as screening.

The accuracy of a test is based on its sensitivity (ability to correctly identify diseased subjects), specificity (ability to correctly identify healthy subjects), and predictive value. The predictive value is determined by a mathematical formula that involves the number of accurate test results and the total number of tests performed. The best tests have both high specificity and high sensitivity, and therefore high predictive value. (See also Medical tests box, previous page.)

test-tube baby

The colloquial term for a baby born following in vitro fertilization, in which an egg (ovum) is taken from a woman’s ovary, fertilized outside the body, and then implanted in the uterus.

tetanus

A serious, sometimes fatal, disease of the central nervous system (brain and spinal cord) caused by infection of a wound with spores of the bacterium Clostridium tetani.

CAUSE

The spores live mainly in soil and manure but are also found elsewhere, including in the human intestine. When the spores infect poorly oxygenated tissues they multiply and produce a toxin that acts on the nerves responsible for controlling muscle activity.

SYMPTOMS

The most common symptom is trismus (stiffness of the jaw, commonly known as lockjaw). Other symptoms include stiffness and aching of the abdominal and back muscles, and contraction of facial muscles, producing a fixed grimace. There may also be a fast pulse, mild fever, and profuse sweating. Painful muscle spasms then develop, and may result in asphyxia if they affect the larynx or chest wall. The spasms usually subside after 10 to 14 days.

DIAGNOSIS AND TREATMENT

The diagnosis is made from the symptoms and signs, and a course of tetanus antitoxin injections is started. Artificial ventilation may be needed. Most people recover completely if treated promptly.

PREVENTION

Prevention of tetanus in the UK relies on the DPT vaccination being given routinely in childhood; and booster injections of tetanus and diphtheria are given at intervals thereafter.

tetany

Spasms and twitching of the muscles, most commonly in the hands and feet, although the muscles of the face, larynx (voicebox), or spine may also be affected. The spasms are caused by a biochemical disturbance and are painless at first; if the condition persists, the spasms tend to become increasingly painful.

Muscle damage may result if the cause is not treated. The most common underlying cause is hypocalcaemia (a low level of calcium in the blood). Other causes include hypokalaemia (a low level of potassium), hyperventilation during a panic attack, or, more rarely, hypoparathyroidism (underactivity of the parathyroid glands).

tetracosactide

A drug used to test the functioning of the adrenal glands. Tetracosactide is a chemical analogue (imitation) of the natural hormone corticotrophin (ACTH). ACTH stimulates the cortices of the adrenal glands to secrete hormones such as cortisol. To diagnose a disorder of the adrenal glands, a tetracosactide injection is given and the blood cortisol level measured. Failure of the level to rise indicates an abnormality.

tetracosactrin

The former name for tetracosactide.

tetracycline drugs

COMMON DRUGS

+ Doxycycline + Minocycline + Oxytetracycline + Tetracycline

A group of antibiotic drugs that are commonly used as a treatment for certain infections including chlamydial infections, flare-ups of chronic bronchitis, Lyme disease, leptospirosis, and certain types of pneumonia. They are also used to treat some cases of acne. It should be noted that if taken with milk or antacid drugs, tetracyclines are not absorbed effectively in the intestines.

Possible side effects of tetracycline drugs include nausea, vomiting, diarrhoea, headache, and worsening of kidney disorders and liver function. Tetracyclines may discolor developing teeth and are therefore not usually prescribed for children under the age of 12 or pregnant women.

tetralogy of Fallot

A form of congenital heart disease in which the heart has four coexisting anomalies: displacement of the aorta, narrowing of the pulmonary valve, a hole in the ventricular septum, and thickening of the right ventricle wall. Because of these defects, blood pumped from the heart to the body is insufficiently oxygenated, resulting in cyanosis (bluish coloration) and breathlessness.

SYMPTOMS AND SIGNS

Affected infants appear normal at birth, although disturbed blood flow in the heart may be heard as murmurs through a stethoscope. Severely affected infants may become cyanosed and breathless early in life, and may be prone to fainting. Those less severely affected develop these symptoms gradually. Other symptoms include failure to gain weight and poor development.

DIAGNOSIS AND TREATMENT

An ECG, echocardiogram (see echocardiography), and sometimes cardiac catheterization are performed to confirm the diagnosis and also to assess the severity of the condition.

Tetralogy of Fallot is corrected by open heart surgery. Carrying out the repair...
before the child reaches school age provides the best chance of success and normal future development.

tetraplegia
An alternative term for the condition quadriplegia.

thalamus
One of a pair of structures in the brain, the thalamus is a walnut-sized mass of nerve tissue. The thalami sit at the top of the brainstem and are connected to all parts of the brain.

Each thalamus relays sensory information flowing into the brain. Some basic sensations, such as pain, may reach consciousness within the thalamus. Other types of sensory information are processed and relayed to parts of the cerebral cortex (the outer layer of the brain), where sensations are perceived.

The thalamus acts as a filter by selecting only information that is of particular importance. Certain centres in the thalamus are also thought to play a part in long-term memory.

thalassaemia
A group of inherited blood disorders in which there is a fault in the production of the oxygen-carrying pigment haemoglobin. This pigment is normally made in the bone marrow for incorporation into red blood cells. Many of the red blood cells become fragile and haemolyse (break up), leading to anaemia (see anaemia, haemolytic). Thalassaemia is prevalent in the Mediterranean, the Middle East, and Southeast Asia, and in families originating from these areas.

CAUSES AND TYPES
Normal adult haemoglobin contains two pairs of globins (protein chains), known as alpha and beta. In thalassaemia, a recessive defective gene results in reduced synthesis of one of the chains. Usually beta-chain production is disturbed (beta-thalassaemia). Beta-thalassaemia minor (thalassaemia trait), which is never severe, is caused by a single defective gene. The presence of two defective genes causes beta-thalassaemia major (Cooley’s anaemia). The rare disorder alpha-thalassaemia varies in severity, but alpha-thalassaemia major usually results in fetal death.

SYMPTOMS
Symptoms of beta-thalassaemia major appear three to six months after birth and include shortness of breath, jaundice, and an enlarged spleen. If the condition is untreated, bone marrow cavities expand, leading to characteristic enlargement of the skull and facial bones; normal body growth is arrested and death is likely to occur in early childhood.

DIAGNOSIS AND TREATMENT
Beta-thalassaemia major is diagnosed by microscopic examination of the blood, and from other blood tests. Treatment is with blood transfusions and, sometimes, splenectomy (removal of the spleen). However, successive blood transfusions cause a build up of iron in the body (see haemosiderosis). Chelating agents are given by mouth or by infusion to help the body excrete the excess iron. A bone marrow transplant offers a cure.

PREVENTION
Genetic counselling is advised for parents or other close relatives of a child with thalassaemia, and also for any person with thalassaemia trait.

thalidomide
A drug that was withdrawn in the UK in 1961 after it was found to cause limb deformities in many babies born to women given the drug during pregnancy. Thalidomide is still used to treat certain forms of Hansen's disease (leprosy) and Behçet's syndrome.

thallium
A rare metallic element that is present as compounds in some zinc and lead ores. Poisoning over a prolonged period causes loss of hair, disorders of the nerves in the limbs, and disturbance of the stomach and intestines. Thallium-201 (an artificial radioactive isotope) is sometimes used during radionuclide scanning of the heart.

THC
The abbreviation for tetrahydrocannabinol, the active ingredient in marijuana.

theca
A sheath of tissue covering a body part. An example is the pericardium, the membrane that encloses the heart.

thenar
The medical name for the palm of the hand. The term thenar is also used to refer specifically to the fleshy part of the palm at the base of the thumb.

theobromine
A substance that is chemically similar to caffeine and occurs naturally in coffee, tea, and cocoa. Theobromine has a weak diuretic effect and also dilates blood vessels. It was formerly used to treat angina but is no longer used medically.

theophylline
A bronchodilator drug sometimes used to treat severe asthma in cases that have failed to respond to other treatments. Theophylline is given orally, but it is sometimes mixed with another drug in a preparation called aminophylline so that it can be given intravenously as emergency treatment.

Possible side effects of theophylline include nausea, vomiting, dizziness, diarrhoea, palpitations, and seizures. Regular blood tests may be carried out during the course of treatment in order to assess the dosage.

therapeutic
A term meaning related to treatment. The therapeutic dose of a drug is the amount required to have the greatest beneficial effect.

therapeutic community
A method of treating drug dependence, alcohol dependence, and some personality disorders that involves patients living together as a group in a nonhospital environment, usually under supervision. (See also social skills training.)

therapy
The treatment of any disease or abnormal physical or mental condition.
therapy, aversion
See: aversion therapy.

therapy, cognitive
See: cognitive–behavioural therapy.

therapy, family
See: family therapy.

therapy, occupational
See: occupational therapy.

thermography
A technique by which temperature patterns on the surface of the skin are recorded in the form of an image. Thermography provides clues to the presence of diseases and abnormalities that alter the temperature of the skin, such as problems of the circulation, inflammation, and tumours. There are two types of thermography. In one, a camera or scanner picks up infrared radiation naturally emitted from the skin. In the other, sheets of temperature-sensitive liquid crystals are applied to the skin; they change colour in response to changes in temperature.

thermometer
An instrument that is used to measure temperature. A traditional clinical thermometer consists of a glass capillary tube (a tube with a very fine bore), which is sealed at one end and has a mercury-filled bulb at the other.

Modern versions of the clinical thermometer include an electronic probe that is connected to a digital display, and an aural thermometer, which measures the temperature of the ear drum. Both of these versions give an almost instant reading. There are also disposable skin thermometers, which employ heat-sensitive chemicals that change colour at specific temperatures. These are not as reliable, however, as standard thermometers.

Clinical thermometers may be calibrated in degrees Celsius (sometimes referred to as centigrade), degrees Fahrenheit, or sometimes both.

thermoregulation
The body’s internal, automatic temperature-regulating mechanism, which is controlled by the hypothalamus in the brain. (See also temperature; heat disorders; hyperthermia; hypothermia.)

thiamine
See: vitamin B complex.

thiazides
A type of diuretic drug.

thiazolidinediones
Sometimes referred to as glitazones, a group of oral hypoglycaemic drugs (see hypoglycaemics, oral) that are used in the treatment of type 2 diabetes mellitus. Thiazolidinediones work by reducing the resistance of the body cells to insulin and are often used in combination with other oral hypoglycaemics, such as metformin or a sulphonylurea drug. The two main thiazolidinediones are pioglitazone and rosiglitazone.

thiopental
A barbiturate drug that is widely used as a general anaesthetic (see anaesthesia, general). Thiopental is given by intravenous injection.

thioridazine
An antipsychotic drug that is used to treat schizophrenia. It is now used under specialist supervision only because of potentially serious side effects affecting the heart and vision.

thirst
The desire to drink. Thirst is one means by which the amount of water in the body is controlled (the other is the volume of urine excreted).

Thirst is stimulated by an increased concentration of salt, sugar, or certain other substances in the blood. As the blood passes through the hypothalamus in the brain, special nerve receptors are stimulated, inducing the sensation of thirst. Thirst is also stimulated if blood volume decreases as a result of sweating, vomiting, diarrhoea, severe bleeding, or extensive burns. Thirst may also be caused by a dry mouth.

thirst, excessive
A strong and persistent need to drink, most commonly due to dehydration.

Other possible causes include untreated diabetes mellitus and diabetes insipidus, kidney failure, treatment with certain drugs such as phenothiazine drugs, and severe blood loss. Abnormal thirst may also be due to a psychological condition known as psychogenic polydipsia.

Thomsen’s disease
A rare inherited disorder, also called myotonia congenita, in which myotonia (a condition in which muscles contract and then cannot relax again) begins in early childhood and persists throughout life. The myotonia is usually mild. An affected person may experience stiffness and cramps at rest, but symptoms usually subside on exercise. The disorder is inherited in an autosomal dominant manner (see genetic disorders).

thoracic outlet syndrome
A condition in which pressure on the brachial plexus (the nerve roots that pass into the arms from the neck) causes pain in the arms and shoulders, pins-and-needles sensation in the fingers, and weakness of grip and other hand movements. Severe symptoms are usually caused by a cervical rib, which is an extra rib located above the first rib. Thoracic outlet syndrome may also be caused by drooping of the shoulders, an enlarged scalenus muscle in the neck, or a tumour. The condition is made worse by lifting and carrying heavy loads or increases in body weight.

Treatment of thoracic outlet syndrome usually consists of exercises to improve posture, which may sometimes be combined with nonsteroidal anti-inflammatory drugs and muscle-relaxant drugs. Severe cases may be treated by surgical removal of the first rib.

thoracic surgery
A surgical speciality that is concerned with operations on organs within the chest cavity. Sometimes, thoracic surgery is combined with heart surgery, in which case it is known as cardiothoracic surgery.
thoracotomy
An operation in which the chest is opened to provide access to organs in the chest (thoracic) cavity.

There are two types of thoracotomy: lateral and anterior. In a lateral thoracotomy the chest is opened between two ribs to provide access to the lungs, major blood vessels, and the oesophagus. In an anterior thoracotomy, an incision down the length of the sternum (breastbone) provides access to the heart and the coronary arteries.

thorax
The medical name for the chest. The thorax extends from the base of the neck to the diaphragm muscle.

thought
The complex mental activity that enables humans to reason, form judgments, and solve problems. The essential features of thought processes include the substitution of symbols (in the form of words, numbers, or images) for objects, the formation of symbols into ideas, and the arrangement of ideas into a certain order in the mind. (See also thought disorders.)

thought disorders
Abnormalities in the structure or content of thought, as reflected in a person’s speech, writing, or behaviour. Schizophrenia causes several types of thought disorder, including the loss of logical connections between associations, the invention of new words (see neologisms), thought blocking (sudden interruption in the train of thought), the feeling that thoughts are being inserted into or withdrawn from the mind, and hallucinations, usually of an auditory form.

Incoherent thoughts occur in all types of confusion, including dementia and delirium. Rapidly jumping from one idea to another occurs in hypomania and mania. In depression, thinking becomes slow, and there is a lack of association and a tendency to dwell in great detail on trivial subjects. In obsessive-compulsive disorder, recurrent ideas seem to come into a person’s mind involuntarily. Delusions, which occur in schizophrenia and other psychotic illnesses, may be an expression of distorted thinking.

threadworm infestation
A common infestation with a small worm, Enterobius vermicularis (also called pinworm), that lives in the intestines. Threadworms mainly affect children.

Female adult threadworms are white and about 1 cm long (large enough to see). They lay eggs in the skin around the anus, and their movements cause itching in the anal region, often at night. Eggs are transferred from the fingers to the mouth to cause reinfection or are carried on toys or blankets to other children. Swallowed eggs hatch in the intestine and the worms reach maturity after a period of two to six weeks. For further information see Cycle of threadworm infestation box, overleaf.

DIAGNOSIS AND TREATMENT
Adult worms can sometimes be seen in the faeces or on the buttocks. The worms and their eggs can be collected by applying a piece of sticky tape to the anal area. Treatment is with an anthelmintic drug, which usually clears up the problem. Doctors recommend that all members of a family be treated at the same time to prevent reinfection.

threatened miscarriage
Warning signs that a pregnancy may be about to end before full term (see miscarriage). There is bleeding from the vagina, although the cervix remains closed and the fetus stays in the uterus. An ultrasound scan may help confirm whether the fetus is alive.

thrilh
A vibrating sensation felt when the flat of the hand is held against an area of the body. Thrill is caused by turbulent blood flow in an artery or the heart. The term is also used to describe the feeling produced by fluid within the abdominal cavity in ascites.

throat
A popular term for the pharynx. The term is also sometimes used to refer to the front of the neck.

throat cancer
See pharynx, cancer of; larynx, cancer of.

thrombectomy
The removal of a thrombus (blood clot) that is blocking a blood vessel. It is performed as an emergency procedure if a major artery is blocked, or as a precautionary measure if there is a risk of an embolus (fragment) breaking off. Before surgery, the site of the thrombus is established by angiography and the patient may be given anticoagulant drugs.
thromboangitis obliterans
Another name for Buerger’s disease.

thrombocyte
An alternative name for a platelet (the smallest type of blood cell).

thrombocytopenia
A reduction in the number of platelets (the smallest type of blood cell) in the blood. Since platelets play a vital role in the blood-clotting process, thrombocytopenia causes a tendency to bleed, especially from smaller vessels. Thrombocytopenic purpura (abnormal bleeding into the skin) sometimes develops.

CAUSES
The cause of thrombocytopenia may be a reduced rate of platelet production or a fast rate of platelet destruction. The disorder can be a feature of certain diseases including leukaemia, lymphoma, systemic lupus erythematosus, megaloblastic anaemia, and hypersplenism. Thrombocytopenia can also be caused by a viral illness, by exposure to radiation, or by an adverse reaction to a prescribed drug such as a thiazide diuretic. Idiopathic thrombocytopenic purpura (ITP) is an autoimmune disorder.

DIAGNOSIS AND TREATMENT
Thrombocytopenia is confirmed by a blood count. Any underlying disease is treated if possible. Children with ITP may not need treatment, but adults are usually given corticosteroid drugs. If thrombocytopenia persists, splenectomy (removal of the spleen) may be performed. When the cause is known, treatment usually results in an increase in platelet numbers.

thromboembolism
The blockage of a blood vessel by a piece of a blood clot (embolus) that has broken off from a thrombus elsewhere in the circulation. (See also thrombosis; embolism.)

thrombolytic drugs
COMMON DRUGS

- Alteplase
- Retepase
- Streptokinase
- Tenecteplase

Sometimes called fibrinolytic drugs, this group of drugs is used to treat acute myocardial infarction (heart attack), and thrombosis and embolism in which a blood vessel is blocked by a blood clot. Thrombolytic drugs act within blood vessels to dissolve clots. They are administered intravenously and must be given promptly after in order for it to be effective. Possible side effects include abnormal bleeding and allergic reaction.

thrombophilia
A tendency for blood to clot too readily, which leads to an increased risk of disorders, such as deep vein thrombosis (see thrombosis, deep vein) and stroke, due to blockage of blood vessels by blood clots (called thrombosis). This tendency may be due to an inherited deficiency or abnormality in proteins such as factor V that are involved in blood clotting. Thrombophilia may also be caused by the immune disorder antiphospholipid syndrome, which is associated with an increased risk of miscarriage as well as of circulatory disorders due to thrombosis.

Thrombophilia may go unrecognized until conditions, such as air travel or injury, that increase the risk of clots cause symptoms or signs. Women with thrombophilia are advised not to take the oral contraceptive pill or hormone replacement therapy.

thrombophlebitis
Inflammation of a section of vein, usually just under the skin, with clot formation in the affected part. This can occur after minor injury to the vein or as a complication of varicose veins or Buerger’s disease. The affected blood vessel is swollen, red, and tender, and feels hard. Fever and malaise may occur. A blood clot may develop.

Treatment includes support with a bandage, nonsteroidal anti-inflammatory drugs, and sometimes antibiotic drugs. The condition usually clears up in 10–14 days.

thrombosis
The formation of a thrombus (blood clot) in an undamaged blood vessel. Clotting is a normal response when a blood vessel wall is injured, but abnormal when a vessel has not been punctured.

A thrombus that forms within an artery supplying the heart muscle (coronary thrombosis) is the usual cause of myocardial infarction (heart attack). A thrombus in an artery of the brain (cerebral thrombosis) is a common cause of stroke.

Thrombi may block arteries supplying blood to the legs, kidneys, retinas, intestines, and other organs, sometimes causing severe damage and symptoms such as pain and loss of function. Another danger is that an embolus (fragment of a thrombus) may break off and be carried by the blood to block an important blood vessel in another area (see embolism).

Thrombi can also form in veins, either just beneath the skin or in deeper veins (see thrombosis, deep vein).

CAUSES
In the blood there is a fine balance between the mechanisms that encourage and discourage clotting, so there
is neither a tendency to bleed nor to form clots (see blood clotting). Thrombosis can occur if this mechanism is disturbed in favour of clotting. (See thrombophilia.)

In arteries, thrombus formation is encouraged by atherosclerosis (a build-up of fatty deposits on the walls of arteries), smoking, hypertension (high blood pressure), and damage to blood vessel walls from inflammation in arteritis and phlebitis. An increased clotting tendency may occur in pregnancy, with the use of oral contraceptives, or through prolonged immobility.

SYMPTOMS
An arterial thrombosis may cause no symptoms until the blood flow is impaired. When this occurs, it leads to reduced function in the tissue supplied by the affected artery, and sometimes severe pain. Venous thrombosis may cause pain and swelling.

DIAGNOSIS AND TREATMENT
Diagnosis of thrombosis is by doppler ultrasound. In some cases, angiography or venography may also be used. Treatment may include anticoagulant drugs or thrombolytic drugs, nonsteroidal anti-inflammatory drugs, and, in some cases, antibiotic drugs. In life-threatening cases, thrombectomy (surgical removal of the blood clot) may be needed.

thrombosis, deep vein
The formation of a thrombus (blood clot) within deep-lying veins in the leg.

CAUSES
The cause is usually a combination of slow blood flow through one part of the body (such as when sitting for long periods or when the tissues are compressed, as occurs in long-haul aircraft flights) and an increase in the clotting tendency of the blood, which occurs in dehydration, after surgery or injury, during pregnancy, in some inherited conditions (see thrombophilia), and in women taking oral contraceptives.

Deep vein thrombosis may also be due to polycythaemia (increased numbers of red cells in the blood). Deep vein thrombosis is common in people with heart failure and those who have had a stroke; it also commonly occurs in people who have been bedridden.

SYMPTOMS
Clots in the leg veins may cause pain, tenderness, swelling, discoloration, and ulceration of the skin, but they can be symptomless. A deep vein thrombosis is not necessarily serious in itself, but part of the clot may break off and travel in

DEEP VEIN THROMBOSIS
Thrombi, or clots, tend to form when blood flow is sluggish or if there is a rise in the level of coagulation factors in the blood. Once a clot has formed, it may provide a site for further clotting, so that a long, snaky clot may grow along the length of a vein. There is a risk that the end of such a clot may break off into the circulation. Thrombi form most commonly in the leg veins and may interfere with the drainage of blood from a leg (below right), causing signs and symptoms of varying severity.

Example of deep vein thrombosis
This MRI of the leg of a patient with deep vein thrombosis shows the vein blocked by a thrombus (blood clot).

Calf vein thrombosis
When clots are localized in the lower-leg veins, there is usually some pain in the calf but there may be little swelling.

Femoral vein thrombosis
If clots are present in the femoral and the lower-leg veins, there is usually pain and swelling up to the region above the knee.

Iliac vein thrombosis
Clots in the iliac vein may affect drainage of blood from the whole leg, causing severe pain and swelling in the leg.
the bloodstream to the lungs. This is known as a pulmonary embolism.

**DIAGNOSIS AND TREATMENT**

A diagnosis is made by doppler ultrasound scanning. Treatment depends on the site and extent of the clots. Small clots may not need treatment if they are confined to the calf and the patient is mobile. Otherwise, anticoagulant drugs or thrombolytic drugs are given. If there is a high risk of pulmonary embolism, thymectomy (surgical removal of the clot) may be performed.

**PREVENTION**

The risk of deep vein thrombosis during long-haul flights can be reduced by wearing elastic stockings, moving the legs and feet around frequently, and drinking plenty of nonalcoholic fluids.

**thrombus**

A blood clot that has formed inside an intact blood vessel. A thrombus is life-threatening if it obstructs the blood supply to an organ such as the heart or brain. A thrombus may also lead to gangrene (tissue death) in an organ or extremity, or to embolism, in which a fragment of the thrombus breaks off and is carried to obstruct the blood circulation elsewhere in the body. (See also blood clotting; thrombosis.)

**thrush**

A common name for the fungal infection candidiasis.

**thumb-sucking**

A common habit in young children, which provides comfort, oral gratification, amusement when bored, and reassurance. Thumb-sucking tends to decrease after age three, and most children grow out of it by age seven. In most cases, it is not harmful. However, malocclusion (incorrect alignment) of the permanent teeth may develop if the habit continues past seven years of age. This problem is usually temporary, but if the thumb-sucking persists, an orthodontic appliance may be needed.

**thymoma**

A rare tumour of the thymus gland. The tumour can arise from any of the cell types in the thymus gland and be cancerous or noncancerous. Thymoma is associated with the autoimmune disorder myasthenia gravis.

**thymoxamine**

See mexitelyte.

### thymus gland

A gland that forms part of the immune system. The thymus gland lies behind the sternum (breastbone) and consists of two lobes that join in front of the trachea (windpipe). Each lobe of the thymus gland is made of lymphoid tissue consisting of lymphocytes (white blood cells), epithelium (lining cells), and fat. The thymus conditions lymphocytes to become T-cells. It plays a part in the immune response until puberty, gradually enlarging during this time. After puberty, it shrinks, but some glandular tissue remains until middle-age.

### thyroglossal disorders

A set of congenital defects caused by failure of the thyroglossal duct to close up during embryonic development. In embryos, this duct runs from the base of the tongue to the thyroid gland. Abnormal development may cause the duct to persist in its entirety or partly as a cyst. A cyst may become infected and swollen, which may lead to formation of a fistula (an abnormal passage that develops between the cyst and the surface of the neck). The cyst and any remaining parts of the duct are removed.

### thyroidectomy

Surgical removal of all or part of the thyroid gland, which is performed as a treatment for thyroid cancer, some cases of hyperthyroidism (overactivity of the thyroid) and of goitre (enlargement of the thyroid), or a noncancerous tumour of the thyroid gland.

### thyroid-function tests

A group of blood tests used to evaluate the function of the thyroid gland and to diagnose under- or overactivity of the gland. Tests may include measurement of levels of the thyroid hormones T₃ and T₄, as well as thyroid-stimulating hormone (TSH), the pituitary gland hormone that stimulates the thyroid gland.
thyroid gland

One of the main endocrine glands, which helps to regulate the rate of all the body’s internal processes. The thyroid is situated in the front of the neck, just below the larynx (voicebox). It consists of two lobes, one on each side of the trachea (windpipe), joined by a piece of tissue called the isthmus.

**STRUCTURE AND FUNCTION**

Thyroid tissue is composed of follicular cells, which secrete the iodine-containing hormones thyroxine (T₄) and triiodothyronine (T₃), and parafollicular cells (or C cells), which secrete the hormone calcitonin. T₄ and T₃ are important in controlling metabolism. Calcitonin helps to regulate calcium balance in the body. (See also thyroid hormones and Disorders of the thyroid gland box.)

**DISORDERS OF THE THYROID GLAND**

The function of the thyroid gland is controlled by both the pituitary gland and the hypothalamus, so thyroid disorders may be due not only to defects in the gland itself, but also to disruption of the hypothalamic-pituitary hormonal control system. Disorders of the thyroid gland may cause overproduction of thyroid hormones (hyperthyroidism), underproduction of these hormones (hypothyroidism), or enlargement or distortion of the gland. Myxoedema, Graves’ disease, and Hashimoto’s thyroiditis are common disorders. Goitre (enlargement of the thyroid gland) may sometimes occur with no accompanying abnormality of thyroid function.

**Congenital disorders**

In rare cases, the thyroid gland is absent at birth, producing cretinism. However, congenital thyroid deficiency more often takes the form of underdevelopment or maldevelopment, in which there is some thyroid tissue but not enough to secrete normal amounts of hormones. A heel-prick blood test is performed on newborns to screen for hypothyroidism. Sometimes the thyroid develops in an abnormal position in the neck, causing, rarely, difficulty swallowing or breathing.

**Genetic disorders**

Rarely, genetic disorder may impair the thyroid’s ability to make hormones. The low blood level of thyroid hormones results in greatly increased secretion by the pituitary gland of thyroid-stimulating hormone (TSH), which, in turn, causes the thyroid to enlarge.

**Infection**

Thyroid infection is uncommon; it leads to thyroiditis (inflammation of the thyroid gland). Viral infection can cause an extremely painful gland and temporary hyperthyroidism.

**Tumours**

Thyroid tumours may be either cancerous or noncancerous. Thyroid adenomas are noncancerous tumours that may secrete thyroid hormone, sometimes in large enough amounts to cause hyperthyroidism. Thyroid cancers are relatively rare. They may be suspected if a single firm or hard lump can be felt in the gland.

**Autoimmune disorders**

Graves’ disease is a form of thyroid overactivity thought to be due to the body’s immune system producing antibodies that attack the thyroid gland. In Hashimoto’s thyroiditis, antibodies damage glandular cells.

**Myxoedema**

Deficiency of thyroid hormone, which may occur for a variety of reasons, causes a condition known as myxoedema, in which the skin becomes dry and thickened and facial features become coarse. Constipation, cold intolerance, and fatigue are other common symptoms.

**Hormonal disorders**

Hormonal changes during puberty or pregnancy may cause a degree of goitre temporarily. Hyperthyroidism due to excessive production of TSH by the pituitary gland is rare but it may result from a pituitary tumour.

**Iodine deficiency**

Because iodine is necessary for the production of thyroid hormone, its deficiency may lead to goitre, but it is uncommon in developed countries. Severe iodine deficiency in children may cause myxoedema.

**LOCATION OF THE THYROID GLAND**

This major gland lies at the base of the neck just in front of the trachea (windpipe).

**thyroid hormones**

The three hormones produced by the thyroid gland are thyroxine (T₄) and triiodothyronine (T₃), which regulate metabolism, and calcitonin, which helps to regulate calcium levels in the body. See Control of thyroid hormone production box, overleaf.

**thyroiditis**

Inflammation of the thyroid gland; it occurs in several different forms. The most common is Hashimoto’s thyroiditis, an autoimmune disorder that causes hypothyroidism (underactivity of the thyroid gland) may sometimes cause myxoedema.
Less commonly, it is associated with a viral infection, or it may occur temporarily in women after childbirth.

**thryroid scanning**
Techniques, such as **radionuclide scanning** and **ultrasound scanning**, that are able to give information on the location, anatomy, and function of the thyroid gland and detect tumours.

**Thyroid-stimulating hormone**
A hormone that is produced in the pituitary gland, which is located at the base of the brain. Thyroid-stimulating hormone (TSH) travels in the bloodstream to the thyroid glands, which are then stimulated by TSH to release other hormones (known as T₃ and T₄) that are involved in the body’s use of energy. (See also thyroid hormones.)

**thyrotoxicosis**
Overactivity of the thyroid gland, also called hyperthyroidism.

**thyroxine**
Represented by the symbol T₄, the most important thyroid hormone. It is synthesized as levothyroxine and given orally for hypothyroidism (an underactive thyroid).

**TIA**
The abbreviation for **transient ischaemic attack**, a brief interruption of the blood supply to part of the brain.

**tiabendazole**
A rarely used **anthelmintic drug** used to treat worm infestations, including strongyloïdiasis. It has largely been replaced by newer anthelmintics.

**tibia**
Also called the shin, the inner and thicker of the two long bones in the lower leg. The tibia is the supporting bone of the lower leg. It runs parallel to the fibula, the narrower bone to which it is attached by ligaments. The upper end articulates with the femur (thigh bone) to form the knee joint; the lower end articulates with the talus to form part of the ankle joint. On the inside of the ankle, the tibia is widened and protrudes to form a bony prominence known as the medial malleolus.

**fracture**
One of the most commonly fractured bones, the tibia may break across the shaft or at the upper end from a blow to the outside of the leg below the knee. Prolonged walking or running on hard ground may cause a stress fracture.

**Location of the tibia**
Also called the shin, the tibia can easily be felt beneath the skin of the lower leg.
tibolone
A drug used in the short-term treatment of menopausal symptoms. Tibolone is also used to protect against osteoporosis (although it is not usually recommended as a first-line treatment). It is given continuously and combines the effects of oestrogen and progestogen drugs. Possible adverse effects are irregular vaginal bleeding, changes in weight, ankle oedema (fluid swelling), dizziness, skin reactions, headache, and facial hair growth.

tic
A repeated, uncontrolled, purposeless contraction of a muscle or group of muscles, most commonly in the face, shoulders, or arms. Typical tics include blinking, mouth twitching, and shrugging. Tics usually develop in childhood and are often a sign of a minor psychological disturbance. They usually stop within a year of onset but in some cases persist into adult life. (See also Gilles de la Tourette’s syndrome.)

tic douloureux
Another name for trigeminal neuralgia.

ticks and disease
Ticks are small, eight-legged animals that feed on blood and sometimes transmit diseases to humans via their bites. They are about 3 mm long before feeding and become larger when full of blood. Ticks may be picked up in long grass, scrub, woodland, or caves.

In the UK, the only disease that is known to be transmitted to humans by ticks is Lyme disease. Other diseases transmitted in various parts of the world include relapsing fever, Rocky Mountain spotted fever, Q fever, tularemia, tick typhus, and certain types of viral encephalitis. The prolonged bite of certain female ticks can cause tick paralysis, in which a toxin in the tick saliva affects the nerves that control movement. In extreme cases, such a reaction to a tick bite can prove fatal.

ticlopidine
A type of antithrombotic drug that is prescribed to prevent unwanted blood clotting in people with a history of stroke and other circulatory disorders.

Tietze’s syndrome
Chest pain localized to an area on the front of the chest wall, usually made worse by movement of the arms or trunk or by pressure on the chest wall. The syndrome, also called costochondritis, is caused by inflammation of one or several rib cartilages and symptoms may persist for months. Treatment is with analgesics, non-steroidal anti-inflammatory drugs, or local injections of corticosteroid drugs into the cartilage.

tildiamide
A brand name for diltiazem, a calcium channel blocker used to treat hypertension (high blood pressure) and angina.

timolol
A beta-blocker drug used to treat hypertension (high blood pressure) and angina pectoris (chest pain due to inadequate blood supply to the heart). Timolol may be given after a myocardial infarction (heart attack). It is used as eye-drops in the treatment of glaucoma (raised pressure within the eyeball).

Possible side effects, such as cold hands and feet, are typical of other beta-blockers. The eye-drops may cause irritation, blurred vision, and headache.

tinea
Any of a group of common fungal infections of the skin, hair, or nails. Most are caused by fungi called dermatophytes. The infections, often called ringworm, may be acquired from other people, animals, soil, shower floors, or household objects, such as chairs or carpets.

TYPES AND SYMPTOMS
The most common type of tinea infection is tinea pedis (athlete’s foot). Tinea corporis (ringworm of the body) causes itchy, usually circular, patches with a prominent edge. Tinea cruris (which is commonly called jock itch) produces a reddened, itchy area spreading from the genitals over the inside thighs. This form of tinea is more common in males. Tinea capitis (scalp ringworm) causes round, itchy packets of hair loss on the scalp; it occurs mainly in children. Ringworm of the nails (tinea unguium) is often accompanied by scaling of the soles or palms. The nails become thick and turn white or yellow.

DIAGNOSIS AND TREATMENT
Most types of tinea are easily recognizable by appearance, but the diagnosis may be confirmed by culturing the organisms in a laboratory. Treatment is usually with topical antifungal drugs in the form of skin creams or ointments. However, for widespread infections or those affecting the hair or nails, oral drug treatment may be necessary.

tinea versicolor
An alternative name for pityriasis versicolor, a common skin disorder caused by a fungus.

tingling
See pins-and-needles.

tinidazole
An antibacterial drug that is particularly useful in treating anaerobic infections. Tinidazole is also used with other drugs to eradicate infection with the Helicobacter pylori bacterium. Possible adverse effects of the drug include nausea, vomiting, gastrointestinal disturbances, headache, and dizziness. Alcohol should be avoided during treatment.

tinnitus
A ringing, buzzing, whistling, hissing, or other noise heard one or both ears in the absence of external noise.

CAUSES
In tinnitus, the acoustic nerve transmits impulses to the brain, not as the result of vibrations produced by external sound waves, but, for reasons that are not fully understood, as the result of stimuli originating inside the head or within the ear itself. Tinnitus is almost always associated with hearing loss, particularly that due to presbyacusis (age-related loss of hearing) and exposure to loud noise. The condition can also occur as a symptom of ear disorders such as tinnitus, Ménière’s disease, otitis media, otosclerosis, ototoxicity, and blockage of the ear canal with earwax. It may also be caused by certain drugs, such as aspirin or quinine, or may follow a head injury.

SYMPTOMS
The noise in the ear can sometimes change in nature or intensity. In most cases, however, it is present continuously, although the affected individual may not be aware of its presence all the time. Tolerance of tinnitus varies from one person to another. Many people learn to accept and live with the condition, while other people find it almost intolerable.

TREATMENT
Any underlying disorder is treated if possible. Many sufferers of tinnitus make use of various means, such as a radio, television, cassette player, or headphones, to block out the noise in their ears. A tinnitus masker, a hearing-aid type device that plays white noise (a random mixture of sounds at a wide range of frequencies), may be effective.
tinzaparin
A type of low molecular weight heparin (anticoagulant drug) that may be injected once daily in the treatment of deep vein thrombosis (see thrombosis, deep vein).

tiotropium
A drug used in the treatment of chronic obstructive pulmonary disease (see pulmonary disease, chronic obstructive). Tiotropium, which is taken by inhalation (see inhaler), can help to relieve shortness of breath.

tiredness
A common complaint that is usually the result of overwork or poor quality or insufficient sleep. Persistent tiredness may be caused by a number of conditions, including depression, anxiety, anaemia, and diabetes mellitus.

tissue
A collection of cells specialized to perform a particular function. Examples include muscle tissue, which consists of cells specialized to contract (shorten); epithelial tissue, which forms the skin and mucous membranes that line the respiratory and other tracts; nerve tissue, comprising cells specialized to conduct electrical impulses; and connective tissue, which includes adipose tissue (fat), and the various fibrous and elastic tissues (such as tendons and cartilage) that hold the body together.

tissue fluid
The watery liquid present in the tiny gaps between body cells, also known as interstitial fluid. Tissue fluid is one component of extracellular fluid (any body fluid outside the cells, including blood and lymph). To reach cells, oxygen and nutrients must pass from the blood vessels and into the tissue fluid. Similarly, there is a reverse movement of carbon dioxide and other waste products from the cells into the tissue fluid, and then into the bloodstream.

In addition to nutrients and wastes, tissue fluid also contains ions. This fluid contains a much higher level of sodium ions, and a much lower level of potassium ions, than intracellular fluid. It is this difference in ion levels that helps to control the movement of water into and out of cells by osmosis; ion levels also play a role in the transmission of electrical impulses through nerves and muscles.

Tissue fluid is formed by the filtration of liquid out through the walls of the first part of blood capillaries (that is, the part nearest an arteriole), where it is forced out by the high blood pressure. In the last part of capillaries (nearest to a venule), blood pressure is much lower, and tissue fluid passes back into the capillaries; some tissue fluid is also drained away into the lymphatic vessels. Thus, there is a continual flow that keeps the amount of tissue fluid constant. Various disorders, for example, congestive heart failure, disrupt the balance between formation and drainage of tissue fluid, leading to the accumulation of excess fluid in the tissues, a condition called oedema.

tissue-plasminogen activator
Also called TPA, a substance produced by the inner lining of blood vessels that helps dissolve blood clots. TPA can be prepared artificially for use as a thrombolytic drug, which is called alteplase. This is used to treat myocardial infarction (heart attack) and pulmonary embolism (blockage of the artery supplying the lungs). Possible side effects of TPA include nausea and vomiting, bleeding or the formation of a haematoma (collection of blood) at the injection site, and an allergic reaction. (See also fibrinolysis.)

tissue-typing
The classification of certain characteristics of the tissues of prospective organ donors and recipients (see transplant surgery). This minimizes the risk of rejection of a donor organ by the recipient’s immune system after transplantation.

A person’s tissue type is classified in terms of his or her histocompatibility antigens, the most important of which are human leukocyte antigens (HLAs), on the surface of cells. A person’s set of HLAs is inherited and unique (except for identical twins, who have the same set). Nevertheless, close relatives often have closely matching HLA types.

HOW IT IS DONE
A person’s tissue-type is established by laboratory tests on cells from a blood sample. In one method, an antiserum containing antibodies to a particular HLA is added to the test specimen. If the HLA is present, it is detected by an observable colour or other change.

titanium dental implants
See implants, dental.

titubation
Tremor or a nodding movement of the head and/or a stumbling gait, seen in some disorders of the central nervous system (brain and spinal cord).

T-lymphocyte
A type of white blood cell, also known as a T-cell, that plays a role in the immune system. (See also helper T-cell; killer T-cell; memory T-cell; suppressor T-cell.)

TMJ dysfunction
See temporomandibular joint dysfunction.

toadstool poisoning
See mushroom poisoning.

tobacco
The dried leaf of the plant Nicotiana tabacum. Tobacco is used for smoking, chewing, or as snuff by billions of people. It contains a variable percentage of nicotine, and several carcinogenic substances. There is a direct relationship between the amount of tobacco used, the period over which it is used, and the likelihood of cancer. All tobacco users have an increased risk of cancers of the oral cavity (see mouth cancer), pharynx (see pharynx, cancer of), larynx (see larynx, cancer of) and oesophagus (see oesophagus, cancer of). Smokers are at increased risk of developing lung cancer, bladder cancer, kidney cancer, and pancreatic cancer (see pancreas, cancer of), as well as several circulatory and lung diseases (see smoking).

tobacco-smoking
See smoking.

tobramycin
An antibiotic drug that is used to treat serious infections such as septicaemia, meningitis, and severe infections of the bile ducts, kidneys, prostate gland, and lining of the heart. Tobramycin is sometimes used in the form of eye-drops to treat eye inflammation. High doses of injected preparations of the drug may result in kidney damage, deafness, nausea, vomiting, and headache. Any preparation of tobramycin may cause rash and itching.

tocography
An obstetric procedure that is used to record muscular contractions of the uterus during childbirth. It is usually combined with fetal heart monitoring (see cardiotocography).
tocopherol
A constituent of vitamin E. Together, four tocopherols (alpha, beta, gamma, and delta) and several tocopherol derivatives make up the vitamin.

toddler’s diarrhoea
A common condition affecting some children for a period after the introduction of an adult diet. It occurs because the child is unable to digest food properly, perhaps because of inadequate chewing. The diarrhoea is no cause for concern, and no treatment is needed.

Todd’s paralysis
Weakness in part of the body following some types of epileptic seizure (see epilepsy). The weakness may last for minutes, hours, or even days, but there is no lasting effect. The cause is thought to be temporary damage to the motor cortex (the area of the brain that controls movement).

toe
One of the digits of the foot. Each toe has three phalanges (bones), except for the hallux (big toe), which has two. The phalanges join at hinge joints, which are moved by tendons that flex (bend) or extend (straighten) the toe. An artery, vein, and nerve run down each side of the toe, and the whole structure is enclosed in skin with a nail at the top. The main function of the toes is to maintain balance during walking.

DISORDERS
Congenital disorders include toes missing at birth, polydactyly (extra toes), syndactyly (fused toes), or webbing (skin flaps between the toes).

Injuries to the toes, including fractures, are fairly common. Inflammation of the joints, with pain, stiffness, and swelling, may be caused by osteoarthritis, rheumatoid arthritis, or gout.

A common deformity of the big toe is hallux valgus, in which the toe turns inwards to the others. This often leads to the development of a bunion (a fluid-filled swelling) over the joint at the base of the toe. Abnormality of a tendon in one of the toes may also cause distortion (see hammer toe).

toenail, ingrowing
A painful condition of a toe (usually the big toe) in which one or both edges of the nail press into the adjacent skin, leading to infection and inflammation. The cause is usually incorrect cutting of the nail or wearing tight-fitting shoes.

Pain relief can be obtained by bathing the foot once or twice daily in a strong, warm, salt solution, then covering the nail with a dry gauze dressing. Antibiotics may be prescribed. In some cases, the edge of the nail is removed and the nail bed obliterated to prevent recurrence.

toilet-training
The process of teaching a young child to acquire complete bowel and bladder control. A child is unlikely to be completely toilet-trained before age three and may normally take much longer to remain dry at night (see enuresis).

WHEN TO START
Up to about 18 months, emptying of the bladder or bowel is a totally automatic reaction. The child is not yet able to connect the actions of defaecation and urination with their results, and cannot control these actions at will.

At around 18 months, a child can usually indicate that he or she has passed urine or a bowel movement, but is not yet aware when he or she is about to do so. At this stage, the child is not quite ready to use a potty, but can practise sitting on it. By the age of two, a child is aware when he or she is about to pass urine or a bowel movement and says so. At this stage, the child is ready to start using the potty.

METHODS
Toilet-training should be approached in a relaxed, unhurried manner. A child should never be forced to sit on a potty. Boys initially urinate sitting down but soon learn how to manage standing up. Once a child uses the potty confidently, he or she can gradually progress to using the toilet.

When reasonable control has been achieved, the child can be taken out of nappies during the day. Nappies should be worn at night until the child is usually dry on waking.

Toilet accidents, particularly wetting, are common up to the age of five, because a young child can delay urination for only a few minutes. Some children revert to soiling or wetting when anxious or under stress. (See also encopresis; enuresis; soiling.)

tolbutamide
An oral hypoglycaemic drug (see hypoglycaemics, oral) used in the treatment of type 2 diabetes mellitus.

tolerance
The need to take increasingly higher doses of a drug to obtain the same physical or mental effect. Tolerance develops after taking a drug over a period of time, and usually results either from the liver becoming more efficient at breaking the drug down or from tissues becoming less sensitive to it.

tolnaftate
An antifungal drug applied to the skin to treat, and sometimes prevent, recurrent tinea infections, including athlete’s foot. In rare cases, tolnaftate may cause skin irritation or a rash.

tomography
An imaging technique that produces a cross-sectional image (“slice”) of an organ or part. Most tomography today is performed using CT scanning and MRI, producing accurate and detailed images.

-tomy
A suffix denoting the operation of cutting or making an incision.

tone, muscle
The natural tension in the muscle fibres. At rest, all muscle fibres are kept in a state of partial contraction by nerve impulses from the spinal cord. Abnormally high muscle tone causes increased resistance to movement, spasticity, and rigidity. Abnormally low muscle tone causes floppiness (see hypotonia).

tongue
A muscular, flexible organ in the floor of the mouth.
TONGUE CANCER

STRUCTURE AND FUNCTION
The tongue is composed of a mass of muscles covered by a mucous membrane. The muscles are attached to the mandible (lower jaw) and hyoid bone above the larynx (voicebox).

Tiny nodules called papillae stick out from the tongue’s upper surface, giving it a rough texture. On the papillae at the sides and base of the tongue are the taste buds. Taste and other sensory signals are picked up by nerve fibres from one of four cranial nerves, and impulses then travel to the brain. The tongue plays an essential part in mastication (chewing), swallowing, and speech.

DISORDERS
A large tongue is a feature of Down’s syndrome, cretinism, and acromegaly. Temporary enlargement of the tongue as a result of swelling and inflammation may occur in glossitis.

Cracks on the surface of the tongue are common and usually cause no problems. However, they are occasionally deep enough to trap food particles, causing discomfort. Unnatural smoothness of the tongue that is accompanied by redness and soreness (glossitis) is a feature of certain types of anaemia (see anaemia, iron-deficiency; anaemia megaloblastic). Dryness or excessive furring of the tongue may be an indication of dehydration or may be symptoms of Sjögren’s syndrome or, in infants, candidiasis.

In rare cases, for unknown reasons, the papillae on the tongue become elongated and turn black or brown, a condition known as black tongue. This disorder is harmless but unsightly and persistent. The discoloration can be removed by cleaning the tongue twice a day with a soft toothbrush dipped in antiseptic mouthwash.

The tongue can be a site for mouth ulcers and leukoplakia (thickened white or grey patches), a condition that occasionally becomes cancerous (see tongue cancer). Any ulcer developing on the tongue that does not disappear within about three weeks should be reported to a doctor without further delay.

tongue cancer
The most serious type of mouth cancer due to its rapid spread. It mainly affects people over 40 and is associated with smoking, heavy alcohol consumption, and poor oral hygiene. The edge of the tongue is most commonly affected. The first sign may be a small ulcer with a raised margin, a white patch of thickened tissue called a leukoplakia, a fissure, or a raised, hard mass.

Diagnosis of tongue cancer is made by a biopsy (tissue sampling). Small tumours, especially those at the tip of the tongue, are removed surgically. Larger tumours or those that have spread often require radiotherapy.

tonic
One of a group of remedies intended to relieve symptoms such as malaise, lethargy, and appetite loss. Evidence suggests that tonics mainly have a placebo effect. The term is also used adjectivally to relate to muscle tone (see tone, muscle), as in tonic neck reflex, one of the primitive reflexes found in newborn infants.

	tonic-clonic seizure
Formerly called grand mal, a type of seizure in which consciousness is lost and there is muscle stiffness followed by uncontrolled jerking movements. The seizure normally lasts only a few minutes; prolonged tonic-clonic seizures can be life-threatening. (See epilepsy.)

tonometry
The procedure for measuring the pressure of the fluid within the eye, usually performed by an ophthalmologist or optician during an eye examination (see eye, examination of). Tonometry is useful in diagnosing glaucoma (increased pressure within the eyeball).
tonsil
One of a pair of oval tissue masses at the back of the throat on either side. The tonsils are made up of lymphoid tissue and form part of the lymphatic system. Along with the adenoids, the tonsils protect against upper respiratory tract infections. The tonsils gradually enlarge from birth until age seven, after which time they shrink substantially. Tonsillitis is a common childhood infection.

tonsillectomy
Surgical removal of the tonsils, which is now performed only if the patient suffers from frequent, recurrent attacks of severe tonsillitis. The operation is also carried out as a treatment for quinsy (an abscess around the tonsil).

PROCEDURE FOR TONSILLECTOMY
A tonsillectomy may be performed if the tonsils are very enlarged, after an abscess on the tonsil, or if tonsil infections are frequent and severe.

Standard technique
With the patient under a general anaesthetic, the tongue is depressed downwards and the tonsils prised from the back of the throat so that they can then be cut away.

tonsillitis
Inflammation of the tonsils as a result of infection. Tonsillitis mainly occurs in children under age nine. Sometimes the tonsils become repeatedly infected by the microorganisms they are supposed to protect against.

SYMPTOMS
The main symptoms are a sore throat and difficulty in swallowing. The throat is visibly inflamed. Other common symptoms are fever, headache, earache, enlarged and tender lymph nodes in the neck, and bad breath. Occasionally, there may be additional problems, such as temporary deafness or quinsy (an abscess around the tonsil).

TREATMENT
Tonsillitis is treated with plenty of fluids and an analgesic drug (painkiller) such as paracetamol; in some cases antibiotic drugs may also be prescribed.

tooth
See teeth.

tooth abscess
See abscess, dental.

toothache
Pain in one or more teeth and sometimes the gums.

CAUSES
Early dental caries (decay) may cause mild toothache when very hot, cold, or sweet food is eaten. More advanced decay or a fractured tooth (see fracture, dental), or a deep, unlined filling (see filling, dental) may lead to pulpitis (pulp inflammation). This usually causes a sharp, stabbing pain, which is often worse when the person is lying down.

If the inflammation spreads, the supporting tissues round the root of the tooth may be affected (a disorder known as periapical periodontitis). This causes localized pain brought on mainly by biting and chewing. A dental abscess (see abscess, dental) may also occur. In this case, pain is severe and often continuous, the gum surrounding the affected tooth is tender and swollen, and there may be swelling of the face and neck accompanied by fever.

Sometimes, toothache is caused by sinusitis (inflammation of the membrane lining the facial air cavities), when pain is referred to the upper molar and premolar teeth (see referred pain).

TREATMENT
Analgesic drugs may provide temporary pain relief. A visit to the dentist should be arranged as early as possible.

tooth avulsion
See avulsed tooth.

tooth brushing
Cleaning of the teeth with a brush in order to remove plaque and food particles from the tooth surfaces and to stimulate the gums. Brushing the teeth should be carried out twice a day using a dentifrice (usually toothpaste) that contains fluoride.

tooth decay
See caries, dental.

tooth extraction
See extraction, dental.

toothpaste
See dentifrice.

tophus
A collection of uric acid crystals that is deposited in certain tissues, especially those around the joints, but occasionally in other places such as the ear. Tophus is a sign of hyperuricaemia, a condition that accompanies gout.

topical
A term describing a drug that is applied to the surface of the body, not swallowed or injected.

toric lens
A type of contact lens specially shaped to correct astigmatism.

torsion
A term that means twisting, often applied to the intestine or testis.

torticollis
Twisting of the neck, causing the head to be tilted and fixed in an abnormal position (wry neck). There is often neck pain and stiffness. The cause is usually a minor neck injury that irritates cervical nerves, leading to muscle spasm. Other causes are sleeping in an awkward position, a neck-muscle injury occurring at birth, and a burn or injury that has caused heavy scarring.

Torticollis resulting from muscle spasm may be treated by use of an orthopaedic collar (see collar, orthopaedic), heat treatment, ultrasound treatment, physiotherapy, or injections of the toxin
The skin contains many thousands of specialized cells that respond to a variety of external stimuli, such as touch, heat, cold, and pressure. These cells (receptors) are divided into two different types. One type of receptor consists only of a thin nerve fibre, which may wrap around an individual hair and respond to its movement. The other type of receptor has a specialized structure, which is known as an end organ, that surrounds the nerve ending. Some skin receptors consist of several layers of cells that are attached to one nerve fibre. Others contain several nerve fibres that are arranged in a loop or coil. It is probable that several varieties of receptors play a part in each of the different types of touch modality.

**Pacinian corpuscle**
These receptors are 1 mm to 4 mm long and occur in hairless areas of skin, especially the fingers.

**DELICATE TOUCH**
The ability to detect light contact between an object and the skin. Areas with more receptors are more sensitive.

**PAIN**
Pain warns the brain about possible injury from an external stimulus and can trigger a reflex withdrawal.

**HEAT**
Some free nerve endings respond to heat. The inner wrist is good for testing temperature. Extreme heat stimulates pain receptors.

**COLD**
Cold on the skin is detected by specialized end organs. Extreme cold also stimulates pain receptors.

**PRESSURE**
A change in pressure on the skin is detected by specialized end organs called pacinian corpuscles.

**Skin receptors**
These receptors vary from free nerve endings to corpuscular or bulb-like structures. Individual receptors do not seem to be associated exclusively with any one skin sensation (e.g. cold or pain).

**General sensations**
General sensations that emanate from various parts of the body are perceived at specific points within the brain’s cerebral cortex. Some of the more highly sensitive body parts, such as the lips and hands, are represented in the brain by correspondingly large regions within the cortex.
that causes *botulism*. When the cause of torticollis is an injury arising from birth, the muscle is gently stretched several times each day; occasionally, an operation is required.

**touch**
The sense by which certain characteristics of objects, such as their shape, size, temperature, and surface texture, can be ascertained by physical contact.

The skin has many types of touch receptors, including Meissner’s corpuscles and Merkel’s discs to detect light touch, and Pacinian corpuscles to sense deep pressure and vibration. Signals from these receptors pass via sensory nerves to the spinal cord, then to the thalamus in the brain, and on to the sensory cortex, where touch sensations are perceived and interpreted.

The various parts of the body differ markedly in their sensitivity to touch discrimination. For example, the fingertips are considerably more sensitive to the sense of touch than the trunk. (See also *sensation*.)

**Tourette’s syndrome**
*See Gilles de la Tourette’s syndrome.*

**tourniquet**
A device that is placed around a limb in order to compress blood vessels. A tourniquet may be used to locate a vein for the purposes of an intravenous injection or the withdrawal of blood. An inflatable tourniquet, called an Esmarch’s bandage, is used to control blood flow in some limb operations. The use of a tourniquet as a first-aid measure to stop severe bleeding can cause gangrene (tissue death); first-aid courses now teach the use of pressure to control bleeding in preference to a tourniquet.

**toxaemia**
Presence in the bloodstream of toxins, commonly produced by bacteria. (See also pre-eclampsia; toxic shock syndrome.)

**toxaemia of pregnancy**
*See pre-eclampsia.*

**toxicity**
The property of being toxic (poisonous). The term also refers to the severity of adverse effects or illness produced by a poison, a poison, or a drug overdose.

**toxicology**
The study of poisons.

---

**toxic shock syndrome**
An uncommon, severe illness caused by a *toxin* produced by the bacterium *Staphylococcus aureus*.

**CAUSES**
The condition occurs mostly in women who use highly absorbent vaginal tampons. Other cases have been linked to use of a contraceptive cap, diaphragm, or sponge (see *contraception*), or to skin wounds or *staphylococcus* infections elsewhere in the body.

**SYMPTOMS AND COMPLICATIONS**
A high fever, vomiting, diarrhoea, headache, muscle aches and pains, dizziness, and disorientation develop suddenly. A widespread skin rash that resembles sunburn and also affects the palms and soles, develops. Blood pressure may fall dangerously low, and shock may develop. Other complications include *kidney failure* and *liver failure*.

**TREATMENT**
Antibiotics and treatment in an intensive care unit may be needed.

**toxin**
A poisonous protein produced by pathogenic (disease-causing) bacteria, various animals, or some plants. Bacterial toxins are sometimes subdivided into three categories: *endotoxins*, which are released from dead bacteria; *exofoods*, which are released from live bacteria; and *enterotoxins*, which inflame the intestine. (See also poison; poisoning; toxemia.)

**toxocariasis**
An infestation of humans, usually children, with the larvae of *Toxocara canis*; a small, threadlike worm that lives in the intestines of dogs.

**CAUSE**
Children who play with an infested dog or soil contaminated with dog faeces, and who then put their fingers in their mouths, may swallow worm eggs. The eggs hatch in the intestines, and the released larvae then migrate to organs such as the liver, lungs, brain, and eyes.

**SYMPTOMS**
Usually, infestation causes mild fever and malaise, which soon clears up; heavy infestation may lead to asthma, pneumonia, and seizures. Vision may be lost if larvae enter the eye and die there.

**DIAGNOSIS AND TREATMENT**
The diagnosis is made from blood tests. Treatment (with *pyrimethamine* and a sulphonamide drug) is necessary only in pregnant women, in children with severe symptoms, in people with an immune system deficiency, and in cases of retinitis or choroiditis.

**TPA**
The abbreviation used for tissue-plasminogen activator.

**trabecula**
A band of fibrous tissue that divides the inner part of an organ, for example the penis, into different sections. The term trabecula (plural trabeculae) is also used to describe the bony struts that make up the meshlike structure that is found inside spongy bone.

**trabeculectomy**
A surgical procedure that is used to control glaucoma (raised pressure within the eyeball). Trabeculectomy operates by allowing the fluid that accumulates in the front chamber of the eye to drain out under the conjunctiva.

---

**toxoid**
An inactivated bacterial toxin. Certain toxoids are used to immunize against specific diseases, such as *tetanus*. **toxoplasmosis**
An infection that is caused by the protozoan *Toxoplasma gondii* that is often caused by eating undercooked meat from infected animals, or by handling faeces from infected cats.

**SYMPTOMS AND COMPLICATIONS**
In most cases, there are no symptoms, but there may be a feverish illness that resembles infectious *mononucleosis* (glandular fever). Retinitis (inflammation of the eye’s retina) and *choroiditis* (inflammation of the choroid of the eye) may also develop. In people who have an *immune deficiency disorder*, toxoplasmosis may cause further problems such as lung and heart damage, stroke, seizures, and severe *encephalitis* (brain inflammation).

Toxoplasmosis that is contracted by a pregnant woman is transmitted to the fetus in about a third of cases. The infection may result in miscarriage or stillbirth, or the infant may have an enlarged liver and spleen, blindness, *hydrocephalus* (fluid around the brain), learning difficulties, seizures, or may die during infancy. Infection in late pregnancy usually has no ill effects.

**DIAGNOSIS AND TREATMENT**
The diagnosis is made from *blood tests*.

Treatment (with *pyrimethamine* and a sulphonamide drug) is necessary only in pregnant women, in children with severe symptoms, in people with an immune system deficiency, and in cases of retinitis or choroiditis.
trace elements

Minerals necessary in minute amounts in the diet to maintain health. Examples are chromium, copper, zinc, and selenium. (See also nutrition.)

tracer

A radioactive substance that is introduced into the body so that its distribution, processing, and elimination from the body can be monitored.

trachea

The air passage, also called the windpipe, that runs from just below the larynx (voicebox) to behind the upper part of the sternum (breastbone), where it divides to form the bronchi.

STRUCTURE

The trachea is made up of fibrous and elastic tissue and also smooth muscle. It also contains about 20 rings of cartilage, which help it to keep it open. The trachea has specialized cells (goblet cells) that secrete mucus and cells with cilia (hairlike structures), which beat the mucus upwards to help keep the lungs and airways clear.

LOCATION OF THE TRACHEA

The trachea extends down from the larynx for about 10 cm to the point where it divides into the two bronchi.

DISORDERS

One of the most common disorders of the trachea is tracheitis (inflammation of the trachea lining), which is usually caused by an infection (especially by a virus) and is often associated with bronchitis or laryngitis. Obstruction of the trachea by an inhaled object is rare because the narrowest part of the upper respiratory tract is the larynx, and any objects that pass through there usually also continue through the trachea. However, the trachea may become obstructed by a tumour or narrowed as a result of scarring from a tracheostomy tube inserted to create an artificial airway through the front of the neck.

Rarely, a congenital malformation occurs in which an abnormal channel forms between the trachea and the oesophagus immediately behind it (see tracheoesophageal fistula).

tracheitis

Inflammation of the trachea (windpipe). Tracheitis is usually caused by a viral infection and is aggravated by inhaled fumes and especially by tobacco smoke; it often occurs with laryngitis and bronchitis in a condition known as laryngotracheobronchitis.

Symptoms include a painful dry cough and hoarseness. In most cases, no treatment is needed.

tracheoesophageal fistula

A rare birth defect in which an abnormal passage connects the trachea (windpipe) with the oesophagus (gullet). In the most common form of this type of fistula, the lower end of the oesophagus connects with the trachea, and the upper end of the oesophagus is underdeveloped, forming a blind-ended pouch.

SYMPTOMS AND SIGNS

The affected baby cannot swallow saliva and drools constantly. During feeding, food is regurgitated and enters the lungs, causing the baby to choke, cough, and sometimes to turn blue due to lack of oxygen. The abdomen swells because inhaled air passes into the stomach through the fistula. The acidic fluid in the stomach passes up into the lungs through the fistula, leading to pneumonia and atelectasis (lung collapse).

DIAGNOSIS AND TREATMENT

The condition is often discovered soon after birth, although mild forms may not be detected until childhood or even adult life, usually after recurrent attacks of pneumonia. The diagnosis may be confirmed by X-rays. Treatment of tracheoesophageal fistula consists of an operation that closes the fistula and connects the trachea and oesophagus together correctly.

tracheostomy

An operation in which an opening is made in the trachea (windpipe) and a tube is inserted in order to maintain an effective airway. A tracheostomy is used for the emergency treatment of various airway problems involving the larynx (voicebox).

A planned tracheostomy is most commonly performed on a person who has lost the ability to breathe naturally and is undergoing long-term ventilation or is unable to keep saliva and other secretions out of the trachea. Permanent tracheostomy is needed after laryngectomy (removal of the larynx).

Tracheostomy tube

The tube readily becomes blocked by secretions; it has a metal inner lining that can be removed for cleaning.

tracheotomy

Cutting of the trachea (windpipe). (See also tracheostomy.)

trachoma

A persistent infectious disease of the cornea and conjunctiva of the eye. Trachoma is caused by the bacteria CHLAMYDIA TRACHOMATIS and is spread by direct contact and possibly by flies (see chlamydial infections). The disease is uncommon in the UK, but, worldwide, trachoma is the most common cause of blindness. Treatment is with antibiotic drugs.

tract

Any one of a group of organs that form a common pathway with the purpose of performing a particular function. The term also refers to a bundle of nerve fibres with a common function.

traction

A procedure in which part of the body is placed under tension to correct the alignment of two adjoining structures.
or to hold them in place. Traction is most commonly used to treat a fracture in which muscles around the bone ends are pulling the bones out of alignment.

tragus
The small projection of cartilage in front of the opening of the ear canal.

training
A programme of exercises that is undertaken to prepare for a particular sport. Training may be concentrated on improving skills or on improving physical fitness. Fitness training should include both aerobic and anaerobic exercises, which together build up strength, flexibility, and endurance. Interval training is a type of fitness programme in which a particular exercise is repeated several times with a rest period between. Circuit training consists of performing a set number of different exercises.

trait
Any characteristic or condition that is inherited (which means that is determined by one or more genes). Blue or brown eye colour, dark or light skin, and nose shape are examples of genetic traits. The term trait is also sometimes used to describe a mild form of a recessive genetic disorder, for example thalassaemia trait.

tramadol
An opioid drug that is used to relieve severe pain following a heart attack, surgery, or serious illness. Tramadol is less likely to cause dependence with long-term use than most opioids. Possible side effects include nausea, vomiting, drowsiness, confusion, and impaired consciousness.

transcervical electrode stimulation
See TENS.

transdermal patch
A method of administering medication through the skin, using a drug-impregnated, adhesive patch. The drug is released from the patch over a period of time and is absorbed by the skin.

transference
The unconscious displacement of emotions from people who were important during one’s childhood, such as parents, to other people during adulthood. For example, during psychotherapy, anger that the analysand feels towards his or her father may be transferred to the therapist. (See also psychoanalysis.)

transfusion
See blood transfusion.

transfusion, autologous
See blood transfusion, autologous.

transient ischaemic attack (TIA)
A brief interruption of the blood supply to part of the brain, which causes temporary impairment of vision, speech, sensation, or movement. The episode typically lasts for several minutes or, at most, for a few hours. TIAS are sometimes described as mini strokes, and can be the prelude to a stroke. A stroke occurs within five years in up to one third of patients who have had a TIA.

CAUSES
TIs may be caused by a blood clot (see embolism) that temporarily blocks an artery supplying the brain, or by narrowing of an artery as a result of atherosclerosis (buildup of fatty deposits in the artery wall).

INVESTIGATION
After a TIA, tests such as CT scanning, blood tests, and angiography or Doppler ultrasound scanning of the carotid artery in the neck may be needed to find a cause. In some cases, the heart is studied as a possible source of blood clots.

TREATMENT
Treatment, which is aimed at preventing a stroke includes endarterectomy (an operation to remove the lining of an artery affected by atherosclerosis), aspirin (which reduces the “stickiness” of blood), or anticoagulant drugs. People who have had a TIA can help prevent a stroke by lifestyle changes such as stopping smoking and adopting a low-fat diet.
**transillumination**
A procedure that is sometimes carried out during the physical examination of a lump or swelling. Light that comes from a small torch is shone onto one side of the lump; if the light can be seen on the other side, the lump contains clear fluid.

**transitional cell carcinoma**
A type of cancerous tumour that can develop in the bladder or kidney. In the bladder, transitional cell carcinomas develop within the bladder lining (see bladder tumours). In the kidney (see kidney cancer), this type of tumour develops in the lining of the renal pelvis (the urine-collecting chamber at the centre of the kidney).

**translocation**
A rearrangement of the chromosomes inside a person’s cells; it is a type of mutation. Sections of chromosomes may be exchanged or the main parts of two chromosomes may be joined. A translocation may be inherited or acquired as the result of a new mutation.

In many cases a translocation has no obvious effect, and causes no apparent abnormality. However, it sometimes means that some of the affected person’s sperm or egg cells carry too much or too little chromosomal material, which may cause a chromosomal abnormality, such as Down’s syndrome, in the individual’s children.

**transmissible**
A term meaning capable of being passed from one person, or one organism, to another.

**transplant surgery**
Replacement of a diseased organ or tissue with a healthy, living substitute. The organ is usually taken from a person who has just died. Some kidneys are transplanted from a patient’s living relatives (see organ donation). The results of surgery have been improved by testing for histocompatibility antigens and tissue-typing.

Rejection is a major problem. A combination of a corticosteroid drug and an immunosuppressant drug are given in order to suppress this response.

Every patient who has to undergo an organ transplant operation must be given immunosuppressant drugs for an indefinite period. (See also heart–lung transplant; heart transplant; kidney transplant; liver transplant.)
transposition of the great vessels
A serious form of congenital heart disease in which the two major vessels that carry blood away from the heart (the aorta and the pulmonary artery) are transposed. This means that insufficient oxygenated blood is supplied to the body’s tissues. Cyanosis (blueness of the skin) usually develops and the baby becomes increasingly short of breath and feeds poorly. Open heart surgery is needed in order to correct the defect.

transsexualism
A rare condition in which an individual wishes to live as a member of the opposite sex. Transsexuals commonly seek hormonal or surgical treatment in order to bring about a physical sex change. A psychiatric evaluation and a physical examination are necessary before such treatment is undertaken.

transverse colon
One of the four major sections of the colon, or large intestine. The transverse colon lies across the abdomen.

transverse fracture
A fracture in which there is a straight break across the bone.

transverse myelitis
See myelitis.

transvestism
A persistent desire by a man to dress in women’s clothing, also known as cross-dressing. Transvestism ranges from the occasional wearing of female underwear to dressing in female clothes in public and involvement in transvestite subculture. Most transvestites are heterosexual and many have a sexual relationship with a female partner who is aware of the cross-dressing and can accept it as a special need.

tranylcypromine
An antidepressant drug that belongs to the monoamine-oxidase inhibitor (MAOI) group and is used mainly in patients with severe depression.

trapezius muscle
A large, diamond-shaped muscle that extends from the back of the skull to the lower part of the spine in the chest and across the width of the shoulders. The trapezius muscle is attached to the top and back of the shoulderblade and to the outermost part of the collarbone. It helps to support the neck and spine and is also involved in moving the arm.

trapped nerve
See nerve, trapped.

trastuzamab
A type of drug used in the treatment of breast cancer. Trastuzamab is given by intravenous infusion, and only in hospital under specialist supervision. The drug can have potentially serious side effects, which include breathing difficulties and disturbance of heart function.

trauma
Any serious physical injury or severe emotional shock. (See also post-traumatic stress disorder.)

trauma surgery
See traumatology.

traumatic amputation
See amputation, traumatic.

traumatology
Emergency treatment of patients suffering from acute trauma (such as severe and/or multiple injuries).

travel immunization
Anyone planning to travel abroad may need immunizations. Although few are compulsory for international travel, some are recommended for the protection of the traveller and to prevent the spread of diseases. (See Guidelines for travel immunization box, overleaf).

Travel agents and tour operators often include information concerning the immunizations that may be needed. However, travellers are recommended to consult a doctor or travel nurse about individual needs. Some vaccines must be given in two or three doses several weeks apart. Therefore, a doctor should be consulted at least two to three months prior to departure. Children under one year of age, pregnant women, and those individuals who have a compromised immune system or a serious illness may not be able to have some vaccinations, such as those for yellow fever and tuberculosis (BCG).

traveller’s diarrhoea
A disorder that occurs in individuals who are visiting foreign countries. Episodes of diarrhoea range in severity and are the result of gastroenteritis. Attention to hygiene, drinking bottled water, avoiding ice in drinks, and eating peelable fruit can prevent a large proportion of episodes.

travel sickness
See motion sickness.

trazodone
An antidepressant drug with a strong sedative effect that is used to treat depression accompanied by anxiety or insomnia. Possible side effects of trazodone include drowsiness, constipation, a dry mouth, dizziness, and, rarely, priapism.

treadmill test
A test that involves exercise at varying degrees of inclination on a treadmill while the heart function is monitored (see exercise ECG).

treatment
A measure taken to prevent or cure a disease or disorder or to relieve symptoms.

trematode
The scientific name for any fluke or schistosome.

trembling
See tremor.
GUARDIANES DE TRAVEL IMMUNIZATION

<table>
<thead>
<tr>
<th>Immunization</th>
<th>Reason for Immunization</th>
<th>Effectiveness</th>
</tr>
</thead>
<tbody>
<tr>
<td>Yellow fever</td>
<td>Compulsory for entry to some countries and advisable for visits to others within yellow fever zones in Africa and South America. May also be needed when travelling from yellow fever zones to some Asian countries.</td>
<td>Almost 100 per cent protection for at least 10 years. Certificate provided.</td>
</tr>
<tr>
<td>Cholera</td>
<td>No longer recommended for routine preventive use. No vaccine is available in the UK. Anyone intending to travel and asked to provide a vaccination certificate is given instead a certificate explaining that the vaccine is not recommended.</td>
<td>Poor.</td>
</tr>
<tr>
<td>Typhoid fever</td>
<td>Recommended when travelling anywhere outside several countries, including Europe, the US, Canada, Australia, New Zealand, and Japan for anyone who has not received immunization or a booster within the past three years.</td>
<td>Gives moderate protection for about three years, after which a booster is needed.</td>
</tr>
<tr>
<td>Tetanus</td>
<td>Advisable for anyone who has not received childhood immunization or a booster within the past 10 years.</td>
<td>Highly effective, with booster needed every 10 years. Usually no more than five doses needed.</td>
</tr>
<tr>
<td>Poliomyelitis</td>
<td>Advisable for anyone who has not received childhood immunization or a booster within the last 10 years.</td>
<td>Highly effective, with booster needed every 10 years in some areas.</td>
</tr>
<tr>
<td>Hepatitis A</td>
<td>Recommended for protection against viral hepatitis type A when travelling to any country where hygiene and sanitary standards are low.</td>
<td>Highly effective. Booster needed every 10 years.</td>
</tr>
<tr>
<td>Diphtheria</td>
<td>Advisable for anyone who has not received childhood immunization.</td>
<td>Highly effective.</td>
</tr>
<tr>
<td>Hepatitis B; rabies</td>
<td>Recommended only for people who are special risk because of their occupation or the nature of their visit abroad.</td>
<td>Highly effective.</td>
</tr>
<tr>
<td>Meningitis A and C</td>
<td>May be recommended when travelling to most of Africa, Brazil, and Nepal and some other areas. An immunization certificate is needed for travel to Mecca.</td>
<td>Highly effective.</td>
</tr>
<tr>
<td>Japanese B encephalitis; tick-borne encephalitis</td>
<td>May sometimes be recommended when travelling to specific risk areas.</td>
<td>Moderately effective.</td>
</tr>
</tbody>
</table>

TREMOR

An involuntary, rhythmic, oscillating movement in the muscles of the body; the most commonly affected muscles are those of the hands, feet, jaw, tongue, or head. Tremor is the result of rapidly alternating muscle contraction and relaxation. Occasional tremors are experienced by the majority of people and are due to increased production of the hormone adrenaline (epinephrine). A slight, persistent tremor is common in elderly people.

Essential tremor, a type that runs in families, is a fine-to-moderate tremor (about six to ten movements per second) that may be temporarily relieved by consuming a small amount of alcohol or by taking beta-blocker drugs.

Coarse tremor (about four to five movements per second) is present at rest but reduced during movement, and is often a sign of the movement disorder Parkinson’s disease. An intention tremor (tremor that is worse on movement of the affected part) may be a sign of cerebellar ataxia.

Tremor may also be caused by multiple sclerosis, Wilson’s disease, mercury poisoning, thyrotoxicosis, or hepatic encephalopathy; drugs, such as amphetamines and caffeine; and withdrawal from drugs, including alcohol.

Trench fever

An infectious disease that is now rare or unknown in most parts of the world. The disease is caused by rickettsiae (microorganisms that are similar to bacteria) spread by body lice. Symptoms include headache, muscle pains, and fever, which may occur in bouts. Treatment is with antibiotic drugs.

Trench foot

See immersion foot.

Trench mouth

See gingivitis, acute ulcerative.

Trendelenburg’s test

A test that is used to assess the function of each hip in turn. It involves standing on one leg and lifting the other leg while keeping the spine straight. Normally, as the leg is raised the pelvis on the same side should lift. Drooping of the pelvis on the side of the raised leg indicates that there may be a problem, such as a hip dislocation or weakness of the buttock muscles.

Trehine

A hollow, cylindrical instrument with a saw-toothed edge used for cutting a circular hole, usually in bone.

Treponema pallidum

The species of bacteria responsible for causing syphilis.

tretinoin

A topical drug that is chemically related to vitamin A and that is used to treat acne and certain skin disorders such as ichthyosis. Tretinoin may aggravate acne at the start of treatment but usually improves the condition within three to four months.

Possible side effects are irritation, peeling, and skin discoloration. Exposing the skin to sunlight while using tretinoin may aggravate irritation and can cause sunburn.
tria
A classification system for establishing priority for treatment among a group of patients. Triage is used in hospital accident and emergency departments to sort patients into categories according to the nature of their injuries and their need for emergency treatment. It is intended to give the best chance of survival to the greatest number of people.

trial, clinical
A test on human volunteers of the effectiveness and safety of a drug. A clinical trial can also involve systematic comparison of alternative forms of medical or surgical treatment for a particular disorder. Patients involved in clinical trials have to give their consent, and the trials are approved and supervised by an ethics committee.

triamcinolone
A corticosteroid drug that is used to treat inflammation of the mouth, gums, skin, and joints.

triamterene
A diuretic drug that is used to treat hypertension (high blood pressure) and oedema (accumulation of fluid in tissues). Possible adverse effects include nausea, vomiting, weakness, and rash.

tribavirin
See ribavirin.

triceps muscle
The muscle at the back of the upper arm. At the upper end of the triceps are three "heads"; one is attached to the outer edge of the scapula (shoulder-blade), and the other two to either side of the humerus (upper-arm bone). The lower part of the triceps is attached to the olecranon process of the ulna (the bony prominence on the elbow). Contraction of the muscle straightens the arm. (See also biceps muscle.)

trichiasis
An alteration in the direction of eyelash growth, in which the lashes grow inwards towards the eyeball. They can rub against the eye, causing severe discomfort and sometimes damage to the cornea. Trachoma is a possible cause.

trichinosis
An infestation with the larvae of the Trichinella spiralis worm, which is usually acquired by eating undercooked pork. Trichinosis is rare in the UK. The thorough cooking of pork products, and freezing meat to a temperature below -18°C for 24 hours, helps to avoid infection.

SYMPTOMS
Slight infestation usually causes no symptoms. However, heavy infestation may cause diarrhoea and vomiting within a day or two of eating the infected meat; gastrointestinal symptoms are followed by fever; swelling around the eyelids; severe muscle pains, which may last for several weeks; and inflammation of the heart muscle (myocarditis).

DIAGNOSIS AND TREATMENT
Trichinosis may be suspected from the symptoms, and the diagnosis is confirmed by blood tests, or by a muscle biopsy (tissue sample). Treatment of the infestation is with an anthelmintic drug.

trichloroethylene
An inhaled drug that produces short-term anaesthesia. Trichloroethylene is not now commonly used.

trichology
The study of hair, including its structure, patterns of growth, and diseases.

trichomoniasis
An infection caused by the protozoan (single-celled microorganism) Trichomonas vaginalis. Trichomoniasis is one of the common causes of vaginitis (inflammation of the vagina) in women. The infection is usually sexually transmitted. Trichomoniasis is less common in men, in whom it affects the urethra.

CAUSES
In women, the causative organism may inhabit the vagina for many years without causing symptoms. However, if symptoms do occur, they include painful inflammation of the vagina and vulva, and a greenish, frothy, offensive-smelling discharge. Sexual intercourse may be painful. Men usually have no symptoms, but some may have discomfort on passing urine.

DIAGNOSIS AND TREATMENT
The diagnosis is made from examination of a sample of the discharge. However, diagnosis is usually difficult to confirm in men.

Treatment is with metronidazole. The sexual partner or partners of an infected person should be treated at the same time to prevent reinfection.

Trichophyton
A genus of fungi that can cause diseases of the hair, skin, and nails in humans (see fungal infections). Athlete’s foot and ringworm of the scalp (see tinea) are among common disorders caused by Trichophyton species.

trichotillomania
The habit of constantly pulling out one’s own hair. It can be associated with severe mental handicap or with a psychotic illness. Trichotillomania may also occur in psychologically disturbed children. The trichotillomania sufferer will typically pull, twist, and break off chunks of hair from his or her scalp, leaving visible bald patches. Occasionally, the pubic hair is pulled out in addition to or instead of hair on the head.
trichuriasis
A parasitic infestation with the mainly tropical worm Trichuris trichuria (whipworm). Children are most commonly affected. Infestation occurs when eggs are ingested and then develop into adult worms in the intestines. Severe infestation may cause bloody diarrhoea, abdominal pain, and weight loss. Treatment of trichuriasis is with antihelmintic drugs.

triclosan
An antiseptic used for disinfecting the skin. For example, triclosan may be used by doctors and other hospital staff for cleansing the hands before carrying out surgical procedures.

tricuspid incompetence
Failure of the heart’s tricuspid valve to close fully, allowing blood to leak back into the right atrium (upper chamber) when the right ventricle (lower chamber) contracts. Tricuspid incompetence, also known as tricuspid insufficiency, reduces the heart’s pumping efficiency.

CAUSES
The usual cause is pulmonary hypertension (high pressure in the blood supply to the lungs). More rarely, it follows rheumatic fever, or, in intravenous drug users, bacterial infection of the heart.

SYMPTOMS
Tricuspid incompetence results in symptoms of right-sided heart failure, notably oedema (fluid swelling) of the ankles and abdomen. The liver is swollen and tender, and veins in the neck are distended.

DIAGNOSIS AND TREATMENT
A diagnosis is made from the symptoms, from hearing a heart murmur through a stethoscope, and by tests that may include an ECG, chest X-rays, echocardiography, and cardiac catheterization. Treatment with diuretic drugs and ACE inhibitors often relieves the symptoms.

tricuspid stenosis
Narrowing of the opening of the tricuspid valve of the heart, usually caused by a previous attack of rheumatic fever. Tricuspid stenosis is uncommon and often occurs with another heart-valve disorder. For example, tricuspid incompetence may also occur in intravenous drug users who have a bacterial infection of the heart. Tricuspid stenosis causes enlargement of the right atrium (upper heart chamber).

The symptoms and diagnosis of tricuspid stenosis are similar to those of tricuspid incompetence. Treatment is with drugs such as diuretic drugs and sometimes a digitalis drug. Heart-valve surgery is sometimes needed.

tricuspid valve
One of the valves in the heart that consists of three flaps that lies between the right atrium (upper chamber) and the right ventricle (lower chamber). Its function is to ensure that blood flow from the atrium to the ventricle occurs in one direction only.

tricyclic antidepressants
A type of antidepressant drug. Tricyclic antidepressants work by preventing neurotransmitters (chemicals released from nerve endings) in the brain from being reabsorbed, thereby increasing their level. Examples include amitriptyline, clomipramine, and imipramine.

trifluoperazine
An antipsychotic drug that is used in the treatment of schizophrenia.

trigeminal nerve
The fifth cranial nerve. The trigeminal nerves, one on each side of the face, arise from the brainstem. Both nerves divide into three branches that supply sensation to the face, scalp, nose, teeth, lining of the mouth, upper eyelid, sinuses, and the front portion of the tongue. They also stimulate contraction of the jaw muscles for chewing.

trigeminal neuralgia
A disorder of the trigeminal nerve in which brief episodes of severe, stabbing pain affect the cheek, lips, gums, or chin on one side of the face. The disorder usually occurs in people over the age of 50. Pain may come in bouts that last for weeks at a time. The cause is uncertain, and pain is often brought on by touching the face, eating, drinking, or talking.
Analogic drugs (painkillers) may be prescribed. However, in many cases, carbamazepine is more effective. If this fails, surgery may prove helpful.

**trigger finger**
Locking of one or several fingers in a bent position due to inflammation of the sheath enclosing the tendon of the affected finger. The finger is usually tender at the base and slightly swollen over the tendon. Treatment involves local injection of a corticosteroid drug or, if this is unsuccessful, surgery.

**triglyceride**
A type of simple fat (see fats and oils) made up of a molecule of glycerol and three molecules of fatty acids. Triglycerides are the main type of fat found in stores of body fat.

**trimeprazine**
A former name for alimemazine, an antihistamine drug.

**trimester**
A period of three months; it is used particularly with reference to human pregnancy, which is conventionally divided into three trimesters.

**trimethoprim**
An antibacterial drug used to treat a range of infections, most commonly those of the urinary tract. Possible side effects include rash, itching, nausea, vomiting, diarrhoea, and a sore tongue.

**trimipramine**
A tricyclic antidepressant drug used to treat depression accompanied by anxiety or insomnia. Possible side effects include dry mouth, blurred vision, dizziness, constipation, and nausea.

**triplets**
Three offspring resulting from one pregnancy (see pregnancy, multiple).

**triple X syndrome**
A group of features that may occur in females due to inheriting three female sex chromosomes (XXX) rather than the usual two (see chromosomes). The defect results from errors in the division of one parent’s egg or sperm cells.

The features of triple X syndrome can vary greatly. In some cases there are no obvious signs. More severely affected females may show delays in developing speech and motor skills, an IQ that may be lower than that of any siblings, and behavioural problems such as tantrums or shyness. Adult women may be taller than average, but show normal sexual development and are fertile.

**triprolidine**
An antihistamine drug that is used as an ingredient of cough and cold remedies. Possible side effects of triprolidine include dry mouth, dizziness, difficulty in passing urine, and hyperactivity.

**trismus**
Involuntary contraction of the jaw muscles, which causes the mouth to become tightly closed; commonly known as lockjaw. Trismus may develop as a symptom of tetanus, tonsillitis, mumps, or acute ulcerative gingivitis (gum disease), or of other dental problems that affect the back teeth. Treatment is for the underlying cause.

**trisomy**
Any condition in which there is an extra chromosome within a person’s cells, making three of a particular chromosome instead of the usual two.

**cause**
A fault during meiosis (cell division) to form egg or sperm cells can sometimes leave an egg or sperm with an extra chromosome. When the egg or sperm takes part in fertilization, the resulting embryo inherits an extra chromosome in each of its cells.

**types and symptoms**
The most common type of trisomy is of chromosome 21 (Down’s syndrome). Trisomy 18 (Edward’s syndrome) and trisomy 13 (Patau’s syndrome) are less common; trisomy 8 and trisomy 22 are very rare. Partial trisomy, with only part of a chromosome reproduced in triplicate, also occurs.

Full trisomies cause abnormalities such as skeletal and heart defects and learning difficulties. Except in Down’s syndrome, babies usually die in early infancy. The effects of partial trisomies depend on the amount of extra chromosomal material present.

**Diagnosis and prevention**
Diagnosis is made by chromosome analysis of cells, which may be obtained from the fetus by amniocentesis or after the birth. There is no specific treatment. Parents of an affected child may wish to have genetic counselling.

**trochanteric bursitis**
Inflammation of the bursa (fluid-filled sac) located towards the upper end of the femur (thigh bone). Trochanteric bursitis may be due to repeated strain on the hip joint in activities such as running, or may result from sudden injury (for example, in a fall or during contact sports). It may also occur after surgery on the hip, or develop in a person whose legs are of different lengths. In some cases, there is no apparent cause. The main symptom is pain at the side of the hip; the pain may also spread down the side of the thigh.
Treatment often includes rest, application of ice packs (or heat treatment), and the use of nonsteroidal anti-inflammatory drugs (NSAIDs) for pain relief. A corticosteroid injection may be given into the bursa, often providing a rapid relief from the symptoms. Physiotherapy may also be helpful.

**trochlear nerve**
The fourth cranial nerve. There are two trochlear nerves, which arise in the brainstem, one on each side of the midbrain. They enter the eye sockets through gaps in the skull bones. Each trochlear nerve controls one of the two superior oblique muscles, which are responsible for rotation of the eyes both downwards and outwards.

**LOCATION OF THE TROCHLEAR NERVE**

This nerve emerges from the brain and supplies a muscle that rotates the eye down and outwards.

**trophic**
A term that means relating to nutrition. It is also used of a hormone or its effects to indicate stimulation of another hormone-producing gland.

**trophic ulcer**
An ulcer that develops when nerves in the skin are damaged or destroyed by disease or injury. Trophic ulcers most commonly appear on the feet and can be a complication of disorders such as diabetes mellitus and Hansen’s disease.

**trophoblastic tumour**
A growth arising from the tissues that develop into the placenta. The most common type is a hydatidiform mole. (See also chorioniccarcinoma.)

**tropical diseases**
Many diseases prevalent in the tropics are primarily caused by overcrowded living conditions and inadequate diet. Malnutrition is one of the major causes of illness in the tropics. Apart from resulting in nutritional deficiency disorders, a poor diet weakens the body’s ability to fight infectious diseases such as measles, diphtheria, and tuberculosis.

Lack of sanitary facilities, which encourages the contamination of water and soil with human excrement, causes a number of diseases, including typhoid fever, shigellosis, cholera, amoebiasis, and nematode and tapeworm infestations.

Diseases that are spread through the tropics by insects include malaria, yellow fever, sleeping sickness, and leishmaniasis. Exposure to strong tropical sunlight causes an increased tendency to skin cancer among people with fair skin; sunlight may also damage the outer tissues of the eye, leading to such disorders as pterygium and pinguecula.

**tropical sprue**
See sprue, tropical.

**tropical ulcer**
An area of persistent skin and tissue loss caused by infection with one or more organisms. The condition is most common in malnourished people living in the tropics. Treatment is cleaning and dressing of the ulcer, a course of antibiotic drugs, and a high protein diet. The ulcer usually heals but may scar.

**tropicamide**
A drug used to dilate the pupil before an eye examination. Adverse effects of the drug include blurred vision, increased sensitivity to light, stinging, and, rarely, dry mouth, flushing, and glaucoma.

**trunk**
The centre of the body, comprising the chest and abdomen. It also refers to any large blood vessel or nerve, from which smaller vessels or nerves branch off.

**truss**
An elastic, canvas, or padded appliance that is used to hold an abdominal hernia in place. Trusses are used only in situations where corrective surgery cannot be undertaken.

**trypanosomiasis**
A tropical disease that is caused by Trypanosoma parasites. (See also Chagas’ disease; sleeping sickness.)

**trypsin**
A type of enzyme, secreted by the pancreas, that plays an important role in the process of digestion by breaking down proteins.

**tryptophan**
An essential amino acid (a building block of proteins). Tryptophan, which is necessary for normal growth, is not manufactured within the body but must be obtained from the diet.

**tsetse fly bites**
The bites of tsetse flies, which are found in Africa, can be very painful. The flies, resembling brown houseflies, spread sleeping sickness.

**TSH**
The abbreviation for thyroid-stimulating hormone.

**T-tube cholangiography**
An imaging technique that is performed in order to check that there are no gallstones left in the bile duct following a cholecystectomy (surgical removal of the gallbladder). A T-shaped rubber tube is inserted into the bile duct during the surgery and is left in place. After about a week, contrast medium is inserted into the tube and X-rays are taken. If there are no stones, the tube is pulled out. If there are, they may be removed by ERCP or by a stone-dissolving solvent administered through the tube.

**tubal ligation**
See sterilization, female.

**tubal pregnancy**
See ectopic pregnancy.

**tubercle**
A grey, nodular mass that is found in tissues affected by tuberculosis. The term also refers to a small rounded protrusion that sometimes occurs on the surface of a bone.
tuberculin tests
Skin tests used to determine whether or not a person has been exposed to the bacterium that causes \textit{tuberculosis}. Tuberculin tests are carried out for diagnosis of tuberculosis, and before BCG vaccination. A small amount of tuberculin (purified protein from the bacteria) is injected into the skin. A few days later, the skin reaction, if any, is noted. A reaction indicates previous exposure, by infection or vaccination.

tuberculosis
An infectious disease, commonly called TB, caused in humans by the bacterium \textit{Mycobacterium tuberculosis}.

CAUSES AND TYPES
TB is usually transmitted in airborne droplets expelled when an infected person coughs or sneezes. Inhaled droplets enter the lungs and the bacteria multiply. The immune system usually seals off the infection at this point, but in some cases the infection spreads to the lymph nodes. It may also spread to other organs in the bloodstream, which may lead to miliary tuberculosis, a potentially fatal form of the disease, or to meningitis (inflammation of the membranes around the brain and spinal cord), bone infection, genitourinary infections, or pericarditis (inflammation of the membranes around the heart).

In other cases, bacteria held in a dormant state by the immune system become reactivated months, or even years, later. Reactivation may occur when old age, poor health, or reduced immunity increase susceptibility to the infection. The infection may then progressively damage the lungs.

SYMPTOMS
The primary infection is usually without symptoms. Progressive infection in the lungs causes coughing (sometimes bringing up blood), chest pain, shortness of breath, fever and sweating, poor appetite, and weight loss. Pleural effusion (collection of fluid between the lung and chest wall) or pneumonia may develop. The lung damage may be fatal.

DIAGNOSIS
A diagnosis is made from the symptoms and signs, from a chest X-ray, and from tests on the sputum. Alternatively, a bronchoscopy may also be carried out to obtain samples for culture.

TREATMENT
Treatment is usually with a course of three or four drugs, taken daily for two months, followed by daily doses of isoniazid and rifampicin for four months. However, TB bacteria are increasingly resistant to the drugs used in treatment, and others may have to be used and treatment carried out for a longer period. If the full course of drugs is taken, most patients recover.

PREVENTION
Tuberculosis can be prevented by BCG vaccination, which may be offered just after birth or routinely at age 10–14. Contacts of an infected person are traced and, if necessary, are treated early to reduce the risk of the infection spreading.

tuberosity
A prominent area on a bone to which tendons are attached.

tuberculous sclerosis
An inherited disorder that affects the skin and nervous system. Symptoms may include a condition of the face that is similar to acne, epilepsy, and learning difficulties. In addition, noncancerous tumours of the brain, kidney, retina, and heart may also develop. There is no cure for tuberous sclerosis, and treatment aims only to relieve symptoms. In serious cases, death occurs before the age of 30. \textit{Genetic counselling} is recommended for affected families.

tuboplasty
Surgery in which a damaged fallopian tube is repaired to treat infertility. It may be performed by microsurgery.

tularaemia
A bacterial infection that affects wild animals that is sometimes transmitted to humans. Tularaemia does not occur in the UK but is seen in North America. It may result from contact with an infected animal or carcass, or a tick, flea, fly, or louse bite. Diagnosis is by blood tests. Treatment of the infection is with \textit{antibiotic} drugs.

tumbu fly
A tropical fly found in Africa whose larvae infest the skin and cause myiasis.

tumour
A term that describes any swelling but which is generally used to refer to an abnormal mass of tissue that forms when cells in a specific area reproduce at an increased rate. Tumours can be \textit{cancerous} or \textit{noncancerous}.

Cancerous tumours invade surrounding tissues and may spread through the bloodstream or lymphatic system to form a secondary growth (a metastasis) elsewhere in the body. A cancerous tumour that arises from epithelial tissues (such as the skin) is known as a carcinoma; one that arises from connective tissue (such as muscle, bone, or fibrous tissue) is called a sarcoma.

Noncancerous tumours usually grow slowly and do not metastasize. Such tumours tend to stay confined within a fibrous capsule, making surgical removal relatively straightforward. Noncancerous tumours sometimes grow large enough to press on nearby structures, which can be dangerous in confined spaces such as the skull.

tumour marker
A substance produced by a tumour that can be detected in the bloodstream. Tests for the presence of markers can assist in the diagnosis and treatment of tumours. Markers are often substances that occur normally in the body, but are produced in larger amounts when a particular kind of tumour is present. For example, \textit{alpha-fetoprotein}, which is produced in normal pregnancy, is present at elevated levels in a certain type of primary liver cancer.

tuning fork tests
Hearing tests that are carried out in order to differentiate between conductive deafness and sensorineural deafness. In the Weber test, a vibrating tuning fork is held against the forehead. If there is conductive hearing loss, the sound seems louder in the affected ear. In the Rinne test, a vibrating tuning fork is held first near the ear, then against the bone behind it. If it sounds louder when against the bone, there is conductive hearing loss.
**Monozygotic, or identical, twins** develop when a single fertilized egg divides at an early stage of development. Incomplete division of the egg results in conjoined twins (see twins, conjoined). Monozygotic twins share the same placenta. Although one is often much bigger than the other at birth, they are always of the same sex and look remarkably alike.

**Dizygotic, or fraternal, twins** develop when two eggs are fertilized at the same time. The ova they develop from may be released by the same or different ovaries; fertilization occurs simultaneously. They each have a placenta and may be of different sexes and look quite different.

Twins occur in about one in 80 pregnancies. (See also pregnancy, multiple.)

**twins, conjoined**

Identical twins physically joined due to a failure to separate during development from a single fertilized egg. Conjoined twins are also called Siamese twins.

**twitch**

See fasciculation; tic.

### Tunnel Vision

**TUNNEL VISION**

Loss of the peripheral visual field to the extent that only objects straight ahead can be seen clearly. Tunnel vision is most often caused by chronic glaucoma (raised pressure within the eyeball). Retinitis pigmentosa (degeneration of the retina) is another possible cause.

**turbinate**

One of the three shell-shaped bony projections in the side of the nasal cavity.

**Turner’s syndrome**

A disorder caused by a chromosomal abnormality that only affects females.

**CAUSES**

The abnormality may arise in one of three ways: affected females may possess only one X chromosome instead of the normal two; they may possess one normal and one defective X chromosome; or they may possess a mixture of cells (see mosaicism), in which some of the cells are missing an X chromosome, some have extra chromosomes, and others have the normal complement of chromosomes.

**SYMPTOMS**

The characteristics of Turner’s syndrome are: short stature; webbing of the skin of the neck; absence or retarded development of sexual characteristics; amenorrhea (failure to menstruate), coarctation of the aorta, and abnormalities of the eyes and bones.

**TREATMENT**

Treatment with growth hormone from infancy helps girls with Turner’s syndrome to achieve near normal height. Coarctation of the aorta is treated surgically. Treatment with oestrogen drugs induces menstruation, but it does not make affected girls fertile.

**TURP**

The abbreviation for transurethral resection of the prostate. TURP is a surgical procedure in which the central part of an enlarged prostate gland is removed (see prostate, enlarged). A viewing instrument called a resectoscope is passed along the urethra until it reaches the prostate. A heated wire loop, or sometimes a cutting edge, is inserted through the resectoscope and used to cut away excess prostate tissue.

**twins**

Two offspring resulting from one pregnancy. Twins may develop from a single ovum (egg) or from two ova.

**Identical twins**

Monozygotic, or identical, twins develop when a single fertilized egg divides at an early stage of development. Incomplete division of the egg results in conjoined twins (see twins, conjoined). Monozygotic twins share the same placenta. Although one is often much bigger than the other at birth, they are always of the same sex and look remarkably alike.

**Dizygotic, or fraternal, twins** develop when two eggs are fertilized at the same time. The ova they develop from may be released by the same or different ovaries; fertilization occurs simultaneously. They each have a placenta and may be of different sexes and look quite different.

Twins occur in about one in 80 pregnancies. (See also pregnancy, multiple.)

**twins, conjoined**

Identical twins physically joined due to a failure to separate during development from a single fertilized egg. Conjoined twins are also called Siamese twins.

**twitch**

See fasciculation; tic.

### Two Types of Twins

<td>Nonidentical twins are the result of two separate ova that have been fertilized by two separate sperm.</td>
</tr>
</tbody>
</table>

**Identical twins in the uterus**

The result is a pair of genetically identical twins sharing the same placenta. They are also known as monozygotic, or monovular, twins.

**Nonidentical twins in the uterus**

The resulting individuals are genetically distinct and have separate placentas. They are also known as dizygotic, or binovular, twins.

**tunnel vision**

Loss of the peripheral visual field to the extent that only objects straight ahead can be seen clearly. Tunnel vision is most often caused by chronic glaucoma (raised pressure within the eyeball). Retinitis pigmentosa (degeneration of the retina) is another possible cause.

**turbin ate**

One of the three shell-shaped bony projections in the side of the nasal cavity.

**Turner’s syndrome**

A disorder caused by a chromosomal abnormality that only affects females.

**CAUSES**

The abnormality may arise in one of three ways: affected females may possess only one X chromosome instead of the normal two; they may possess one normal and one defective X chromosome; or they may possess a mixture of cells (see mosaicism), in which some of the cells are missing an X chromosome, some have extra chromosomes, and others have the normal complement of chromosomes.

**SYMPTOMS**

The characteristics of Turner’s syndrome are: short stature; webbing of the skin of the neck; absence or retarded development of sexual characteristics; amenorrhea (failure to menstruate), coarctation of the aorta, and abnormalities of the eyes and bones.

**TREATMENT**

Treatment with growth hormone from infancy helps girls with Turner’s syndrome to achieve near normal height. Coarctation of the aorta is treated surgically. Treatment with oestrogen drugs induces menstruation, but it does not make affected girls fertile.

**TURP**

The abbreviation for transurethral resection of the prostate. TURP is a surgical procedure in which the central part of an enlarged prostate gland is removed (see prostate, enlarged). A viewing instrument called a resectoscope is passed along the urethra until it reaches the prostate. A heated wire loop, or sometimes a cutting edge, is inserted through the resectoscope and used to cut away excess prostate tissue.

**twins**

Two offspring resulting from one pregnancy. Twins may develop from a single ovum (egg) or from two ova.
**tympanic cavity**
The medical term for the middle ear.

**tympanic membrane**
The medical term for the *eardrum*.

**tympanometry**
A type of *hearing test* that is used to establish the cause of conductive deafness. During the test, a probe that contains a tone generator, a microphone, and an air pump is introduced into the outer-ear canal. The air pressure in the ear is varied and tones are played into it. The tone pattern reflected from the *eardrum* and received by the microphone shows if the eardrum is moving normally.

Tympanometry is a particularly useful technique for use in children because it does not rely on a response from the person being tested.

**tympanoplasty**
An operation on the *ear* to treat conductive deafness (see *myringoplasty*) or by repositioning or reconstructing the diseased ossicles (tiny bones in the middle ear that conduct sound).

**tympanum**
A term referring either to the middle-ear cavity (tympanic cavity) or to the *eardrum* (tympanic membrane).

**type 1 diabetes**
See *diabetes mellitus*.

**type 2 diabetes**
See *diabetes mellitus*.

**typhoid fever**
An infectious disease, also known as enteric fever, contracted by eating food or drinking water contaminated with the bacterium *Salmonella typhi*. An almost identical disease, *paratyphoid fever*, is caused by related bacteria.

**CAUSES**
The infection is contracted from the faeces of a person who has the disease or who is a symptomless carrier of the bacteria. Typhoid fever is commonly spread by drinking water contaminated with sewage, by flies carrying the bacteria from faeces to food, or by infected people handling food.

The bacteria pass from the intestines into the blood, then to the spleen and liver, where they multiply. The organisms are excreted from the liver, accumulate in the gallbladder, and are released in large numbers into the intestine. Carriers, after recovering from the condition, may continue to harbour typhoid bacteria in the gallbladder and shed them in faeces for many years.

**SYMPTOMS**
Typhoid has an incubation period of 7 to 21 days. The first symptom is usually a severe headache followed by fever, loss of appetite, *malaise*, abdominal pain, constipation, and often delirium. Diarrhoea soon develops. In the second week of illness, small, raised pink spots develop on the chest and abdomen, and the liver and *spleen* enlarge.

The illness usually clears up within four weeks. However, potentially fatal complications may develop, including intestinal bleeding, perforation of the intestine leading to *peritonitis*, *osteomyelitis*, *pyelonephritis*, and *kidney failure*.

**DIAGNOSIS AND TREATMENT**
Diagnosis of typhoid is confirmed by a *blood test* or by obtaining a culture of typhoid bacteria from blood, faeces, or urine. Treatment with *antibiotic drugs* usually brings the disease under control within a few days.

**typhus**
Any of a group of infectious diseases with similar symptoms that are caused by *rickettsiae* (microorganisms similar to bacteria) and are spread by insects or similar animals.

**TYPES**
Of the various types, epidemic typhus, which is spread between humans by body lice, is historically the most important. This disease formerly killed hundreds of thousands of people in times of war, famine, or other natural disasters. Except in some highland areas of tropical Africa and South America, epidemic typhus is rare today.

Endemic typhus, also called murine typhus, is a disease of *rats* that is occasionally spread to humans by fleas; sporadic cases occur in North and Central America. Scrub typhus is spread by *mites* and occurs in India and Southeast Asia.

**SYMPTOMS**
The symptoms and complications of all types of typhus are similar. Symptoms include severe headache, back and limb pain, coughing, constipation, high fever, a measles-type rash that may develop into *purpura*, confusion, and exhaustion. If typhus is left untreated, the condition may be fatal, especially in elderly or debilitated people.

**DIAGNOSIS AND TREATMENT**
Diagnosis is made by *blood tests*, and the infection is treated with *antibiotic drugs* and supportive treatment.

**typing**
A general term for procedures by which blood or tissues are classified (see *blood groups*; *tissue-typing*).

**tyramine**
An *amino acid* present in various foods, including cheese, chocolate, red wine, and beer. Tyramine has a stimulating effect on the body. The substance interacts with certain drugs (*monoamine oxidase inhibitors*) used to treat depression; taking both together can cause adverse reactions such as headache and a rise in blood pressure.

**tyrosine**
A non-essential *amino acid* (a building-block of proteins). Tyrosine plays a role in the healthy functioning of the nervous and endocrine systems.
Ulcer

An open sore appearing on the skin or on a mucous membrane that results from the destruction of surface tissue. Ulcers may be shallow, or deep and crater-shaped, and they are usually inflamed and painful. An indolent ulcer is one that is slow to heal but is not painful.

Skin Ulcers

Skin ulcers most commonly occur on the leg (see leg ulcer), usually as the result of inadequate blood supply to, or drainage from, the limb. In some cases skin cancers, particularly basal cell carcinomas or squamous cell carcinomas, may be ulcerated. Rarely, a cancer may develop in the skin at the edge of a longstanding ulcer.

Digestive Tract Ulcers

Ulcers of the mucous membranes most commonly develop within the digestive tract (the collection of tubular structures that runs from the mouth to the anus). The ulcers include mouth ulcers (see also ulcer, aphthous), peptic ulcers (affecting the stomach or duodenum), and the ulcers that occur in ulcerative colitis, an inflammatory disorder of the colon or rectum.

Genital Ulcers

Ulcers may also affect the skin or mucous membranes of the genitalia (see genital ulcer). Most genital ulcers are caused by sexually transmitted infections. Examples of this type of ulcer are hard chancres (see chancre, hard), which develop during the first stage of syphilis, and soft chancres (see chancre).

Eyes Ulcers

Ulcers may also develop on the cornea, the transparent covering at the front of the eyeball (see corneal ulcers).

Solitary Rectal Ulcer

A break in the lining of the lower part of the large intestine that fails to heal. Symptoms may include bleeding or mucus discharge from the anus, tenesmus (a feeling that the rectum has not been completely emptied), and pain. There may also be diarrhoea or constipation; and rectal prolapse (in which part of the rectum protrudes outside the anus) is often present.

Diagnosis may be made by endoscopy (use of a viewing instrument) of the rectum and biopsy (taking a tissue sample). Treatment may include laxatives and a high-fibre diet. Surgery may be recommended to excise the ulcer.

Ulcer, Aphthous

A small, painful ulcer that occurs, alone or in a group, on the inside of the cheek or lip or underneath the tongue. Aphthous ulcers are most common in people between the ages of 10 and 40 and affect more women than men. The most severely affected people have continually recurring ulcers; others have just one or two ulcers each year.

Causes

The ulcer, which usually lasts for one to two weeks, may be a hypersensitive reaction to haemolytic streptococcus bacteria. Other factors that are commonly associated with the occurrence of these ulcers are minor injuries (such as at an injection site or from a toothbrush), acute stress, or allergies. In women, aphthous ulcers are most common during the premenstrual period. They may also be more likely to occur if other family members suffer from recurrent ulcerative conditions such as Crohn’s disease.

Symptoms

Each ulcer is usually small and oval, with a grey centre and a surrounding red, inflamed halo. The ulcers usually last for one to two weeks.

Treatment

Analgesic mouth gels or mouthwashes may ease the pain of an aphthous ulcer. Some ointments form a waterproof covering that protects the ulcer while it is healing. Ulcers heal by themselves, but a doctor may prescribe a paste containing a corticosteroid drug or a mouthwash containing an antibiotic drug to speed up the healing process.

Ulceration

The formation or presence of one or more ulcers.

Ulcerative Colitis

Chronic inflammation and ulceration of the lining of the colon and rectum, or, especially at the start of the condition, of the rectum alone. The cause of ulcerative colitis is unknown, but the condition is most common in young and middle-aged adults.

Symptoms

The main symptom of ulcerative colitis is bloody diarrhoea; the faeces may also contain mucus. In severe cases, the diarrhoea and bleeding are extensive, and there may be abdominal pain, fever, weight loss, and general malaise. The incidence of attacks varies considerably from person to person. Most commonly, the attacks occur at intervals of a few months. However, in some cases, there may be only a single episode.

Complications

Ulcerative colitis may lead to anaemia, due to blood loss. Other complications include a toxic form of megacolon (an abnormally enlarged colon), which may become life-threatening; rashes; mouth ulcers; arthritis; conjunctivitis (inflammation of the membrane covering the eyeball); and uveitis (inflammation of the iris or choroid of the eye). In addition, people whose entire colon has been affected for more than 10 years are at increased risk of developing cancer of the colon (see colon, cancer of).

Diagnosis

Diagnosis is based on examination of the rectum and the lower colon (see sigmoidoscopy) or of the entire colon (see colonoscopy), or is made by a barium enema (see barium X-ray examination). During sigmoidoscopy or colonoscopy, a biopsy (removal of a tissue sample) may be performed. Samples of faeces may be taken for analysis in a laboratory to exclude the possibility of infection by bacteria or parasites. Blood tests may also be necessary.

People who have suffered from ulcerative colitis for a number of years need periodic colonoscopy and biopsy to check for the development of cancer.

Treatment

In most cases, medical treatment effectively controls the disease by relieving
symptoms and preventing complications from occurring. For ulcerative colitis occurring in the last part of the colon or the rectum, the drugs may be administered as suppositories. If the condition occurs higher up in the intestine, the drugs are taken orally.

Aminosalicylate drugs, such as sulfasalazine (or the newer drugs mesalazine and olsalazine, which have fewer side effects), are used to treat acute attacks and maintain long-term freedom from symptoms. Corticosteroid drugs are given to reduce inflammation during sudden flare-ups. Once the disease is under control, immunosuppressant drugs may be used to prevent relapses.

Colectomy (surgical removal of the colon) may be required for a severe attack that fails to respond to other treatments, for those with complications such as toxic megacolon, or to avoid colonic cancer in those people who are at high risk. This operation usually produces a dramatic improvement in health, although the person is usually left with an ileostomy (an opening in the surface of the abdomen through which faeces are passed).

**Ulcer-healing drugs**

**COMMON DRUGS**

- **H₂-Receptor Antagonists**: Cimetidine
- **Famotidine**
- **Nizatidine**
- **Ranitidine**
- **Proton Pump Inhibitors**: Lansoprazole
- **Omeprazole**
- **Pantoprazole**
- **Rabeprazole**
- **Other Drugs**: Antacids, Antibiotics
- **Bismuth**
- **Carbonoxolone**
- **Misoprostol**
- **Ranitidine bismuth citrate**
- **Sucralfate**

A group of drugs used to treat or to prevent ulcers of the stomach or duodenum (see peptic ulcers). The ulcers occur when some of the mucus covering these areas is eroded and irritants attack the tissues, causing a sore to develop. Causes of peptic ulcers include infection with the bacterium Helicobacter pylori; external irritants, such as tobacco smoke, alcohol, or nonsteroidal anti-inflammatory drugs (NSAIDs); or excessive production of stomach acid.

**HOW THEY WORK**

Ulcer-healing drugs work in several ways. They may either reduce or neutralize stomach acid or protect the ulcerated area, thus allowing the damaged tissue to heal.

Taking antacid drugs regularly may be effective in healing duodenal ulcers because the drugs neutralize excess acid; however, the rate of healing may be slow. H₂-receptor antagonists function by blocking the effects of histamine, a chemical that normally stimulates the release of acid into the stomach. Drugs such as omeprazole are called proton pump inhibitors. They work by blocking an enzyme system called the proton pump, which stimulates the secretion of acid; as a result, they stop acid production until the body can make new supplies of the enzymes. Other drugs, such as misoprostol, also work by reducing acid secretion.

Other ulcer-healing drugs, such as sucralfate, are believed to work by forming a protective barrier over the ulcer, allowing healing of the underlying tissues to take place.

**Choice of Drug**

The eradication of Helicobacter pylori infection by treatment with antibiotic drugs, together with the use of a drug to reduce acid secretion, is the preferred treatment for most cases of peptic ulceration. The choice of ulcer-healing drugs may depend on the length of time for which symptoms have been present and the appearance of the ulcer when viewed by gastroscopy. If the ulcer has developed only recently, a course of acid-blocking drugs or antacids often gives rapid relief. Recurrent ulcers usually need antibiotic treatment.

**Possible adverse effects**

Ulcer-healing drugs do not usually have side effects. Those that do occur may include diarrhoea, constipation, skin rashes, or dizziness. H₂-receptor antagonists may cause confusion in elderly people. Misoprostol can induce miscarriage or may cause fetal abnormalities, so it should not be taken by any woman who is (or may be) pregnant.

**Ulcer, trophic**

See trophic ulcer.

**Ulna**

The longer of the two bones of the forearm; the other is the radius. The ulna is the bone running down the forearm on the side of the little finger.

The upper end of the ulna articulates with the radius and extends into a rounded projection (which is known as the olecranon process) that fits around the lower end of the humerus to form part of the elbow joint. The lower end of the ulna articulates with the carpals (wrist bones) and the lower part of the radius.

**Ulna, fracture of**

A fracture of the ulna, one of the two bones of the forearm. Ulnar fractures typically occur across the shaft or at the olecranon process (the rounded projection at the tip of the elbow).

A fracture to the shaft usually results from a blow to the forearm or a fall on to the hand. Sometimes the radius (the other bone in the forearm) is fractured at the same time (see radius, fracture of). Surgery is usually needed to reposition the broken bone ends and fix them together using either a plate and screws or a long nail down the centre of the bone. The arm is immobilized in a cast, with the elbow at a right-angle, until the fracture heals.

A fracture of the olecranon process is usually the result of a fall on to the elbow. If the bone ends have not been displaced, the arm is immobilized in a cast that holds the elbow at a right-angle. If the bone ends are displaced, however, they are fitted together and fixed with a metal screw.

**Ulnar nerve**

One of the principal nerves of the arm. The ulnar nerve, which is a branch of the brachial plexus, runs down the full length of the arm and into the hand. The ulnar nerve controls muscles that move the thumb and fingers. It also conveys sensation from the fifth finger, part of the fourth finger, and the area of the palm that is closest to these fingers.
DISORDERS
A blow to the olecranon process (the rounded projection at the tip of the elbow), over which the ulnar nerve passes, causes a pins-and-needles sensation and pain in the forearm and fourth and fifth fingers. Repeated leaning on the elbow can have a similar effect.

Persistent numbness and weakness in areas controlled by the ulnar nerve may be caused by an abnormal bony outgrowth from the humerus (upper-arm bone), which may be due to osteoarthritis or to a fracture of the humerus. Surgery is needed to relieve the pressure on the nerve. If the condition is left untreated, it may cause permanent damage to the ulnar nerve, which can result in claw-hand.

ultrasonography, Doppler
See Doppler ultrasonography.

ultrasound
Sound with a frequency that is greater than the human ear’s upper limit of perception: that is, higher than 20,000 hertz (cycles per second). Ultrasound is used in medicine to produce images of body structures and thus aid diagnosis (see ultrasound scanning), or in treatment to aid healing or to destroy abnormalities such as kidney stones (see ultrasound treatment; lithotripsy). Ultrasound that is used for these purposes is typically in the range of 1–15 million hertz.

ultrasound scanning
A diagnostic technique in which very high frequency sound waves are passed into the body and the reflected echoes analysed to build a picture of the internal organs or of a fetus in the uterus. Unlike most other imaging techniques, ultrasound scanning can produce moving images. The procedure is painless and is considered safe.

WHY IT IS DONE
The ability of ultrasound scanning to show soft tissues makes the procedure useful for examining fluid-filled or soft structures within the body. Ultrasound waves cannot, however, pass through bone or gas; therefore, they are of limited use for viewing any areas that are surrounded by bone (such as the brain in adults) or those that are filled with gas (such as the lungs or the intestines).

Obstetric and neonatal uses
One of the most common uses of ultrasound is to view the uterus and fetus, at any time during pregnancy.

The age, size, and growth rate of the fetus can be determined by means of ultrasound. If the date of conception is known, the scan shows whether the fetus is of the expected size for its age; conversely, the size of the fetus can help to establish the accurate date of conception and therefore help doctors and midwives to predict the expected date of delivery.

Ultrasound scans will show if there is more than one fetus (see pregnancy, multiple). They also aid the detection of certain problems in the fetus, such as neural tube defects or congenital heart disease, so that an affected infant can receive treatment as soon as possible after birth. In addition, the scans show the position of the placenta (the organ through which the fetus receives oxy-
gen and nutrients). If the placenta is in a position that could obstruct normal delivery (see placenta praevia), delivery by caesarean section may be necessary.

Scans are often performed at 18–20 weeks. They may be taken early in pregnancy if problems such as an ectopic pregnancy (the presence of an embryo outside the uterus) or impending miscarriage are suspected. Scanning is also a vital part of procedures such as amniocentesis (removal of amniotic fluid for analysis) and chorionic villus sampling (removal of tissue from the placenta); it shows the position of the fetus and placenta, and helps in guiding the needle into the uterus. Scans may be performed later in pregnancy if the growth rate of the fetus seems slow, if fetal movements cease or become excessive, or if the mother has vaginal bleeding. For high-risk or overdue pregnancies, a scan may be carried out just before delivery to check on fetal size, development, and position in the uterus, and assess the amount of amniotic fluid, and to recheck the position of the placenta.

Ultrasound scanning can also be used in newborn babies to examine the brain through a gap in the skull, to investigate abnormalities such as hydrocephalus (an excessive amount of fluid within the skull).

**Non-obstetric uses** The liver can be clearly viewed by ultrasound; scans can be used to diagnose liver disorders such as cirrhosis, cysts, abscesses, or tumours. Ultrasound shows the presence of gallstones in the gallbladder or bile ducts. In a patient with jaundice, a scan can help to establish whether the jaundice is due to obstruction of the bile ducts or to liver disease. The pancreas can be scanned for cysts, tumours, or for pancreatitis, and the kidneys for congenital defects, cysts, tumours, and hydronephrosis (swelling due to obstruction preventing the outflow of urine). Other organs that may be scanned by ultrasound (primarily for the purpose of looking for cysts, solid tumours, or foreign bodies) include the thyroid gland, breasts, bladder, testes, uterus, fallopian tubes, ovaries, spleen, and eyes. Ultrasound can be used to assess the risk of fracture in suspected osteoporosis.

**Echocardiography** is an ultrasound technique that is used to look at the heart. This technique is particularly useful for investigating heart murmurs, congenital heart disease, heart failure, and disorders of the heart valves.

Ultrasound scanning is also used during needle biopsy (insertion of a very thin hollow needle into an organ to remove cells, tissue, or fluid for examination) to help guide the needle accurately to a specific spot.

**Doppler ultrasound scanning** This technique is a modified form of ultrasound scanning that uses the Doppler effect (the change in pitch that occurs when a sound source is moving relative to the detector) for the purposes of investigating moving objects. Doppler ultrasound scanning can be used to examine the fetal heartbeat and to obtain information about the rate of blood flow in blood vessels, for example through the fetus’s umbilical cord.

**HOW IT IS DONE**

The patient removes all clothing that is covering the area to be viewed. A gel is then smeared over the skin to ensure that there is good contact between the skin and the transducer (the device that emits and receives ultrasonic waves). Doppler scanning can be used to examine the pelvic bones and to obtain information about the rate of blood flow in blood vessels, for example through the fetus’s umbilical cord.

**ultrasound treatment**

The use of high-frequency sound waves in order to treat soft-tissue injuries (such as injuries to ligaments, muscles, and tendons). Ultrasound treatment reduces inflammation and speeds up the healing process. It is thought to work by improving blood flow in tissues under the skin.

**ultraviolet light**

Invisible light from the part of the electromagnetic spectrum immediately beyond the violet end of the visible light spectrum (see colour vision). Long-wavelength ultraviolet light is termed UVA, intermediate UVB, and short-wavelength UVC.

Ultraviolet light occurs in sunlight, but much of it is absorbed by the ozone layer of the atmosphere. The ultraviolet light (mainly UVA) that reaches the Earth’s surface causes the tanning effects of sunlight and the production of vitamin D in the skin. It can also have harmful effects, such as skin cancer (see sunlight, adverse effects of). This form of light is generated by tanning beds to produce a suntan. Tanning beds are designed to emit only UVA rays; in practice they also give off a small amount of UVB (which is more likely to cause burning than UVA). Tanning beds may also cause skin cancer. Ultraviolet light is also produced by certain other types of equipment, such as...
as welding torches, carbon arcs, and lasers. Special precautions, such as the use of goggles, should always be taken when using such equipment.

**MEDICAL USES**

Ultraviolet light is sometimes used in *phototherapy* to treat certain skin disorders, such as psoriasis and eczema, and jaundice in newborn babies. A mercury-vapour lamp (Wood’s light) can be used to produce ultraviolet light artificially. This device is used to diagnose skin conditions such as *tinea* because it causes the infected area to fluoresce.

**umbilical cord**

The ropelike structure connecting the *fetus* to the *placenta*. The umbilical cord supplies the fetus with oxygen and nutrients from the mother’s circulation. It is usually 40–60 cm long. It consists of a jellylike substance that contains two arteries and a vein.

After delivery, the umbilical cord is clamped and then cut about 2.5 cm from the baby’s abdomen. The stump falls off within a couple of weeks, leaving a scar called the umbilicus (navel).

**DISORDERS**

In rare cases, the umbilical cord protrudes down through the mother’s cervix during labour. This situation is dangerous, because the cord can be squeezed between the mother’s pelvis and the baby’s body, causing the baby’s oxygen supply to be cut off. Prompt delivery, by caesarean section or forceps, is necessary. Another problem that may occur during delivery is the cord wrapping around the baby’s neck, causing strangulation. This problem can usually be remedied by someone slipping the cord over the baby’s head.

Rarely, there is only one artery in the umbilical cord. This condition may be associated with birth defects.

**umbilical hernia**

A soft swelling at the *umbilicus* (navel) caused by the protrusion of the abdominal contents through a weak area of the abdominal wall. Umbilical hernias, which are common in newborn babies, occur twice as often in boys as in girls. The swelling increases in size when the baby cries, and may cause discomfort. Umbilical hernias usually disappear without treatment by the age of two. If a hernia is still present at the age of four, surgery may be needed.

Umbilical hernias sometimes develop in adults, especially in women after childbirth. Surgery may be needed for a large, persistent, or disfiguring hernia.

**umbilicus**

The scar on the abdomen that marks the site of attachment of the *umbilical cord* to the *fetus*. It is commonly called the navel or belly button.

**DISORDERS**

Various umbilical disorders may occur in newborns. Occasionally, problems may occur in adults.

**Problems in newborns**

The baby’s umbilical stump sometimes becomes infected and may ooze pus. Called omphalitis, this condition generally begins during the first week of life. Treatment involves gently wiping the umbilicus with sterile cotton wool and water. Treatment with *antibiotic* drugs may also be necessary. Another common problem is the development of an *umbilical hernia*.

Quite commonly, a fleshy protuberance called a granuloma grows on the umbilical stump, sometimes as a result of chronic infection. Umbilical granulomas may be destroyed by topical application of silver nitrate. Another form of growth is an umbilical polyp (also called umbilical adenoma): a shiny, bright red, raspberry-like growth. Such polyps may require surgical removal.

**Problems in adults**

Adults occasionally develop umbilical hernias. Other problems are rare.

One possible problem is a discharge from the umbilicus, which may be due either to an infection or to an abnormal connection between the umbilicus and the urinary, biliary, or intestinal tracts. Such structural abnormalities may result from a birth defect, cancer, or tuberculosis. It may be possible to correct them surgically. Occasionally, secondary cancerous tumours may develop in the umbilicus as a result of cancers in the breast, colon, ovary, or stomach. In rare cases, women develop *endometritis* in the umbilicus, which causes it to bleed during *menstruation*.

**unconscious**

A specific part of the mind in which ideas, memories, perceptions, or feelings that a person is not currently aware of are stored and processed. The contents of the unconscious mind are not easily retrieved, in contrast to those of the *subconscious*. (See also *Freudian theory*, *Jungian theory*.)

**unconsciousness**

An abnormal loss of awareness of self and one’s surroundings due to a reduced level of activity in the reticular formation of the *brainstem*. An unconscious person can be roused only with difficulty or not at all. Unconsciousness may be brief and light, as in *fainting* or *concussion*, or deep and prolonged (see *coma*).

**underbite**

See *prognathism*.

**undescended testis**

See *testis*, *undescended*.

**undulant fever**

Another name for *brucellosis*.

**unguent**

An alternative term for an *ointment*.

**unit of alcohol**

See *alcohol*, *unit of*.

**unsaturated fats**

See *fats and oils*.

**unstable angina**

A form of *angina pectoris* (chest pain due to impaired blood supply to the heart muscle) that develops during sleep or without provocation (the pain is usually provoked by exercise in angina). The term unstable may also refer to angina that is becoming more frequent or more severe. Unstable angina is a medical emergency because there is a high risk of *myocardial infarction* (heart attack). Drugs are given and *angioplasty* may be necessary.

**unstable bladder**

Another name for *irritable bladder*.

**uraemia**

The presence of excess *urea* and other chemical waste products in the blood, caused by *kidney failure*. 
uranium
A radioactive metallic element that does not occur naturally in its pure form but is widely found in ores such as pitchblende, carnottite, and uraninite. Radioactive decay of uranium causes radiation to be emitted and yields a series of radioactive products, including radium and radon, which may cause tissue damage or cancer (see radiation hazards; radiation sickness). Uranium is also chemically poisonous and can cause damage to the urinary system.

urea
A waste product from the breakdown of proteins. Proteins in food are digested to form amino acids. In the liver, excess amino acids are converted into urea, which is carried by the bloodstream to the kidneys and excreted in the urine. A high-protein diet increases the amount of urea produced.

The kidneys are usually highly efficient at eliminating urea from the body. Healthy kidneys can cope with increased urea production, but kidney failure lessens this ability and leads to uraemia (abnormally high blood levels of urea). For this reason, the measurement of urea levels in the blood may be one of the routine kidney-function tests.

Urea is also formed in the body from the breakdown of cell proteins. If there is a large increase in urea from this source (due, for example, to severe tissue damage resulting from injury or surgery), the kidneys are sometimes unable to cope and uraemia results.

Certain conditions (such as liver damage) may lead to a decrease in the blood level of urea. Blood levels of urea also fall during pregnancy, when the blood is more dilute than usual.

MEDICAL USES
Urea is used in various creams and ointments to moisturize and soften the skin in disorders such as psoriasis, atopic dermatitis, ichthyosis, and other conditions in which the skin is dry and scaly.

ureter
One of the two tubes that carry urine from the kidneys to the bladder. Urine flows down the ureters, partly by gravity, but mainly by peristalsis (rhythmic contractions of the muscular ureter walls).

Each ureter is 25–30 cm long. The walls of the ureters have three layers: a fibrous outer layer; a muscular middle layer; and an inner watertight layer. The ureters are supplied by blood vessels and nerves. They join the bladder via a tunnel in the bladder wall, which is angled to prevent reflux (backflow) of urine, into the ureters when the bladder muscle contracts.

DISORDERS
Some people are born with duplex (double) ureters, on one or both sides of the body, usually in association with partial duplex kidney on an affected side. Double ureters may be separate along their entire length, or they may join to form a Y shape. In many cases, the condition causes no problems, but if duplicated ureters enter the bladder separately there may be vesicoureteric reflux (backflow of urine into the ureter). There may also be problems, such as incontinence or infection, if a ureter enters the urethra or the vagina instead of the bladder. Corrective surgery can be performed if necessary.

Spasms of the ureter may occur if a stone (see calculus, urinary tract) passes down or becomes stuck in a ureter. This extremely painful condition is commonly known as renal colic.

Ureteritis is an inflammatory condition that may occur if the ureter is blocked by a stone, or be caused by the spread of infection from the bladder.

ureteric colic
See renal colic.

ureterolithotomy
The surgical removal of a stone (see calculus, urinary tract) from a ureter (tube that carries urine from a kidney to the bladder). Ureterolithotomy is not often used because lithotripsy and cystoscopy can deal with stones.

urethra
The tube through which urine is excreted from the bladder. In females, the urethra is short and opens to the outside of the body in front of the vagina. In males, the urethra is much longer; it is surrounded by the prostate gland at its upper end, and it forms a channel through the length of the penis, with its outlet in the glans. (see Location of the urethra box, overleaf).

DISORDERS
Urethral infections, scarring, and congenital abnormalities occur in both sexes, but these are much more common and serious in males than in females.

Inflammation of the urethra, called urethritis, may be due to an infection such as chlamydia or gonorrhoea, irritation, or minor surgery. It may lead to urethral stricture (narrowing of a section of the urethra) in men. In addition, the male urethra is easily damaged in accidents involving pelvic injury and may require surgical repair.

Male infants sometimes have a urethral valve, which is a flap that grows from the lining of the urethra. The valve impedes the flow of urine and causes back pressure on the kidneys as urine overfills the bladder, ureters, and collecting ducts of the kidneys. Permanent and severe damage to the kidneys can occur if the urethral valve is not removed surgically.

urethral dilatation
The procedure in which a urethral stricture (a narrowed section of the urethra) in a male is widened by the insertion of a slim, round-tipped instrument through the opening of the urethra at the tip of the penis.

urethral discharge
A fluid, distinct from urine, that flows from the urethra in some cases of urethritis (urethral inflammation) caused by infection. In most types of infection, the discharge is clear; in gonorrhoea, it is yellow and contains pus.
urethral stricture

A rare condition in which the male urethra becomes narrowed and sometimes shortened due to shrinkage of scar tissue in its walls. Scar tissue may form after injury to the urethra or persistent urethritis (inflammation of the urethra).

A stricture may make passing urine or ejaculation difficult or painful, and it may cause some deformation of the penis when erect. It may also encourage the development of urinary tract infection due to a build-up of stagnant urine. In some cases, trapped urine puts back-pressure on the kidneys and may result in kidney damage.

Treatment is usually by urethral dilatation (surgical widening of the urethra). If this operation fails, a surgeon may cut through the scar tissue or, in some cases, the stricture may be completely removed and the urethra is reconstructed by plastic surgery.

urethral syndrome, acute

A set of symptoms, usually affecting women, that are very similar to cystitis but which occur without the presence of any infection. The symptoms consist of pain and discomfort in the lower abdomen, a frequent urge to pass urine, and, in women, pain around the vulva. Middle-aged women are the most commonly affected by this syndrome.

In most cases, kidney function and urinary tract anatomy are normal. The symptoms often occur after sexual intercourse. In women who have gone through the menopause, the symptoms may be due to inflammation of the vulva associated with thinning of tissues (see vulvitis). Emotional and psychological factors may contribute.

Treatment may be difficult. Cases due to vulvitis may be relieved by creams containing oestrogen or corticosteroid drugs. Antiseptic creams and strong soaps should be avoided because they may worsen the symptoms. Good personal hygiene and a high fluid intake are usually recommended. Changing sex positions, for example, with the woman on top, may be helpful, as may passing urine before and after sex.

urethritis

Inflammation of the urethra. Urethritis may be caused by various infectious organisms, including chlamydia and the bacterium that causes gonorrhoea. Non-gonococcal urethritis may be caused by any of a large number of different types of microorganism. Urethritis may also be caused by damage from an accident or from a catheter or cystoscope. Other possible causes include irritant chemicals, such as some spermicides.

SYMPTOMS AND TREATMENT

Urethritis causes a burning sensation and intense pain when passing urine. The urine may be bloodstained and, particularly if gonorrhoea is the cause, may contain a pus-filled discharge.

The inflammation may lead to urethral stricture (narrowing), which can make it difficult for the person to pass urine.

The cause of urethritis is identified by analysis of a urine sample or swabs taken from the urethra. Infections are treated with antibiotic drugs.

urethrocele

An anatomical abnormality in females caused by a weakness in the tissues in the front wall of the vagina. The urethra bulges backwards and downwards into the vagina. A urethrocele may be congenital, but more commonly develops after childbirth. It is usually treated by surgery to tighten the vaginal tissues.

-uria

A suffix relating to urine. For example, haematuria means blood in the urine.

uric acid

A waste product of the breakdown of nucleic acids in body cells. A small amount is also produced by the digestion of foods rich in nucleic acids, such as liver, kidney, and other offal. Most uric acid produced in the body passes to the kidneys, which excrete it in the urine, but some goes into the intestine, where it is broken down into chemicals excreted in the faeces.

When uric acid excretion is disrupted, for example by kidney disease, it may result in hyperuricaemia (abnormally high levels of uric acid in the blood), which may in turn lead to gout or kidney stones (see calculi, urinary tract).

urinal

A container for urine, useful for bedridden men (women use a bedpan).

urinalysis

Tests that are carried out on urine, including measurements of its physical characteristics (such as colour, cloudiness, and concentration); microscopic examination to identify abnormalities such as blood or uric acid crystals; a urine culture to detect infectious organisms; and chemical testing such as dipstick urinalysis.

Dipstick urinalysis involves dipping a test stick into a urine sample; chem-
ically impregnated squares on the stick change colour in the presence of test substances. The intensity of the colour change shows the amount of the substance present in the urine.

Urinalysis can be used to check kidney function and to diagnose urinary tract infections and disorders such as diabetes mellitus. Urinalysis is also used in pregnancy tests.

**urinary diversion**

Any surgical procedure (temporary or permanent) that enables urine to flow when the outlet of the urinary tract, via the bladder and urethra, is obstructed or cannot be used, or the bladder has been surgically removed.

**URINARY DIVERSION USING ILEAL CONDUIT**

This is one of the standard operations that can be performed when the bladder has to be removed. A midline incision in the abdomen is used; before making the incision, the surgeon creates an opening through the abdominal wall in a good position for later attachment of the collecting bag.

1. A short length is cut out of the ileum (the lower part of the small intestine), retaining the mesentery (supporting folds of tissue) and the essential blood vessels that supply the freed section.

2. The cut ends of the intestine are rejoined. One end of the freed length of intestine is closed, and the other end is temporarily clamped. The bladder is removed.

3. The ureters are now implanted into the isolated length of ileum. The open end of this segment is brought through the abdominal wall and stitched in place.

4. A disposable collecting bag for receiving the patient’s urine is attached with adhesive around the new stoma (opening) in the wall of the abdomen.

**TEMPORARY DIVERSION**

Temporary urinary diversion may be necessary when the passage of urine is blocked by prostate gland enlargement or by urethral stricture (narrowing of the urethra). A tube is passed into the bladder through an opening in the abdomen (see catheterization, urinary). Temporary diversion is also required after some urinary tract operations; a tube is introduced into the kidney and brought to the abdominal surface.

**PERMANENT DIVERSION**

Permanent urinary diversion is needed when the bladder has been surgically removed; when neurological bladder control is severely disturbed, such as after severe spinal injury; or if there is an irreparable fistula (abnormal opening) between a woman’s bladder or urethra and her vagina.

A section of the ileum (the lower part of the small intestine) is removed to create a substitute bladder, into one end of which the surgeon implants the ureters. The other end of the substitute bladder is then brought out through an incision in the abdominal wall. The patient wears a bag attached to the skin to collect urine.

**urinary incontinence**

See incontinence, urinary.

**urinary retention**

Inability to empty the bladder or difficulty in doing so. Urinary retention may be complete (in which urine cannot be passed voluntarily at all) or incomplete (in which the bladder fails to empty completely).

**CAUSES**

In males, causes of urinary retention include phimosis (tight foreskin), urethral stricture (narrowing of the urethra), prostatitis (inflammation of the prostate gland), a stone in the bladder (see calculus, urinary tract), and enlargement or tumour of the prostate (see prostate, enlarged; prostate, cancer of). In females, causes include pressure on the urethra from uterine fibroids or from a growing fetus in the uterus. In either sex, the cause may be a bladder tumour.

Urinary retention may also be caused by a defective functioning of the nerve pathways that supply the bladder as a result of general or spinal anaesthesia, of drugs affecting the bladder, of surgery, of injury to the nerves, or of disease of the spinal cord.

**SYMPTOMS**

Complete urinary retention causes discomfort and lower abdominal pain (except when the nerve pathways are defective). The full bladder can be felt above the pubic bone. Chronic or partial urinary retention, however, may not cause problems, and the affected individual may be unaware of the condition. Urinary retention can lead to kidney damage and, often, a urinary tract infection.

**TREATMENT**

The condition is treated by catheterization (see catheterization, urinary). The cause is then investigated. Obstruction can usually be treated; if nerve damage is the cause, permanent or intermittent catheterization is sometimes necessary.
urinary system
See urinary tract.

urinary tract
The part of the body concerned with the formation and excretion of urine. The urinary tract consists of the kidneys (with their blood and nerve supplies), the renal pelvices (funnel-shaped ducts that channel urine from the kidneys), the ureters, the bladder, and the urethra.

The kidneys make urine by filtering blood. The urine collects in the renal pelvices and is then passed down the ureters into the bladder by the actions of gravity and peristalsis (wavelike contractions of the muscular ureter walls). Urine is stored in the bladder until there is a sufficient amount present to stimulate micturition (passage of urine). When the bladder contracts, the urine is expelled through the urethra. (See also urinary tract infection.)

urinary tract infection
An infection anywhere in the urinary tract. These often cause inflammation of the urethra (see urethritis), bladder (see cystitis), or kidneys (see pyelonephritis). The symptoms depend on the area affected.

CAUSES AND INCIDENCE
Urethritis is often due to a sexually transmitted infection, such as gonorrhoea, but may have other causes. Cystitis and pyelonephritis are almost always the result of a bacterial infection that has travelled up the urinary tract from the urethra; the causative organisms are often bacteria from the rectum that have entered the urethra. Backflow of urine into the ureters from the bladder (see vesicoureteric reflux) causes recurrent urinary infection in children that often results in acute pyelonephritis. Infectious organisms may also be carried to the urinary tract in the bloodstream.

Infections of the urethra are more common in men. Infections further up the urinary tract are more common in women, and are more likely to occur during pregnancy. However, an enlarged prostate gland (see prostate, enlarged) is often a predisposing factor to bladder or kidney infection in men.

In both sexes, causes of urinary tract infections include stones (see calculus, urinary tract), bladder tumours, congenital abnormalities of the urinary tract, or defective bladder emptying as a result of spina bifida or a spinal injury.

The risk of a urinary tract infection can be reduced by care over personal hygiene, regularly emptying the bladder, and drinking plenty of fluids.

TYPES AND SYMPTOMS
Urethritis causes a burning sensation when urine is passed. Cystitis causes a frequent urge to pass urine, lower abdominal pain, haematuria (blood in the urine), and, often, general malaise with a mild fever. Pyelonephritis causes fever, pain in the back under the ribs, and sometimes also violent shivering, nausea, and vomiting.

COMPLICATIONS
Urethritis can lead to the formation of a urethral stricture (narrowing of a section of the urethra). Cystitis does not usually cause complications unless the infection spreads to the kidneys. Pyelonephritis, if left untreated, can lead to permanent kidney damage, septicaemia (blood poisoning), and septic shock.

DIAGNOSIS AND TREATMENT
Urinary tract infection is diagnosed by examination of a urine culture. Further investigations using intravenous urography or ultrasound scanning may be necessary. Most urinary tract infections are treated with antibiotic drugs. Increasing fluid intake and taking preparations such as potassium citrate that make the urine less acidic can relieve the symptoms.

urination, excessive
The production by an individual of more urine than is usual for them. In an adult, an output of about 3 litres a day would be considered abnormal, a condition known medically as polyuria.

CAUSES
Various diseases may cause abnormal amounts of certain substances to be excreted in the urine; these substances draw water with them, thus increasing the urine volume. The most important disease in this group is diabetes mellitus, in which excess glucose passes from the blood into the urine. Certain kidney diseases, called salt-losing states, lead to excessive salt loss in the urine, with an accompanying increase in volume.

Excessive urination may also be due to diabetes insipidus. In central diabetes insipidus, the production of ADH (anti-diuretic hormone) by the pituitary gland is reduced. ADH normally acts on the kidneys to concentrate the urine, so low levels of this hormone cause a marked increase in urine volume. In nephrogenic diabetes insipidus, which may result from various kidney disorders, normal amounts of ADH are produced but the kidneys fail to respond to it.

Excessive urination is sometimes due to psychiatric problems, which may cause a person to drink compulsively. This leads inevitably to a high urine output.

Alcoholic drinks and drinks containing caffeine have a diuretic effect, which temporarily increases urine output.

DIAGNOSIS
Any person who starts to pass larger quantities of urine than is usual for them should consult a doctor.

One simple diagnostic test involves restricting the patient’s fluid intake. In a compulsive drinker, urine volume soon drops if water intake is restricted, but if a person has diabetes insipidus, urine production will remain excessive. If diabetes insipidus is suspected, synthetic ADH may be given to establish the type; central diabetes insipidus improves after administration of ADH, but the nephrogenic form does not.

Chemical tests on urine (see urinalysis) may also aid diagnosis. In patients with diabetes mellitus, the glucose level in the blood and urine is high; in salt-losing patients, an excessive amount of sodium is detectable in the urine.

TREATMENT
Treatment of excessive urination varies according to the underlying cause. (See also urination, frequent.)

urination, frequent
Also known as urinary “frequency”, passing of urine more often than the average of four to six times daily.

Causes of frequent urination include excessive production of urine (see urination, excessive), cystitis (inflammation of the bladder), anxiety, stones in the bladder (see calculus, urinary tract), enlargement of the prostate gland (see prostate, enlarged) in men, and, rarely, a bladder tumour. In addition, some people who are suffering from kidney failure pass urine more frequently, especially during the night. A temporary increase in frequency can result from consuming alcoholic or caffeinated drinks.

Treatment of frequent urination is always aimed at the underlying cause.

urination, painful
Pain or discomfort that occurs when urine is being passed. Painful urination is known medically as dysuria. The pain is often described as burning; sometimes it is preceded by difficulty in starting urine flow. Pain after the flow has ceased, with a strong desire to continue, is called strangury.
The urinary tract

Also known as the urinary system, the urinary tract consists of the kidneys, in which urine is formed to carry away waste materials from the blood; the ureters, which transport the urine from the kidneys; the bladder, where the urine is stored until it can be conveniently disposed of; and the urethra, through which the bladder is emptied to the outside. The kidneys require a large blood supply and are connected close to the body’s main artery, the aorta. More than a litre of blood passes through the kidneys every minute.

COMPOSITION OF URINE

Urine consists almost entirely of water, with only small amounts of urea (the main waste product), other waste products (e.g., creatinine and uric acid), and sodium chloride (salt).

Interior of bladder

The two ureteral openings, shown on the right, and the urethral orifice form a triangle at the base of the bladder. In males, the urethra runs through the body of the prostate gland situated below the bladder.
The most common cause of strangury, especially in women, is cystitis (inflammation of the bladder). Other causes include a bladder tumour, bladder stone (see calculus, urinary tract), and urethritis (inflammation of the urethra). In men, possible causes include balanitis (inflammation of the head of the penis) and prostatitis (inflammation of the prostate gland). Vaginal candidiasis (thrush) may be a cause in women.

Strangury is usually caused by spasms of an inflamed bladder wall, but it may be due to bladder stones. Mild discomfort when passing urine may be caused by highly concentrated urine.

Dysuria may be investigated by means of a physical examination, urinalysis, intravenous urography, or cystoscopy. Treatment is of the cause. (See also urethral syndrome, acute.)

## Urine

The pale yellow fluid produced by the kidneys and excreted from the body via the ureters, bladder, and urethra. Urine is normally sterile when passed and has only a faint odour. Stale urine has an unpleasant smell, however, because of the action of bacteria, which causes the release of ammonia.

### Urine Production

Urine is produced when blood is filtered through the kidneys to remove waste products and excess water or chemical substances.

A healthy adult produces 0.5–2 litres of urine per day. The minimum volume needed to remove all waste products is about 0.5 litres. A high fluid intake increases the amount of urine produced. High fluid loss from sweating, vomiting, or diarrhoea leads to reduced production.

### Composition

After water, the main component of urine is urea. The other substances that are normally excreted in urine are shown in the diagram on p.775.

The volume, acidity, and salt concentration of urine are carefully regulated by hormones such as ADH (antidiuretic hormone), atrial natriuretic peptide, and aldosterone. These hormones act on the kidneys to ensure that the body’s levels of water and salt, and the acid-base balance (the acidity or alkalinity of the blood and tissue fluids), are kept within narrow limits.

Measurements of the composition of urine are useful in the diagnosis of numerous conditions, from kidney disease and diabetes mellitus to pregnancy.

### Urine, abnormal

Urine may be produced in abnormal amounts or have an abnormal appearance or composition.

#### Abnormal Volume

Certain conditions may cause excess urine to be passed (see urination, excessive): in adults, more than about 3 litres of urine per day. In contrast, abnormally low urine production (see oliguria), of less than about 0.4 litres per day, may occur in severe dehydration or acute kidney failure. If severely damaged, the kidneys may fail to produce any urine (see anuria). Obstruction of the urinary tract by a stone, for example, may also cause the cessation of urine flow.

#### Abnormal Appearance

Cloudy urine may be due to a urinary tract infection, a stone (see calculus, urinary tract), or the presence of salts. Haematuria (blood in the urine) may be due to bleeding in the urinary tract. Urine may become discoloured due to ingestion of certain foods or drugs. An excess of protein may cause urine to become frothy.

#### Abnormal Composition

Certain disorders cause abnormal substances to be excreted in the urine. In diabetes mellitus, glucose enters the urine. Glomerulonephritis (inflammation of the filtering units of the kidneys) or nephrotic syndrome cause protein to leak into the urine. Some disorders cause abnormal levels of normal waste products, or other chemical imbalances. Kidney failure reduces the total amounts of waste products such as urea. Other kidney disorders, such as Fanconi’s syndrome and renal tubular acidosis, may make the urine too acid or alkaline, or may cause it to contain excess amino acids, phosphates, salts, or water.

### Urine tests

See urinalysis.

### Urodynamics

A group of tests carried out to investigate problems with bladder control, such as incontinence. These studies involve the insertion of probes into the bladder and the rectum or vagina to monitor pressure changes while the bladder is filled and emptied. The patient may also wear an absorbent electronic pad to detect any leakage of urine.

#### How it is done

In X-ray monitoring, the patient stands against an upright table while his or her bladder is filled with a contrast medium through a catheter and is then emptied again. The shape of the bladder, and the functioning of the urethra, can then be viewed on an X-ray monitor. At the same time, the probes make a continuous recording of pressure changes within the bladder, which is transmitted to a computer and then printed out on a paper trace. As the bladder is being filled, the patient is asked to cough. This action increases the pressure in and around the bladder; if it causes leakage of urine on to the electronic pad, the patient has stress incontinence (see incontinence, urinary).

### Urography

See intravenous urography.

### Urology

A branch of medicine concerned with the structure, functioning, and disorders of the urinary tract in males and females, and of the reproductive system in males. Investigative techniques that are used in urology include intravenous urography, cystoscopy, ultrasound scanning, cystometry, and urinalysis.

### Ursodeoxycholic acid

A drug used to dissolve gallstones. Ursodeoxycholic acid is suitable only if the stones are made exclusively of cholesterol and only if the gallbladder is functioning normally. Side effects of the drug are rare but can include diarrhoea, indigestion, and a rash. Drug treatment is less commonly used since the introduction of minimally invasive surgery.

### Urticaria

A skin condition, also known as nettle rash or hives, characterized by the development of itchy weals, usually on the limbs and trunk. Large weals may merge to form irregular, raised patches.

#### Symptoms

Urticaria is generally harmless and lasts only a few hours, but sometimes a persistent or recurrent form develops. The condition is sometimes accompanied by angioedema (an allergic condition in which swelling occurs in various parts of the body). Dermographism is a less common form of urticaria in which weals form after the skin is stroked.

#### Causes

The cause is often unknown. The most common known cause is an allergic reaction (see allergy), often to a food or drug. Urticaria may also follow exposure to heat, cold, or sunlight. Less commonly, it may be associated with...
another disorder, such as vasculitis, systemic lupus erythematosus, or cancer.

TREATMENT
Itching can be relieved by the application of calamine lotion or by taking antihistamine drugs. Severe cases of urticaria may require corticosteroid drugs. Identifying and avoiding trigger factors can help prevent future reactions. A tendency to urticaria often disappears in time without treatment.

urticaria, neonatal
A very common, harmless skin condition, also called erythema neonatorum or toxic erythema, that affects newborn infants. The cause is unknown. Neonatal urticaria produces a blotchy rash, in which raised white or yellow lumps are surrounded by ill-defined red areas of inflammation. The rash mainly affects the face, chest, arms, and thighs. It usually clears up without treatment.

uterine muscle relaxants
Drugs that are used to delay premature delivery of a fetus. Beta-2-adrenoceptor stimulants, such as salbutamol, may be used in at-risk pregnancies of 24–33 weeks’ gestation; these drugs relax the muscles of the uterus and may postpone labour for days or weeks. Delaying of premature labour for up to 48 hours allows time for corticosteroid drugs to be given to the mother, to help the fetus’s lungs to mature.

uterovaginal prolapse
See uterus, prolapse of.

uterus
The hollow, muscular organ of the female reproductive system in which the fertilized ovum (egg) normally becomes embedded and in which the unborn baby (see embryo; fetus) develops. The uterus, which is commonly known as the womb, is situated within the pelvic cavity, behind the bladder and in front of the intestines.

STRUCTURE
In a nonpregnant woman, the uterus is 7.5–10 cm long and weighs 60–90 g. The lower part of the uterus opens into the vagina at the cervix; the upper part opens into the fallopian tubes.

The inside of the uterus is lined with endometrium. During the menstrual cycle, the endometrium thickens to prepare for the possible implantation of a fertilized egg. If conception and fertilization do not occur, hormone levels fall, causing the endometrium to be expelled from the uterus (see menstruation). After the menopause (when egg production and menstruation cease), the endometrium atrophies (becomes thinner) and muscle and connective tissue are reduced.

The uterus expands in size during pregnancy to accommodate the growing baby. At full term, the powerful uterine muscles expel the baby via the birth canal (see childbirth).

DISORDERS
Conditions that affect the uterus include congenital disorders such as malformation or absence of the uterus, duplex uterus, or septate uterus; tumours, including polyps, fibroids, and cancer of the endometrium (see uterus, cancer of); infections, causing inflammation of the uterus.

ANATOMY OF THE UTERUS
The nonpregnant uterus lies deep in the pelvis immediately behind and above the urinary bladder and in front of the rectum. It is usually tilted forwards at an angle to the vagina, and is curved downwards slightly. When the bladder is full, the uterus is pushed up and back.

The uterus
This thick-walled organ consists mainly of muscle. The fallopian tubes enter on both sides of the uterus just below its uppermost point. The small uterine cavity is lined with a mucous membrane called the endometrium, which undergoes changes during the different phases of the menstrual cycle. The vaginal surface of the cervix is lined with a flatter mucous membrane, which is identical to that of the vagina.
lining of the uterus (see endometritis); and hormonal disorders. (See also uterus, prolapse of; uterus, retroverted.)

uterus, cancer of

A malignant growth in the tissues of the uterus. Cancer of the uterus mainly affects the cervix (see cervix, cancer of) and endometrium (lining of the uterus). Rarely, the uterine muscle is affected by a type of cancer called a leiomyosarcoma. The term “uterine cancer” usually refers to cancer of the endometrium.

CAUSES
Risk factors for endometrial cancer include anything that may raise levels of the female sex hormone oestrogen in the body, such as obesity, a history of failure to ovulate, or taking oestrogen hormones long term if these are not balanced with progestagen drugs. The drug tamoxifen, used to treat breast cancer, increases the risk of uterine cancer. The cancer is more common in women who have had few or no children.

SYMPTOMS
Before the menopause, the first symptom of cancer of the uterus may be menorrhagia (heavy periods), or bleeding between periods or after sexual intercourse. After the menopause, the first symptom is usually a bloodstained vaginal discharge.

DIAGNOSIS AND TREATMENT
Diagnosis is made by hysteroscopy (examination of the inside of the uterus using a viewing instrument), with a biopsy (tissue sampling for microscopic analysis). Very early endometrial cancer is usually treated by hysterectomy (surgical removal of the uterus) and removal of the fallopian tubes and ovaries. If the cancer has spread beyond the uterus, radiotherapy and anticancer drugs may also be used.

uterus, prolapse of

A condition in which the uterus descends from its normal position into the vagina. The degree of prolapse varies from first-degree prolapse, in which there is only slight displacement of the uterus, to third-degree prolapse (procidentia), in which the uterus can be seen outside the vulva.

The condition may sometimes be associated with defects of the vagina that include cystocele, in which the bladder bulges into the front wall of the vagina; urethrocele, in which the urethra bulges into the front wall of the vagina; and rectocele, in which the rectal wall bulges into the back wall of the vagina.

CAUSES
Stretching of the ligaments that support the uterus is the most common cause of prolapse. Prolapse of the uterus is also aggravated by obesity.

SYMPTOMS AND DIAGNOSIS
There are often no symptoms, but there is sometimes a dragging feeling in the pelvis. In severe cases, part or all of the uterus may be visible. An accompanying cystocele, urethrocele, or rectocele may cause leakage of urine or difficulty in passing urine or faeces. Diagnosis is made by examination.

PREVENTION AND TREATMENT
Pelvic floor exercises strengthen the muscles of the vagina and can therefore reduce the risk of a prolapse, especially following childbirth. Often, surgery is necessary to repair structures that support the uterus.

For a severe prolapse, treatment usually involves hysterectomy (removal of the uterus) and tightening of the ligaments. Rarely, if surgery is not advised, a plastic, ring-shaped pessary may be inserted into the vagina to hold the uterus in position. (See also cystocele; rectocele; urethrocele.)

uterus, retroverted

A harmless variation in the position of the uterus, which is normally retroverted in infancy, tilting forwards at puberty; a
retroverted uterus inclines backwards. About 1 in 5 females has a retroverted uterus. In some cases, the uterus has failed to incline forwards during the normal process of maturation. Other cases are due to changes in position after childbirth. Less commonly, retroversion is caused by a disease, such as a tumour; scarring caused by endometriosis; or pelvic inflammatory disease.

A retroverted uterus rarely causes problems. If it is associated with underlying disease, however, it may cause symptoms such as dysmenorrhoea (painful periods), pain during intercourse (see intercourse, painful), and infertility. Rarely, a retroverted uterus may fail to lift out of the pelvis after about 12 weeks of pregnancy, as is usual, which may lead to urinary retention needing catheterization.

Diagnosis of a retroverted uterus is by means of physical examination (see pelvic examination). Laparoscopy (examination of the abdominal cavity with a viewing instrument) may be performed if an underlying disease is suspected. Treatment of the condition is not necessary unless the retroversion is causing symptoms, in which case the underlying cause is treated or the uterus may be manipulated back into position or surgically repositioned.

**uvea**
Part of the eye, comprising the iris (the pigmented area around the pupil), the ciliary body and its muscle, which focuses the lens, and the choroid (the blood-rich layer just under the retina).

The uvea is well supplied with blood vessels. Those in the iris supply the muscles that control dilation (widening) and constriction (narrowing) of the pupil. The vessels in the choroid supply oxygen and nutrients to the retina.

Pigment cells, which are concentrated in the back of the iris and scattered throughout the choroid, give the eye its colour and improve optical efficiency.

**uveitis**
Inflammation of the uvea. Uveitis may affect any part of the uvea, including the iris (when it is called iritis), the ciliary body (when it is known as cyclitis), or the choroid (when it is called choroiditis). It may seriously affect vision.

The most common cause is an autoimmune disorder, and it is associated with joint problems. Other causes include infections such as tuberculosis and syphilis.
vaccination
A form of immunization in which a vaccine, in the form of weakened or killed microorganisms or inactivated bacterial toxins, is introduced into the body. A vaccine is given, usually in the form of an injection, in order to sensitize the immune system. If disease-causing organisms or toxins of the same type enter the body in the future, the sensitized immune system rapidly produces antibodies that destroy them.

vaccine
A preparation that is given to induce immunity against an infectious disease. Most vaccines contain the organisms (or parts of the organisms) against which protection is sought.

Vaccines are usually given by injection into the upper arm, but some (such as the poliomyelitis vaccine) may be given orally. Some vaccines require several doses that are spaced some weeks apart; others require only one dose. (See also immunization.)

vacuum extraction
An obstetric procedure to facilitate the delivery of a baby. Vacuum extraction may be used if the second stage of labour (see childbirth) is prolonged, if the mother becomes exhausted, or if the baby shows signs of fetal distress.

The vacuum extraction instrument consists of a suction cup connected to a vacuum bottle. The suction cup is placed on the baby’s head in the birth canal, and the vacuum machine sucks the baby’s scalp into the cup. The obstetrician draws the baby out of the mother’s vagina by gently pulling on the cup with each uterine contraction.

The baby is born with a swelling on the scalp, but this disappears after a few days, usually without treatment. Vacuum suction techniques are also used to perform early abortions.

vagina
The muscular passage, forming part of the female reproductive system, occurring between the cervix (the neck of the uterus) and the external genitalia. The vagina has highly elastic muscular walls to enable sexual intercourse and childbirth to take place and are richly supplied with blood vessels.

vaginal bleeding
Bleeding, via the vagina, that may originate in the uterus, the cervix (neck of the uterus), or in the vagina itself.

BLEEDING FROM THE UTERUS
The uterus is the most common source of vaginal bleeding and the most likely cause is menstruation. From puberty to the menopause, menstrual bleeding usually occurs at regular intervals. However, problems may occur with either the character or the timing of the bleeding (see menstruation, disorders of).

Nonmenstrual bleeding from the uterus may have a variety of causes. Hormonal drugs, such as oral contraceptives, can cause spotting. Endometritis (infection of the uterine lining) and endometrial cancer (see uterus, cancer of) are other possible causes. Bleeding in early pregnancy may be a sign of threatened miscarriage. Later in pregnancy, it may indicate placenta praevia (implantation of the placenta in the lower part of the uterus) or placental abruption (separation of all or part of the placenta from the uterus wall).

BLEEDING FROM THE CERVIX
Bleeding from the cervix may be due to cervical erosion, in which case it may occur after intercourse. Cervicitis (infection of the cervix) and cervical polyps may also cause bleeding. More seriously, bleeding may be a sign of cervical cancer (see cervix, cancer of).

BLEEDING FROM THE VAGINA
A possible cause of bleeding from the vagina is injury during intercourse, especially following the menopause, when the walls of the vagina become thinner and more fragile. Occasionally, severe vaginitis (inflammation of the vagina)
leads to bleeding. Rarely, vaginal bleeding is caused by cancer of the vagina.

vaginal discharge
The emission of secretions from the **vagina**. Some mucous secretion from the vaginal walls and the cervix is normal in the reproductive years; its amount and nature vary from woman to woman and at different times in the menstrual cycle (see menstruation). Oral contraceptives can increase or decrease this discharge. Secretions tend to be greater during pregnancy. Sexual stimulation also produces increased vaginal discharge.

**ABNORMAL DISCHARGE**
Discharge may be abnormal if it is excessive, offensive-smelling, yellow or green, or if it causes itching. Abnormal discharge may accompany **vaginitis** (inflammation of the vagina), which may be the result of infection, such as **candidiasis** (thrush) or **trichomoniasis**, or may be due to a foreign body, such as a forgotten tampon, in the vagina.

vaginal itching
Irritation in the **vagina**, often associated with **vulval itching**. Itching is, in many cases, a symptom of **vaginitis** (inflammation of the vagina), which may be due to infection or by an allergic reaction to chemicals in hygiene or spermicidal products. Vaginal itching is common after the **menopause**, when it may be caused by low oestrogen levels. Treatment depends on the cause; it may involve **antibiotic drugs** or hormones.

vaginal repair
An operation to correct prolapse (displacement) of the vaginal wall. This may be accompanied by a vaginal **hysterectomy** (surgical removal of the uterus and vagina) if the uterus is also prolapsed (see uterus, prolapse of).

vaginismus
Painful, involuntary spasm of the muscles surrounding the entrance to the **vagina**. Vaginismus interferes with sexual intercourse. It can sometimes also interfere with medical vaginal examinations. The cause of the condition is usually psychological. (See also intercourse, painful, psychosexual dysfunction.)

vaginitis
Inflammation of the **vagina** that may be caused by infection, commonly with the fungus **Candida albicans** (see candidiasis), the parasite **Trichomonas vaginalis** (see trichomoniasis), or bacteria.

After the **menopause** the vaginal lining becomes fragile and prone to inflammation. This is called **atrophic vaginitis** and is due to a reduction in the production of **oestrogen hormones**.

Infections are treated with **antibiotic drugs** or **antifungal drugs**. In cases of allergy, irritants should be avoided. Any foreign bodies, including tampons that may have been left in, are removed. Atrophic vaginitis is treated with **oestrogen drugs**. (See also vulvitis; vulvovaginitis.)

vagotomy
An operation in which the **vagus nerve**, which controls production of digestive acid by the stomach wall, is cut. Once widely used to treat some cases of **peptic ulcer**, it has now largely been replaced by drug treatment.

vagus nerve
The tenth **cranial nerve** and the principal component of the parasympathetic division of the **autonomic nervous system**. The vagus nerve passes from the medulla oblongata (in the **brainstem**) through the neck and chest to the abdomen and has branches to most of the major organs, including the larynx (voicebox), pharynx (throat), trachea (windpipe), lungs, heart, and digestive system.

valgus
The medical term for outward displacement of a part of the body.

Valium
A former brand name for diazepam, a **benzodiazepine** antianxiety drug, muscle relaxant, and **anticonvulsant drug**.

valproate
See sodium valproate.

Valsalva’s manoeuvre
A forcible attempt to breathe out when the airway is closed. The manoeuvre occurs naturally when an attempt is made to breathe out while holding the vocal cords tightly together. This happens, for example, at the beginning of a sneeze. When performed deliberately by pinching the nose and holding the mouth closed, the manoeuvre can prevent pressure damage to the eardrums (see barotrauma).

valve
A structure that allows fluid or semi-fluid material to flow through a tube or passageway in one direction but which closes to prevent reflux (backflow) in the opposite direction. The valves at the exits from the **heart** chambers and in the **veins** are essential components of the **circulatory system**. There are also small valves in the vessels that make up the **lymphatic system**.
valve replacement
A surgical operation to replace a defective or diseased heart valve. (See also heart-valve surgery.)

valvotomy
An operation that is performed to correct a narrowed heart valve. Cuts are made, or pressure is applied, to separate the flaps of the valve where they have joined, reducing the degree of narrowing. Valvotomy is performed either by opening the heart up (see heart-valve surgery) or by balloon valvuloplasty.

valvular heart disease
A defect that occurs in one or more of the heart valves.

valvuloplasty
Reconstructive or repair surgery on a defective heart valve (see heart-valve surgery). Valvuloplasty may be performed as open heart surgery. However, the technique of balloon valvuloplasty makes it possible to treat a narrowed valve without opening the chest. A balloon catheter is passed through the skin into a blood vessel and from there to the heart. Inflation of the balloon via the catheter then separates the flaps of a narrowed valve.

vaporizer
A device for converting a drug or water into a fine spray so that medication can be taken by inhalation or so that inhaled air can be moistened.

variant angina
A form of angina pectoris (chest pain as a result of insufficient blood supply to the heart muscle), also known as Prinzmetal’s angina, in which chest pain occurs when at rest, often during sleep. The pain may be accompanied by breathlessness and palpitations. Variant angina is thought to be due to narrowing of the coronary arteries by muscular spasm in their walls. Treatment with calcium channel blockers or nitrate drugs is usually effective.

variant CJD
One form of Creutzfeldt–Jakob disease.

varicella
Another name for chickenpox.

varicella–zoster
The virus that is responsible for chickenpox and shingles.

varices
Enlarged, tortuous, or twisted sections of vessels, usually veins. Varices is the plural of varix. A vein affected by varices is called a varicose vein.

varicocele
Varicose veins surrounding a testis. Varicocele is a common condition. It almost exclusively affects the left testis and is usually harmless, although there may be aching in the scrotum or an abnormally low sperm count (see infertility). Aching may be relieved by supportive underwear. Surgery to divide and tie off the swollen veins may be performed if the sperm count is low.

varicose veins
Enlarged, tortuous veins just beneath the surface of the skin. Varicose veins most commonly occur in the legs but can also occur in the anus (see haemorrhoids), oesophagus (see oesophageal varices), and scrotum (see varicocele).

CAUSES
A defect of the valves in the leg’s perforating veins (which lie between the superficial veins (those near the skin’s surface) and the deep-lying veins) causes blood to pool in the superficial veins. The buildup of pressure in these veins causes them to become varicose. Factors that contribute to varicose veins include obesity, hormonal changes and pressure on the pelvic veins during pregnancy, hormonal changes occurring at the menopause, and standing for long periods of time. Varicose veins are common, tend to run in families, and affect more women than men.

SYMPTOMS
Varicose veins may not cause any problems, but they may ache severely and the feet and ankles may be swollen; persistent itching can also occur. These symptoms may worsen during the day and may be relieved by sitting with the legs raised. In women, symptoms are often worse just before menstruation. In severe cases, leg ulcers may develop. Thrombophlebitis (inflammation and clotting of blood in the veins) may be associated with varicose veins.

TREATMENT
Usually, support stockings, regular walking, and sitting with the feet up as much as possible are the only measures required. In more severe cases, sclerotherapy may be carried out. Varicose veins may require surgical removal (by an operation known as stripping) if they become painful or ulcerated, however, they may later develop elsewhere.

variola
Another name for smallpox.

varus
The medical term for an inward displacement of part of the body.

vascular
Relating to the blood vessels (see circulatory system).
vasculitis
Inflammation of blood vessels. Vasculitis usually leads to damage to the lining of vessels, with narrowing or blockage, that restricts or stops blood flow. As a result, the body tissues supplied by the affected vessels are damaged, or they are destroyed by ischaemia.
Vasculitis is thought to be caused in most cases by the presence of minute bodies, called immune complexes, in the circulating blood. Immune complexes (consisting of antigens bound to antibodies) are normally destroyed by white blood cells, but sometimes adhere to the walls of blood vessels, where they cause inflammation. In some cases, the antigens are viruses.
Vasculitis is the basic disease process that occurs in a number of disorders. These include polyarteritis nodosa, erythema nodosum, Henoch–Schönlein purpura, serum sickness, temporal arteritis, and Buerger’s disease.

vas deferens
Either of a pair of tubes that convey sperm from each testis to the urethra (the tube that carries sperm and urine through the penis to be expelled). The plural form is vasa deferentia.

vasectomy
The operation of male sterilization. Vasectomy is a minor surgical procedure, performed under a local anaesthetic (see anaesthesia, local), that consists of cutting out a short length of each vas deferens (a duct that carries sperm from a testis to the urethra). For more detail on how the procedure is performed, see How vasectomy is performed box, above. After vasectomy, the man continues to achieve orgasm and ejaculate as normal, but the semen no longer contains sperm, which are reabsorbed in the testes.

Male sterilization is a safe and effective method of contraception. Rarely, the severed ends of a vas deferens reunite, and sperm appear in the ejaculate. If this occurs, the man can safely undergo another vasectomy. Some operations to restore fertility after vasectomy are successful, but the process should be regarded as irreversible.

vasoconstriction
Narrowing of blood vessels, causing reduced blood flow to a part of the body. Vasoconstriction under the skin occurs in response to the cold and reduces heat loss from the body.

vasodilation
Widening of blood vessels that causes increased blood flow to a part of the body. Vasodilation under the skin occurs as a response to hot weather, resulting in increased heat loss from the body.

vasodilator drugs
A group of drugs that widen the blood vessels. Vasodilator drugs include ACE inhibitor drugs, alpha-blocker drugs, calcium channel blockers, and nitrate drugs. Some vasodilators are used to treat disorders in which abnormal narrowing of blood vessels reduces blood flow through the tissues, thereby impairing the supply of oxygen. Such disorders include angina pectoris and peripheral vascular disease. Vasodilators are also used to treat hypertension (high blood pressure) and heart failure (reduced pumping efficiency). Vasodilator drugs may cause flushing, headaches, dizziness, fainting, and swollen ankles.

vasopressin
Another name for ADH.

vasovagal attack
Temporary loss of consciousness as a result of sudden slowing of the heartbeat, usually brought on by severe
pain, stress, shock, or fear. A vasovagal attack, a common cause of fainting in healthy people, results from overstimulation of the vagus nerve.

**VD**

The abbreviation for venereal disease, an outdated term for sexually transmitted infections.

**VDRL test**

A blood test that is used to screen for syphilis. The initials “VDRL” stand for Venerable Disease Research Laboratory. Occasionally, the VDRL test may give a positive result in other conditions, such as glandular fever (see mononucleosis, infectious); the test is therefore often carried out alongside a test for specific antibodies to syphilis to enable doctors to confirm the diagnosis.

**vector**

An animal that transmits a particular infectious disease. A vector picks up disease-causing organisms from a source of infection (such as the blood or faeces of an infected person or animal), carries them in or on its body, and then deposits them, where they go on to infect a new host. Part of the disease-causing organism’s lifecycle usually take place in the body of a vector.

Mosquitoes, fleas, lice, ticks, and flies are the most important vectors of disease to humans. Many organisms have developed a close relationship with a specific vector, as Trypanosoma parasites have with tsetse flies.

**veganism**

The adoption of a diet that excludes all meat and fish and all animal products, including milk and eggs. A vegan diet is likely to result in the deficiency of vitamin $B_{12}$. Supplements of this vitamin are essential during pregnancy.

**vegetarianism**

Eating a diet that excludes meat and fish, and sometimes all other animal products. Humans do not need to eat meat or animal products to maintain health as long as the nutrients supplied by plant foods provide a balanced diet (see nutrition). However, those people who exclude all animal products (vegans) need to plan their diet carefully or take supplements to avoid being deficient in vitamin $B_{12}$ or calcium. Vegetarian diets are also relatively rich in fibre, which may help to protect against diverticular disease and cancer of the intestine (see colon, cancer of; rectum, cancer of). Vegetarian diets are also likely to contain much less sodium and more potassium, and vegetarians tend to have lower blood pressure than people who eat meat.

**vegetative state, persistent**

See persistent vegetative state.

**vein**

A blood vessel that returns blood towards the heart from the various organs and tissues of the body. The walls of veins, like those of arteries, consist of a smooth inner lining, a muscular middle layer, and a fibrous outer covering. However, blood pressure in the veins is lower than that in the arteries. In addition, the walls of veins are thinner, less elastic, less muscular, and weaker than those of arteries.

The linings of many veins contain folds, which act as valves, ensuring that the blood flows only towards the heart. Blood is helped on its way through the veins by pressure on the vessel walls from the contraction of surrounding muscles. (See also circulatory system.)

**LOCATION OF THE VENAE CAVAE**

All the circulating blood, after being pumped to the body, returns to the heart via the venae cavae. The superior vena cava collects blood from the whole of the upper trunk, head, neck, and arms. The inferior vena cava drains blood from all parts of the body below the chest.
veins, disorders of
Common disorders that affect the veins include varicose veins, in which the affected vein becomes enlarged, tortuous, or twisted; deep vein thrombosis (see thrombosis, deep vein), in which a blood clot forms in a deep-lying vein of the leg; and thrombophlebitis, which involves inflammation of and blood clotting in a vein.

vena cava
Either of two large veins into which all circulating deoxygenated blood drains. The venae cavae (superior and inferior) deliver blood to the right atrium (the upper chamber) of the heart for pumping to the lungs.

SUPERIOR VENA CAVA
The superior vena cava starts at the top of the chest, near the sternum (breastbone), and passes down through the pericardium (outer lining of the heart) before connecting to the right atrium. It collects blood from the upper trunk, head, neck, and arms.

INFERIOR VENA CAVA
The inferior vena cava starts in the lower abdomen and travels upwards in front of the spine, behind the liver, and through the diaphragm before joining the right atrium. It collects blood from the legs, pelvic organs, liver, and kidneys.

venepuncture
A common procedure in which a vein, usually in the forearm, is pierced with a needle to inject fluid or withdraw blood. A tourniquet is used to swell the veins, and a sterile needle is inserted. A syringe is attached to the needle if blood is to be taken or medication injected. For intravenous infusion, a cannula (tube) is inserted via the needle. After fluid has been injected or withdrawn, the needle or cannula is removed. The area is then covered and pressure applied to stop any bleeding. The procedure is not usually painful but may cause discomfort.

venereal diseases
See sexually transmitted infections.

venereology
The former name for the medical discipline concerned with the study and treatment of sexually transmitted infections. It is now called genito-urinary medicine.

venesection
The process of withdrawing blood from a vein for blood donation or therapeutic bloodletting. Regular bloodletting is performed in the treatment of polycythaemia (a disorder in which the blood is too thick) and haemochromatosis (a disorder of body iron chemistry).

venlafaxine
A serotonin and noradrenaline reuptake inhibitor (SNRI) drug that is used in the treatment of depression. Venlafaxine combines the effects of selective serotonin reuptake inhibitors and tricyclic antidepressants. The drug produces fewer side effects than other tricyclic antidepressants. Side effects may include nausea, dry mouth, and constipation.

venography
A diagnostic procedure that enables veins to be seen on an X-ray film after they have been injected with a substance opaque to X-rays. It is used to detect abnormalities or diseases of the veins, such as narrowing or blockage from thrombosis (formation of blood clots).

venomous bites and stings
The injection of venom by certain animals via their mouthparts (bites) or other injecting apparatus (stings). Venoms are often carried to discourage predators, and are sometimes used to kill or immobilize prey. It is rare for a venomous animal to attack a person unless it has been provoked or disturbed. Specific antivenoms are available to treat many, though not all, types of animal venom. (See also insect stings; jellyfish stings; scorpion stings; snake bites; spider bites.)

ventilation
The use of a machine called a ventilator to take over or assist breathing. Arrested or severely impaired breathing may be due to head injury, brain disease, an overdose of opioid drugs, chest injury, respiratory disease, a nerve or muscle disorder, or major chest or abdominal surgery.

Ventilation may be needed if a muscle relaxant has been given, as part of general anaesthesia, during an operation. Premature babies with respiratory distress syndrome may also need ventilation for a period until their lungs develop sufficiently. Positive pressure ventilation (continuous pumping of air under high pressure) may be used in the home in the treatment of sleep apnoea (temporary cessation of breathing during sleep).

ventilator
A device used for the artificial ventilation of a person who is unable to breathe naturally. A ventilator is an electrical pump connected to an air supply that works like bellows. Air is directed through a tube passed down the windpipe to inflate the lungs. The air is then expelled by the natural elasticity of the lungs and ribcage. A valve on the ventilator prevents the expelled air from re-entering the lungs.

Technique of artificial ventilation
Machine-assisted breathing may be needed when a person has lost the ability to breathe naturally (often following a severe head injury, narcotic drug overdose, or in various other medical emergencies). It may also be needed when a muscle relaxant has been given during an operation as part of a general anaesthetic.

Procedure
The air is delivered to the patient’s lungs via a tube inserted into the windpipe. After each inflation, the air is expelled by the natural elasticity of the lungs. Fluids and drugs must be given to the patient by intravenous infusion.
ventilatory failure
See respiratory failure.

ventouse
See vacuum extraction.

ventral
Relating to the front of the body, or describing the lowermost part of a body structure when a person is lying face-down. The opposite is dorsal.

ventricle
A cavity or chamber. Both the heart and brain have anatomical parts that are known as ventricles. The brain has four ventricles: one in each of the two cerebral hemispheres; a third at the centre of the brain, above the brainstem; and a fourth between the brainstem and cerebellum. These cavities are filled with cerebrospinal fluid.

The ventricles of the heart are its two lower chambers. The ventricles receive blood from each atrium (upper chamber) and pump it to the lungs and to the rest of the body.

ventricular aneurysm
A balloonlike bulge in the wall of the left ventricle of the heart (the chamber that pumps oxygen-rich blood around the body). Commonly developing as a result of a myocardial infarction (heart attack), ventricular aneurysm may, in turn, cause heart failure (reduced pumping efficiency) or arrhythmias (abnormal heart rhythms). Another possible complication is that a blood clot may form within the bulge, and fragments may become dislodged and travel around the circulation to block blood vessels elsewhere in the body (see embolism). Diagnosis is by echocardiography. Treatment involves drugs to treat heart failure or arrhythmias, as well as anticoagulant drugs. Surgical removal of the aneurysm may be needed in some cases.

ventricular ectopic beat
A type of cardiac arrhythmia in which abnormal heartbeats are initiated from electrical impulses within the ventricles (the lower chambers) of the heart. In a normal heart, beats are initiated by the sinoatrial node in the right atrium. Ventricular ectopic beats may be detected on an ECG. For frequent abnormal beats causing symptoms, or beats that arise from more than one site in the ventricles, an antiarrhythmic drug may be required.

ventricular fibrillation
One of the two life-threatening cardiac arrhythmias that occur in cardiac arrest. The heart has rapid, uncoordinated, ineffective contractions and does not pump blood. The problem is due to abnormal heartbeats initiated by electrical activity in the ventricles (lower heart chambers). It is a common complication of myocardial infarction (heart attack) and may also be caused by electrocution or drowning. The diagnosis is confirmed by ECG. Emergency treatment is with defibrillation (administration of an electric shock to the heart) and antiarrhythmic drugs.

ventricular septal defect
The medical term meaning a hole between the lower two chambers of the heart. The abnormality is present from birth and in many cases is small and closes without treatment. Surgery may be performed for larger defects, usually with good results.

ventricular tachycardia
A serious cardiac arrhythmia in which each heartbeat is initiated from electrical activity in the ventricles (lower heart chambers) rather than from the sinoatrial node in the right atrium (upper heart chamber). It is an abnormally fast heart rate due to serious heart disease, such as myocardial infarction (heart attack) or cardiomyopathy (disease of the heart muscle). It may last for a few seconds or for several days. Diagnosis is confirmed by ECG. Emergency treatment is with defibrillation (administration of an electric shock to the heart) and an antiarrhythmic drug.

verapamil
A drug that acts as a calcium channel blocker to treat hypertension (high blood pressure), angina pectoris (chest pain due to inadequate blood supply to the heart), and certain arrhythmias (abnormalities of the heartbeat). Possible side effects include headache, flushing, dizziness, and ankle swelling.

vernix
The white, cheeseslike substance covering a newborn baby. Vernix comprises fatty secretions and dead cells. It protects the skin, insulates against heat loss before birth, and lubricates the baby’s passage down the birth canal.

verruca
The Latin name for a wart, commonly applied to warts on the soles.

version
A change in the direction in which a fetus lies so that a malpresentation, most commonly a breech (bottom-down) presentation, replaces the normal head-down presentation.
vertebra
Any of the 33 roughly cylindrical bones that form the spine. There are seven vertebrae in the cervical spine; 12 in the thoracic; five in the lumbar; five (fused) in the sacrum; and four (fused) in the coccyx. The top 24 vertebrae are separated by discs of cartilage (see disc, intervertebral). Each vertebra has a hole in the centre through which the spinal cord runs, and processes to which muscles are attached. (See also Location and structure of the vertebrae box, overleaf.)

vertebrobasilar insufficiency
Intermittent episodes of dizziness, weakness, double vision, and difficulty in speaking caused by reduced blood flow to parts of the brain. The condition is usually a result of atherosclerosis (narrowing due to accumulation of fatty deposits) of the basilar and vertebral arteries and other arteries in the base of the brain. Vertebrobasilar insufficiency sometimes precedes a stroke.

vertigo
An illusion that an individual or his or her surroundings are spinning. Vertigo is usually the result of a disturbance of the semicircular canals in the inner ear or the nerve tracts leading from them. The condition may also be caused by certain brain disorders affecting the brainstem, the cerebellum, or the cerebral cortex. Sudden-onset vertigo is treated with rest and antihistamine drugs, which, in some cases, are also given to prevent recurrent attacks.

vesicle
A small blister, usually filled with clear fluid, that forms at a site of skin damage. The term is also used to refer to any small saclike structure in the body.

vesicoureteric reflux
Backflow of urine from the bladder into the ureters (the tubes that carry urine from the kidneys to the bladder). Vesicoureteric reflux causes recurrent urinary infection in children that often results in acute pyelonephritis and scarring of the kidneys. The condition, which is caused by a faulty valve mechanism, is diagnosed using micturating cystourethrography (see cystourethrography, micturating). Antibiotic drugs are given to prevent infection, but corrective surgery may also be needed.

VESTIBULOOCOCHLEAR NERVE

**VESTIBULOCOCHLEAR NERVE**

**TYPES OF VENTRICULAR ARRHYTHMIA**

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Normal heartbeat</td>
<td>This is the normal ECG appearance of the heartbeat. The regular spikes coincide with beats of the ventricles (lower heart chambers). The small rises before each spike coincide with contractions of the atria (upper chambers).</td>
</tr>
<tr>
<td>Ventricular tachycardia</td>
<td>Here, there is a rapid succession of abnormal beats, caused by an abnormal focus of electrical activity in a ventricle. It usually indicates serious underlying heart disease. The rate of beating may be very high – up to 220 beats per minute.</td>
</tr>
<tr>
<td>Ventricular fibrillation</td>
<td>This pattern is seen only when the heart is in a state of virtual arrest, usually after a heart attack, with the ventricles twitching in a rapid and totally irregular manner. Unless a normal rhythm can be restored, the condition is rapidly fatal.</td>
</tr>
<tr>
<td>Ventricular ectopic beat</td>
<td>Here there is an abnormal beat, which has a broad, bizarre-looking waveform on the ECG; it occurs just before the expected normal beat. To the patient, the heart may seem to stop at time A and restart with a thump at time B.</td>
</tr>
</tbody>
</table>

The ventricles (lower chambers) of the heart usually beat regularly in response to excitatory waves that spread from the upper chambers. Any disturbances to that rhythm (arrhythmia) may be associated with heart disease. The different types of ventricular arrhythmia can be seen on these electrocardiograph (ECG) recordings.
caused by an infection, such as meningitis or encephalitis, or to a reaction to a drug such as streptomycin.

viability
The capability of independent survival and development.

Viagra
The brand name for sildenafil, a drug used in the treatment of impotence.

villus
A minute fingerlike projection from a membranous surface. Millions of villi are present on the mucous lining of the small intestine. Each intestinal villus contains a small lymph vessel and a network of capillaries (tiny blood vessels). Its surface is covered with hundreds of hairlike structures (microvilli). The villi and microvilli provide a large surface area for the absorption of food molecules from the intestine into the blood and the lymphatic system.

vinca alkaloids
A group of substances derived from the periwinkle plant (Vinca rosea) that are used to treat leukaemias (cancers of the blood), lymphomas (cancers of lymphoid tissue), and some solid tumours, such as breast cancer and lung cancer.

All vinca alkaloids can cause neurological toxicity, which appears as neuropathy (nerve damage). Other side effects may include abdominal pain, constipation, and reversible alopecia (hair loss). Common vinca alkaloids include vinblastine, vindesine, and vincristine.

Vincent’s disease
A severe form of gingivitis (gum disease) in which bacterial infection causes painful ulceration of the gums. (See also gingivitis, acute ulcerative.)

vincristine
A vinca alkaloid used to treat certain cancers. One particular side effect of vincristine is peripheral or autonomic neuropathy (nerve damage); but, unlike the other vinca alkaloids, it causes very little reduction in blood-cell production by the bone marrow. Other side effects may include abdominal pain, constipation, and reversible alopecia (hair loss).

viraemia
The presence of virus particles in the blood. Viraemia can occur at certain stages in various viral infections. Some viruses, such as those responsible for viral hepatitis, yellow fever, and poliomyelitis, are transported in the bloodstream to their target tissue or organ, for example the liver, where they multiply. Others, such as the rubella virus and HIV, multiply in, and spread via, certain white blood cells. If viraemia is a feature of a viral infection, there may be a risk that the infection will be transmitted to other people in blood or blood products, or by insects that feed on blood.

viral haemorrhagic fever
Diseases that are prevalent in Africa and cause severe bleeding. There are several types, including Ebola fever, Lassa fever, Hantavirus, and Marburg fever. The diseases are fatal in a large percentage of cases, but Lassa fever may respond to antiviral drugs if given in the first week.

virginity
The physical state of not having experienced sexual intercourse.

virilism
The presence in a woman of masculine characteristics, caused by excessive levels of androgen hormones. Androgens are male sex hormones which, in women, are normally secreted in small amounts by the adrenal glands and ovaries.

Raised levels induce various changes in women, including hirsutism (excessive hairiness); male-pattern baldness (see alopecia); disruption or cessation of menstruation; enlargement of the clitoris; loss of normal fat deposits around the hips; development of the arm and shoulder muscles; and deepening of the voice (see virilization).

virility
A term used to describe the quality of maleness, especially in sexual characteristics and performance.

virilization
The development in a woman of male characteristics as a result of overproduction of androgen hormones by the adrenal glands and/or ovaries. This may be due to various conditions such as certain adrenal tumours, polycystic ovary (see ovary, polycystic) and some other ovarian cysts, or congenital adrenal hyperplasia (a rare genetic disorder).

virion
A single, complete, virus particle.

virology
The study of viruses and the epidemiology and treatment of diseases caused by viruses. In a more restricted sense, virology also refers to the isolation and identification of viruses to diagnose specific viral infections. Depending on the type of virus, this may involve growing viruses in cultures of human or animal cells, staining or microscopic examination of specimens containing viruses, or immunoblotting techniques.

virulence
The ability of a microorganism to cause disease. This can be assessed by measur-
ing what proportion of the population exposed to the microorganism develops symptoms of disease, how rapidly the infection spreads through the body, or the mortality from the infection.

viruses
One of the smallest known types of infectious agent. It is debatable whether viruses are truly living organisms or just collections of molecules capable of self-replication under specific conditions. Their sole activity is to invade the cells of other organisms, which they then take over to make copies of themselves. Outside living cells, viruses are inert.

STRUCTURE
A single virus particle (virion) consists of an inner core of nucleic acid, which may be either DNA or RNA, surrounded by one or two protective protein shells (capsids). Surrounding the outer capsid may be another layer, the viral envelope, which consists mainly of protein. The nucleic acid consists of a string of genes that contain coded instructions for making copies of the virus (see Viruses and disease box, overleaf).

VIRAL DISEASES
Common viral conditions include the common cold (see cold, common), influenza, chickenpox, cold sores, and warts. AIDS is caused by the human immunodeficiency virus (see HIV).

viscera
A collective term used to describe the internal organs.

viscosity
The resistance to flow of a fluid; its “stickiness”. The viscosity of blood affects its ability to flow through small vessels. An increased blood viscosity increases the risk of thrombosis (abnormal blood clotting).

vision
The faculty of sight. When light-rays reach the eye, most of the focusing is done by the cornea, but the eye also has accommodation, an automatic fine-focusing facility that operates by altering the curvature of the lens. Together, these systems form an image on the retina. The light-sensitive rod and cone cells in the retina convert the elements of this image into nerve impulses that pass into the visual cortex of the brain via the optic nerves. The rods, which are more concentrated at the periphery of the retina, are highly sensitive to light but not to colour. The colour-sensitive cones are concentrated more at the centre of the retina (see colour vision). The brain coordinates the motor nerve impulses to the six tiny muscles that move each eye to achieve alignment of the eyes. Accurate alignment allows the brain to fuse the images from each eye, but because each eye has a slightly different view of a given object, the brain obtains information that is interpreted as solidity or depth. This stereoscopic vision is important in judging distance. (See also Types of vision test box, overleaf; The sense of vision box, p.792.)

vision, disorders of
The most common visual disorders are refractive errors, such as astigmatism (the abnormal curvature of the front of
VIRUSES AND DISEASE

All viruses have the same basic structure (right), but they come in various shapes and sizes. Examples from the main families are shown below (some in cross-section). All are tiny – from about 15 to 300 nanometres in diameter (one nanometre equals one thousand-millionth of a metre); most are so small that they can be seen only with an electron microscope. All types of viruses can multiply only within cells of their host (far right).

VIRAL REPLICATION

The sequence below shows how a virus multiplies. The signs and symptoms of viral infection are caused by the virus interfering with or destroying the host's cells.

1. The virus particle first attaches itself to and then injects itself into the host cell.

2. The viral capsid breaks down and the viral nucleic acid (DNA or RNA) contained inside is released.

3. The viral nucleic acid replicates itself; the new copies are made from raw materials in the host cell.

4. Each of the new copies of the viral nucleic acid now directs the manufacture of a capsid for itself.

5. The newly formed virus particles are released in large numbers, and the host cell may be destroyed.
the eye), myopia (shortsightedness), and hypermetropia (longsightedness), which can almost always be corrected by glasses or contact lenses. Other disorders of vision include amblyopia (lazy eye); double vision; and disorders of the eye or optic nerve, of the nerve pathways connecting the optic nerves to the brain, and of the brain itself.

CAUSES IN THE EYE
The eye may lose its transparency through corneal opacities, cataract, or vitreous haemorrhage (bleeding into the gel of the eye behind the lens). Defects near the centre of the retina cause loss of the corresponding parts of the visual field (see macular degeneration). Floaters, which are usually insignificant, may indicate a retinal tear or haemorrhage, or they may herald a retinal detachment. Optic neuritis (inflammation of the optic nerve) can cause a blind spot in the centre of the visual field.

CAUSES IN THE BRAIN
Damage to the brain (for example, from a stroke) may cause visual impairments such as hemianopia (loss of half the visual field), agnosia (failure to recognize objects), visual perseveration (in which a scene continues to be perceived after the direction of gaze has shifted), and visual hallucinations.

vision loss of
The inability to see. Loss of vision may develop slowly or suddenly, and it may be temporary or permanent, depending on the cause. Loss of vision may affect one eye or both of the eyes. It can cause complete blindness or may affect only peripheral or central vision.

SLOW VISION LOSS
Progressive loss of visual clarity is common with age and may be due to a number of disorders (see vision, disorders of).

SUDDEN VISION LOSS
Sudden loss of vision may be caused by disorders such as hyphaema (bleeding into the aqueous humour), severe uveitis (inflammation of the iris or the choroid), vitreous haemorrhage (bleeding into the gel within the eye), or retinal haemorrhage. Optic neuritis (inflammation of the optic nerve) can reduce vision in one eye.

Damage to the nerve connections between the eyes and brain, or to the visual area of the brain, can cause loss of peripheral vision. This nerve damage may be caused by a number of disorders such as an embolism, ischaemia, tumour, inflammation, or injury.

vision tests
The part of an eye examination that determines reduction in the ability to see.

VISUAL ACUITY TESTS
Tests of visual acuity (sharpness of central vision) include a Snellen chart, which is used to test a patient’s distance vision, and close-reading test cards, which may be used to assess his or her near vision.

REFRACTION TESTS
Refraction tests assess the ability of the eye to focus light clearly on the retina via the cornea and lens. They can be used to detect hypermetropia (longsightedness), myopia (shortsightedness), and astigmatism (abnormal curvature of the front of the eye). By observing the effect of different lenses on movement
**THE SENSE OF VISION**

Vision starts in the retina, the membrane at the back of the eye that contains the light-sensitive rod and cone cells. Much of the rest of the eye is concerned with focusing light, in the right quantities, on to the retina. Huge amounts of data are sent from the retina, through the optic nerves, to the brain for analysis.

**Pathways to the brain**
Signals pass from the eyes along the optic nerves to the optic chiasma and then to the visual cortices in the brain. There is some crossover of nerve fibres at the optic chiasma, so both sides of the brain receive signals from both eyes.

**Stereoscopic vision**
The two eyes receive slightly different views of all but the most distant objects; information from the two images is compared and processed in the brain to give a single 3-D interpretation of the object.

**EYEBALL MOVEMENTS**
In order to maintain the image of any moving object on the centre of the retina, precise eyeball movements, which are achieved by the six muscles shown below, are necessary. The muscles act to swivel the eyeball (here, the right) in the directions indicated. The muscles always act in groups to achieve movement.
of light reflected from the eye, the strength and type of glasses or contact lenses needed to correct the visual defect can be assessed objectively. Visual acuity tests are then used to check that the patient can see clearly using the new lenses. Further minor adjustments to the lenses may be required.

**VISUAL FIELD TESTS**
Tests of the visual field may be performed to assess disorders of the eye, such as glaucoma (increased pressure of fluid within the eyeball), or disorders of the nervous system, such as a stroke.

**visual acuity**
Sharpness of central vision. Refractive errors, such as myopia (shortsightedness), hypermetropia (longsightedness), and astigmatism (abnormal curvature of the front of the eye), are the most common causes of poor visual acuity. Poor visual acuity for near objects occurs in presbyopia (age-related deterioration in focusing power).

**visual field**
The total area in which visual perception is possible while a person is looking straight ahead. The visual fields normally extend outwards over an angle of about 90 degrees on either side of the midline of the face, but are more restricted above and below, especially if the eyes are deep-set or the eyebrows are prominent. The visual fields of the two eyes overlap to a large extent, giving binocular vision (see the illustrated box). Partial loss of the visual field may occur in glaucoma (raised pressure within the eyeball) or stroke.

**vital sign**
An indication that a person is still alive. Vital signs include chest movements that are caused by breathing, the presence of a pulse, and the constriction of the pupil of the eye when it is exposed to a bright light.

**vitamin**
Any of a group of complex organic substances essential, for small amounts, for the normal functioning of the body. There are 13 vitamins: A, C, D, E, K, B₁₂, and seven grouped under the vitamin B complex. Apart from vitamin D, which the body can synthesize itself, vitamins must be obtained from the diet. A varied diet is likely to contain adequate amounts of all the vitamins, but vitamin supplements may be helpful for: young children, pregnant or breast-feeding women, or those taking drugs that interfere with vitamin function.

**TYPES**
Vitamins can be categorized as fat-soluble or water-soluble.

Fat-soluble vitamins (A, D, E, and K) are absorbed with fats from the intestine into the bloodstream and are then stored in fatty tissue (mainly in the liver). Because body reserves of some of these vitamins last for several years, a daily intake is not usually necessary. Deficiency of a fat-soluble vitamin is usually due to a disorder in which intestinal absorption of fats is impaired (see malabsorption) or to a prolonged poor diet.

Vitamins C, B₁₂, and those of the B complex are water-soluble. Vitamin C and B complex vitamins can be stored in the body in only limited amounts and are excreted in the urine if taken in greater amounts than needed. A regular intake is therefore essential to prevent deficiency. However, vitamin B₁₂ is stored in the liver; these stores may last for years.

**FUNCTION IN THE BODY**
The role of all the vitamins in the body is not fully understood. Most have several important actions on one or more body systems, and many are involved in the activities of enzymes. (See also individual vitamin entries; Reference Nutrient Intake table, overleaf.)

**vitamin A**
A fat-soluble vitamin vital for growth, for bone and teeth formation, for cell struc-
Vitamin A

The first symptom of deficiency is night blindness, followed by dryness and eye inflammation (see xerophthalmia), keratomalacia (damage to the cornea), and eventually blindness. Deficiency also causes reduced resistance to infection, dry skin, and, in children, stunted growth.

**EXCESS**

Prolonged excessive intake of vitamin A can cause headache, nausea, loss of appetite, skin peeling, hair loss, and irregular menstruation. In severe cases, the liver and spleen become enlarged. Excess vitamin A, especially in the form of retinol, has been linked with an increased risk of bone fractures. Excessive intake during pregnancy may cause birth defects. In infants, excessive intake may cause skull deformities, which disappear if the diet is corrected.

**MEDICAL USES**

The drug tretinoin (a derivative of vitamin A) is used to treat severe acne.

### vitamin B

See vitamin B₁₂; vitamin B complex.

### vitamin B₁₂

A water-soluble vitamin that plays a vital role in the activities of several enzymes in the body. Vitamin B₁₂ is important in the production of the genetic material of cells (and thus in growth and development), in the production of red blood cells, and in the maintenance of the nervous system.

ture, for night vision, and for protecting the linings of the respiratory, digestive, and urinary tracts against infection.

Vitamin A is absorbed by the body in the form of retinol. This is found in liver, fish-liver oils, egg yolk, dairy produce, and is added to margarines. Carotene, which the body converts into retinol, is found in various vegetables and fruits.

**DEFICIENCY**

Vitamin A deficiency is rare in developed countries. In most cases, it is due to maldigestion. Vitamin A deficiency may also result from long-term treatment with certain lipid-lowering drugs. Deficiency is common in some developing countries due to poor diet.

**REFERENCE NUTRIENT INTAKE (RNI) FOR SELECTED VITAMINS**

The table below gives the reference nutrient intake (RNI) of vitamins for which amounts have been established; the RNI for males and females, when they are different, are denoted by the letters M and F.

** Vitamin D is derived from sunlight. Certain individuals or at-risk groups may require dietary vitamin D.
† For people aged 65 years or more only
blood cells in bone marrow, in the utilization of folic acid in the diet, and in the functioning of the nervous system. Foods that are rich in vitamin \(B_{12}\) include liver, kidney, chicken, beef, pork, fish, eggs, and dairy products.

**Deficiency**

Deficiency is almost always due to inability of the intestine to absorb vitamin \(B_{12}\), usually because of pernicious anaemia (see *anaemia, megaloblastic*). Less commonly, deficiency may result from *gastrectomy* (removal of all or part of the stomach), *malabsorption*, or *veganism*.

The effects of deficiency are megaloblastic anaemia, sore mouth and tongue, and symptoms resulting from damage to the *spinal cord*, such as numbness and tingling in the limbs. There may also be depression and loss of memory.

**Excess**

A high intake of vitamin \(B_{12}\) has no known harmful effects.

**Vitamin B Complex**

A group of water-soluble *vitamins* that comprise thiamine (vitamin \(B_1\)), riboflavin (vitamin \(B_2\)), niacin, pantothenic acid, pyridoxine (vitamin \(B_6\)), biotin (vitamin \(H\)), and folic acid. Vitamin \(B_{12}\) is discussed above.

**Thiamine**

Thiamine plays a role in the activities of various *enzymes* that are involved in the utilization of *carbohydrates* and thus in the functioning of nerves, muscles, and the heart. Sources include whole-grain cereals, wholemeal breads, brown rice, pasta, liver, kidney, pork, fish, beans, nuts, and eggs.

Those who are susceptible to deficiency include elderly people on a poor diet, and people with *hyperthyroidism* (overactivity of the thyroid gland), *malabsorption*, or severe alcohol dependence. Deficiency may also occur as a result of severe illness, surgery, or injury.

Mild deficiency of the vitamins may cause tiredness, irritability, and loss of appetite. Severe deficiency may cause abdominal pain, constipation, depression, memory impairment, and *beriberi*; in alcoholics, it may cause *Wernicke–Korsakoff syndrome*. Excessive intake is not known to cause harmful effects.

**Riboflavin**

Riboflavin is necessary for the activities of various enzymes that are involved in the breakdown and utilization of carbohydrates, fats, and proteins; production energy in cells; utilization of other B vitamins; and hormone production by the adrenal glands. Liver, whole grains, milk, eggs, and brewer’s yeast are good sources of these vitamins.

People who are susceptible to riboflavin deficiency include those taking phenothiazine *antipsychotic drugs*, tricyclic *antidepressant drugs*, or oestrogen-containing *oral contraceptives*, and those with malabsorption or severe alcohol dependence. Deficiency may also occur through serious illness, surgery, or injury.

Prolonged deficiency may cause soreness of the tongue and the corners of the mouth, and eye disorders such as *amblyopia* and *photophobia*. Excessive intake is not known to have any harmful effects.

**Niacin**

Niacin plays an essential role in the activities of various enzymes involved in the metabolism of carbohydrates and fats, the functioning of the nervous and digestive systems, the manufacture of sex hormones, and the maintenance of healthy skin. The main dietary sources are liver, lean meat, fish, nuts, and dried beans. Niacin can be made in the body from tryptophan (*an amino acid*).

Most cases of deficiency are due to malabsorption disorders or to severe alcohol dependence. Prolonged niacin deficiency causes *pellagra*, the main symptoms of which are soreness and cracking of the skin, inflammation of the mouth and tongue, and mental disturbances. Excessive intake of niacin is not known to cause harmful effects.

**Pantothenic Acid**

Pantothenic acid is essential for the activities of various enzymes that are involved in carbohydrate and fat metabolism, manufacture of corticosteroids and *sex hormones*, utilization of other vitamins, the functioning of the nervous system and *adrenal glands*, and growth and development. It is present in almost all vegetables, cereals, and animal foods.

Deficiency of pantothenic acid usually occurs as a result of malabsorption or alcoholism, but may also occur after severe illness, surgery, or injury. The effects include fatigue, headache, nausea, abdominal pain, numbness and tingling, muscle cramps, and susceptibility to respiratory infections. Excessive intake has no known harmful effects.

**Folic Acid**

Folic acid is vital for various enzymes involved in the manufacture of *nucleic acids* and consequently for growth and reproduction, the production of red blood cells, and the functioning of the nervous system. Sources of folic acid include green vegetables, mushrooms, liver, nuts, dried beans, peas, egg yolk, and wholemeal bread.

Mild folic acid deficiency is common, but it can usually be corrected by increasing dietary intake. More severe deficiency may occur during pregnancy or breast-feeding, in premature or low-birthweight infants, in people on *dialysis*, in people with certain blood disorders, the skin disorder *psoriasis*, malabsorption, or alcohol dependence, and in people taking certain drugs.

The main effects include anaemia, sores around the mouth, and, in children, poor growth. Supplements of folic acid taken just before conception, and for the first 12 weeks of pregnancy, have been shown to reduce the risk of a *neural tube defect* in the baby.

**Biotin**

Biotin is essential for the activities of various enzymes involved in the breakdown of fatty acids and carbohydrates and for the excretion of the waste products of protein breakdown. It is present in many foods, especially liver, peanuts, dried beans, egg yolk, mushrooms, bananas, grapefruit, and watermelon. Biotin is also manufactured by bacteria in the intestines.

Deficiency of biotin may occur during prolonged treatment with *antibiotics* or *sulphonamide drugs*. Symptoms are weakness, tiredness, poor appetite, hair loss, depression, inflammation of the tongue, and eczema. Excessive intake has no known harmful effects.

**Vitamin B Complex**

V
vitamin C

A water-soluble vitamin that plays an essential role in the activities of various enzymes. Vitamin C is important for the growth and maintenance of healthy bones, teeth, gums, blood vessels, and ligaments; in the production of certain neurotransmitters (chemicals that transmit nerve impulses) and adrenal gland hormones; in the response of the immune system to infection; in wound healing; and in the absorption of iron.

The main dietary sources are fruits and vegetables. Considerable amounts of vitamin C are lost when foods are processed, cooked, or kept warm.

DEFICIENCY
Mild deficiency of vitamin C may result from a serious injury or severe burn. It may also occur from use of oral contraceptives or continual inhalation of carbon monoxide (from traffic fumes or tobacco smoke), or after major surgery or a fever. It may cause weakness, general aches, swollen gums, and nosebleeds. More serious deficiency is usually due to a very restricted diet. Severe deficiency leads to scurvy and anaemia.

EXCESS
If the daily dose of vitamin C exceeds about 1g, it may cause nausea, stomach cramps, diarrhoea, or kidney stones (see calculus, urinary tract).

VITAMINS AND MAIN FOOD SOURCES

A varied diet usually provides all the body’s vitamin needs. For vegans (who eat no fish or animal products, including dairy products), vitamin B12 and vitamin D may be lacking; these vitamins can be obtained from supplements or, in the case of vitamin D, through adequate exposure to sunlight.

</tbody>
</table>

vitamin D

The collective term for a group of substances that help to regulate the balance of phosphate and calcium in the body, aid calcium absorption in the intestine, and promote strong bones and teeth.

Good sources of vitamin D include oily fish, liver, and egg yolk; the vitamin is also added to margarines. In the body, vitamin D is synthesized by the action of ultraviolet light on a particular chemical in the skin.

DEFICIENCY
Deficiency of vitamin D may occur in individuals with a poor diet, in premature infants, and in those who are deprived of sunlight. It can also result from malabsorption. Other causes include liver or kidney disorders and some genetic defects. Prolonged use of certain drugs, such as the anticonvulsant phenytoin, may also lead to deficiency. Deficiency in young children causes the bone disorder rickets; long-term deficiency in adults leads to osteomalacia.

EXCESS
Excessive intake of vitamin D may lead to hypercalcaemia (an abnormally high level of calcium in the blood) and abnormal calcium deposits in the soft tissues, kidneys, and blood vessel walls. In children, it may cause growth retardation.

vitamin E

The collective term for a group of substances that are essential for normal cell structure, for maintenance of the activities of certain enzymes, and for the formation of red blood cells. Vitamin E also protects the lungs and other tissues from damage by pollutants and is believed to slow ageing of cells. Sources include vegetable oils, nuts, meat, green vegetables, cereals, and egg yolk.

DEFICIENCY
Dietary deficiency of vitamin E is rare; deficiency is most common in people
with malabsorption, certain liver disorders, and in premature infants. It leads to the destruction of red blood cells, which eventually leads to anaemia. In infants, it causes irritability and oedema (accumulation of fluid in tissues).

**EXCESS**
Prolonged excessive intake of vitamin E may cause abdominal pain, nausea, and diarrhoea. It may also reduce intestinal absorption of vitamins A, D, and K.

**vitamin K**
A fat-soluble vitamin that is essential for the formation in the liver of substances that promote blood clotting. Green vegetables, vegetable oils, egg yolk, cheese, pork, and liver are good sources of vitamin K, which is also manufactured by bacteria in the intestine.

**DEFICIENCY**
Dietary deficiency of vitamin K rarely occurs. Deficiency may develop in people with malabsorption, certain liver disorders, or chronic diarrhoea. It may also result from prolonged treatment with antibiotic drugs. Newborn babies lack the intestinal bacteria that produce vitamin K and are routinely given supplements to prevent deficiency. Vitamin K deficiency may cause nosebleeds and bleeding from the gums, intestine, and urinary tract. In rare, severe cases, brain haemorrhage may result.

**EXCESS**
Excessive intake of vitamin K is not known to cause harmful effects.

**vitamin supplements**
A group of dietary preparations containing one or more vitamins. Some multivitamin preparations also contain minerals, such as iron and calcium. A healthy person with a balanced diet should not need to take supplements (see nutrition). Excessive doses of certain vitamins (especially vitamins A, B12, and D) may actually be harmful.

Vitamin supplements may be given in order to prevent vitamin deficiency in susceptible people, including those individuals with increased requirements (such as women who are pregnant or breast-feeding); those people who follow a restricted diet (such as veganism); those who have severe alcohol dependence; and those people suffering from disorders that may cause vitamin deficiencies, such as malabsorption and some liver and kidney disorders.

Vitamin supplements are also used in the treatment of certain disorders, including diagnosed vitamin deficiency. For example, vitamin D is used to treat the bone condition osteomalacia and vitamin A derivatives are given in the treatment of severe acne. Supplementary vitamins may be given orally or may be injected (as is the case with vitamin B12 and vitamin K).

**vulgaris**
A common disorder of skin pigmentation in which patches of skin, most commonly on the face, hands, armpits, and groin, lose their colour. Vitiligo is thought to be an autoimmune disorder (in which the body’s immune system attacks its own tissues). The condition may occur at any age, but it usually develops in early adulthood.

Spontaneous repigmentation occurs in some cases. A course of phototherapy using PUVA can also induce repigmentation of the skin, and creams containing corticosteroid drugs may help.

**vivisection**
The performance of a surgical operation on a live animal, particularly for the purposes of research. (See also animal experimentation.)

**vocal cords**
Two fibrous sheets of tissue in the larynx (voicebox) that are responsible for voice production. The vocal cords are attached at the front to the thyroid cartilage and at the rear to the arytenoid cartilages. In order to produce sound, the vocal cords (which normally form a V-shaped opening) close and vibrate as air that is expelled from the lungs passes between them. Alterations in cord tension produce sounds of different pitch, which are modified by the tongue, mouth, and lips to form speech.

**voicebox**
See larynx.

**voice, loss of**
Inability to speak normally. Temporary partial loss of voice commonly results from straining of the muscles of the larynx (voicebox) through overuse of the voice or from inflammation of the vocal cords in laryngitis.

Persistent or recurrent loss of voice may be the result of polyps on the vocal cords, thickening of the vocal cords in hypothyroidism (underactivity of the thyroid gland), or interference with the nerve supply to the larynx muscles as a result of cancer of the larynx, thyroid gland, or oesophagus. Total loss of voice is rare and is usually of psychological origin. (See also hoarseness; larynx, disorders of).

**Volkmann’s contracture**
A disorder of the wrist and fingers in which they become permanently fixed in a bent position.

**CAUSE**
Volkmann’s contracture occurs because of an inadequate blood supply to the forearm muscles that control the wrist and fingers. This is most likely to be the result of an injury.

**SYMPTOMS**
Initially, the fingers become cold, numb, and white or blue. Finger movements are weak and painful, and there is no pulse at the wrist. Unless treatment is started within a few hours, wrist and finger deformity develops.
LOCATION OF THE VOCAL CORDS

The vocal cords are located at the top of the larynx (voicebox). Their top edges stretch between the thyroid cartilage at the front and the arytenoid cartilages at the back. If they are brought close together, the vocal cords vibrate and emit sounds as air passes between them.

VOLVULUS

TREATMENT
Treatment of the condition is by manipulation back into position of displaced bones, followed, if necessary, by surgical restoration of blood flow in the forearm. If there is permanent deformity, physiotherapy may help to restore function of the affected parts.

volvulus
Twisting of a loop of intestine or, in rare cases, of the stomach. Volvulus is a serious condition that causes obstruction of the passage of intestinal contents (see intestine, obstruction of) and a risk of strangulation. If strangulation occurs, blockage of blood flow to the affected area leads to potentially fatal gangrene (death of tissues in the area).

The symptoms of volvulus are severe episodes of abdominal pain followed by vomiting. Volvulus may be present from birth or may be a result of adhesions (areas of scar tissue binding loops of intestine). It requires emergency treatment, usually by surgery.

vomiting
The involuntary forcible expulsion of stomach contents through the mouth. Vomiting may be preceded by nausea, pallor, sweating, excessive salivation, and a slowed heart rate.

MECHANISM
It occurs when the vomiting centre in the brainstem is activated by signals from one of three places in the body: the digestive tract; the balancing mechanism of the inner ear; or the brain, either due to thoughts and emotions or via the part of the brain that responds to poisons in the body.

The vomiting centre sends messages to both the diaphragm, which presses down on the stomach, and the abdominal wall, which presses inwards, thereby expelling the stomach contents upwards through the oesophagus.

CAUSES
Vomiting may be the result of overindulgence in food or alcohol, it is a common side effect of many drugs, and it may follow general anaesthesia. Vomiting is also common in gastrointestinal disorders such as peptic ulcer, acute appendicitis, gastroenteritis, and food poisoning. Less commonly, it is due to obstruction, due for example to pyloric stenosis or intussusception, or to a tumour of the digestive tract. It may also be due to inflammation of associated organs (see hepatitis; pancreatitis; cholecystitis).

Other possible causes of vomiting are pressure within the skull (see encephalitis; hydrocephalus; a brain tumour; a head injury), migraine, conditions that affect the ear’s balancing mechanism (see Ménière’s disease; labyrinthitis; motion sickness), and hormonal disorders such as Addison’s disease.

Vomiting may be a symptom of ketoacidosis in poorly controlled diabetes mellitus. It may also be a symptom of an emotional problem or be part of the disorders anorexia nervosa or bulimia.

TREATMENT
Persistent vomiting requires medical investigation. Treatment depends on the cause. Antiemetics may be given. (See also vomiting blood; vomiting in pregnancy.)

vomiting blood
A symptom of bleeding from within the digestive tract. The vomiting of blood may be the result of a tear in the lower oesophagus (see Mallory–Weiss syndrome), bleeding from oesophageal varices (enlarged veins in the oesophagus), erosive gastritis (inflammation of the stomach lining), a peptic ulcer, or, rarely, stomach cancer. A person can also vomit blood if the blood is swallowed during a nosebleed.

Vomited blood may be dark red, brown, black, or it may resemble coffee grounds. Vomiting of blood is often accompanied by the passing of black, tarry faeces.

The cause of vomiting blood is investigated by endoscopy of the oesophagus and stomach, or by barium X-ray examinations. If blood loss is severe, blood transfusion, and possibly surgery to stop the bleeding, may be required.

vomiting in pregnancy
Nausea and vomiting in early pregnancy are common and are most likely to be caused by changes in hormone levels. Vomiting occurs most frequently in the morning, but it may occur at any time. It is sometimes precipitated by stress, travelling, or food.

In rare cases, the vomiting becomes severe and prolonged. This can cause
dehydration, nutritional deficiency, alterations in blood acidity, and weight loss. Immediate hospital admission is then required to replace lost fluids and chemicals by intravenous infusion, to rule out any serious underlying disorder, and to control the vomiting.

von Recklinghausen’s disease
Another name for neurofibromatosis.

von Willebrand’s disease
An inherited lifelong bleeding disorder that is similar to haemophilia. People with the condition have a reduced concentration in their blood of a substance called von Willebrand factor, which helps platelets in the blood to plug injured blood vessel walls and forms part of factor VIII (a substance that is vital to blood coagulation).

SYMPTOMS
Symptoms of deficiency of this factor include excessive bleeding from the gums and from cuts and nosebleeds. Women may have heavy menstrual bleeding. In severe cases, bleeding into joints and muscles may occur.

DIAGNOSIS AND TREATMENT
The disease is diagnosed by means of blood-clotting tests and measurement of blood levels of von Willebrand factor. Bleeding episodes can be prevented or controlled by desmopressin (a substance resembling ADH). Factor VIII or concentrated von Willebrand factor may also be used to treat bleeding.

voyeurism
The observation, on a regular basis, of unsuspecting individuals who may be naked, getting undressed, or who are engaged in sexual activity, in order to achieve sexual arousal.

VSD
The abbreviation for ventricular septal defect.

vulva
The external part of the female genitalia, comprising the clitoris and two pairs of skin folds called labia.

Conditions that affect the vulva include vulval itching; inflammation (see vulvitis and vulvovaginitis); skin conditions, such as dermatitis and lichen sclerosus et atrophicus; genital warts (see warts, genital); genital herpes (see herpes, genital); leukoplakia (raised white patches due to tissue thickening); and cancer (see vulva, cancer of).

vulva, cancer of
A malignant tumour of the vulva (the external part of the female genitalia), a rare disorder that most commonly affects postmenopausal women. Cancer of the vulva may be preceded by a phase of vulval cell changes that cause itching, but, in many cases, the first symptom of the condition is a lump or painful ulcer on the vulva.

Diagnosis is confirmed using biopsy (removal of a small sample of tissue for microscopic analysis). Treatment is by surgical removal of the affected tissue. The outlook depends on how early treatment is commenced.

vulval itching
Irritation of the vulva (the external part of the female genitalia), known medically as pruritus vulvae. Vulval itching may be caused by localized conditions, including infections (such as candidiasis), infestations (such as with pubic lice), or abnormal changes in the vulval skin (due, for example, to leukoplakia or cancer). It may also be caused by any condition leading to generalized itching or by skin conditions, such as dermatitis and psoriasis. Itching may also result from an allergy to chemicals in spermicidal or hygiene products.

Treatment of vulval itching depends on the cause, but may involve antibiotic drugs or hormones.

vulvitis
Inflammation of the vulva (the external part of the female genitalia). Infections that may lead to vulvitis include candidiasis (thrush) and genital herpes (see herpes, genital). Infestations with pubic lice or scabies are other possible causes. Vulvitis may also occur as a result of changes in the vulval skin, which tend to affect women after the menopause. Such changes may take the form of red or white patches and/or thickened or thinned areas that may be inflamed (see lichen sclerosus et atrophicus; leukoplakia). Other possible causes of vulvitis include allergic reactions to hygiene products, excessive vaginal discharge, or urinary incontinence (see incontinence, urinary).

Treatment depends on the cause, but may involve the topical application of a combination of drugs; good hygiene is usually recommended. If there are skin changes, a biopsy (tissue sample) may be taken to exclude the possibility of vulval cancer. (See also vaginitis; vulvovaginitis.)

vulvovaginitis
Inflammation of the vulva (see vulvitis) and vagina (see vaginitis). Vulvovaginitis is often caused by infections such as candidiasis (thrush) or trichomoniasis.
walking
Movement of the body by lifting the feet alternately, bringing one foot into contact with the ground before the other starts to leave it. A person’s gait (style of walking) is determined by body shape, size, and posture. The age at which children first walk varies enormously.

Walking is controlled by nerve signals to the muscles. The signals travel to the muscles, via the spinal cord, from the motor cortex of the brain (see cerebrum, basal ganglia, and cerebellum).

**Disorders**
Abnormal gait may be caused by joint stiffness, muscle weakness (sometimes due to conditions such as poliomyelitis or muscular dystrophy), skeletal abnormalities (see, for example, arthritis; bone tumour; hip, congenital dislocation of; scoliosis; talipes). A painful limp may be due to a fracture or disease of the leg bones (the tibia, the fibula, or the femur). Children may develop knock-knee or bow leg; synovitis of the hip and Perthes’ disease are also common. Adolescents may develop a painful limp due to a slipped epiphysis (see femoral epiphysis, slipped).

Abnormal gait may also be caused by neurological disorders such as stroke (commonly causing hemiplegia), multiple sclerosis, parkinsonism, peripheral neuritis, various forms of myelitis, and chorea. Ménière’s disease may cause severe loss of balance and instability.

**Walking aids**
Equipment for increasing the mobility of people who have a disorder affecting their ability to walk. Such aids include sticks, crutches, and frames.

**Walking, delayed**
Most children start to walk by around 15 months of age. Delayed walking may be suspected if the child is unable to walk unassisted by the age of 18 months (see developmental delay).

**Warfarin**
An anticoagulant drug used in the prevention and treatment of abnormal blood clotting. Warfarin is used to treat deep vein thrombosis (formation of a blood clot within the deep-lying veins of the leg; see thrombosis, deep vein), pulmonary embolism (a fragment of a blood clot travelling in the bloodstream becoming lodged in the lungs), and people with atrial fibrillation (an abnormality of the heartbeat) who are at risk of an embolism. It is also prescribed to prevent emboli from developing on replacement valves (see heart-valve surgery).

A faster-acting anticoagulant, such as heparin, may also be prescribed for the first few days following a deep vein thrombosis or pulmonary embolism.

Warfarin may cause abnormal bleeding in different parts of the body, so regular tests are carried out to allow careful regulation of dosage. Warfarin may also cause nausea, diarrhoea, and a rash.

**Wart**
A common, contagious, and harmless growth that occurs on the skin or mucous membranes. Only the topmost layer of skin is affected. An overgrowth of cells in this layer causes a visible lump to develop.

**Causes and types**
Warts are caused by the human papillomavirus, of which at least 70 different types are known. These cause different

---

**The Mechanics of Walking**

Many different muscles take part in the walking process. They contract in a complex, rhythmic sequence in response to programmes of signals sent from the motor cortex in the brain. Feedback of information from the muscles and joints to the brain helps to ensure that the gait is smooth, steady, and coordinated.

Route of the signals
The signals for walking originate in the motor cortex and are carried via the spinal cord and nerve fibres to muscles.

1. As the left foot touches the ground, the right arm swings forward and the right foot shifts on to tiptoe.
2. Once the left foot is fully planted on the ground and supporting the body, the right foot is raised.
3. A sequence of muscle contractions advances the right leg, and the left arm swings forward.
WARTS, GENITAL

Fleshy, painless, usually soft lumps that grow in and around the vagina, around the anus, and on the penis. Genital warts are transmitted by sexual contact, and they are caused by some forms of human papillomavirus (HPV). The warts appear from a few weeks to 18 months after infection. They may be removed by cryosurgery or the drug podophyllin, but they tend to recur.

Genital warts are not associated with the development of cervical cancer (see cervix, cancer of); the two conditions are caused by different forms of HPV.

WASP STINGS

See insect stings.

WATER

A simple compound that is essential for all life. Its molecular structure is H₂O (two atoms of hydrogen bonded to one of oxygen). Water is the most common substance in the body, accounting for about 99 per cent of all molecules, but a smaller percentage of total body weight. Approximately two-thirds of the body's water content is contained within cells, and the remaining third is extracellular (found, for example, in blood plasma, lymph, cerebrospinal fluid, and tissue fluid).

ROLE IN THE BODY

Water provides the medium in which all metabolic reactions take place (see metabolism), and transports substances around the body. The blood plasma carries water to all body tissues, and excess water from tissues for elimination via the liver, kidneys, lungs, and skin. The passage of water in the tissue fluid into and out of cells takes place by osmosis.

WATER BALANCE

Water is taken into the body in food and drink and is lost in urine and faeces, as exhaled water vapour, and by sweating (see dehydration). The amount of water excreted in urine is regulated by the kidneys. Extra water is needed to excrete excess amounts of substances, such as sugar or salt, in the blood.

In some disorders, such as kidney failure or heart failure, insufficient water is excreted in the urine, resulting in oedema (accumulation of water in body tissues).

WATER-BORNE INFECTION

A disease caused by infective or parasitic organisms transmitted via water. Infections can be contracted if infected water is drunk, if it contaminates food, or if individuals swim or wade in it. Worldwide, contamination of drinking water is an important mode of transmission for various diseases, including hepatitis A, many viral and bacterial causes of diarrhoea, typhoid fever, cholera, amoebiasis, and some types of worm infestation.

Swimming in polluted water should be avoided because, if swallowed, there is a risk of contracting disease. A form of leptospirosis is caused by contact with water contaminated by rat’s urine. In tropical countries, there is also a risk of contracting schistosomiasis (bilharzia) — a serious disease caused by a fluke that can burrow through the swimmer’s skin.

WATERBRASH

The sudden filling of the mouth with tasteless saliva. It is not to be confused with acid reflux (the regurgitation of gastric juices), which has a sour taste. Waterbrash normally has other symptoms, such as abdominal pain before a meal, and usually indicates a disorder of the upper gastrointestinal tract.

WATERHOUSE–FRIDERICHSEN SYNDROME

A serious condition caused by infection of the bloodstream by bacteria of the meningococcus group. The main features are bleeding into the skin, low blood pressure, and shock. Without medical treatment, coma and death follow within
hours. The syndrome is often associated with meningitis, which affects the membranes covering the brain and spinal cord.

watering eye
An increase in volume of the tear film, usually producing epiphora (overflow of tears). It may be caused by excess tear production due to emotion, conjunctival or corneal irritation, or an obstruction to the channel that drains tears. (See also lacrimal apparatus.)

water intoxication
A condition that is caused by excessive water retention in the brain. The principal symptoms are headaches, dizziness, nausea, confusion, and, in severe cases, seizures and unconsciousness.

Various disorders can disrupt the water balance in the body, leading to accumulation of water in the tissues. Examples include kidney failure, liver cirrhosis, severe heart failure, diseases of the adrenal glands, and certain lung or ovarian tumours producing a substance similar to ADH (antidiuretic hormone).

Water intoxication is also seen in association with the use of Ecstasy (MDMA), during which excessive amounts of water are drunk. There is also a risk of water intoxication after surgery, caused by increased ADH production.

water on the brain
A nonmedical term for hydrocephalus.

water on the knee
A popular term for accumulation of fluid in or around the knee joint. A common cause is bursitis (inflammation of a bursa, one of the fluid-filled sacs that cushion pressure points in the body). (See also effusion, joint.)

water retention
Accumulation of fluid in body tissues (see oedema).

water tablets
A nonmedical term for diuretic drugs.

wax bath
A type of heat treatment in which hot liquid wax is applied to a part of the body in order to relieve pain and stiffness in an inflamed or injured joint. Wax baths may be used to treat the hands of people with rheumatoid arthritis.

wax, ear
See earwax.

weakness
A term used to describe a lack of vigour or strength. This is a common symptom of a range of conditions, such as anaemia, emotional problems, and various disorders affecting the heart, nervous system, bones, joints, and muscles. When associated with emotional disorders, weakness may represent lack of desire or ambition, rather than loss of muscle strength.

More specifically, the term describes loss of power in particular muscle groups, which may be accompanied by muscle wasting and loss of sensation. (See also paralysis.)

weal
A raised bump on the skin that is paler than the adjacent tissue and may be surrounded by red inflammation. Weals are characteristic of urticaria (hives).

weaning
The gradual substitution of solid foods for milk or milk formula in an infant’s diet (see feeding, infant).

Webbing
A flap of skin, such as that which might occur between adjacent fingers or toes. Webbing is a common congenital (present from birth) abnormality that often runs in families and which may affect two or more digits. Mild webbing is completely harmless, but surgical correction may be performed for cosmetic reasons. In severe cases, adjacent digits may be completely fused (see syndactyly). Webbing of the neck is a feature of the condition Turner’s syndrome.
or ulcers on the skin; and damage to the heart muscle, which may be fatal.

weight

The heaviness of a person or object. In children, weight is routinely used as an index of growth. In healthy adults, weight remains more or less stable if dietary energy intake matches energy expenditure (see metabolism). Weight loss or weight gain occurs if the net balance is disturbed.

WEIGHT ASSESSMENT

One method of assessment is to use the body mass index (BMI, or Quetelet’s index), obtained by dividing weight in kilograms by the square of height in metres. 20–25 kg/m² is considered to be a healthy weight; a score of greater than 25, however, may indicate that a person is overweight (see the accompanying table).

However, BMI has its limitations when assessing whether a person is medically overweight or underweight: a person with a good muscle bulk may have a high BMI but a healthy body composition; a small-framed person with a lot of body fat may have a normal BMI. For this reason, assessment of the percentage of a person’s body fat gives a more accurate idea of healthy versus unhealthy weight. Distribution of body fat is also important: people with central obesity (measured by a high waist:height ratio) are considered to be less healthy than those with a more even distribution of fat.

In children, weight can be compared with standardized predictions for age, which differ according to the gender and race of a child. Such weight charts are used to assess how well a child is thriving. At all ages, divergence from standard figures (either using BMI or body fat percentages) may have medical implications. If an individual is found to be “underweight”, their nutrition may be inadequate as a result of a poor diet or disease; if an individual is significantly “overweight”, he or she may be suffering from obesity.

weight loss

Any time that there is a decrease in energy intake compared with energy expenditure, weight loss is likely to occur. The decrease may be the result of deliberate weight reduction or a change in diet or activity level. Weight loss may also result from fluid loss (for example, because of sweating in a hot climate) or it may be a symptom of a disorder. Unexplained weight loss should always be investigated by a doctor.

LOSS OF APPETITE

Many diseases can disrupt the appetite to the extent that an individual loses the desire to eat, which in turn leads to weight loss. Loss of appetite may also be a sign of generalized ill health. Depression reduces a person’s motivation to eat; peptic ulcer causes pain and, in some cases, food avoidance; and some kidney disorders cause loss of appetite due to the effects of ureaemia (raised levels of the waste product urea in the blood). In the conditions anorexia nervosa and bulimia, complex psychological factors affect an individual’s eating pattern, sometimes with dramatic results.

DIGESTIVE CAUSES

Digestive disorders, such as gastroenteritis, lead to weight loss as a result of vomiting or diarrhoea. Weight is also affected by cancer of the oesophagus (see oesophagus, cancer of) and stomach cancer. Malabsorption of nutrients in certain disorders of the intestine or the pancreas also affect weight.

METABOLIC CAUSES

Some disorders cause weight loss by increasing the rate of metabolic activity in cells. Examples are any type of cancer, chronic infection such as tuberculosis, and hyperthyroidism (overactivity of the thyroid gland). Untreated diabetes mellitus may also cause weight loss.

weight reduction

The process of losing excess body fat. A person who is severely overweight (see obesity) is at an increased risk of developing various illnesses, such as diabetes mellitus, hypertension (high blood pressure), and heart disease, so a weight loss programme is a good idea to reduce the risk of developing such conditions.

HOW IT IS DONE

The most efficient way to lose weight is to eat a healthy balanced diet (see nutrition). This may involve a reduction in the intake of excess calories (those that are over the recommended daily limit), combined with regular exercise, both aerobic (fat-burning) and toning (muscle-building). Motivation, emotional support, and exploration of the psychological factors affecting eating are also important factors for success.

DRUG TREATMENTS

In most circumstances, drugs play little part in a weight-loss programme. However, orlistat (an antiobesity drug) may be a useful adjunct to a reduced diet, and they may, in some cases, be appropriate for those individuals who have a high body mass index. Appetite suppressants that are related to amphetamines are not recommended.

WEIGHT/HEIGHT GRAPH FOR MEN AND WOMEN

To find out whether or not you are underweight, normal weight, or overweight, first find your height, then run your finger up to your present weight. People with a BMI of 20–25 kg/m² are considered to be a healthy weight; those whose BMI is greater than 25, however, may be considered to be overweight.
Weil's disease
Another name for leptospirosis.

welder's eye
Also known as arc eye, acute conjunctivitis and keratopathy (corneal damage) that is caused by the intense ultraviolet light emitted by an electric welding arc. Welder’s eye is a consequence of the failure to wear adequate eye protection while performing welding tasks.

wen
A name for a sebaceous cyst.

Werdnig–Hoffmann disease
A very rare inherited disorder of the nervous system that affects infants. Also known as infantile spinal muscular atrophy, Werdnig–Hoffmann disease is a type of motor neuron disease, affecting the nerve cells in the spinal cord that control muscle movement.

Marked floppiness and paralysis occur during the first few months, and affected children rarely survive beyond the age of three.

There is no cure for the disease. Treatment aims to keep the affected infant as comfortable as possible.

Wernicke–Korsakoff syndrome
An uncommon brain disorder, almost always related to malnutrition, that occurs in chronic alcohol dependence. It may also occasionally occur in cancer.

CAUSES
Wernicke–Korsakoff syndrome results from a deficiency of thiamine (see vitamin B complex), which affects the brain and nervous system.

CAUSE OF WHIPLASH INJURY
This injury to the neck section of the spine may occur when a car is subjected to a sudden violent force and the occupant’s body is restrained in the seat but his or her head is not restrained by an appropriate head restraint.

Sudden acceleration
Here, there is a sudden force from behind (usually due to another vehicle’s striking the rear of the car). As the body accelerates forwards, the head jerks violently backwards relative to the body, stretching and bending the neck; the head then rebounds forwards.

Sudden deceleration
Here, there is a sudden violent force from the front towards the back of the vehicle, due, for example, to a collision with a tree. The seat belt restrains the body, but the head continues to move forwards, stretching the neck; the head then rebounds backwards.

Wein.
A name for a sebaceous cyst.

West Nile virus
A virus that is transmitted from infected animals or birds to humans by a mosquito bite. In most cases, there are either no symptoms or there is a flu-like illness. Rarely, a serious and potentially fatal illness, in which the virus infects the brain, can develop. The virus is...
found in Africa, Eastern Europe, West Asia, the Middle East, and, since 1999, the east coast of the USA.

**wet dream**
Ejaculation of semen from the penis that occurs during sleep. (See also *nocturnal emission*.)

**wet gangrene**
A type of gangrene.

**wheelchair**
A chair mounted on wheels used to provide mobility for a person unable to walk. Manual wheelchairs are designed so that the hand-rims can be easily gripped by a disabled person. They can also be pushed by a helper. Powered wheelchairs use batteries and are controlled electronically by finger or chin pressure, or by breath control.

**wheeze**
A high-pitched, whistling sound produced in the chest, usually on breathing out, that is caused by narrowing of the airways. It is a feature of the lung disorders *asthma*, *bronchitis*, *bronchiolitis*, and *pulmonary oedema* (the accumulation of fluid in the lungs). Inhalation of a foreign body may also be a cause. (See also *breathing difficulty*.)

**whiplash injury**
An injury to the soft tissues, *ligaments*, and spinal joints of the neck caused by a forcible and violent bending of the neck backwards (hyperextension) and then forwards (flexion), or vice versa. Such injury most commonly results from sudden acceleration or deceleration, as occurs in a car collision (see the illustrated box, left).

Damage to the spine usually involves minor *sprain* of a neck ligament or *subluxation* (partial dislocation) of a cervical joint. Occasionally, a ligament may rupture or a cervical vertebra may fracture (see *spinal injury*). Characteristically, pain and stiffness in the neck are much worse 24 hours after the injury.

Treatment of whiplash injury may involve immobilization of the neck in an orthopaedic collar, *analgesic drugs* (painkillers), *muscle-relaxant drugs*, and *physiotherapy*. It may take a few weeks for pain-free movement to occur.

**Whipple’s disease**
A rare disorder, also called intestinal lipodystrophy, that can affect many organs. Symptoms include *steatorrhoea* (the presence of fat in the faeces) as a result of *malabsorption*, abdominal pain, joint pains, swollen lymph nodes, progressive weight loss, anaemia, and fever. The heart, lungs, and brain can also be affected. The condition is most common in middle-aged men.

The cause is thought to be bacterial; affected tissues are found to contain macrophages (a type of scavenging cell) containing rod-shaped bacteria.

Treatment is with *antibiotic drugs* for at least 1 year. Dietary supplements are used to correct nutritional deficiencies occurring as a result of malabsorption.

**Whipple’s operation**
A type of *pancreatectomy* in which the head of the pancreas and the loop of the duodenum (first section of the small intestine) are surgically removed.

**whipworm infestation**
Small, cylindrical whiplike worms that live in the intestines for up to 20 years. They may live in a person’s intestine for up to 20 years. Most infestations do not cause symptoms.

Light infestation causes no symptoms, but heavy infestation may cause symptoms.

Treatment is with *anthelmintic drugs*, such as *mebendazole*. A heavy infestation may require more than one course of treatment.

**white blood cell**
A type of leucocyte, a *blood cell* that contains a nucleus. Granulocytes, lymphocytes, and monocytes are three types of white blood cell that are involved in the production of antibodies and protection of the body against foreign substances as part of the *immune system*. (See also *red blood cell*.)

**whitehead**
A very common type of skin blemish (see *milia*).

**white matter**
Tissue in the nervous system composed of nerve fibres (*axons*). White matter makes up the bulk of the cerebrum (the two large hemispheres of the *brain*) and continues down into the *spinal cord*; its main role is to transmit nerve impulses. (See also *grey matter*.)

**whitlow**
An abscess on the fingertip or toe that causes the affected digit to swell and become extremely painful and sensitive to pressure and touch. A whitlow may be due to the virus that causes *herpes simplex* or to a bacterial infestation. In some cases, pus needs to be drained from the abscess.
WHO

The commonly used abbreviation for the World Health Organization.

whooping cough
See pertussis.

will, living
See living will.

Wilms’ tumour
A type of kidney cancer, also called nephroblastoma, that occurs mainly in children.

Wilson’s disease
A rare, inherited disorder in which copper accumulates in the liver, resulting in conditions such as hepatitis and cirrhosis. Copper is slowly released into other body parts, damaging the brain, causing mild intellectual impairment, and leading to debilitating rigidity, tremor, and dementia. Symptoms of Wilson’s disease usually appear in adolescence, but they can occur much earlier or later.

Lifelong treatment with penicillamine is necessary and, if begun soon enough, it can produce an improvement. If the disease is discovered before symptoms begin, the drug may prevent them.

wind
A common name for gas in the gastrointestinal tract, which may be expelled through the mouth (see belching) or passed through the anus (see flatus).

Babies often swallow air during feeding which, unless the baby is “winded”, can accumulate in the stomach and cause discomfort.

windpipe
Another name for the trachea.

wiring of the jaws
Immobilization of the jaws by means of metal wires to allow a jaw fracture to heal or as part of treatment for obesity. When a fracture is being treated, the jaws are kept wired in a fixed position for about six weeks. For promoting weight loss, the jaws are wired for as long as a year. In both cases, the person is unable to chew and can take only a liquid or semi-liquid diet. This form of diet treatment often fails because the person resumes previous eating habits following removal of the wires.

wisdom tooth
One of the four rearmost teeth, also known as third molars. The wisdom teeth normally erupt between the ages of 17 and 21 but often erupt later; in some people, one or more fails to develop or erupt. In many cases, wisdom teeth are unable to emerge fully from the gum as a result of overcrowding (see impaction, dental).

Wiskott-Aldrich syndrome
An inherited condition in which the function of the immune system is impaired and there is a low number of platelets (blood cells that are needed for clotting). The defect is inherited in an X-linked recessive manner (see genetic disorders). It causes disease in males; females may have no symptoms, but may pass the gene to their children.

Features may include recurrent infections (caused by impaired immunity), an increased tendency to bleed (due to the reduced number of platelets), and eczema. Symptoms first develop soon after birth or during the first year of life. Affected individuals also have an increased risk of developing cancers, such as lymphoma and leukaemia, usually in adolescence or early adulthood.

Treatment is aimed at relieving the symptoms of the condition.

witches’ milk
A thin, white discharge from the nipple of a newborn infant, caused by maternal hormones that entered the fetus’s circulation through the placenta. Witches’ milk occurs quite commonly. It is usually accompanied by enlargement of one or both of the baby’s breasts. The condition is harmless and usually disappears within a few weeks.

withdrawal
The process of retreating from society and from relationships with others; usually indicated by aloofness, lack of interest in social activities, preoccupation with one’s own concerns, and difficulty in communicating.

The term is also applied to the psychological and physical symptoms that develop on discontinuing use of a substance on which a person is dependent (see withdrawal syndrome).

withdrawal bleeding
Vaginal blood loss that occurs when the level of oestrogen or progesterone hormones or progestogen drugs in the body drops suddenly.

The withdrawal bleeding that occurs at the end of each month’s supply of combined oral contraceptive pills mimics menstruation but is usually shorter and lighter. Discontinuation of an oestrogen-only or progestogen-only preparation also produces bleeding, which may differ from normal menstruation in its amount and duration.

withdrawal method
See coitus interruptus.

withdrawal syndrome
Unpleasant mental and physical symptoms experienced when an individual stops using a drug on which he or she is dependent (see drug dependence). Withdrawal syndrome most commonly occurs in those with alcohol dependence or dependence on opioid analgesics, in smokers, and in people addicted to tranquilizers, anxiolytics, and synthetic hallucinogens.

ALCOHOL WITHDRAWAL
In an alcohol-dependent person, alcohol withdrawal symptoms start six to eight hours after cessation of intake and may last up to seven days. They include trembling of the hands, nausea, vomiting, sweating, cramps, anxiety, and, sometimes, seizures and visual hallucinations.

OPIOID WITHDRAWAL
Withdrawal symptoms from opioids start after eight to 12 hours, and may last for seven to 10 days. Symptoms include restlessness, sweating, runny
eyes and nose, yawning, dilated pupils, diarrhoea, vomiting, abdominal cramps, loss of appetite, irritability, weakness, tremor, and depression.

**TRANQUILLIZER WITHDRAWAL**
Withdrawal symptoms from barbiturate drugs and meperidine begin, after 12 to 24 hours, with tremors, anxiety, restlessness, and weakness, sometimes followed by delirium, hallucinations, and, occasionally, seizures. A period of prolonged sleep occurs three to eight days after onset. Withdrawal from benzodiazepine drugs may begin much more slowly and can be serious, often resulting in depression, confusion, agoraphobia (fear of open spaces and public places), and/or psychosis.

**STOPPING SMOKING**
Withdrawal symptoms from nicotine develop over 24 to 48 hours and include irritability, concentration problems, frustration, headaches, and anxiety.

**WITHDRAWAL FROM OTHER DRUGS**
Discontinuation of cocaine or amphetamines results in dizziness, lethargy, and extreme tiredness. Cocaine withdrawal may also lead to tremor, sweating, and severe depression. Withdrawal symptoms from marijuana include tremor, nausea, vomiting, diarrhoea, sweating, irritability, and sleep problems. Withdrawal from caffeine may lead to tiredness, headaches, and irritability.

**TREATMENT**
Severe withdrawal syndromes require medical treatment. Symptoms may be suppressed by giving the patient small quantities of the drug he or she had been taking. More commonly, a substitute drug is given, such as methadone for opioid drugs or a benzodiazepine drug for alcohol. The dose of the drug is then gradually reduced.

**wobble board**
A balancing board used during physiotherapy to improve muscle strength and coordination in the feet, ankles, and legs. A wobble board is sometimes used after an ankle sprain.

**womb**
See uterus.

**word blindness**
See alexia; dyslexia.

**World Health Organization (WHO)**
An international organization established in 1948 as an agency of the United Nations with responsibilities for international health matters and public health. The WHO headquarters are in Geneva, Switzerland.

The WHO has campaigned effectively against some infectious diseases, most notably smallpox, tuberculosis, and malaria. Other functions include sponsoring medical research programmes, organizing national laboratories, and providing expert health advice and specific targets to its 192 member states.

**worm infestation**
Several worms, or their larvae, existing as parasites of humans. They may live in the intestines, blood, lymphatic system, bile ducts, or in organs such as the liver. In many cases, they cause few or no symptoms, but some cause chronic illness. The two main classes are: roundworms and platyhelminths, with subdivisions, cestodes (tapeworms) and trematodes (flukes).

Worm diseases occurring in developed countries include threadworm infestation, ascariasis, whipworm infestation, toxocariasis, liver-fluke infestation, and various tapeworm infestations. Those occurring in tropical regions include, in addition, hookworm infestation, filariasis, guinea worm disease, and schistosomiasis.

Worms may be acquired by eating undercooked, infected meat, contact with soil or water containing worm larvae, or accidental ingestion of worm eggs from soil contaminated by infected faeces. Most infestations can be easily eradicated with anthelmintic drugs.

**wound**
Any damage to the skin and/or underlying tissues caused by an accident, act of violence, or surgery. Wounds in which the skin or mucous membrane is broken are called "open"; those in which they remain intact, for example bruises, are termed "closed".

Wounds can be divided into the following categories: an incised wound; an abrasion (or graze); a laceration; a penetrating wound; and a contusion (see Types of wounds box, overleaf).

**wound infection**
Any type of wound is susceptible to the entry of bacteria; the resultant infection may delay healing, result in disability, and even cause death. Infection of a wound is indicated by redness, swelling, warmth, pain, and, sometimes, by the presence of pus or the formation of an abscess. Infection may spread locally, to adjacent organs or tissue, or to more distant parts of the body via the blood.

The type of infection depends upon how the wound occurred. For example, a wound in contact with soil can cause tetanus. Staphylococcal bacteria, including MRSA, commonly infect wounds.

Once infection is discovered, a sample of pus or blood may be taken and the patient is given an antibiotic drug. An abscess should be drained surgically.

**wrinkle**
A furrow in the skin. Wrinkles are a natural feature of ageing. Wrinkling is the result of loss of skin elasticity. Premature deep wrinkling is usually caused by overexposure to sunlight, and to smoking. No treatment of wrinkles can restore the skin’s elasticity permanently. However, some vitamin A derivatives are believed to reduce wrinkling. A face-lift smoothes out wrinkles by stretching the skin, but the effects last for only about five years.

**wrist**
The joint between the hand and the arm that allows the hand to be bent forward and backward relative to the arm and also to be moved side to side. The wrist contains eight bones (known collectively as the carpus), arranged in two rows, one articulating with the forearm bones, and the other connecting to the bones of the palm. Tendons connect the forearm muscles to the fingers and thumb, and arteries and nerves supply the muscles, bones, and skin of the hand and fingers.

**DISORDERS**
Wrist injuries may lead to disability by limiting hand movement. A common injury in adults is Colles’ fracture, in which the lower end of the radius is fractured and the hand is displaced backwards. In young children, similar displacement results from a fracture through the epiphysis (growing end) of the radius. A sprain can affect ligaments at the wrist joint, but most are not severe. (See also carpal tunnel syndrome; osteoarthritis; tenosynovitis; wrist-drop.)

**wrist-drop**
Inability to straighten the wrist, so that the back of the hand cannot be brought into line with the back of the forearm, causing weakness of grip. Wrist-drop is caused by damage to the radial nerve, either by prolonged pressure in the armpit (see crutch palsy) or by fracture of the humerus (upper-arm bone; see humerus, fracture of). Treatment involves holding the wrist straight. This may be achieved with a splint, but if damage to the radial nerve is permanent, the treatment is arthrodesis (surgical fusion) of the wrist bones.

**writer’s cramp**
See cramp, writer’s.

**wry neck**
Abnormal tilting and twisting of the head. It may be partly due to neck muscle injury or spasm (see torticollis).
Xalacom
A brand-name drug containing latanoprost, a prostaglandin drug, and timolol, a beta-blocker drug. Xalacom is used as eye-drops to treat glaucoma (increased pressure of fluid in the eyeball).

Xalatan
A brand name for latanoprost, a prostaglandin drug that is used in the form of eye-drops to treat glaucoma (increased pressure of fluid in the eyeball).

xanthelasma
A yellowish deposit of fatty material in the skin around the eyes. Xanthelasmas are common in elderly people and are usually not significant. In younger people, however, they may be associated with hyperlipidaemias (excess fat in the blood). Xanthelasmas may be removed, if necessary, by a simple surgical procedure under a local anaesthetic. Any associated hyperlipidaemia must also be treated. (See also xanthomatosis.)

xanthoma
A yellowish deposit of fatty material in the skin, often on the elbow or buttock. Xanthomas may be associated with hyperlipidaemias, a group of disorders in which there are raised levels of fats in the blood (see xanthomatosis).

xanthomatosis
A condition in which deposits of yellowish, fatty material develop in various parts of the body, particularly in the skin, internal organs, corneas of the eyes, brain, and tendons. The deposits may occur only in the eyelids (see xanthelasma). A key feature of xanthomatosis is the tendency for fatty material to be deposited in the linings of blood vessels, leading to generalized atherosclerosis. Xanthomatosis is often associated with hyperlipidaemias (a group of disorders in which there are raised levels of fats in the blood).

Treatment aims to lower the levels of fats in the blood by means of a diet that is low in cholesterol and high in polyunsaturated fat, and by drug treatment.

X chromosome
A sex chromosome, of which every normal female body cell has a pair. Male body cells have one X and one Y chromosome; each sperm carries either an X or a Y chromosome. Abnormal genes that are located on X chromosomes result in X-linked disorders.

Xenical
A brand name for orlistat, a drug used in the treatment of severe obesity.

xenotransplantation
The transplantation of an organ (a heart or lung, for example) from one species into another species, such as the transplantation of pig organs into humans. Research into the genetic engineering of pig embryos is currently underway in order to produce animals with organs that will not be rejected by a human body following transplant surgery.

xeroderma pigmentosum
A rare, inherited skin disease. The skin is normal at birth, but photosensitivity (extreme sensitivity to sunlight) causes it to become dry, wrinkled, freckled, and prematurely aged by about the age of five. Noncancerous skin tumours and skin cancers also develop. Xeroderma pigmentosum is often accompanied by related eye problems, such as photophobia and conjunctivitis.

Treatment of the condition consists of protecting the skin from sunlight. Skin cancers are usually treated surgically or with radiotherapy.

xerophthalmia
An eye disorder in which deficiency of vitamin A causes the conjunctiva and cornea to become abnormally dry. Without treatment, xerophthalmia may progress to keratomalacia, a condition in which severe damage is caused to the cornea.

xerostomia
Abnormal dryness of the mouth, which can cause bad breath and may predispose the sufferer towards tooth decay (see caries, dental). Xerostomia is sometimes a symptom of Sjögren’s syndrome. (See also mouth, dry.)

xipamide
A thiazide diuretic drug that is used to treat oedema (accumulation of fluid in the body tissues) and hypertension (high blood pressure). Side effects of xipamide may include dizziness and mild gastrointestinal disturbances.

xiphisternum
An alternative name for the xiphoid process, the small, leaf-shaped projection
X-rays are perhaps the most widely used method of imaging the body. When passed through body tissues onto photographic film, X-rays cast images of internal structures, allowing alterations in silhouette to be seen. Soft tissues do not show up as well as bone on X-rays, but, by using a contrast medium, they too can be visualized. New computer techniques produce even clearer, more detailed images, making X-ray an increasingly efficient diagnostic tool.

**3-D CT scan**
A computer can transform X-ray images of body slices into a three-dimensional image of part of the body.

**Barium X-ray**
Introducing barium, which is opaque to X-rays, into the large intestine allows it to be visualized.

**X-rays of knee joint**
The X-ray on the left shows erosion of bone and cartilage. The parts of an artificial knee are seen in the X-ray on the right.

**Chest X-ray**
X-rays allow bones and internal organs to be imaged.

**X-ray of hip joint**
This X-ray of an osteoarthritic hip shows almost complete degeneration of the cartilage.

**X-ray of foot**
All the bones can be clearly seen in this X-ray of a healthy foot.

**CT scan**
Combined use of a computer and X-rays produces cross-sectional images. In this brain scan, the white area is a mass of blood (haematoma) caused by a stroke.

**X-ray of knee joint**
The X-ray on the left shows erosion of bone and cartilage. The parts of an artificial knee are seen in the X-ray on the right.
that forms the lowest of the three parts of the sternum (breastbone).

**xiphoid process**
The lowermost section of the sternum (breastbone). The xiphoid process is initially composed of cartilage (connective tissue formed of collagen), which gradually ossifies throughout a person’s life until it is completely replaced by bone. This section of the sternum does not articulate with any of the ribs.

**X-linked disorders**
Sex-linked genetic disorders in which the abnormal gene or genes (the causative factors) are located on the X chromosome. Almost all affected people are males. Haemophilia, fragile X syndrome and colour vision deficiency are examples of X-linked disorders.

**X-rays**
A form of electromagnetic radiation of short wavelength and high energy. X-rays are widely used in medicine for diagnosis because they can be used to image bones, organs, and internal tissues. They are also used in medicine for treatment, particularly of cancer.

**HOW THEY WORK**
X-rays are produced artificially by bombarding a heavy metal tungsten (or other such metal) target with electrons, in a device known as an X-ray tube. Low doses of the X-rays that are emitted are passed through body tissue and form images on film or a fluorescent screen. The X-ray image, also called a radiograph or roentgenogram, shows the internal structure of the area being examined. Dense structures, such as bone, absorb X-rays well and appear white on an X-ray image. Soft tissues, such as muscle, absorb less well and appear grey.

**SPECIAL X-RAY TECHNIQUES**
Hollow or fluid-filled parts of the body often do not show up well on X-ray film unless they first have a contrast medium (a substance that is opaque to X-rays) introduced into them. Contrast-medium X-ray techniques are used to image the gallbladder (see cholecystography), bile ducts (see cholangiography), the urinary tract (see urography), the gastrointestinal tract (see angiography; venography), and the spinal cord (see myelography).

X-rays can be used to obtain images of “slices” through an organ or part of the body by using a technique known as tomography. More detailed images of a body slice are produced by combining tomography with the capabilities of a computer (see CT scanning).

**X-RAY SAFETY**
Large doses of X-rays can be extremely hazardous, and even small doses carry some risk (see radiation hazards). Modern X-ray film, equipment, and techniques produce high-quality images with the lowest possible radiation exposure to the patient. The risk of genetic damage can be minimized by using a lead shield to protect the patient’s reproductive organs from X-rays. Radiographers and radiologists wear a film badge to monitor their exposure to radiation.

**RADIOTHERAPY**
Because X-rays can damage living cells, especially those that are dividing rapidly, high doses of radiation are used in the treatment of cancer (see radiotherapy). (See also imaging techniques; radiography; radiology.)

**X-rays, dental**
See dental X-ray.

**xylitol**
A naturally occurring carbohydrate that is only partially absorbed by the body. Xylitol is sometimes used as a noncariogenic (does not cause dental caries) sweetener in confectionery and drinks. It is also used as a sweetener, in place of sugar, by people with diabetes. Xylitol chewing gum has been shown to reduce recurrent ear infections in some children. Excess xylitol may lead to abdominal discomfort and flatulence.
YAG laser

The abbreviation for yttrium–aluminum–garnet laser, a versatile laser that may be used in a range of treatments, including hair and tattoo removal, dentistry, lithotripsy (the breaking up of kidney stones), and the cutting of tissue, for example during iridotomy.

Yasmin

The brand name for a combined contraceptive pill (see oral contraceptives) that contains drospirenone (a progestogen drug) and ethinylestradiol (an oestrogen drug).

yawning

An involuntary act, or reflex action, that is usually associated with drowsiness or boredom. The mouth is opened wide and a slow, deep breath is taken. Yawning is accompanied by a momentary increase in the heart rate and, in many cases, watering of the eyes.

The purpose of yawning is unknown, but one theory suggests that it is triggered by raised levels of carbon dioxide in the blood; its purpose, therefore, could be to reduce the level of carbon dioxide and increase the level of oxygen in the blood.

yaws

An infectious disease that is found in poorer subtropical and tropical areas of the world. Yaws is caused by a form of spirochaete (a spiral-shaped bacterium) called Treponema pertenue, which is similar to the bacterium that causes syphilis. Yaws is not, however, a sexually transmitted infection; it spreads principally in conditions in which there is poor hygiene. The infection is almost always acquired in childhood, and it mainly affects the skin and bones.

SYMPTOMS

The bacteria enter the body through abrasions in the skin. Three or four weeks after infection, a raspberry-like, itchy growth appears at the site of infection, sometimes preceded by fever and pains. The lesion (abnormal area of tissue) is highly infectious; scratching the area spreads the infection and causes more growths to develop elsewhere.

Without treatment, the growths heal slowly over the course of about six months, but recurrence is common. In some untreated cases, widespread tissue loss eventually occurs. This may eventually lead to gross destruction of the skin, bones, and joints of the legs, nose, palate, and upper jaw.

TREATMENT

Yaws can be cured by a single large dose of a penicillin drug, which is given by injection into muscle.

Y chromosome

A sex chromosome that is present in every normal male body cell. It is paired with an X chromosome. Males inherit the Y chromosome from their fathers. Every egg (from the mother) carries an X chromosome, but each sperm (from the father) may carry either a single X or a single Y chromosome. When fertilization occurs, the combination of two X chromosomes creates a female offspring, while the combination of an X and a Y produces a male offspring.

Unlike the X chromosome, the Y chromosome carries little genetic material. Its principal function is to stimulate development of the testes in the male embryo. No significant diseases are related to Y chromosome abnormalities, but hairy ears is a trait thought to be determined by a Y-linked gene.

yeasts

Types of fungi in which the body of the fungus comprises individual cells that occur either singly, in pairs, or in longer chains. Certain yeasts can cause infections of the skin or mucous membranes. The most important of these disease-causing yeasts is Candida albicans, which causes candidiasis (thrush). Yeasts may also cause dandruff, seborrhoeic dermatitis, and the nail condition paronychia, in which there is swelling of the nail folds.

yellow card system

A method of reporting adverse drug reactions (see side effect) in the UK. Doctors or pharmacists complete a yellow card if they suspect that an unwanted or unexpected symptom has occurred as a reaction to a prescribed drug (including vaccines), self medicaiton, or herbal remedy. This information is collected and analysed centrally. The yellow card system is very important for recognising problems that were not identified during the testing phase of newly introduced drugs.

yellow fever

An infectious disease of short duration and variable severity that is caused by a virus transmitted by mosquitoes. In severe cases, the skin of the sufferer turns yellow due to jaundice, from which the name “yellow fever” is derived.

CAUSES

The infection may be spread from monkeys to humans in forest areas through various species of mosquito. In urban areas it can be transmitted from human to human by Aedes aegypti mosquitoes.

INCIDENCE

Today, yellow fever is endemic in Central America, parts of South America, and a large area of Africa. The eradication of the infection-bearing mosquito from populated areas has greatly reduced the incidence of the condition.

SYMPTOMS

Yellow fever is characterized by a sudden onset of fever and headache, often with nausea and nosebleeds, which occurs three to six days after infection. Despite the high fever, the heart rate is very slow. In many cases, the affected person recovers quickly.

In serious cases, the fever is higher and there is severe headache and pain in the neck, back, and legs. Damage may occur rapidly in the liver and kidneys, causing jaundice and kidney failure. This may be followed by severe agitation and delirium, leading to coma and death.

PREVENTION

Vaccination confers long-lasting immunity and should always be obtained before travel to affected areas. A single injection of the vaccine gives protection for at least 10 years. Reactions to the
vaccine are rare and are usually mild, although children under the age of one year should not be vaccinated.

**DIAGNOSIS**
During yellow fever epidemics, a diagnosis can be made by the symptoms. It can be confirmed by carrying out blood tests to isolate the causative virus or to find antibodies (proteins manufactured by the immune system) to the virus.

**TREATMENT**
No drug is effective against the yellow fever virus; and treatment is directed at maintaining the blood volume. Transfusion of fluids is often necessary.

Many patients recover in about three days and, in mild to moderate cases, complications are few. Relapses do not occur and one attack confers lifelong immunity. However, the disease is severe in 20–50 per cent of cases and may, in some circumstances, be fatal.

**yellow nail syndrome**
A condition in which the nails become thickened and yellow, or sometimes green, in colour; this is accompanied by swelling of the legs and pleural effusion (the accumulation of fluid around the lungs). Yellow nail syndrome is caused by a defect of lymphatic drainage (see lymphatic system).

**Yersinia**
A group of bacteria containing the organism responsible for the plague (Yersinia pestis). This organism is carried by fleas on rats, ground squirrels, and other rodents. It is transmitted from rodents to humans by bites from infected fleas. The organism can affect the lymph nodes resulting in large swellings, such as occurs in the bubonic form of plague. If the lungs are affected, the result is pneumonic plague; this can be transmitted from person to person if an infected individual spreads droplets in a cough.

Another form, Yersinia enterocolitica, can cause the development of gastrointestinalitis, particularly in young children, and arthritis and septicaemia (blood poisoning) in adults.

**yield**
The amount or quantity of a particular substance, such as an enzyme or hormone, that has been produced. For example, higher yields of insulin may be prepared for medical purposes using genetic engineering than through the natural production of the hormone in the pancreas of an animal.

**yin and yang**
The two opposing and interdependent principles that are fundamental to traditional Chinese medicine and philosophy. Yin is associated with the female, darkness, coldness, and quiescence; yang embodies maleness, brightness, heat, and activity. In a healthy body, yin and yang are in balance. Disorders are said to arise if one or other quality predominates; an excess of yin is said to cause conditions such as osteoarthritis, while an excess of yang causes inflammatory disorders. The concepts of yin and yang are also central to the dietary system known as macrobiotics.

**yoga**
A system of Hindu philosophy and physical discipline that is popular throughout the world. The main form of yoga practised in the West is hatha yoga. The follower adopts a series of poses called asanas, to stimulate nerves and organs and to strengthen muscles, and performs a system of breathing control techniques called pranayama to relax the body and calm the mind. Popular forms of hatha yoga include Iyengar and ashtanga ("power yoga").

The practice of yoga maintains flexibility, teaches physical and mental control, and is a relaxation technique.

Yoga should be practised only under the guidance of a qualified teacher. If yoga is attempted by people in poor health, or if it is practised incorrectly, it may pose certain health hazards, such as back disorders, hypertension (high blood pressure), and glaucoma (an increase in pressure in the eye).

**yohimbine**
A naturally occurring alkaloid that dilates the pupil of the eye and increases blood flow to the peripheries of the body. Yohimbine has been used in the treatment of impotence, due to its aphrodisiac properties, but newer, more effective treatments are generally recommended.

**yolk sac**
The membranous sac, also called the vitelline sac, that is attached to the front of the embryo during the early stages of its existence. The yolk sac is believed to help transfer nutrients from the mother’s bloodstream to the early embryo. The size of the sac decreases proportionately to the body, reducing finally to a narrow duct that passes through the umbilicus.

**YTTRIUM**

---

**Yoga position**
This woman is sitting in a loose lotus position, with her legs crossed and palms open. The position is used for relaxation and meditation.
Deficiency of zinc may also be hair loss and inflammation of the skin, mouth, tongue, and eyelids. In children, zinc deficiency impairs growth and delays sexual development.

**EXCESS**

Prolonged excessive intake of zinc may interfere with the intestinal absorption of iron and copper, leading to a deficiency of these minerals.

**MEDICAL USES**

Zinc compounds, such as zinc oxide, are included in many preparations for treating skin and scalp disorders.

**zinc oxide**

An ingredient of many skin preparations that has a mild astringent action and a soothing effect. Zinc oxide is used for painful, itchy, or moist skin conditions and to ease pain due to haemorrhoids and insect bites or stings. It also blocks the sun’s ultraviolet rays (see sunscreens).

**Zollinger–Ellison syndrome**

A rare condition characterized by severe and recurrent peptic ulcers in the stomach and the duodenum and jejunum (first and middle sections of the small intestine). Zollinger–Ellison syndrome is caused by one or more gastrin-secreting tumours, which usually arise in the pancreas but occasionally develop in the stomach or duodenum. Gastrin stimulates production of large quantities of acid by the stomach, leading to ulceration. The high levels of acid in the digestive tract often also cause diarrhoea.

The tumours are often cancerous but are slow-growing. If possible, they are removed surgically. Proton pump inhibitor drugs are given to treat the ulcers.

**zolmitriptan**

A serotonin agonist that is used in the treatment of acute attacks of migraine.

**zolpidem**

A drug used in the short-term treatment of insomnia. Zolpidem causes little hangover effect. Possible side effects include diarrhoea, nausea, and dizziness.

**zona pellucida**

The thick, transparent, noncellular layer that surrounds a developing egg cell in the ovarian follicle. At the time of fertilization, the zona pellucida is penetrated by at least one sperm.

</table>
zygomatic arch
The arch of bone, commonly known as the cheek bone, on either side of the skull just below the eye socket. The zygomatic arch is formed of the zygomatic and temporal bones.

zygote
The cell that is produced when a sperm fertilizes an ovum (egg). A zygote, measuring about 0.1 mm in diameter in humans, contains all the genetic material for a new individual. The zygote is surrounded by a protein-rich layer known as the zona pellucida.

The zygote travels down one of the woman’s fallopian tubes, dividing as it does so. After about a week, the mass of cells (now called a blastocyst) implants into the lining of the uterus, and the next stage of embryological growth begins. (See also embryo; fertilization.)

zygote intrafallopian transfer
A type of in vitro fertilization, also referred to as ZIFT, in which ova (eggs) are fertilized outside the body and returned to a fallopian tube rather than to the uterus.

zoonosis
Any infectious or parasitic disease affecting animals that can be transmitted to humans. Unlike many disease organisms, zoonotic organisms are flexible, and they can adapt themselves to a large number of different species.

Zoonoses are usually caught from animals that are closely associated with humans, either as pets, as food sources, or as scavenging parasites, such as rats. Examples of such zoonoses include toxocariasis, cat-scratch fever, some fungal infections, psittacosis, brucellosis, trichinosis, and leptospirosis. Rabies can infect virtually any mammal, but dog bites are a common cause of zoonosis infection in humans worldwide.

Other zoonoses are transmitted from animals less obviously associated with humans, usually by insect vectors. For example, yellow fever is transmitted by mosquito bites. (See also cats, diseases from; dogs, diseases from; insects and disease; rats, diseases from.)

zopiclone
A drug that is used in the short-term treatment of insomnia. Zopiclone has a brief duration of action and causes little hangover effect. Because of the risk of dependence, zopiclone is intended for occasional use only. Possible side effects of the drug include a bitter metallic taste, nausea, and a dry mouth.

Zovirax
A brand name for aciclovir, an antiviral drug used to treat viral infections such as herpes simplex, herpes zoster, and some cases of chickenpox.

Z-plasty
A technique that is used in plastic surgery to change the direction of a pre-existing scar in order for it to be hidden within the natural creases of the skin. Z-plasty is also used to relieve skin tension occurring as a result of contracture of a scar. The technique is especially useful for revising unsightly scars on the face and for releasing scarring across joints, such as on the fingers or in the armpits, that may restrict normal movement or cause deformity.

Zyban
A brand name for amfebutamone, a drug that is used, along with self-help measures, as an aid to stopping smoking.
